Gyrostemonaceae	*Codonocarpus cotinifolius*		

Family	Species name	Conservation status	Weed
Haloragaceae	*Haloragis gossei*		
	Haloragis odontocarpa		
	Haloragis sp.		
Hemerocallidaceae	*Tricoryne* sp. Hamersley Range (S. van Leeuwen 915)		
Lamiaceae	*Clerodendrum floribundum* var. *angustifolium*		
	Clerodendrum tomentosum var. *lanceolatum*		
	Newcastelia sp. Hamersley Range (S. van Leeuwen 4264)		
	Teucrium teucriiflorum		
Lauraceae	*Cassytha capillaris*		
	Cassytha filiformis		
	Cassytha sp.		
Loranthaceae	*Amyema fitzgeraldii*		
	Amyema hilliana		
	Amyema miquelii		
	Amyema sp.		
Malvaceae	*Abutilon amplum*		
	Abutilon cryptopetalum		
	Abutilon fraseri subsp. *fraseri*		
	Abutilon lepidum		
	Abutilon ?lepidum		
	Abutilon macrum		
	Abutilon malvifolium		
	Abutilon otocarpum		
	Abutilon sp.		
	Abutilon sp. Dioicum (A.A. Mitchell PRP 1618)		
	Androcalva luteiflora		
	Brachychiton acuminatus		
	Corchorus crozophorifolius		
	Corchorus lasiocarpus subsp. *lasiocarpus*		
	Corchorus lasiocarpus subsp. *parvus*		
	Corchorus tridens		
	Gossypium australe		
	Gossypium robinsonii		
	Gossypium sturtianum var. *sturtianum*		
	Hibiscus burtonii		
	Hibiscus coatesii		
	Hibiscus ?coatesii		
	Hibiscus leptocladus		
	Hibiscus sp.		

Family	Species name	Conservation status	Weed
Malvaceae	*Hibiscus* sp. Gurinbiddy Range (M.E. Trudgen MET 15708)	P2	
	Hibiscus sturtii		
	Hibiscus sturtii var. *campylochlamys*		
	Hibiscus sturtii var. *platychlamys*		
	Hibiscus verdcourtii		
	**Malvastrum americanum*		*
	Melhania oblongifolia		
	Seringia elliptica		
	Seringia nephrosperma		
	Seringia sp.		
	Sida arenicola		
	Sida calyxhymenia		
	Sida cardiophylla		
	Sida echinocarpa		
	Sida ?ectogama		
	Sida fibulifera		
	Sida platycalyx		
	Sida sp.		
	Sida sp. Articulation below (A.A. Mitchell PRP 1605)		
	Sida sp. dark green fruits (S. van Leeuwen 2260)		
	Sida ?sp. dark green fruits (S. van Leeuwen 2260)		
	Sida sp. *Excedentifolia (J.L. Egan 1925)*		
	Sida sp. Golden calyces glabrous (H.N. Foote 32)		
	Sida sp. Pilbara (A.A. Mitchell PRP 1543)		
	Sida sp. Shovelanna Hill (S. van Leeuwen 3842)		
	Sida sp. spiciform panicles (E. Leyland s.n. 14/8/90)		
	Triumfetta chaetocarpa		
	Waltheria indica		
Menispermaceae	*Tinospora smilacina*		
Molluginaceae	*Trigastrotheca molluginea*		
Moraceae	*Ficus brachypoda*		
Myrtaceae	*Calytrix carinata*		
	Corymbia deserticola		
	Corymbia deserticola subsp. *deserticola*		
	Corymbia ferriticola		
	Corymbia hamersleyana		
	Corymbia hamersleyana sens lat.		
	Corymbia opaca		
	Corymbia sp.		

Family	Species name	Conservation status	Weed
Myrtaceae	*Eucalyptus camaldulensis* subsp. *obtusa*		
	Eucalyptus gamophylla		
	Eucalyptus kingsmillii		
	Eucalyptus leucophloia subsp. *leucophloia*		
	Eucalyptus pilbarensis		
	Eucalyptus repullulans		
	Eucalyptus socialis subsp. *eucentrica*		
	Eucalyptus socialis subsp. *?eucentrica*		
	Eucalyptus victrix		
	Eucalyptus xerothermica		
	Eucalyptus xerothermica x *Eucalyptus tephrodes*		
	Melaleuca bracteata		
	Melaleuca eleuterostachya		
	Melaleuca glomerata		
Nyctaginaceae	*Boerhavia coccinea*		
	Boerhavia ?coccinea		
Oleaceae	*Jasminum didymum* subsp. *lineare*		
Phyllanthaceae	*Phyllanthus erwinii*		
	Phyllanthus maderaspatensis		
Plantaginaceae	*Stemodia grossa*		
Poaceae	*Acrachne racemosa*		
	Amphipogon sericeus		
	Aristida burbidgeae		
	Aristida contorta		
	Aristida holathera var. *holathera*		
	Aristida inaequiglumis		
	Aristida ?inaequiglumis		
	Aristida ingrata		
	Aristida latifolia		
	Aristida lazaridis	P2	
	Aristida obscura		
	Aristida sp.		
	Astrebla elymoides		
	Astrebla sp.		
	Bothriochloa ewartiana		
	**Cenchrus ciliaris*		*
	**Cenchrus setiger*		*
	**Chloris virgata*		*
	Chrysopogon fallax		

Family	Species name	Conservation status	Weed
Poaceae	*Cymbopogon ambiguus*		
	Cymbopogon obtectus		
	Cymbopogon sp.		
	Cynodon convergens		
	**Cynodon dactylon*		*
	Cynodon prostratus		
	Dactyloctenium radulans		
	Dactyloctenium ?radulans		
	Dichanthium sericeum subsp. *humilius*		
	Dichanthium sp.		
	Digitaria ammophila		
	Digitaria brownii		
	**Echinochloa colona*		*
	Enneapogon caerulescens		
	Enneapogon lindleyanus		
	Enneapogon polyphyllus		
	Enneapogon robustissimus		
	Enneapogon sp.		
	Enteropogon ramosus		
	Eragrostis cumingii		
	Eragrostis eriopoda		
	Eragrostis setifolia		
	Eragrostis tenellula		
	Eragrostis xerophila		
	Eriachne aristidea		
	Eriachne benthamii		
	Eriachne ?benthamii		
	Eriachne lanata		
	Eriachne mucronata		
	Eriachne obtusa		
	Eriachne pulchella		
	Eriachne pulchella subsp. *dominii*		
	Eriachne pulchella subsp. *pulchella*		
	Eriachne tenuiculmis		
	Eulalia aurea		
	Iseilema eremaeum		
	Iseilema membranaceum		
	Iseilema sp.		
	Iseilema vaginiflorum		

Family	Species name	Conservation status	Weed
Poaceae	*Panicum decompositum*		
	Panicum effusum		
	Paraneurachne muelleri		
	Paspalidium clementii		
	Paspalidium jubiflorum		
	Paspalidium rarum		
	Perotis rara

	**Setaria verticillata*		*
	Sporobolus australasicus		
	Themeda avenacea		
	Themeda sp.		
	Themeda sp. Mt Barricade (M.E. Trudgen 2471)		
	Themeda triandra		
	Tragus australianus		
	Triodia angusta		
	Triodia ?angusta		
	Triodia basedowii		
	Triodia brizoides		
	Triodia longiceps		
	Triodia pungens		
	Triodia sp. Mt Ella (M.E. Trudgen 12739)	P3	
	Triodia vanleeuwenii		
	Triodia ?vanleeuwenii		
	Triodia wiseana		
	Triraphis mollis		
	Urochloa ?occidentalis		
	Yakirra australiensis var. *australiensis*		
Polygalaceae	*Polygala isingii*		
Portulacaceae	*Portulaca oleracea*		
Proteaceae	*Grevillea berryana*		
	Grevillea saxicola	P3	
	Grevillea wickhamii subsp. *hispidula*		
	Hakea chordophylla		
	Hakea lorea subsp. *lorea*		
Pteridaceae	*Cheilanthes lasiophylla*		
Pteridaceae	*Cheilanthes sieberi* subsp. *sieberi*		
Rhamnaceae	*Cryptandra monticola*		

Family	Species name	Conservation status	Weed
Rubiaceae	*Oldenlandia crouchiana*		
	Psydrax latifolia		
	Psydrax suaveolens		
Santalaceae	*Anthobolus leptomerioides*		
	Santalum lanceolatum		
	Santalum spicatum		
Sapindaceae	*Atalaya hemiglauca*		
	Dodonaea coriacea		
	Dodonaea lanceolata var. *lanceolata*		
	Dodonaea pachyneura		
	Dodonaea petiolaris		
	Dodonaea viscosa subsp. *spatulata*		
Scrophulariaceae	*Eremophila* aff. *clarkei*		
	Eremophila canaliculata		
	Eremophila forrestii subsp. *forrestii*		
	Eremophila fraseri		
	Eremophila fraseri subsp. *fraseri*		
	Eremophila jucunda subsp. *pulcherrima*		
	Eremophila lanceolata		
	Eremophila latrobei		
	Eremophila latrobei subsp. *filiformis*		
	Eremophila latrobei subsp. *glabra*		
	Eremophila latrobei subsp. *latrobei*		
	Eremophila longifolia		
	Eremophila magnifica subsp. *magnifica*	P4	
	Eremophila phyllopoda subsp. *obliqua*		
	Eremophila platycalyx subsp. *pardalota*		
	Eremophila sp. Hamersley Range (K. Walker KW 136)	P3	
	Eremophila sp. West Angelas (S. van Leeuwen 4068)	P1	
Solanaceae	**Datura leichhardtii*		*
	**Datura leichhardtii* subsp. *leichhardtii*		*
	Nicotiana benthamiana		
	Nicotiana sp.		
	Solanum cleistogamum		
	Solanum ferocissimum		
	Solanum gabrielae		
	Solanum horridum		
	Solanum lasiophyllum		
	Solanum phlomoides		

Family	Species name	Conservation status	Weed
Solanaceae	*Solanum* sp.		
Surianaceae	*Stylobasium spathulatum*		
Violaceae	*Hybanthus aurantiacus*		
Zygophyllaceae	*Tribulus platypterus*		
	Tribulus suberosus		

Table M.2: Vascular flora species list from previous projects in the vicinity of the survey area.

Table N.1: Conservation significant flora recorded in the survey area.

Species	Description[1]	Habitat[1]
Eremophila sp. West Angelas (S. van Leeuwen 4068) P1 	Erect-branched spindly whip shrub with narrow leaves to 3 m high. Flower purple with corolla medial lobe of lower lip completely closes the throat.	Rocky hills or ridges and mulga bands in clay soil between rocky ridges. Very steep hillslope of brown silty loam. Breakaways, skeletal red gritty soil over massive banded iron.
Aristida lazaridis P2 	Densely clumped grass with clumps to 1.4 m high. Leaf-blade surface scaberulous. Flowers April.	Sand, loam, clayey soils. Plains, ironstone hills in *Triodia* spp. hummock grassland with sparse overstorey of *Eucalyptus leucophloia*. Mulga Shrublands
Hibiscus sp. Gurinbiddy Range (M.E. Trudgen MET 15708) P2 	Spindly upright shrub to 3 m high. Flowers May to July.	Near summit of hill, high in landscape, skeletal red-brown stony soil over massive ironstone of the Brockman Iron Formation. Sheltered or rocky drainage lines below associated cliff lines or rocky ridges.

Species	Description[1]	Habitat[1]
Acacia subtiliformis P3 	Spindly, slender, erect shrub, to 3.5 m high, new growth slightly viscid, resinous, aromatic. Flowers yellow, June.	Low, undulating country on calcareous rises adjacent to drainage lines.
Eremophila sp. Hamersley Range (K. Walker KW 136) P3 	Erect shrub. Flowers white-cream-yellow-pink-purple, August to September.	High in the landscape, cliff tops, gorge tops, steep rocky slopes, gullies and rock faces associated with large hills and cliffs. Skeletal red-brown soils.
Goodenia lyrata P3[2] 	Prostrate herb, with lyrate leaves. Flowers yellow, August.	Red sandy loam. Near claypan. In sand and clay on poorly drained flats often occurring with various *Calandrinia* spp. and *Eucalyptus victrix.*

Species	Description[1]	Habitat[1]
Goodenia sp. East Pilbara (A.A. Mitchell PRP 727) P3[2] 	Small rosetted herb (with spathulata leaves), to 0.2 m high. Flowers yellow, March to September.	Red-brown clay soil, calcrete pebbles. Low undulating plain, swampy plains, stony plains, hill slopes.
Grevillea saxicola P3 	Erect shrub to 2.5 m high. Flowers February, April, November.	Low rocky hill, red-brown sandy loam with ironstone pebble cover, steep scree slopes often associated with banded iron formation. Mulga woodlands.
Rhagodia sp. Hamersley (M. Trudgen 17794) P3 	Shrub, 2.5 m high. Leaves small lanceolate, not aromatic. Flowers yellow. Fruit small red drupelets.	Mulga plains. Alluvial plains. Red brown clay to loamy clay. Occasionally on slopes.

Species	Description[1]	Habitat[1]
Triodia sp. Mt Ella (M.E. Trudgen 12739) P3 	Grass-like or herb, 0.4 m high.	Light orange-brown, pebbly loam. Amongst rocks and outcrops, gully slopes.
Acacia bromilowiana P4 	Tree or shrub, to 12 m high. Flowers yellow/pink, July to August.	Red skeletal stony loam, orange-brown pebbly, gravel loam, laterite, banded ironstone, basalt. Rocky hills, breakaways, scree slopes, gorges, creek beds.
Eremophila magnifica subsp. *magnifica* P4 	Shrub, 0.5 m to 1.5 m high. Flowers blue, August to November.	Skeletal soils on the slopes and summits of ironstone hills in the Hamersley Range area.

Species	Description[1]	Habitat[1]
Lepidium catapycnon P4 	Open, woody herb or shrub, 0.2 m to 0.3 m high, stems zigzag. Flowers white, October.	Occurs on hillsides in skeletal soils, shale, ironstone.
Ptilotus mollis P4 	Compact shrub, to 0.5 m high, soft grey foliage. Flowers white/pink, May or September.	Stony hills, steep rocky sites and screes. Usually in full sun on massive ironstone formations.

[1] – Florabase (Western Australian Herbarium 1998-2019).
[2] – Species not observed in current survey, but previously recorded within survey area. For project presence see Table N.2.

Table N.2: Conservation significant flora recorded in HD2 Detailed Survey Area (GDA94, Zone 50).

Table O.1: Weed species recorded in the survey area.

Species	Description[1]	Habitat[1]
**Bidens bipinnata* (bipinnate beggartick) 	Erect annual, herb, 0.1 m to 0.9(-1.5) m high. Flowers yellow, March to September.	Alluvium, clay, loam over sandstone, limestone. Along rivers and creeks, coastal areas, rocky hillsides.
**Brassica tournefortii* (Mediterranean turnip)[2] 	Annual, herb, 0.1 m to 0.6 m high. Flowers yellow-cream-white, June to November.	Sandy soils. Aggressive weed of disturbed ground, roadsides, cultivation and seaside.
**Cenchrus ciliaris* (buffel grass) 	Tufted or sometimes stoloniferous perennial, grass-like or herb, 0.2 m to 1.5 m high. Flowers purple, February to October.	White, red or brown sand, stony red loam, black cracking clay.

Species	Description[1]	Habitat[1]
**Cenchrus setiger* (birdwood grass) 	Erect, tussocky, stoloniferous perennial, herb or grass-like, to 0.5 m high. Flowers cream-purple, April to May.	Brown sands, red loam, pindan soils. Sand dunes, plains, rangelands, stony hillsides, floodplains.
**Chloris virgata* (feathertop rhodes grass) 	Annual, grass-like or herb, (0.15-)0.23-0.45(-0.95) m high. Flowers green-purple, April to May or September.	Clay, sand. Sand dunes.
**Conyza bonariensis* (flaxleaf fleabane) 	Erect annual, herb, 0.15 m to 1.5 m high. Flowers white, January to December.	Variety of soils. Weed of cultivation, waste places and roadsides.

Species	Description[1]	Habitat[1]
**Cynodon dactylon* (Couch) 	Rhizomatous (or stoloniferous), prostrate perennial, grass-like or herb, 0.05 m to 0.3 m high. Flower green-purple, June to November or February.	Sand, loam, clay.
**Datura leichhardtii* subsp. *leichhardtii* (Native Thornapple) 	Stout annual, herb, 0.2 m to 1 m high. Flowers white, January to October.	Alluvium. Along watercourses.
**Flaveria trinervia* (speedy weed) 	Erect annual shrub. Flowers yellow, May to July.	Sandy flat, along watercourses.

Species	Description[1]	Habitat[1]
**Lactuca serriola* (prickly lettuce) 	Erect annual or biennial, herb, 0.4 m to 2 m high. Flowers yellow, October to December or January to February.	Roadsides, gardens, cultivated fields, disturbed sites.
**Malvastrum americanum* (spiked malvastrum) 	Erect perennial, herb or shrub, 0.5 m to 1.3 m high. Flowers yellow-orange, April to July.	Orange/red/yellow sands, gritty alluvial sand, black/brown clay, alluvial cracking clays, limestone, calcrete. Stony ridges and hillsides, floodplains, along drainage lines.
**Rumex vesicarius* (ruby dock)[2] 	Erect, stout, fleshy, hollow-stemmed annual, herb, 0.2 m to 1 m high. Flowers red-pink, July to September.	Sandy alluvial soils, gravelly ironstone soils. Along roadsides, in disturbed areas.

Species	Description[1]	Habitat[1]
**Setaria verticillata* (whorled pigeon grass) 	Loosely tufted annual, grass-like or herb, 0.1 m to 1.3 m high. Flowers December or January to June.	Sand, clay, loam.
**Sigesbeckia orientalis* (Indian weed) 	Erect, slender annual, herb, 0.15 m to 1 m high. Flowers yellow, January to December.	Loamy soils over limestone or granite. Rocky gullies, limestone ranges, creek beds.
**Solanum nigrum* (black berry nightshade) 	Erect perennial, herb or shrub (short-lived), 0.3 m to 1 m high. Flowers white, January to December.	Dampland, along drainage line. Plain, hillslope, disturbed ground. Sand.

Species	Description[1]	Habitat[1]
**Sonchus oleraceus* (common sowthistle) 	Erect annual, herb, to 1.5 m high. Flowers yellow, January to December.	Variety of soils. Weed of waste places and disturbed ground.
**Vachellia farnesiana* (mimosa bush) 	Erect, spreading, thicket-forming, thorny tree or shrub, to 4 m high, bark dark grey, rough; leaves pinnate. Flowers yellow, June to August.	Stony sandy, clay or loam soils, gravel. Low-lying areas, river and creek banks, disturbed sites.

[1] – Florabase (Western Australian Herbarium 1998-2018).
[2] – Species not observed in current survey, but previously recorded within survey area. For project presence see Table O.2.

Table O.2: Locations of weed species recorded in the survey area (GDA94, Zone 50).

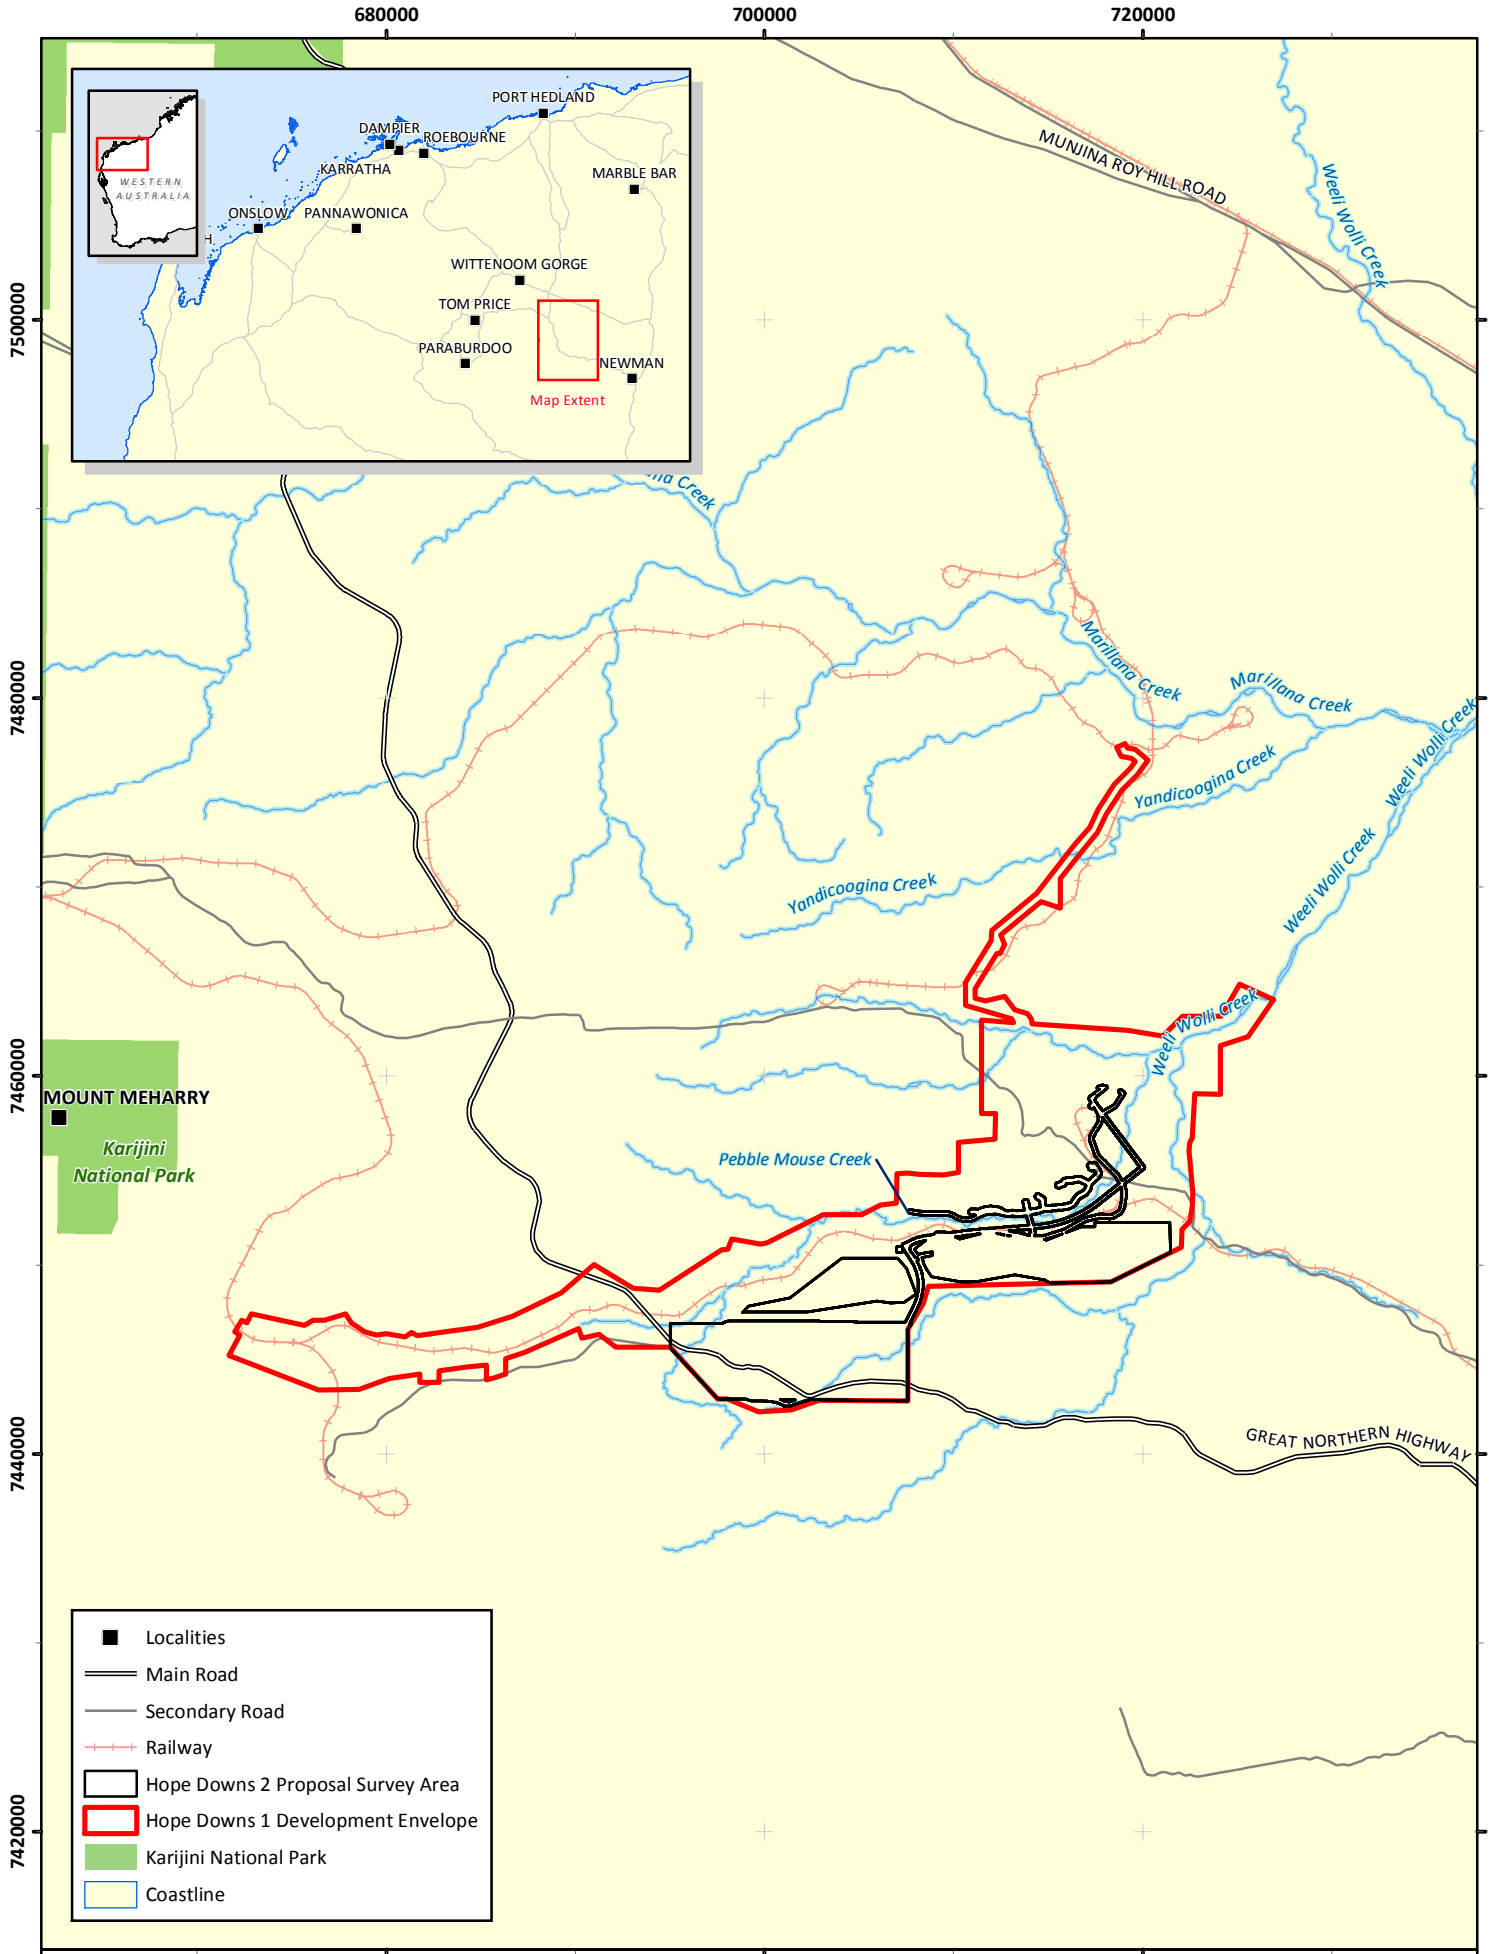
Dear Michelle,

Re: Hope Downs Development Envelope - Vegetation Mapping



1 Introduction

Early in 2019 Rio Tinto commissioned a consolidation of all previous vegetation mapping across the Hope Downs 1 (HD1) Development Envelope. The proposed HD1 Development Envelope is approximately 36,944 ha and encompasses the Hope Downs 2 (HD2) Proposal area and the existing approved and operational Hope Downs 1 and Baby Hope mine sites, and corridors linking the West Angelas and Yandicoogina operations (Figure 1).

In 2017 to 2019 Astron conducted a Detailed flora and vegetation assessment within the HD2 Proposal area, the results of which are presented in Astron Environmental Services (2019). The results of the consolidated vegetation mapping and consolidated vegetation condition mapping as well as opportunistic conservation significant flora and weed locations for parts of the HD1 Development Envelope not captured in Astron Environmental Services (2019) are presented in this letter.

2 Methods

A combination of previous vegetation mapping within the HD1 Development Envelope and high resolution aerial imagery were used to produce a single desktop generated consolidated vegetation map using vegetation codes from Astron Environmental Services (2018). Vegetation units described in Astron Environmental Services (2018) were reviewed for typical vegetation structure, species composition and position in the landscape to assist with assigning codes to vegetation polygons observed on aerial imagery.

Rio Tinto

Hope Downs 1 Development Envelope – Vegetation Mapping

N

A number of other flora and vegetation surveys have previously been carried out within the HD1 Development Envelope; these were also reviewed to provide vegetation unit and vegetation condition information. Vegetation unit boundaries from the following surveys were used to inform interpretation of vegetation units and condition in the HD1 Development Envelope:

- Hope Downs 2 Bedded Hilltop and Wonmunna Detailed Flora and Vegetation Survey (Astron Environmental Services 2018)
- Hope Downs Rail Corridor (Juna Downs Section) Vegetation and Flora Survey (Biota Environmental Sciences 2006)
- Baby Hope Downs Flora and Vegetation Survey (Biota Environmental Sciences 2014)
- Yandi Vegetation and Flora Integration Report (Biota Environmental Sciences 2015)
- Hope Downs Biological Survey (Ecologia Environment 1997)
- Flora and Vegetation, Northern Transport Corridor, Yandicoogina Junction Project Area (Mattiske 1995)
- Flora and Vegetation, Southern Transport Corridor, Yandicoogina Junction Project Area (Mattiske Consulting 1995)
- Flora and Vegetation of the Hope Downs 1 Area (Mattiske Consulting 2009a)
- Flora and Vegetation on the Hope Downs 4 Mine Pipeline Corridor to Opthalmia Dam (Mattiske Consulting 2009b)
- Flora and Vegetation of the Hope Downs 2 Area (Mattiske Consulting 2010)
- Flora and Vegetation Surveys of Orebody A and Orebody B in the West Angela Hill Area (Trudgen 1998).

Following the desktop assessment, a reconnaissance level field survey was undertaken to verify the accuracy of the desktop mapping and inform the mapping consolidation. The survey was conducted in May 2019 concurrently with the HD2 Proposal area Phase 3 survey, by Astron Senior Botanists Ben Eckermann (Flora Permit SL012522; DRF Permit 75-1819), Dr Kellie McMaster (Flora Permit SL012520; DRF Permit 56-1819), Daniel Roocke (Flora Permit SL012517) and Botanist Lucy Dadour (Flora Permit SL012524; DRF Permit 44-1819).

The survey involved ground-truthing of vegetation in areas able to be readily accessed by vehicle, and sampling of 11 quadrats (50 m x 50 m). Information collected from the quadrats included:

- Location – coordinates measured using a handheld global positioning system (GPS) unit (MGA50, GDA94) at each of the four corners of the site.
- Recorder and date –personnel involved in sampling that site and the survey date.
- Habitat – a broad description of the surrounding landscape based on landform, topography and soil.
- Soil – including colour and texture.
- Rock type and abundance – general description of surface geology and amount of ground covered by rocks.

- Vegetation description – vegetation described according to level V of the NVIS (Department of the Environment and Energy 2017) and classified according to the Aplin (1979) modification of the vegetation classification system of Specht (1970) (Appendix F).
- Vegetation condition – assessed according to the vegetation condition classification adapted from Trudgen (1988).
- Species list – percentage foliar cover and maximum height were recorded for each vascular plant taxon present within the site.
- Disturbances – records of any obvious disturbances such as fire, tracks or grazing.
- Photographs – a photograph was taken at the north-west and south-east corners of each quadrat.

Areas that could not be accessed on foot were viewed from a nearby vantage point to assist with vegetation mapping interpretation where possible. However, due to limited vehicle access and time constraints, not all of the HD1 Development Envelope was able to be ground-truthed.

Following the Phase 3 detailed survey of the HD2 Proposal area the description of some vegetation units was updated; as such the post-survey consolidated vegetation mapping was updated to reflect the vegetation units defined in Astron Environmental Services (2019).

In areas not visited during the field survey and where no vegetation mapping has previously been conducted, the boundaries of vegetation units were extrapolated using high resolution aerial imagery. Given that large areas of the HD1 Development Envelope were not able to be ground-truthed the vegetation mapping was given a confidence rating based on level of likely accuracy (Table 1).

Table 1: Criteria for confidence rating of consolidated vegetation unit mapping.

Confidence rating	Description
High	Recent, detailed vegetation mapping supported by traversing and/or quadrats in nearby area.
Medium	Previous detailed vegetation mapping conducted but is old (>5 years) or describes vegetation units similar to Astron Environmental Services (2019). If the area has been surveyed by Astron it has been conducted in a single poor season, or there is considerable distance to areas of high confidence.
Low	No vegetation mapping has been conducted, or previous detailed vegetation mapping is very old (>10 years) or presents vegetation units that Astron Environmental Services (2019) has not described.

Previous vegetation condition mapping within the HD1 Development Envelope, including Biota Environmental Sciences (2014) and Astron Environmental Services (2018), and the locations of introduced flora (weeds) and known disturbances within the HD1 Development Envelope were reviewed. This data informed the production of a single consolidated desktop vegetation condition map using the Trudgen (1988) scale. During the field survey, the desktop condition mapping was opportunistically verified where access and time allowed. Vegetation condition was mapped according to the vegetation unit polygons and overlaid with disturbance mapping provided by Rio Tinto.

Locations of conservation significant flora and weeds were recorded opportunistically from quadrats, and as the team traversed the HD1 Development Envelope.

3 Results

Twenty-seven vegetation units were mapped within the HD1 Development Envelope. Each vegetation unit is detailed in Table 2 and presented in Figure A (Attachment A). Twenty-three of the recorded and extrapolated vegetation units have been previously described in Astron Environmental Services (2019) and further detail on the vegetation units is presented in that report. Three plains units (P5, P6, and P7) and one drainage line unit (D6) have been described only from the HD1 Development Envelope. Data recorded from each quadrat is presented in Attachment B.

Table 2: Vegetation units described for the HD1 Development Envelope.

Vegetation unit code and description	HD1 Development Envelope Sites(s)[1]	HD2 Proposal Area Site(s)[2]	Vegetation condition	Mapped area (ha)
Vegetation of Hills and Slopes				
H1 – *Eucalyptus leucophloia* subsp. *leucophloia*, *Corymbia hamersleyana* sens. lat. scattered low trees to low open woodland over *Petalostylis labicheoides, Senna glutinosa* subsp. *glutinosa* scattered tall shrubs over *Gompholobium oreophilum*, *Acacia hilliana, A. spondylophylla* low open shrubland to low shrubland over *Triodia vanleeuwenii*, *T. wiseana*, *T. pungens* open hummock grassland with *Amphipogon sericeus* scattered tussock grasses	N/A	HD04, HD13, HD15	Excellent	1,628
H2 – *Eucalyptus repullulans* scattered low mallees over *Acacia catenulata* subsp. *occidentalis*, *A. aptaneura*, (*Grevillea saxicola*) tall shrubland to tall open scrub over *Scaevola acacioides, Dodonaea pachyneura, Eremophila latrobei* subsp. *filiformis* scattered shrubs to open shrubland over *Triodia pungens* scattered hummock grasses to very open hummock grassland with *Eriachne mucronata* scattered tussock grasses to very open tussock grassland	N/A	HD03, HD07, HD52, GH11	Very Good - Excellent	439
H3 – *Corymbia deserticola* subsp. *deserticola* scattered low trees over *Acacia inaequilatera*, *Hakea chordophylla* scattered tall shrubs to tall open shrubland over *Senna glutinosa* subsp. *pruinosa* scattered shrubs over *Triodia vanleeuwenii* open hummock grassland with *Amphipogon sericeus* scattered tussock grasses to very open tussock grassland	N/A	HD05, HD43, HDR14, HDR16, GH19	Excellent	917

[1] Sites were sampled from within the HD1 Development Envelope and outside of the HD2 Proposal area.

[2] Sites were sampled from within the HD2 Proposal area and data presented in Astron Environmental Services (2019).

None of the vegetation recorded or extrapolated in the HD1 Development Envelope (outside of the areas previously reported for the HD2 Proposal area in Astron Environmental Services (2019)) are considered to represent a threatened ecological community under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) or the *Biodiversity Conservation Act 2016* (BC Act).

A Department of Biodiversity, Conservation and Attractions (DBCA) mapped location of the priority 1 priority ecological community (PEC) '*Weeli Wolli Spring Community*' occurs within the HD1 Development Envelope. The D6 vegetation unit is inferred to be associated with this PEC based on the presence of *Melaleuca argentea* (considered an obligate phreatophyte), *Eucalyptus camaldulensis* subsp. *obtusa* and *E. victrix* (considered facultative phreatophytes) and the assemblage of sedgeland and herbland understorey taxa.

Some areas of the DBCA mapped PEC are associated with vegetation units outside of the D6 boundary, however this is considered a result of the broader scale of mapping used to define the PEC. The majority of other vegetation units within the DBCA mapped PEC are small in area (<3 ha) and described from the surrounding hills and slopes, with the exception of D4 (75.6 ha within the DBCA mapped PEC) which is separated from D6 due to the absence of *Melaleuca argentea* and dominance of tussock and hummock grasses rather than sedges and herbs which are present in the D6 understorey taxa, and typical of the PEC.

Despite the dry seasonal conditions an average of 58 species were recorded from each D6 quadrat; it is likely that the number of grasses, sedges and herbs would likely be considerably higher following rainfall and the community would have the diverse sedgelands and herbfields typical of the PEC. The vegetation unit D6 does not occur within the HD2 Proposal area and no vegetation is considered to have affinity with the priority 1 PEC '*Weeli Wolli Spring Community*' within the HD2 Proposal area. Permanent water pools are likely to occur upstream (outside of the HD1 Development Envelope) along Weeli Wolli Creek, and may be associated with the priority 2 '*Riparian flora and plant communities of springs and river pools with high water permanence of the Pilbara Region*' PEC.

One further vegetation unit (P2) which occurred as a fine scale mosaic of shrublands and tussock grasslands on cracking-clays and alluvial plains is considered to share similarities with the priority 1 PEC '*West Angelas Cracking-Clays*', however is unlikely to represent the PEC. The degree to which P2 aligns with the PEC was difficult to determine given the poor seasonal conditions and therefore limited occurrence and/or poor condition of annual and short-lived perennial species which characterise the community, however the mosaic and small scale nature of the tussock grasslands is not consistent with mapped occurrences of the PEC (Astron Environmental Services 2019).

Vegetation condition within the HD1 Development Envelope ranges from 'Excellent' to 'Completely Degraded', with the majority of vegetation being in 'Excellent' condition (67% of total area) (Table 3 and Figure C – Attachment C). Approximately 4,900 ha of the HD1 Development Envelope has been previously cleared for tracks, roads, railways, mine site and other associated infrastructure; these areas have been mapped as 'Completely Degraded'.

Table 3: Desktop vegetation condition mapped for the HD1 Development Envelope.

Vegetation condition	Total mapped area within the HD1 Development Envelope (ha)	Proportion of HD1 Development Envelope (%)
Excellent	24,790	67
Very Good	6,846	19
Good	408	<1
Completely Degraded	4,900	13

The confidence of vegetation mapping ranged from 'low' to 'high'. There was 'high' confidence associated with 39% of the vegetation mapping within the HD1 Development Envelope; these areas were either ground-truthed during the field visit and had supporting quadrats and traverses or abutted other areas of 'high' confidence and able to have this rating applied. An estimated 37% of the vegetation mapping was considered 'low' confidence; these areas were not accessed during the field survey and had no previous, or outdated, vegetation mapping in the vicinity. Confidence ratings for desktop vegetation mapping are shown in Table 4 and Figure D (Attachment D).

Table 4: Confidence of vegetation mapping within the HD1 Development Envelope.

Confidence rating	Total mapped area within the HD1 Development Envelope (ha)	Proportion of HD1 Development Envelope (%)
High	14,236	39
Medium	4,045	11
Low	13,763	37
Disturbed	4,900	13

No flora listed as threatened under the EPBC Act or BC Act were recorded. There were seven conservation significant flora recorded within, and adjacent to, the HD1 Development Envelope during the survey: *Aristida lazaridis* P2, *Acacia subtiliformis* P3, *Grevillea saxicola* P3, *Rhagodia* sp. Hamersley (M. Trudgen 17794) P3, *Rostellularia adscendens* var. *latifolia* P3, *Eremophila magnifica* subsp. *magnifica* P4 and *Lepidium catapycnon* P4. Due to changes in the survey boundary, some conservation significant flora records are located outside of the HD1 Development Envelope. Location and abundance details for each conservation significant flora species recorded are presented in Table E.1 and locations are mapped in Figure E (Attachment E). Six of the seven species (excluding *R. adscendens* var. *latifolia* P3) have been previously recorded in the HD2 Proposal area. A further eight species: *Eremophila* sp. West Angelas (S. van Leeuwen 4068) P1, *Hibiscus* sp. Gurinbiddy Range (M.E. Trudgen MET 15708) P2, *Eremophila* sp. Hamersley Range (K. Walker KW 136) P3, *Goodenia lyrata* P3, *Goodenia* sp. East Pilbara (A.A. Mitchell PRP 727) P3, *Triodia* sp. Mt Ella (M.E. Trudgen 12739) P3, *Acacia bromilowiana* P4 and *Ptilotus mollis* P4 were recorded in the HD2 Proposal area only and are presented in Astron Environmental Services (2019).

Sixteen introduced (weed) species were recorded: **Bidens bipinnata, *Cenchrus ciliaris, *C. setiger, *Conyza bonariensis, *Cynodon dactylon, *Euphorbia hirta, *Flaveria trinervia, *Lactuca serriola, *Malvastrum americanum, *Melinis repens, *Setaria verticillata *Sigesbeckia orientalis, *Solanum nigrum, *Sonchus oleraceus, *Tridax procumbens* and **Vachellia farnesiana.* None of these species is a declared pest in Western Australia (Department of Primary Industries and Regional Development 2019) or a listed Weed of National Significance (Australian Weeds Committee 2012). The locations of weeds recorded are presented in Table F.2 and mapped in Figure F (Attachment F). All but three of the 15 weed species have been previously recorded in the HD2 Proposal area: **E. hirta, *M. repens* and **T. procumbens*, and a further five weed species: **Brassica tournefortii, *Chloris virgata*, **Datura leichhardtii* subsp. *leichhardtii, *Rumex vesicarius* and **Setaria verticillata* were recorded in the HD2 Proposal area only and are presented in Astron Environmental Services (2019).

4 Limitations

A number of limitations were encountered during the mapping consolidation; however, most of these were able to be overcome and therefore did not restrict the outcomes of the assessment. A summary of the limitations includes:

- The confidence of the consolidated vegetation mapping is limited by the consistency and quality of the previous adjacent surveys; the quality of previous survey effort is difficult to assess without ground-truthing. The development of confidence ratings assisted in indicating where there was uncertainty in the extrapolated mapping.
- Aerial imagery provided by Rio Tinto for the purposes of the vegetation mapping consolidation had been compiled from a number of separate images and the resolution was of low quality despite being quite recent. As such, imagery from other sources was used for the majority of the desktop mapping.
- There was low confidence in some previous vegetation mapping due to age or scale (Mattiske 1995, Mattiske Consulting 1995, 2009a, 2009b, 2010, Ecologia Environment 1997, Trudgen 1998)
- Some extensive areas had limited previous vegetation mapping, in particular the corridor connecting to the Yandicoogina project area. Vegetation extrapolation was limited to aerial imagery interpretation in these areas which led to low confidence in the vegetation mapping codes applied.
- The field survey was conducted during below mean seasonal conditions. Rainfall recorded in the 12 months prior to the survey in May 2019 was 110.1 mm, 210.2 mm less than the long-term mean. In the three months preceding the survey, 71.8 mm was recorded, 62.6 mm less than the long-term mean for the same period. This may have limited interpretation of some vegetation units and the opportunistic observation of some priority flora species with potential to occur.

5 Conclusions

The limitations outlined in this letter must be considered when interpreting the results; the majority of vegetation mapping and vegetation condition mapping has been extrapolated based on previous survey effort and aerial imagery, not all parts of the HD1 Development Envelope were accessed to verify the desktop mapping, and seasonal conditions were poor at the time of the ground-truthing. The confidence mapping assists in interpretation of the vegetation unit and vegetation condition mapping, however the conservation significant flora and weed locations presented and the interpretation of vegetation significance should not be considered comprehensive.

This letter was prepared by Principal Scientist Janelle Atkinson and reviewed by Senior Scientist Ben Eckermann. If you would like to discuss this further, please feel free to contact me on 9421 9600.

Yours sincerely
ASTRON ENVIRONMENTAL SERVICES

Vegetation of Drainage Lines

D1 *Corymbia hamersleyana* sens. lat., *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees to low open woodland over *Petalostylis labicheoides*, *Acacia monticola, A. maitlandii* scattered tall shrubs to tall shrubland over *Dodonaea lanceolata* var. *lanceolata, Androcalva luteiflora* scattered shrubs to open shrubland over *Triodia pungens* very open hummock grassland to open hummock grassland with *Themeda triandra*, *Eriachne mucronata* very open tussock grassland to open tussock grassland

D2 *Acacia aptaneura, A. catenulata* subsp. *occidentalis*, *A. pruinocarpa* tall shrubland to tall open scrub over *Petalostylis labicheoides* scattered shrubs to open shrubland over *Triodia pungens* very open hummock grassland with *Chrysopogon fallax* scattered tussock grasses

D3 *Corymbia ferriticola*, *Eucalyptus leucophloia* subsp. *leucophloia* low open woodland over *Petalostylis labicheoides*, *Acacia hamersleyensis, Dodonaea viscosa* subsp. *spatulata* tall open shrubland over *Triodia pungens* very open hummock grassland with *Eriachne mucronata*, *Themeda* sp. Mt Barricade (M.E. Trudgen 2471), *Cymbopogon ambiguus* very open tussock grassland to tussock grassland

D4 *Eucalyptus victrix*, (*E. camaldulensis* subsp. *obtusa*) low open woodland to open woodland over *Acacia citrinoviridis*, *Petalostylis labicheoides* scattered tall shrubs to tall shrubland over *Androcalva luteiflora*, *Gossypium sturtianum* var. *sturtianum* scattered shrubs to open shrubland over *Triodia longiceps* scattered hummock grasses to very open hummock grassland with *Themeda triandra*, *Eulalia aurea*, (**Cenchrus ciliaris*) very open tussock grassland to tussock grassland and **Bidens bipinnata* scattered herbs

D5 *Eucalyptus xerothermica* scattered low trees to low open woodland over *Petalostylis labicheoides, Acacia maitlandii*, *A. pyrifolia* tall open shrubland to tall shrubland over *Androcalva luteiflora* scattered shrubs over *Triodia longiceps* very open hummock grassland to open hummock grassland with *Themeda triandra*, *Eulalia aurea* open tussock grassland to tussock grassland and **Bidens bipinnata* scattered herbs

D6 *Melaleuca argentea, Eucalyptus camaldulensis* subsp. *obtusa, (E. victrix*) open forest over *Acacia citrinoviridis, Atalaya hemiglauca* scattered tall shrubs over *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) scattered low shrubs over *Cyperus vaginatus, Typha domingensis* scattered sedges

D7 *Acacia citrinoviridis, A. aptaneura, A. pruinocarpa* scattered tall shrubs to tall shrubland over *Senna artemisioides* subsp. *oligophylla* scattered low shrubs over *Triodia longiceps* open hummock grassland to hummock grassland

D8 *Eucalyptus xerothermica* scattered low trees to low open woodland over *Acacia aptaneura, A. catenulata* subsp. *occidentalis* tall open shrubland to tall open scrub over *Triodia pungens* scattered hummock grasses to very open hummock grassland with *Themeda triandra* very open tussock grassland to open tussock grassland

Vegetation of Plains

P1 *Acacia aptaneura*, *A. catenulata* subsp. *occidentalis*, (*A. pruinocarpa*) tall shrubland to tall open scrub over *Eremophila forrestii* subsp. *forrestii* open shrubland to shrubland over *Triodia pungens*, (*T. vanleeuwenii*) scattered hummock grasses to very open hummock grassland

P2 *Acacia aptaneura*, *A. pruinocarpa, A. tetragonophylla* scattered tall shrubs to tall open shrubland over *Eremophila forrestii* subsp. *forrestii, A. synchronicia* scattered shrubs over *Ptilotus obovatus, Sida fibulifera* scattered low shrubs over *Aristida latifolia*, *Astrebla elymoides*, *Eragrostis xerophila* open tussock grassland to tussock grassland

P3 *Acacia aptaneura*, *A. catenulata* subsp. *occidentalis*, *A. pruinocarpa* tall open shrubland to tall shrubland over *Eremophila forrestii* subsp. *forrestii* scattered shrubs to open shrubland over *Triodia pungens* open hummock grassland to hummock grassland

P4 *Acacia pruinocarpa, A. aptaneura*, *A. catenulata* subsp. *occidentalis* tall open shrubland to tall shrubland over *Rhagodia eremaea* scattered shrubs

P5 *Acacia aptaneura* tall shrubland over *Aristida obscura, Aristida ingrata, Themeda triandra* very open tussock grassland

P6 *Acacia aptaneura* scattered tall shrubs to tall open shrubland over *Ptilotus schwartzii* var. *schwartzii* scattered low shrubs over Poaceae sp., *Aristida contorta* scattered tussock grasses to very open tussock grassland

P7 *Acacia aptaneura, A. catenulata* subsp. *occidentalis*, (*Grevillea berryana*) tall shrubland over *Ptilotus schwartzii* var. *schwartzii* scattered low shrubs over *Triodia melvillei* scattered hummock grasses to very open hummock grassland over *Aristida contorta* scattered tussock grasses

Vegetation of Hills and Slopes

H1 *Eucalyptus leucophloia* subsp. *leucophloia*, *Corymbia hamersleyana* sens. lat. scattered low trees to low open woodland over *Petalostylis labicheoides, Senna glutinosa* subsp. *glutinosa* scattered tall shrubs over *Gompholobium oreophilum*, *Acacia hilliana, A. spondylophylla* low open shrubland to low shrubland over *Triodia vanleeuwenii*, *T. wiseana*, *T. pungens* open hummock grassland with *Amphipogon sericeus* scattered tussock grasses

H2 *Eucalyptus repullulans* scattered low mallees over *Acacia catenulata* subsp. *occidentalis*, *A. aptaneura*, (*Grevillea saxicola*) tall shrubland to tall open scrub over *Scaevola acacioides, Dodonaea pachyneura, Eremophila latrobei* subsp. *filiformis* scattered shrubs to open shrubland over *Triodia pungens* scattered hummock grasses to very open hummock grassland with *Eriachne mucronata* scattered tussock grasses to very open tussock grassland

H3 *Corymbia deserticola* subsp. *deserticola* scattered low trees over *Acacia inaequilatera*, *Hakea chordophylla* scattered tall shrubs to tall open shrubland over *Senna glutinosa* subsp. *pruinosa* scattered shrubs over *Triodia vanleeuwenii* open hummock grassland with *Amphipogon sericeus* scattered tussock grasses to very open tussock grassland

H4 *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Senna glutinosa* subsp. *glutinosa*, *S. glutinosa* subsp. *pruinosa* scattered shrubs over *Triodia vanleeuwenii* and/or *T. wiseana* open hummock grassland to hummock grassland

H5 *Eucalyptus socialis* subsp. *eucentrica* scattered low mallees to low open mallee woodland over *Acacia bivenosa* scattered tall shrubs to tall open shrubland over *Senna glutinosa* subsp. × *luerssenii* scattered shrubs over *Ptilotus obovatus* scattered low shrubs over *Triodia wiseana* very open hummock grassland to open hummock grassland

H6 *Acacia aptaneura*, *A. catenulata* subsp. *occidentalis* tall open shrubland to tall shrubland over *Eremophila forrestii* subsp. *forrestii*, *Senna stricta* scattered shrubs to open shrubland over *Triodia pungens* and/or *T. vanleeuwenii* and/or *T. wiseana* scattered hummock grasses to very open hummock grassland with *Eriachne mucronata* scattered tussock grasses

H7 *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees to low open woodland over *Senna glutinosa* subsp. *glutinosa, Acacia maitlandii* scattered shrubs over *Triodia wiseana* and/or *T. vanleeuwenii* and/or *T. pungens* open hummock grassland to hummock grassland

H8 *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees to low open woodland over *Acacia pruinocarpa*, *Hakea chordophylla* scattered tall shrubs to tall open shrubland over *Triodia vanleeuwenii*, (*T. pungens*) open hummock grassland to hummock grassland with *Amphipogon sericeus* scattered tussock grasses

H9 *Acacia arida, Grevillea wickhamii* subsp. *hispidula* open shrubland over *Triodia wiseana* open hummock grassland with *Themeda* sp. Mt Barricade (M.E. Trudgen 2471) very open tussock grassland

H10 *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees with *E. repullulans* and/or *E. socialis* subsp. *eucentrica* and/or *E. pilbarensis* scattered low mallees to low open mallee woodland over *Acacia bivenosa* scattered shrubs over *Triodia wiseana, (T. angusta)* open hummock grassland to hummock grassland

H11 *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees with *E. gamophylla* low open mallee woodland over *Acacia ancistrocarpa* scattered tall shrubs to tall open shrubland over *A. hilliana* scattered low shrubs to low open shrubland over *Triodia vanleeuwenii*, (*T. pungens*) open hummock grassland to hummock grassland

H12 *Corymbia hamersleyana* sens. lat. scattered low trees over *Acacia inaequilatera*, *Hakea chordophylla*, *A. bivenosa* scattered tall shrubs to tall open shrubland over *Senna artemisioides* subsp. *oligophylla* scattered low shrubs over *Triodia wiseana* open hummock grassland to hummock grassland with *Themeda* sp. Mt Barricade (M.E. Trudgen 2471), *Cymbopogon ambiguus* scattered tussock grasses and *Heliotropium ovalifolium, Corchorus lasiocarpus* subsp. *parvus* scattered herbs

Maireana tomentosa subsp. *tomentosa*	0.1	0.3
Poaceae sp.	0.1	0.2
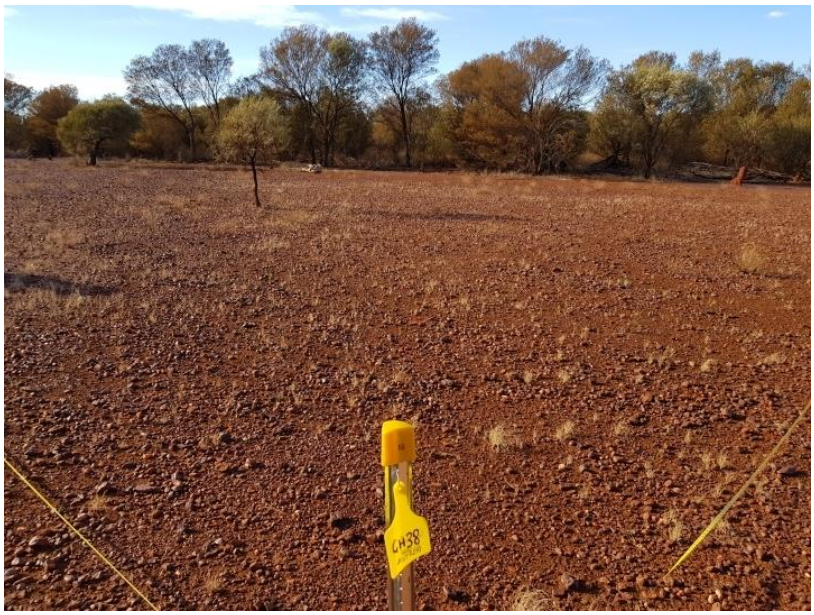
Psydrax suaveolens	0.1	0.2
Ptilotus exaltatus	0.1	0.2
Ptilotus obovatus	0.1	0.3
Rhagodia sp. Hamersley (M. Trudgen 17794) P3	0.1	1.3
Salsola australis	0.1	0.3
Solanum lasiophyllum	0.1	0.5
Triodia melvillei	0.1	0.5
Triodia pungens	0.1	0.2

* denotes weed species

Site: GH37
Location: HD1 Development Envelope **Type:** Quadrat
Phase 3 Date: 31/05/2019 **Described by:** LD
MGA Zone: 50 **Easting:** 682857 **Northing:** 7444808
Habitat: Plain
Soil: Light reddish brown Clay loam
Rock type: Ironstone
Veg code: P6
Vegetation: *Corymbia candida* subsp. *candida* scattered low trees over *Acacia aptaneura* tall open shrubland over *Themeda triandra* and *Eragrostis* sp. very open tussock grassland
Veg Condition: Very Good
Fire Age: >10 years



Species List:

Name	Cover (%)	Height (m)
Acacia aptaneura	7	5
Aristida contorta	0.1	0.2
Aristida ingrata	0.1	0.5
Aristida sp.	0.1	0.3
**Bidens bipinnata*	0.1	0.4
Centipeda minima subsp. *macrocephala*	0.1	0.1
Cheilanthes sieberi subsp. *sieberi*	0.1	0.2
Corymbia candida	1	8
Digitaria ammophila	0.1	0.1
Enneapogon sp.	0.1	0.3
Eragrostis sp.	1	0.2
Malvaceae sp.	0.1	0.1

Name	Cover (%)	Height (m)
Ptilotus exaltatus	0.1	0.1
Salsola australis	0.1	0.1
Solanum lasiophyllum	0.1	0.1
Sporobolus australasicus	0.1	0.1
Themeda triandra	1	0.5

* denotes weed species

Site: GH38
Location: HD1 Development Envelope **Type:** Quadrat
Date: 31/05/2019 **Described by:** LD
MGA Zone: 50 **Easting:** 679646 **Northing:** 7444390
Habitat: Plain
Soil: Light reddish brown Clay loam
Rock type: Ironstone
Veg code: P7
Vegetation: *Acacia aptaneura*, *Acacia catenulata* subsp. *occidentalis* and *Grevillea berryana* tall shrubland over *Sida calyxhymenia* open shrubland
Veg Condition: Very Good
Fire Age: Very long unburnt

Species List:

Name	Cover (%)	Height (m)
Acacia aptaneura	12	7
Acacia catenulata subsp. *occidentalis*	12	6
Aristida contorta	0.5	0.2
Aristida obscura	0.1	0.1
**Bidens bipinnata*	0.1	0.4
Cheilanthes sieberi subsp. *sieberi*	0.1	0.2
Enneapogon polyphyllus	0.1	0.1
Eragrostis sp.	0.1	0.1
Eremophila latrobei subsp. *filiformis*	0.1	1.2
Grevillea berryana	1	5
Maireana tomentosa subsp. *tomentosa*	0.1	0.3
Poaceae sp.	0.1	0.3

Name	Cover (%)	Height (m)
Psydrax latifolia	1	2.8
Ptilotus exaltatus	0.1	0.1
Ptilotus obovatus	0.1	0.4
Ptilotus roei	0.1	0.1
Ptilotus schwartzii var. *schwartzii*	0.5	0.3
Rhagodia sp. Hamersley (M. Trudgen 17794) P3	0.1	1.2
Sida calyxhymenia	3	1.2
Solanum lasiophyllum	0.1	0.4
Triodia melvillei	0.1	0.4

* denotes weed species

B.3: Targeted Riparian Values Assessment of the Greater Hope Downs 1 Area

RioTinto

Hope Downs 2 Proposal

Targeted Riparian Survey of the Greater Hope Downs 1 Area

November 2023

RioTinto

Disclaimer and Limitation

This report has been prepared by Rio Tinto's Iron Ore Group (Rio Tinto), on behalf of Hamersley HMS Pty Limited (the Proponent), specifically for the Hope Downs 2 Iron Ore Proposal. Neither the report nor its contents may be referred to without the express approval of Rio Tinto, unless the report has been released for referral and assessment of proposals.

1. Introduction

Rio Tinto is progressing with the assessment of its Hope Downs 2 (HD2) Proposal. In order to support the Environmental Impact Assessment (EIA) process and improve understanding of environmental values in the area, Rio Tinto have undertaken a targeted study (desktop and field survey) of riparian vegetation communities within and surrounding the proposed development envelope. This study was completed to provide updated and targeted vegetation mapping as well as an assessment of the significance of local riparian values within the Hope Downs 2 Proposal area (the Proposal).

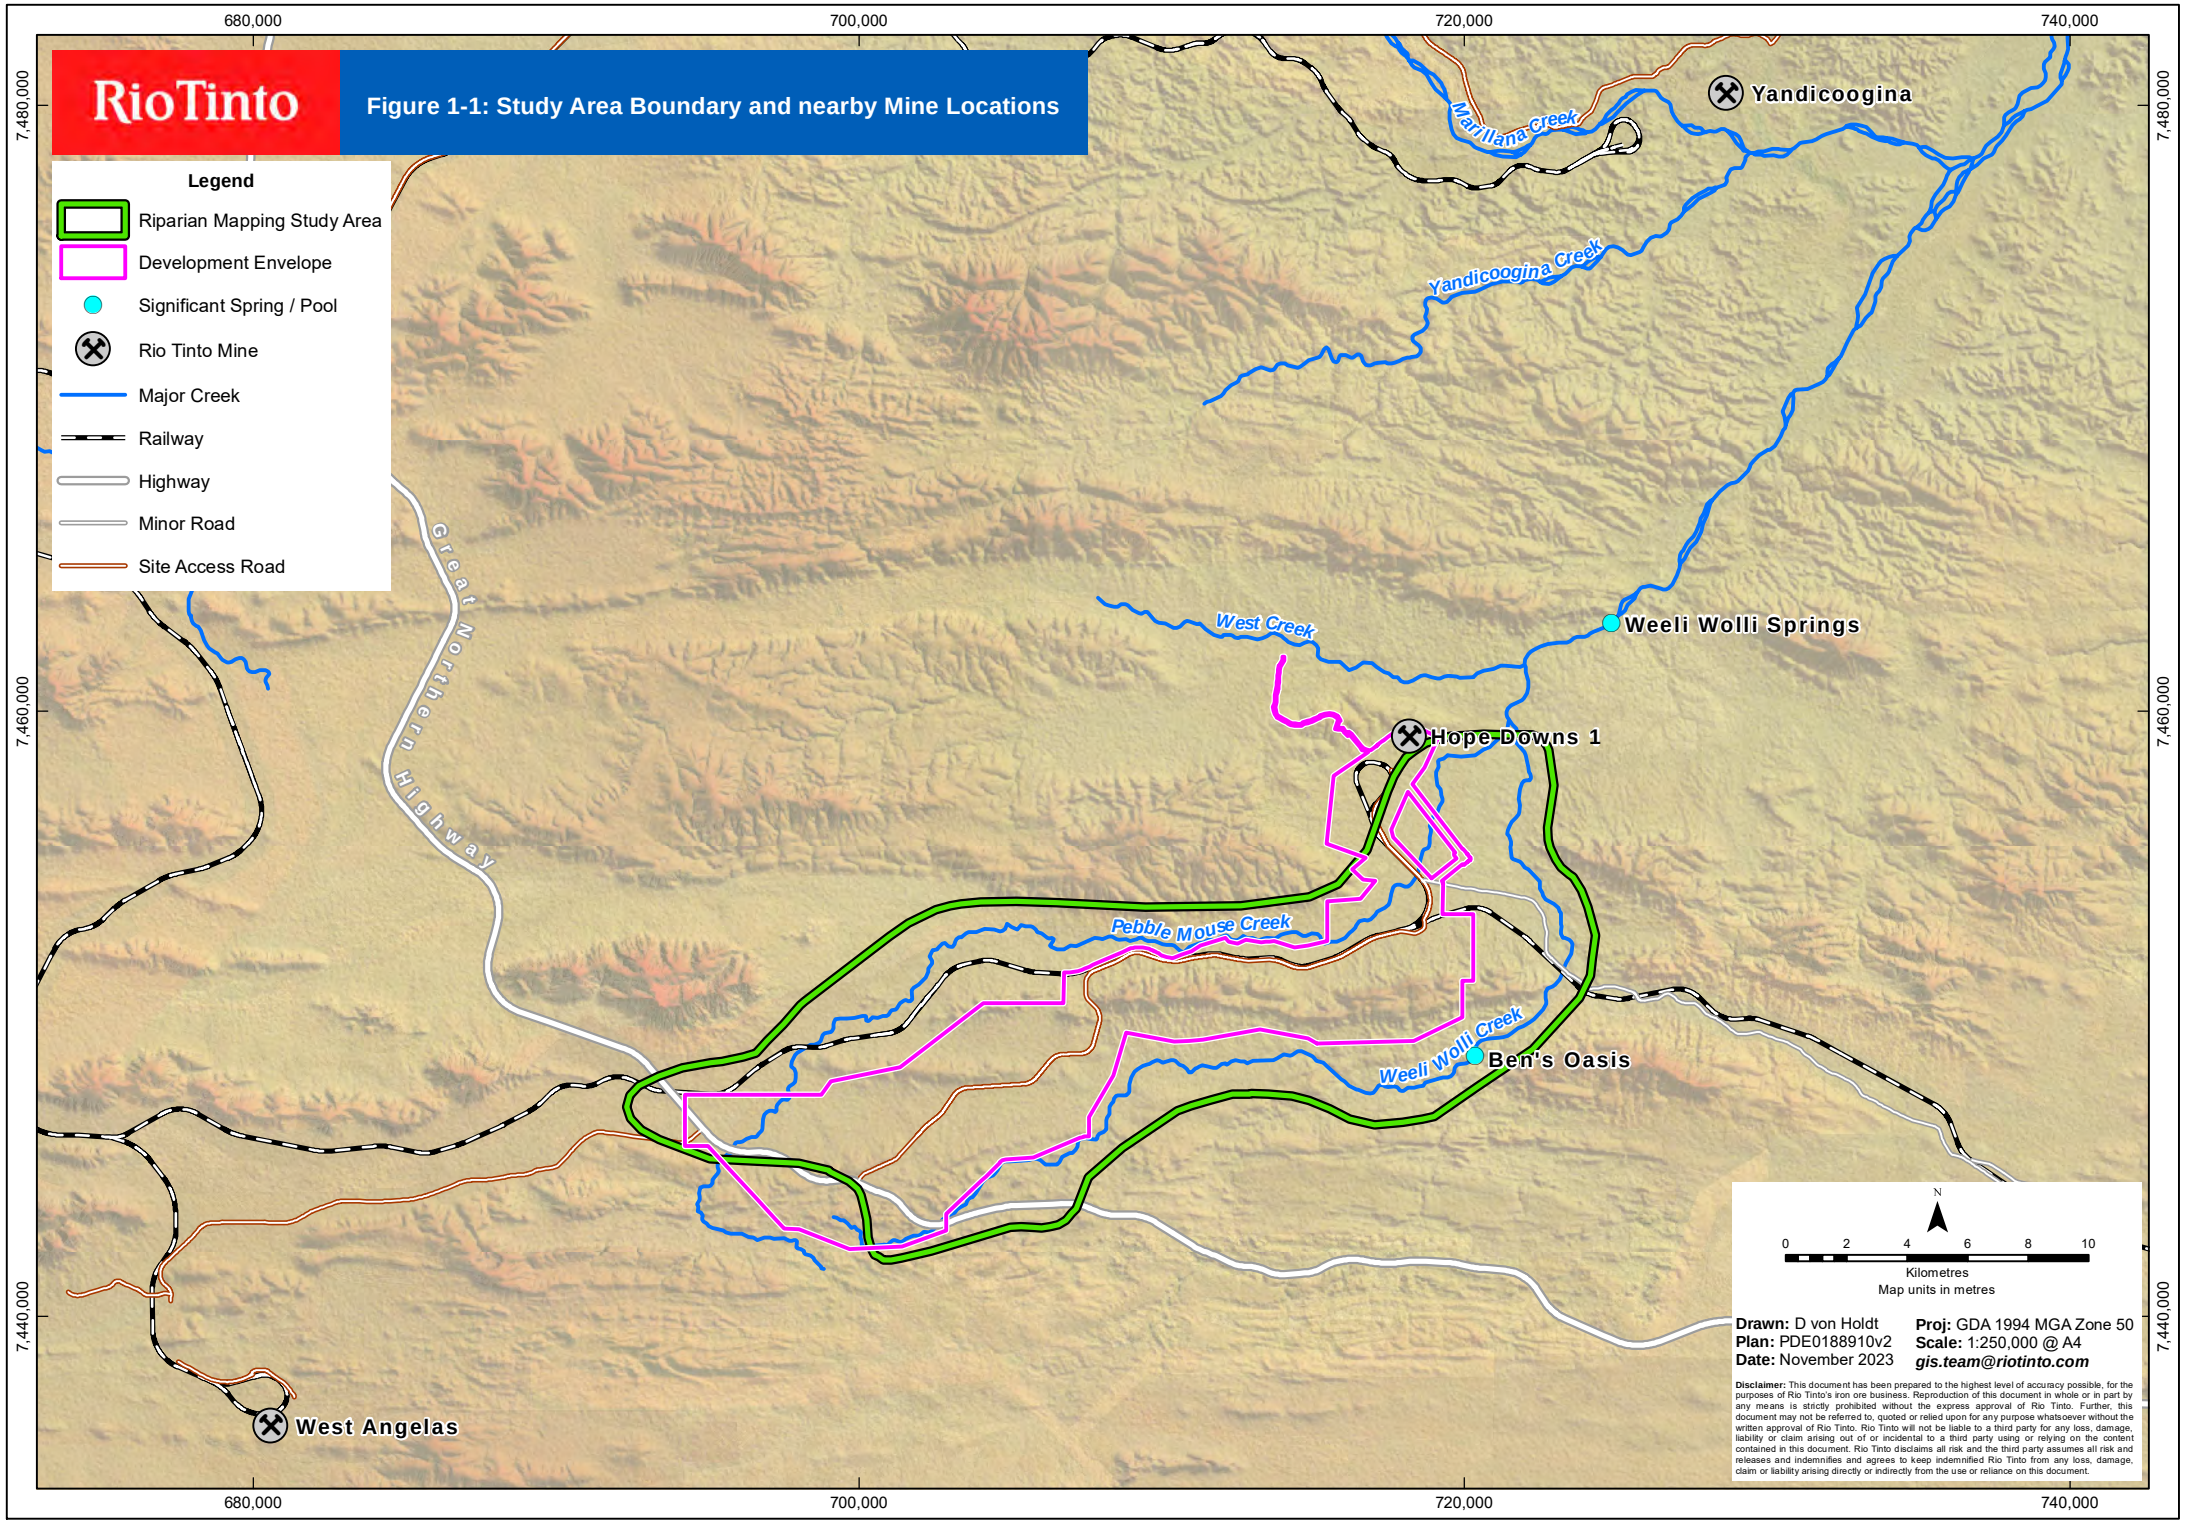
1.1. Study Objectives

The key objective of this targeted survey was to further study riparian ecosystems (beyond baseline flora and vegetation studies) on moderate to major sized drainage systems within and surrounding the Proposal. Proposed outcomes of this study were to produce refined riparian vegetation mapping (of higher detail) along with Groundwater Dependent Vegetation (GDV) likelihood mapping, relevant surface water mapping and ultimately a detailed significance assessment of the riparian communities mapped across the Study Area. The proposed objectives were created in order to identify, characterise and contextualise any riparian ecosystems (and potential GDV) occurring within and surrounding the Hope Downs 2 Development Envelope.

The current study used aerial photo interpretation, remote sensing tools/analyses (namely NDVI/NDMI persistence mapping), historical flora and vegetation surveys, select field investigations and a targeted survey to assess riparian systems in and around the proposed Development Envelope, hereafter known as the Study Area.

This report has been prepared to address the information requirements outlined in the Environmental Scoping Document (ESD) for the Environmental Review Document (ERD) as presented in Table 1-1.

Table 1-1: Work required to address riparian/Groundwater Dependent Ecosystem (GDE) associated with the Proposal



Description
Flora and Vegetation
• Describe and assess the extent of any cumulative impacts within local, regional and State contexts as appropriate. • Describe and quantify the potential direct and indirect impacts of the construction and operational elements of the proposal on identified environmental values. • Include an assessment of impacts to groundwater/surface water dependent vegetation, including riparian vegetation. • Include a quantitative assessment of levels of impact on significant flora, listed ecological communities and all vegetation units.
Inland Waters
• Describe and assess potential cumulative groundwater and surface water impacts, including changes in groundwater levels, surface water flows within the relevant catchments, and possible impacts to GDV and GDEs within the Weeli Wolli Spring PEC, including “Ben’s Oasis”. • Assess the nature, extent and duration of potential impacts of groundwater abstraction with a focus on possible impacts.

1.2. The Study Area

The Study Area incorporates the majority of Pebble Mouse Creek (PMC), stretching approximately 35 km, and a section of Weeli Wolli Creek (WWC) (which focuses on the west tributary of WWC) stretching approximately 40 km (Figure 1-1).

Although the Study Area covers a large portion of Hope Downs 1, it does not cover any of Weeli Wolli Spring (WWS). WWS is located approximately 5 km’s downstream of the north-eastern tip of the Study Area. The small spring up stream of WWS, colloquially named “Ben’ s Oasis” which consists of

series of pools and associated GDV/riparian vegetation occurring along WWC is covered by the Study Area.

2. Background Information

2.1. Large creek systems of the Hamersley sub-region

The Hamersley IBRA (Interim Biogeographic Regionalisation for Australia) subregion of the Pilbara IBRA bioregion is essentially represented by those areas occurring on and adjacent to the ranges, valleys, and plateau formations of the Hamersley Ranges (DoE, 2014a). These ranges are unique in the Pilbara due to their size, relatively vast expanses of upland area, and associated large and extremely rugged/rocky habitats.

Rainfall patterns in the Hamersley Ranges (the Hamersley IBRA subregion), when compared to the remainder of the Pilbara bioregion are also different, with higher annual rainfall over the Hamersley Ranges (up to 500 mm). This higher average rainfall is known to be a product of advection and convergence of moist sea breezes together with uplift from orography and heating associated with the steep and rocky features of the Hamersley Range (Charles *et al* 2015).

The climate is hot and semi-arid, with annual evaporation typically exceeding annual rainfall. Rainfall occurs as localised, infrequent, high intensity thunderstorms between prolonged periods of drought. The region is warmest and wettest between December and March, with average maximum temperatures often above 40°C. During the winter months temperatures fall to around 25°C.

Within the Hamersley subregion these factors combine to produce a significant number of large and relatively unique creek systems. The number and spread of these large creek systems, along with the spatial boundaries of their respective catchments, are depicted in Figure 2-1. To provide a comparative look at the size of each of these creek systems the areal extent of the catchment of each is provided below in Table 2-1.

The creek systems within the Hamersley's that form the focus of this study are Weeli Wolli Creek and one of its tributaries Pebble Mouse Creek. The Weeli Wolli Creek system forms part of the overall catchment of the Fortescue River Basin, which includes the Fortescue Marsh. The Fortescue Marsh is the largest ephemeral wetland in the Pilbara region and is recognised as being nationally important. The Fortescue Marsh extends over approximately 1,048 square kilometres (km^2) and lies within a broader catchment area of the upper Fortescue River (29,791 km^2). The catchment of the Fortescue Marsh is also rich in ore deposits and multiple mining operations operate in the region.

Creeks in the Pilbara are typically ephemeral and flashy hydrological systems, with flow only occurring after occasional, localised intense rainfall events. The area often experiences periodic heavy rainfall during summer because of both monsoonal effects and cyclones. Although the average surface flow is 2.8 GL/year it has been as high as 22 GL during an exceptional flood year. The pisolite and calcrete, where present below the water table, constitute a significant aquifer which is recharged via direct rainfall infiltration and creekline infiltration (Johnson & Wright 2001).

For most its length, Weeli Wolli Creek behaves and supports similar biota to that of the majority of typical Pilbara creeks. It is the ecology and nature of Weeli Wolli Springs (WWS) and its associated PEC's that make the creek unique in the region.

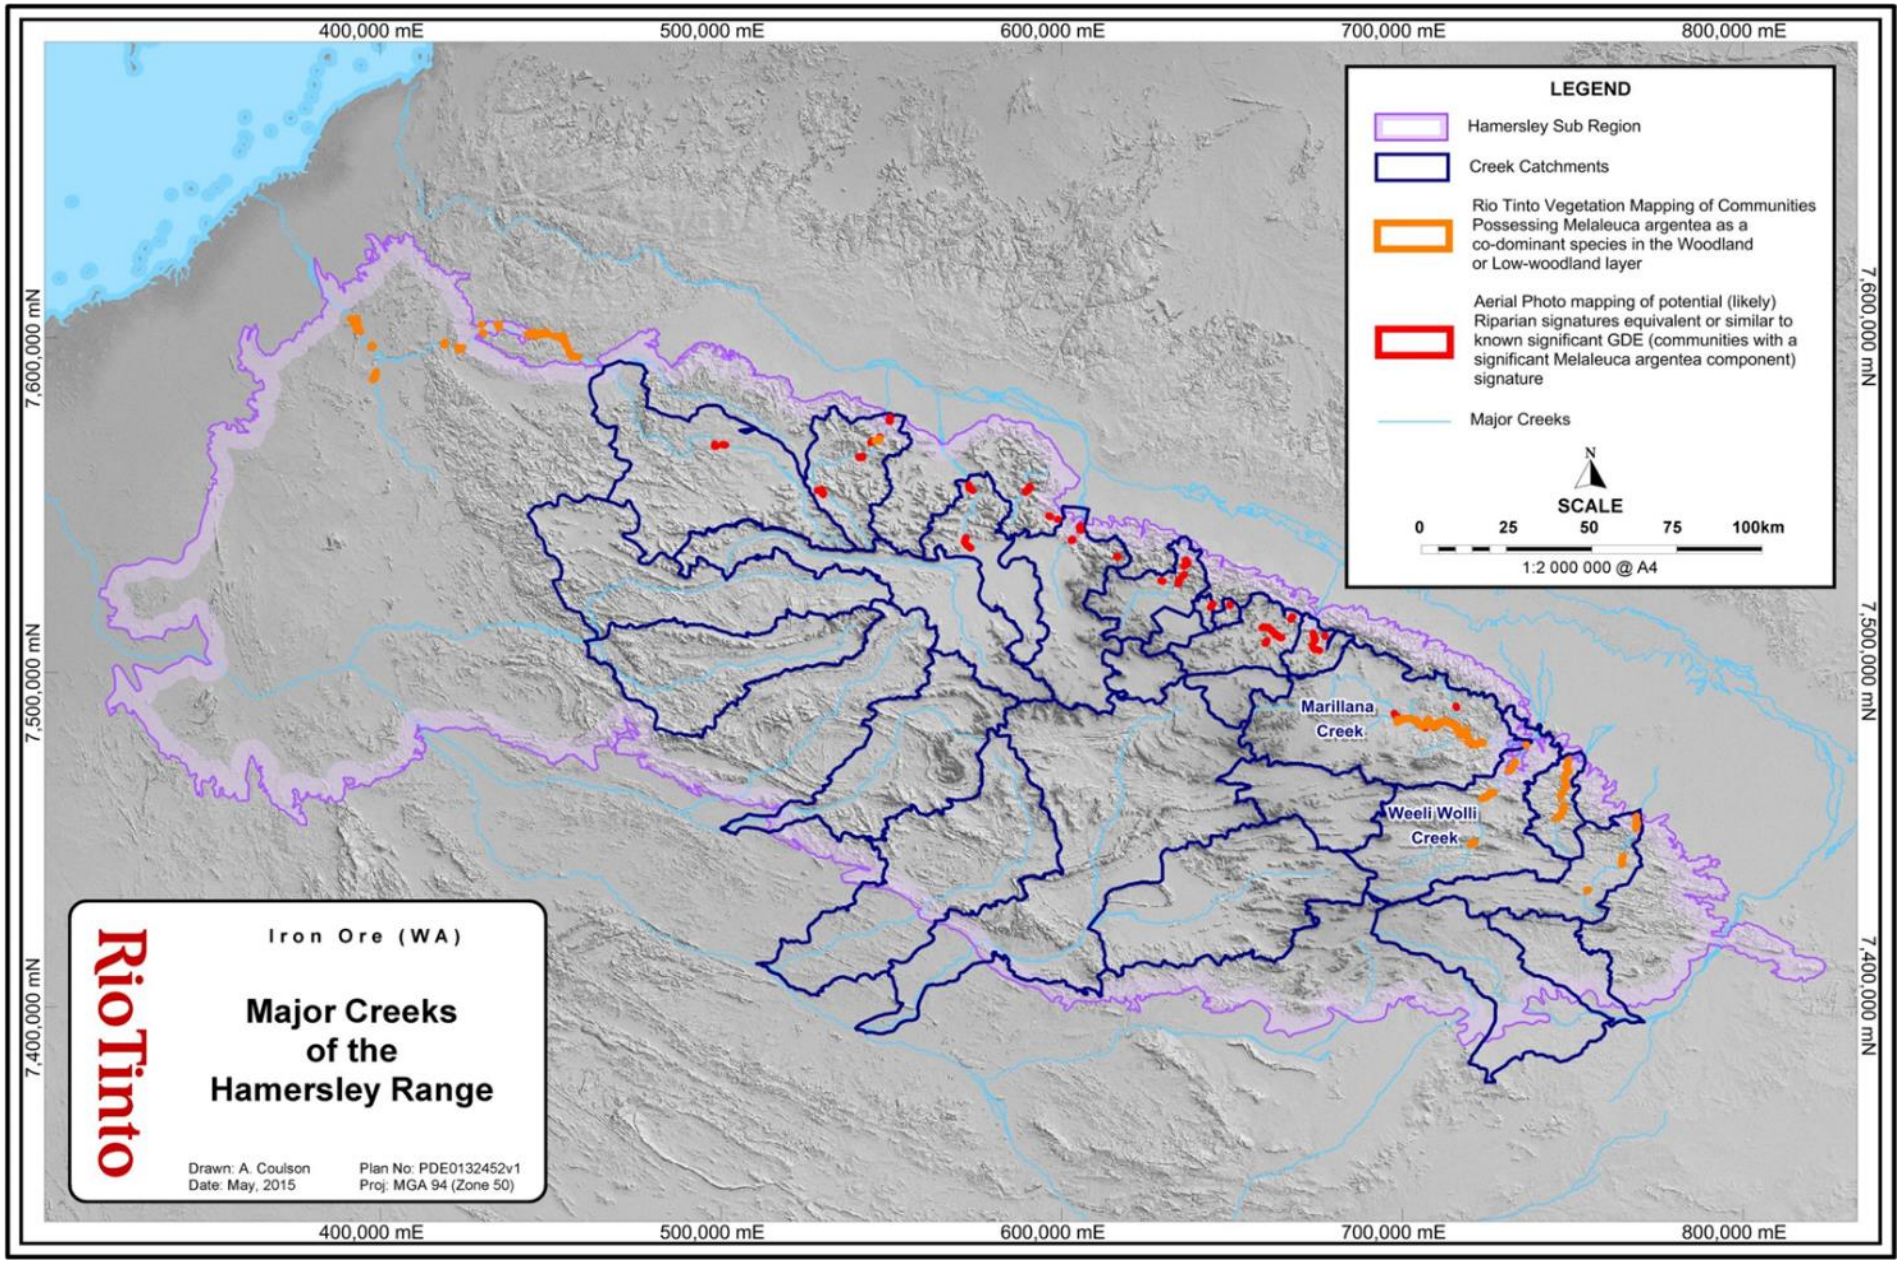

Figure 2-1: Major Creeks of the Hamersley sub-region

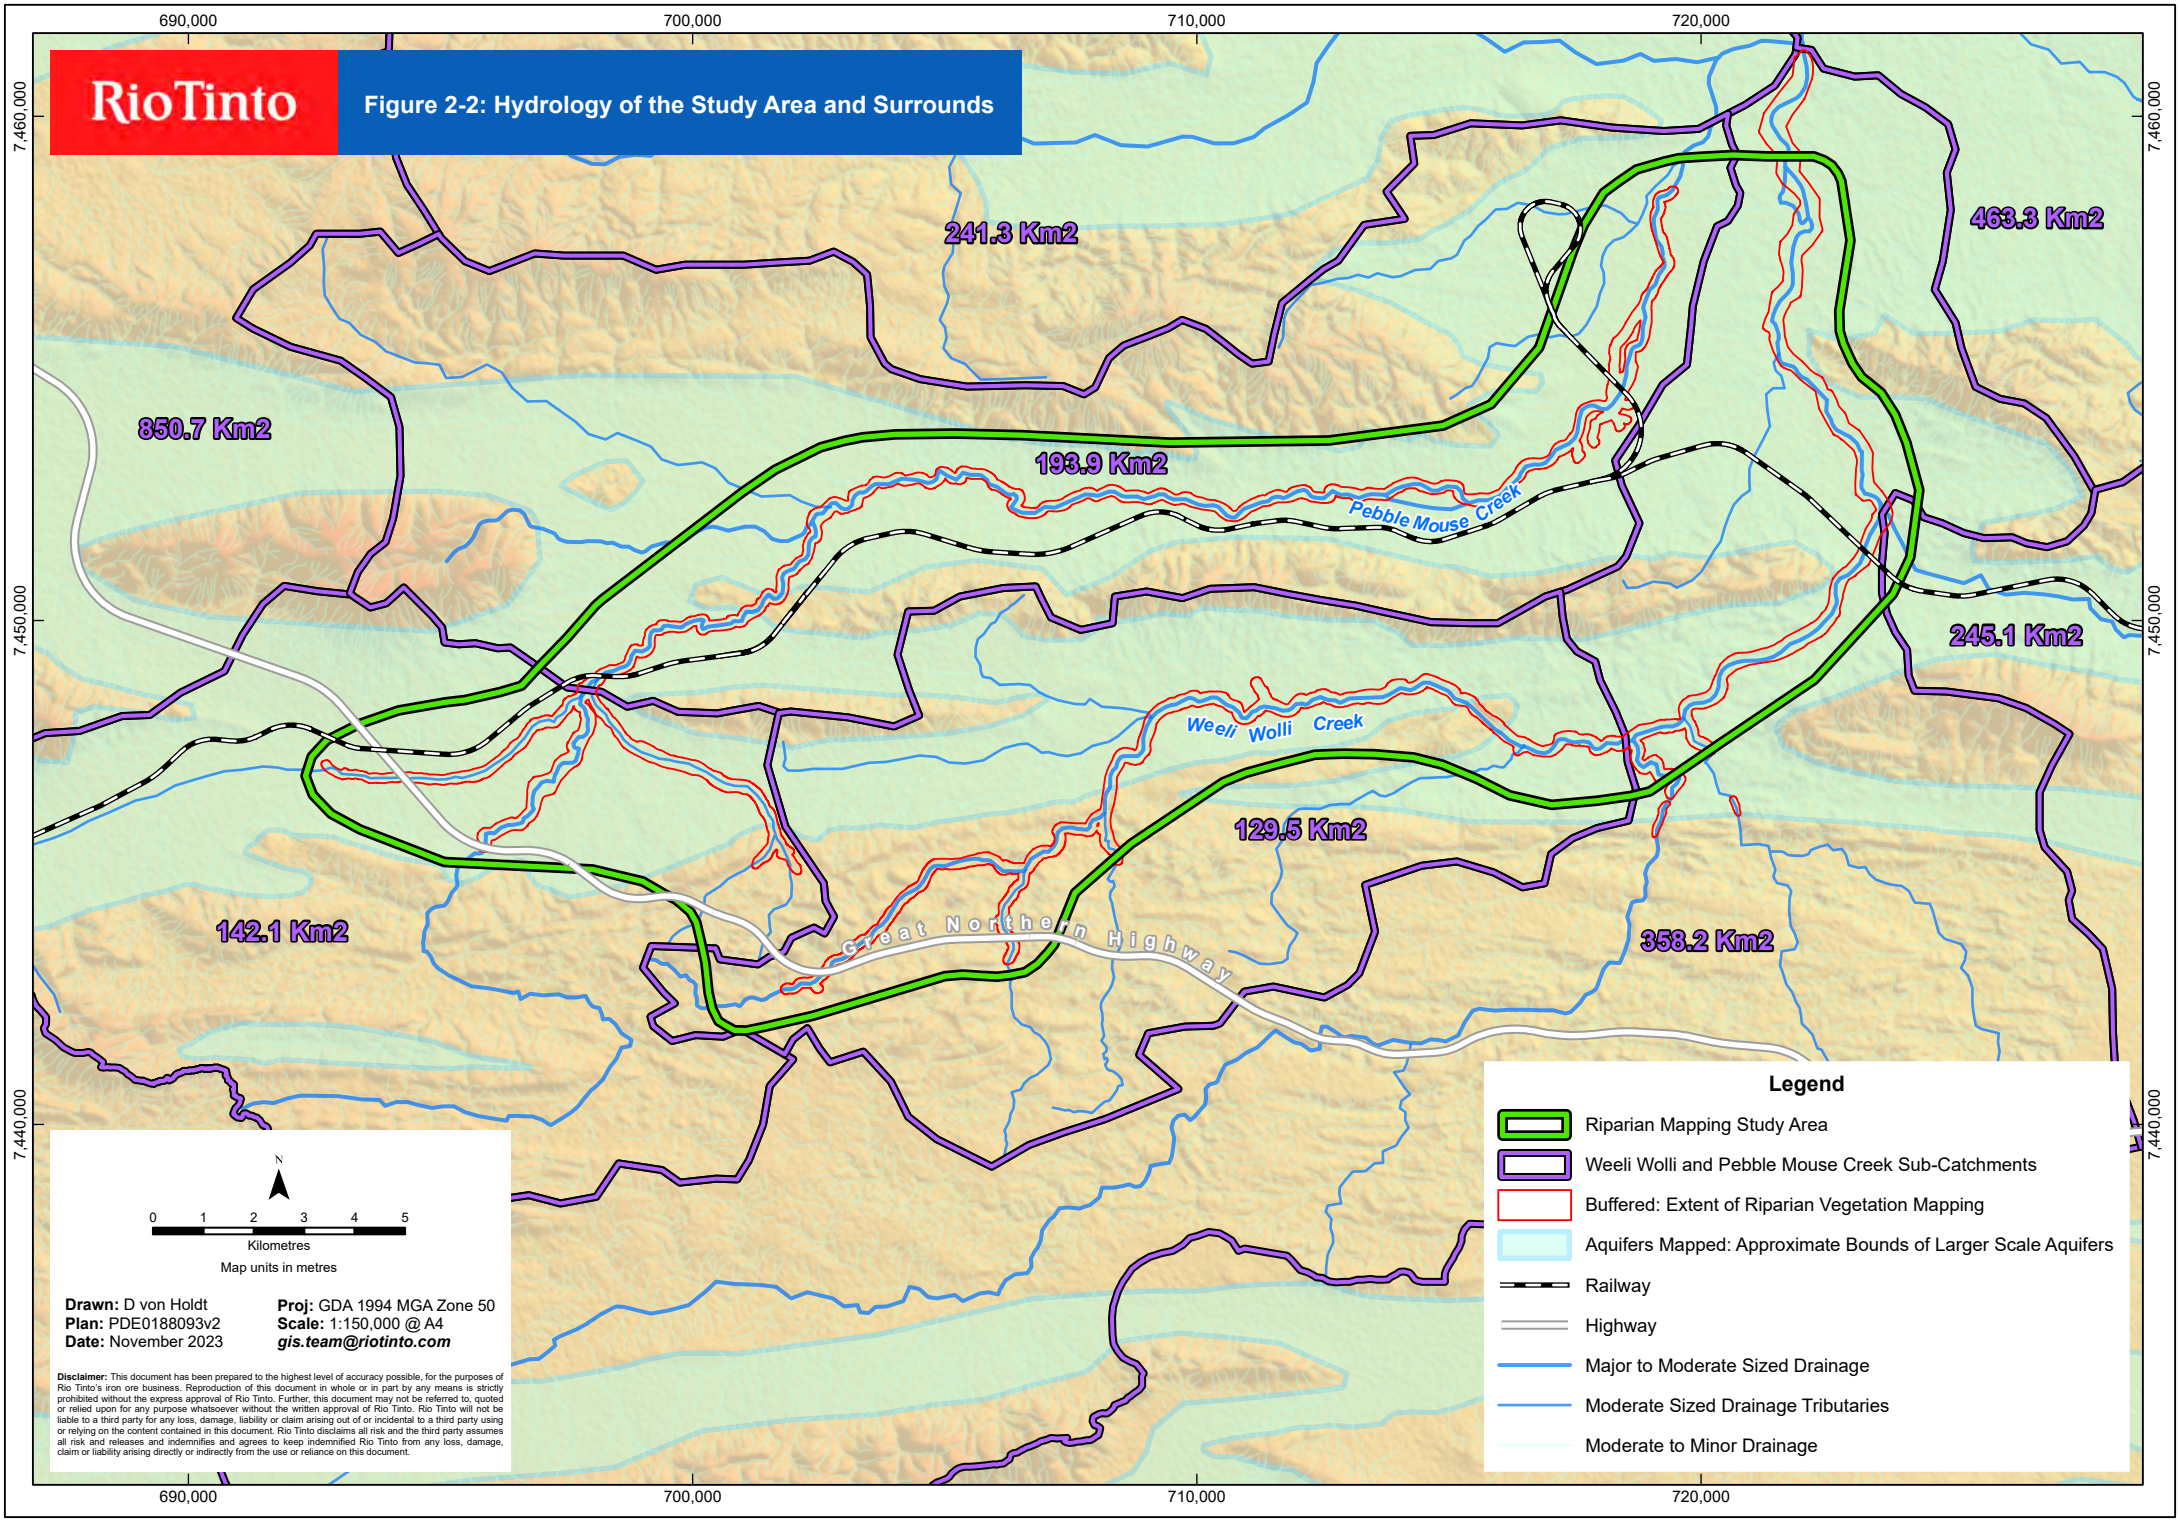
2.2. Local Hydrology and catchment characteristics

The Study Area intersects the Weeli Wolli Creek (WWC) catchment and the Pebble Mouse Creek (PMC) catchment. Approximately 40 km of WWC and approximately 35 km of PMC run through the Study Area.

The WWC catchment forms part of the Fortescue River Basin, and including the catchment of Marillana Creek, WWC drains an overall catchment of approximately 4,770 km^2 (if the internally draining portions of its extent are included) (EPA, 2018a) and contributes approximately 5 to 10% of the total catchment area of the Fortescue Marsh. Approximately 40% or ~1000 km^2 of the overall WWC catchment intersects the Study Area. The PMC catchment is approximately 570 km^2 in size (depending on which tributaries are included in its namesake) and represents a major tributary of WWC. The majority of the south tributary of PMC (~90% or 330 km^2) occurs within the bounds of the Study Area, with the north tributary dissecting areas influenced by BHP's Area C and South Flank operations.

The catchment is underlain by formations of the Hamersley and Fortescue Groups, comprising dolomites, basalts, shales and ironstone, with minor felsic volcanics and intrusive dolerite dykes and sills. The Brockman, Marra Mamba Iron formations and Channel Iron Deposits (CID) host most of the known major iron ore deposits in the area. The dolomites of the Wittenoom Formation form a regionally important aquifer.

The WWC catchment includes a large spring (Weeli Wolli Spring) and associated pools that support unique flora and fauna communities. The main part of Weeli Wolli Springs (WWS) is located approximately 8 km to the northeast of the Study Area and holds high biodiversity value, along with being representative of two Pilbara PEC's. An increase in significant threats (i.e. cattle grazing, inappropriate fire regimes and mining practices) has resulted in the listing of the WWS community as a Priority 1 (P1), Priority Ecological Community (PEC). In addition to this, WWS is also representative of the Springs and River Pools PEC (Appendix J:) due to (among other things) the assemblage of relictual macrophytes which it supports.



The Weeli Wolli Spring PEC (Appendix I:) is also mapped to occur at "Ben's Oasis", which is another significant feature on WWC and occurs within the Study Area on the west branch of WWC. This feature represents a small spring and permanent pool where groundwater emerges from outcropping Wittenoom Formation.

With the exception of the WWS (downstream of the Study Area) reach and the preceding "Ben's Oasis" reach on its west tributary, WWC broadly represents a typical ephemeral Pilbara creek system. One of its tributaries, and a focus of this study is PMC. Pebble Mouse Creek represents a highly ephemeral creek system, and while its minor tributaries dissect steep range systems within its catchment, the majority of larger channels of PMC dissect relatively broad alluvial valleys dominated by fine loamy sediments supporting a relatively sparse core-riparian zone flanked by broad and sparsely but variably vegetated floodplains.

The catchment of WWC in the area surrounding the Hope Downs 1 mining hub has been exposed to substantial water abstraction associated with dewatering at the Hope Downs mine. In addition, in the area of WWS, substantial discharge of surplus mine dewater associated with dewatering at the Hope Downs mine has also occurred. Prior to dewatering at Hope Downs 1, WWS was naturally groundwater fed, but for now it remains supported by discharge from HD1.

The south tributary of PMC previously joined the north tributary and WWC just to the north of the HD1 mine, but now open-cut mining has led to this tributary being diverted around the NE pit and into WWC approximately 2 km upstream of its previous confluence with WWC. Beside the area of direct influence from diversion and the influence of seasonal water ponding in the diversion area, PMC remains relatively unchanged.

Figure 2-2 shows the hydrology of the Study Area, including the WWC and PMC sub-catchments, Large Scale Aquifer (LSA) approximate boundary and major to moderate drainage and tributaries.

2.3. Local Hydrogeology

Broad Geology & ecohydrological properties

The Study Area predominantly intersects tertiary detritals (which generally overlay the basement lithology) as well as three dominant geological units within the Hamersley Group; the Brockman Iron Formation, the Wittenoom Formation, and the Marra Mamba Iron Formation (MMIF). These units typically have higher permeabilities and are therefore likely to host aquifers throughout. Some of the southern reaches of the Study Area (upper reaches of Weeli Wolli Creek west tributary) intersect the Fortescue Group geology, which is dominated by Jeerinah Formation (basalt) and associated dolerite dyke formations. The Fortescue Group typically possesses very low hydraulic conductivity, and as such, utilisation of regional aquifers within the Hamersley Group is unlikely to influence any riparian features within areas overlying Fortescue Group geology.

From a fluvial point of view, the more porous lithologies like those of the Hamersley Group, at least in situations where basement outcropping is shallow or at surface, tend to soak up a reasonable proportion of the incident rainfall, and resulting surface water flows which their catchments transport. This leads to smaller volumes of water transported per unit of time from such systems, as well as shorter residence times for surface water which ends up either perched within creek channels and their alluvium, or perched over covered or exposed porous basement lithology. This has a flow on effect to the typical ecohydrology of systems dissecting Hammersley Group lithology, which is 2-fold. Where fluvial habitats intersect shallow aquifers supported by the porous lithology, dry season moisture persistence is elevated via the groundwater access/proximity, often supporting mesic and highly productive riparian vegetation. For the remainder of situations (the vast majority) where such aquifers are not accessible, dry season water persistence in the fluvial environment is generally reduced, and riparian vegetation is also typically highly ephemeral.

For fluvial systems dissecting Fortescue Group geology, and particularly the basaltic and doleritic formations, hydraulic conductivity is generally very low, and this reduces the amount of water uptake by the lithology following rainfall events. Particularly in situations where basement outcropping is shallow or at surface, this very low uptake by the environment leads to high rates of catchment shed following rain events and poor infiltration within the channel. This in turn leads to high volumes of water transported per unit of time from such systems (leading to increased scour), as well as potentially longer residence times for surface water which ends up either perched within creek channels and their alluvium (particularly the fine-grained terraces), or perched over covered or exposed basement lithology. More broadly this typically leads to longer dry season water persistence in the fluvial environment, due to channels continuing to transport or perch water over their basement into the dry season, rather than absorbing the water away from riparian root zones. These ecohydrological characteristics tend to support intermediate riparian vegetation, which is somewhat disproportionately mesic (in floristic composition and productivity) in relation to the reporting catchment size.

Proposed abstraction

The proposed development involves above water table mining only. However, the proposal has a construction and operational demand which needs to be met. This demand will either be met by abstracting from the mined orebody aquifers (namely HD2), or via a portion of the surplus from the HD1 operations which is currently being discharged in the vicinity of WWS. There is a high likelihood that it will be a combination of the two sources. For the HD2 aquifer to meet operational demand, modelling estimated that a total combined volume of 38 GL may be abstracted across the life of the project (approximately 13 years).

Relevant Aquifers

Within the Study Area, there are two main geological units that comprise regional aquifers with potential to be utilised/influenced by the development:

1. Wittenoom Formation and closely aligned Marra Mamba Iron Formations.

   Occurring at HD1 and HD2, comprising the often karstic dolomite within the Bee Gorge and Paraburdoo Members of the Wittenoom Formation and the mineralised and/or fractured zones of the underlying Mt Newman Member of the Marra Mamba Iron Formation.

2. Brockman Iron Formation

   Occurring at Bedded Hilltop (BHT), and comprising the mineralised zones of the Dales Gorge Member and Joffre Member where fractures are encountered.

The HD2 aquifer is intended as a supply source for the proposal and is considered fairly well isolated from the significant local environmental receptors. In fact, both aquifer complexes are well compartmentalised via the bounds of the key porous geological units, as well as dykes and other aquitards. The result is that modelled abstraction associated with the development and its operational demands is relatively tightly contained within the bounds of the HD2 aquifer. In addition, a large data set of groundwater level response from abstraction at HD1 shows that HD2 is separated from the HD1 aquifer, and as such it is considered that abstraction from HD2 poses no risk to the key receptors in the area (WWS and “Ben’s Oasis” spring systems). These receptors are located in proximity of the HD1 mine (WWS to its northeast), or adjacent to the eastern end (south of) of BHT, and outside of the HD2 groundwater system.

The broad geological groups and the aquifer complexes they are thought to support in the broader HD1 locality are presented in Figure 2-3. To view the position of finer scale aquifer boundaries and compartmentalisation relevant to the groundwater modelling refer to Rio Tinto (2022), for specific mapping outputs.

2.4. Proposed and historical groundwater abstraction

2.4.1. Historical Influence

Dewatering in the HD1 area has brought about two key changes in groundwater in the area. Firstly, it has dewatered a significant volume of water from the surrounding aquifer such that groundwater heights are no longer high enough for groundwater discharge to occur into and through the WWS area. This impact to the groundwater system is mitigated in the vicinity of the springs by discharge and groundwater mounding at the gabion as well as from a series of irrigation spurs within the initial parts of the springs (prior to the gabion) and broadly correlated with the baseline extent of Obligate Phreatophytic Species (OPS). Secondly it has led to a drawdown cone in the area of the operations which extends below parts of WWC and PMC. At baseline, groundwater heights in the now affected reaches of WWC were in the order of 6 to 10 metres below ground level (mbgl) at the north extent and 15 to 20 mbgl (and potentially deeper) at the southern extent, in the vicinity of where the east and west tributaries of WWC separate. In this zone, since mining has begun, groundwater has transitioned from generally accessible/potentially accessible (but not clearly accessible) to clearly inaccessible. In some areas along WWC, directly east of the HD1 pit's, groundwater has dropped to as low as 70 m, but regardless of depth the outcome of such changes is that the regional aquifer is no longer accessible below an 8 to 10 km stretch of WWC adjacent to the mine. Despite this, monitoring results to date through this area don't show a significant or clearly attributable impact from dewatering apart from general but not substantial reductions in canopy cover in low flow phreatophytes. Furthermore, a census of the condition of every Facultative Phreatophytic Species (FPS) individual in a 4 km stretch of WWC directly adjacent to the mine found that in 2018 only 15 trees were detected to have died since mining began in 2007. This number is clearly in the realm of natural attrition given that it was out of approximately 2000 individuals assessed. Furthermore, as part of this same assessment, no patterns in increased mortality or significantly reduced condition were recorded for floodplain *Eucalyptus camaldulensis* individuals positioned several hundred meters away from the seasonal recharge afforded to trees in or adjacent to the low flow. It was concluded that populations in that area of highest groundwater drawdown were most likely being afforded protection from this influence by the vadose zone and small-scale groundwater reserves seemingly positioned in the extensive calcrete formations in this area which WWC and its floodplains dissect.

For PMC, the story is quite different. Outside of the area of direct influence from its diversion and the influence of seasonal water ponding in the diversion area, PMC remains relatively unchanged. This is predominantly because of the fact that groundwater heights within the regional aquifer in the PMC area are generally beyond 30 mbgl.

2.4.2. Proposed Groundwater changes

The deposits associated with the Proposal (i.e. BHT and HD2 deposits), are proposed to be restricted to above water table (AWT) mining, and as a result the only groundwater abstraction proposed as part of the development is relatively low volume abstraction to support mining construction and operational demands such as dust suppression, infrastructure and processing.

A restriction to AWT mining combined with a general dearth of Groundwater Dependent Ecosystems (GDE's) and potential GDE's in the proposed development/abstraction areas indicates that the risk of impact to riparian ecosystems and potential GDV or associated GDE's is quite low.

Some risks to GDV/GDE's still remain, and this is primarily in the form of the springs at "Ben's Oasis", noting that WWS is further afield and currently supported by mine discharge. Hydrogeological work to date suggests the risk to "Ben's Oasis" remains very low, but given the elevated significance of the feature, further work is ongoing in order to properly understand this small but potentially credible risk.

2.5. Existing Riparian Vegetation Information

Several previous flora and vegetation surveys have been completed in the Greater Hope Downs 1 area (Figure 2-4). Of note are the surveys that have included parts of Pebble Mouse Creek and Weeli Wolli Creek within the current survey bounds (Astron Environmental Services Pty Ltd, 2020; E.M. Mattiske and Associates, 1995; Mattiske Consulting Pty Ltd, 2008; 2010), and the biannual monitoring conducted by Mattiske Consulting Pty Ltd that includes transects within the "Bens Oasis" area.

Astron's (2020) survey included the majority of Pebble Mouse Creek targeted within the current study, as well as some sections of Weeli Wolli Creek and surrounding vegetation on minor drainage. The 27 vegetation units were associated with three major landforms, with 'Vegetation of Drainage Lines' including eight vegetation units described as:

- **D1 –** *Corymbia hamersleyana* sens. lat., *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees to low open woodland over *Petalostylis labicheoides*, *Acacia monticola, A. maitlandii* scattered tall shrubs to tall shrubland over *Dodonaea lanceolata* var. *lanceolata, Androcalva luteiflora* scattered shrubs to open shrubland over *Triodia pungens* very open hummock grassland to open hummock grassland with *Themeda triandra*, *Eriachne mucronata* very open tussock grassland to open tussock grassland.
- **D2 –** *Acacia aptaneura, A. catenulata* subsp. *occidentalis*, *A. pruinocarpa* tall shrubland to tall open scrub over *Petalostylis labicheoides* scattered shrubs to open shrubland over *Triodia pungens* very open hummock grassland with *Chrysopogon fallax* scattered tussock grasses.
- **D3 –** *Corymbia ferriticola*, *Eucalyptus leucophloia* subsp. *leucophloia* low open woodland over *Petalostylis labicheoides*, *Acacia hamersleyensis, Dodonaea viscosa* subsp. *spatulata* tall open shrubland over *Triodia pungens* very open hummock grassland with *Eriachne mucronata*, *Themeda* sp. Mt Barricade (M.E. Trudgen 2471), *Cymbopogon ambiguus* very open tussock grassland to tussock grassland.
- **D4 –** *Eucalyptus victrix*, (*E. camaldulensis* subsp. *obtusa*) low open woodland to open woodland over *Acacia citrinoviridis*, *Petalostylis labicheoides* scattered tall shrubs to tall shrubland over *Androcalva luteiflora*, *Gossypium sturtianum* var. *sturtianum* scattered shrubs to open shrubland over *Triodia longiceps* scattered hummock grasses to very open hummock grassland with *Themeda triandra*, *Eulalia aurea*, (**Cenchrus ciliaris*) very open tussock grassland to tussock grassland and **Bidens bipinnata* scattered herbs.
- **D5 –** *Eucalyptus xerothermica* scattered low trees to low open woodland over *Petalostylis labicheoides, Acacia maitlandii*, *A. pyrifolia* tall open shrubland to tall shrubland over *Androcalva luteiflora* scattered shrubs over *Triodia longiceps* very open hummock grassland to open hummock grassland with *Themeda triandra*, *Eulalia aurea* open tussock grassland to tussock grassland and **Bidens bipinnata* scattered herbs.
- **D6 –** *Melaleuca argentea, Eucalyptus camaldulensis* subsp*. obtusa, (E. victrix*) open forest over *Acacia citrinoviridis, Atalaya hemiglauca* scattered tall shrubs over *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) scattered low shrubs over *Cyperus vaginatus, Typha domingensis* scattered sedges.
- **D7 –** *Acacia citrinoviridis, A. aptaneura, A. pruinocarpa* scattered tall shrubs to tall shrubland over *Senna artemisioides* subsp. *oligophylla* scattered low shrubs over *Triodia longiceps* open hummock grassland to hummock grassland.
- **D8 –** *Eucalyptus xerothermica* scattered low trees to low open woodland over *Acacia aptaneura, A. catenulata* subsp*. occidentalis* tall open shrubland to tall open scrub over *Triodia pungens* scattered hummock grasses to very open hummock grassland with *Themeda triandra* very open tussock grassland to open tussock grassland.

The remaining 19 vegetation units occurred outside of the riparian zones of moderate to major sized drainage, which were the focus of this study. Of these eight riparian vegetation units above, three units (D1, D2, D3) were associated with minor to moderate drainage lines that occurred on the smaller tributaries of Pebble Mouse Creek and Weeli Wolli Creek, and one unit (D6) was mapped outside of the area that the current study focuses on. Areas mapped by Astron (2020) as vegetation units D4, D5, D7 and D8 were of most relevance to the current study.

Mattiske's (2008) survey included the majority of Weeli Wolli Creek targeted within the current assessment and surrounding non-riparian vegetation. The 25 vegetation units mapped by Mattiske (2008) were associated with two major landforms, with 'Flowlines (creeklines and drainage areas)'

including five vegetation units and 'Flats and Broad Plains' including one vegetation unit associated with creeklines, described as:

- **STC C1 –** Open Woodland of *Eucalyptus victrix*, *Eucalyptus camaldulensis* var. *obtusa* over *Acacia citrinoviridis* and *Acacia coriacea* subsp. *pendens* over *Petalostylis labicheoides*, *Gossypium robinsonii*, *Acacia pyrifolia*, *Melaleuca lasiandra*, *Androcalva luteiflora* over *Tephrosia rosea* var. *clementii*, *Themeda triandra*, *Cyperus vaginatus* and *Cleome viscosa* on major creeklines with sandy soils.
- **ATA C2 –** Low Woodland of *Eucalyptus xerothermica* and *Eucalyptus victrix* over *Acacia citrinoviridis*, *Acacia maitlandii*, *Gossypium australe*, *Melaleuca lasiandra*, *Petalostylis labicheoides*, *Androcalva luteiflora* over *Triodia epactia*, *Chrysopogon fallax* and *Triodia pungens* on minor creeklines with sandy soils.
- **MF C3 –** Tall Shrubland of *Acacia arida*, *Acacia bivenosa*, *Acacia ancistrocarpa*, *Acacia maitlandii*, *Acacia monticola* with occasional emergent *Corymbia deserticola* subsp. *deserticola*, *Eucalyptus gamophylla* and *Eucalyptus leucophloia* over *Gompholobium polyzygum*, *Indigofera monophylla*, *Androcalva luteiflora* over mixed *Triodia* species on sandy-loam soils in minor gullies.
- **MR C4 –** Open Woodland of *Eucalyptus victrix, Eucalyptus camaldulensis* var. *obtusa, Melaleuca argentea* over *Acacia citrinoviridis, Acacia coriacea* subsp. *sericophylla* and *Melaleuca lasiandra* over *Cyperus vaginatus* on major creeklines with pools with sandy soils.
- **MF X3 –** Tall Shrubland of *Acacia bivenosa, Acacia monticola, Acacia marramamba, Petalostylis labicheoides* with occasional emergent *Eucalyptus leucophloia* over *Triodia pungens* and *Triodia basedowii* on calcrete soils in minor gullies.
- **ATC M2 –** Low Woodland of *Acacia aneura* var. *aneura* to a Tall Shrubland of *Acacia pyrifolia*, *Acacia bivenosa*, *Acacia ancistrocarpa* and *Acacia maitlandii* with occasional emergent *Eucalyptus xerothermica*, *Corymbia aspera*, *Psydrax latifolia* and *Acacia citrinoviridis* over *Gompholobium polyzygum*, *Androcalva luteiflora*, *Themeda triandra*, *Triodia epactia* and *Triodia pungens* on sandy soils on flats on edges of major creeklines.

The remaining 19 vegetation units occurred outside the riparian zones covered by this study. Of these six riparian vegetation units above, one unit (MF X3) was associated with minor drainage lines that occurred in the small tributaries of Weeli Wolli Creek.

In addition to these, Mattiske's (2010) survey included sections of Weeli Wolli Creek targeted within the current assessment and surrounding non-riparian vegetation that weren't covered by the 2008 survey, and described an additional vegetation unit within the 'Flowlines (creeklines and drainage areas)' landform that was associated with the southwest section of Weeli Wolli Creek and described as follows:

- **MF C5 –** Tall Shrubland of *Acacia bivenosa*, *Acacia maitlandii*, *Acacia monticola* with occasional emergent *Eucalyptus victrix*, *Eucalyptus xerothermica* over *Gossypium australe*, *Gossypium robinsonii*, *Petalostylis labicheoides*, *Melaleuca bracteata*, *Androcalva luteiflora* over mixed *Cymbopogon ambiguus*, *Chrysopogon fallax*, *Cyperus vaginatus*, *Triodia angusta* on sandy-loam soils in minor gullies.

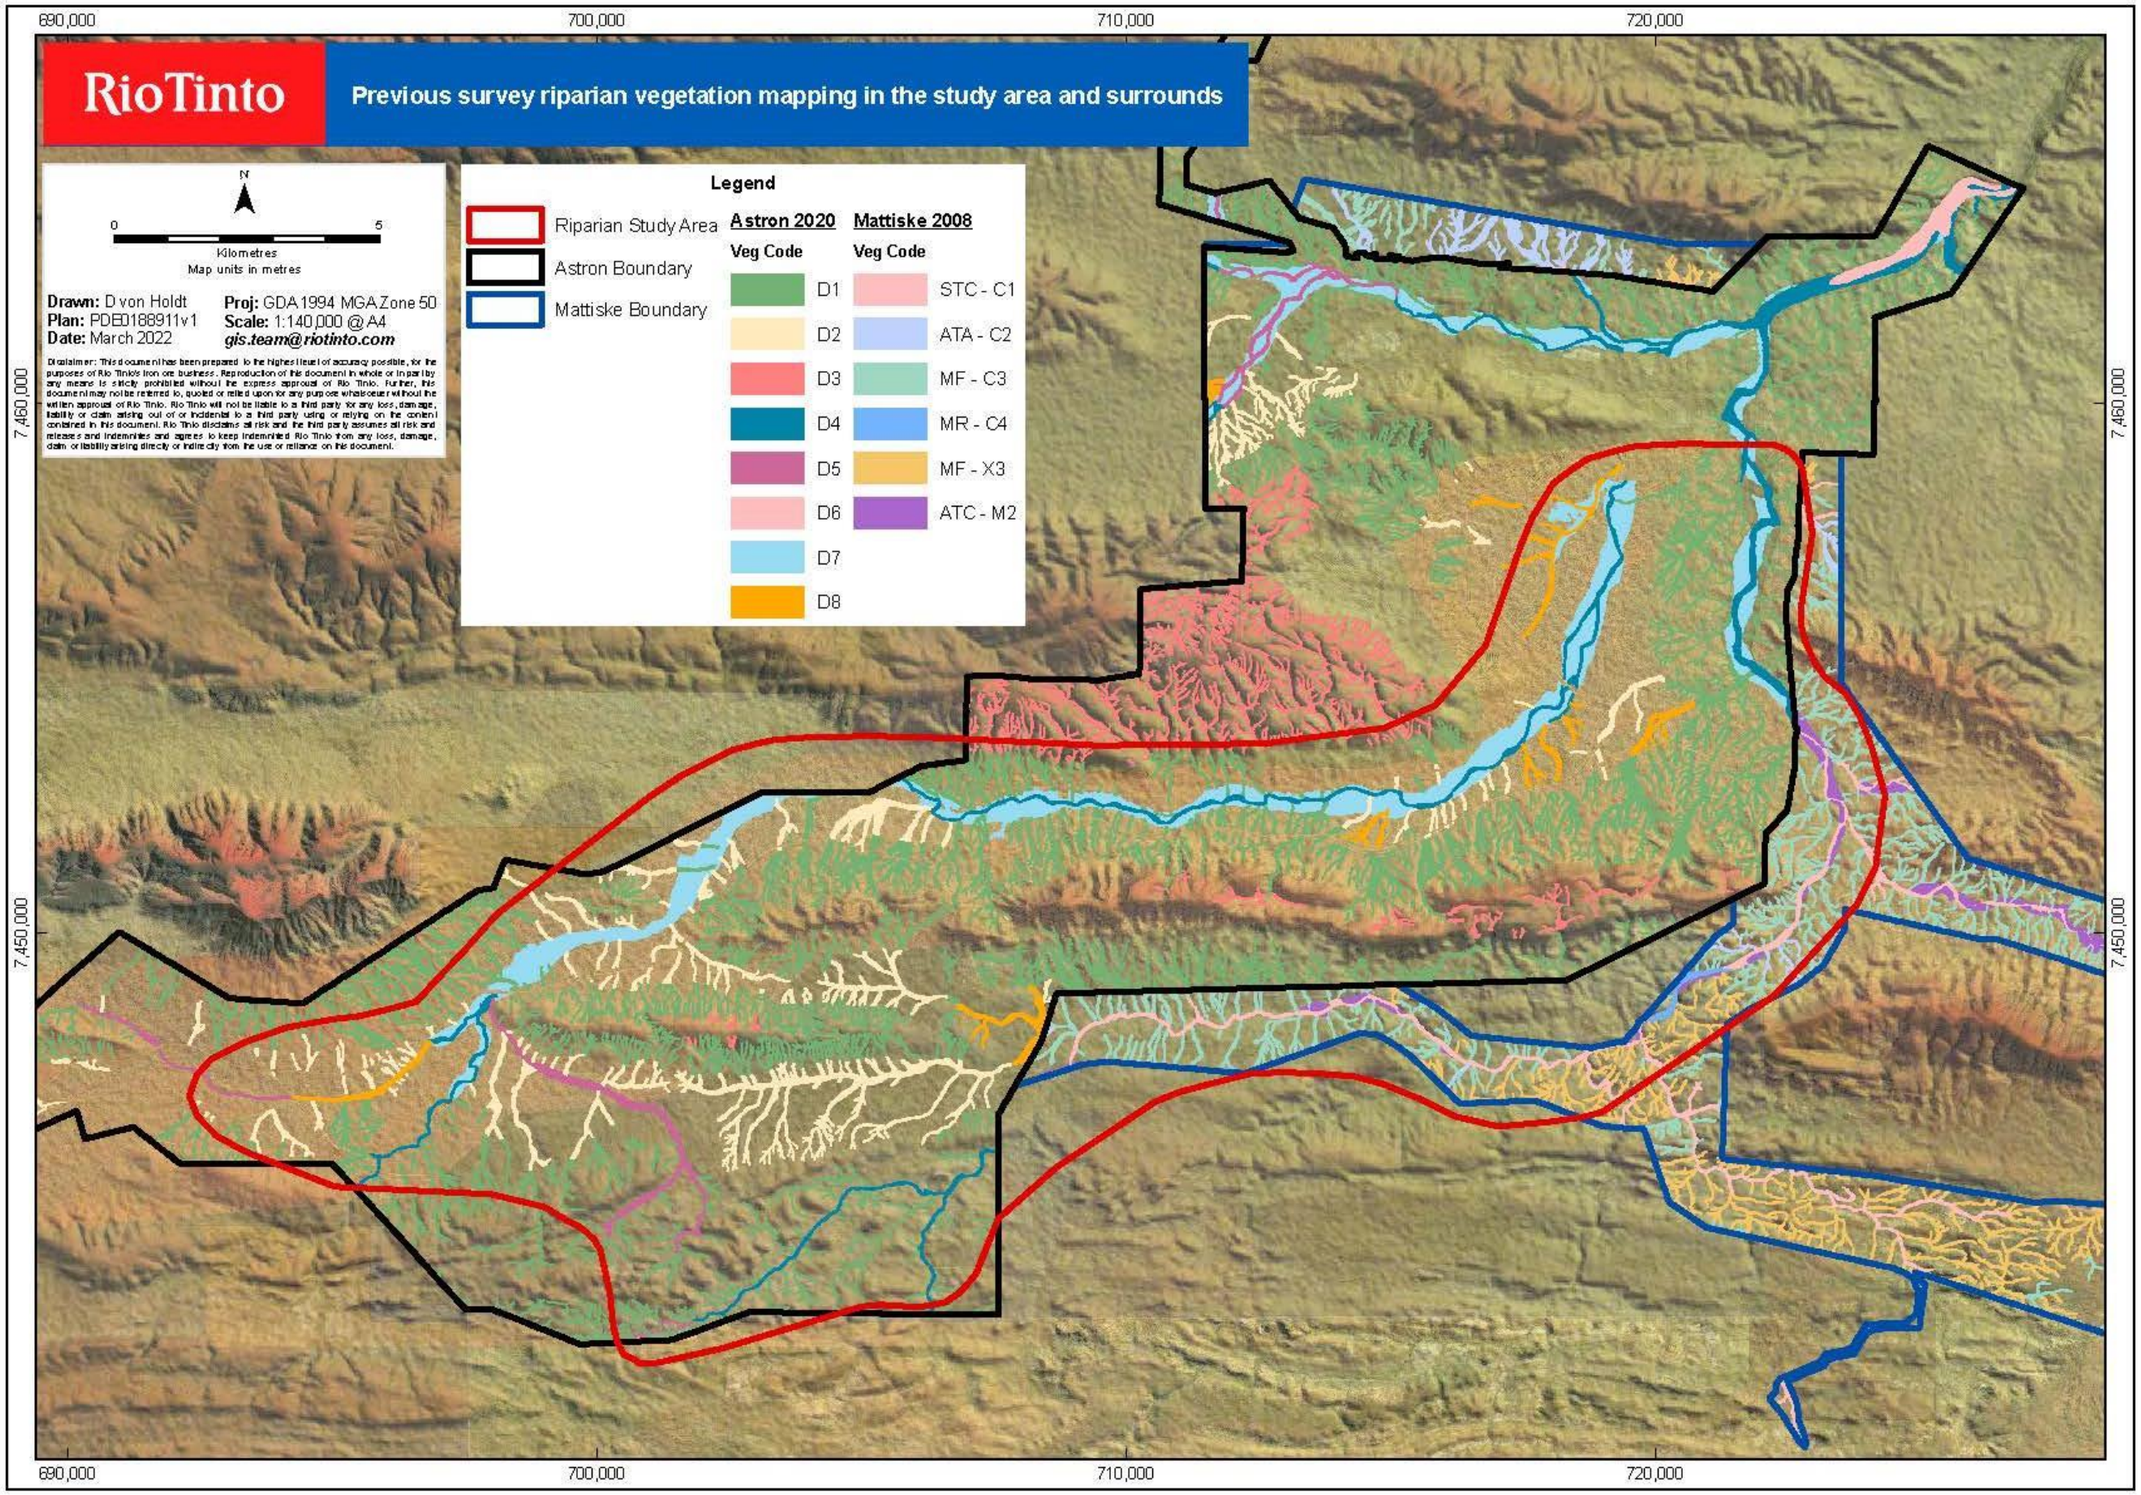

Figure 2-4: Riparian vegetation mapping from flora and vegetation surveys conducted by Astron (2020) and Mattiske (2008) in the Greater Hope Downs area.

2.6. Landsat & Sentinel derived remote sensing products for GDE mapping

The use of remote sensing (RS) techniques which leverage off available historical Landsat or Sentinel imagery is an underused and highly valuable tool that can assist in determining and mapping the presence/absence/potential of GDEs. Previous work undertaken by the CSIRO for the Pilbara region has led to the development of a remote sensing technique capable of mapping/identifying potential GDE presence, as well as their historical changes (Barron *et al*., 2012; Barron *et al*., 2017). This technique is highly applicable to hot tropical regions and works by assessing the degree of persistence exhibited by terrestrial riparian vegetation through remote sensing derived vegetation indices (Normalised Difference Vegetation Index (NDVI)) and their behaviour across seasons.

The GDE delineation methods developed within the Pilbara Water Resources Assessment (PWRA) are based on the spatio-temporal analysis of Landsat 5 imagery for a period from 1987 to 2011 (more than 180 image dates from over 1,000 remotely sensed images) combined with available information on climate variability, water regime and GDE ecohydrological characteristics (Barron & Emelyanova, 2015). This technique allows the development of an understanding of the temporal and spatial variability of land cover classes and the extrapolation of this local knowledge over large scales. Two advantages of RS techniques are the availability of historical (baseline) satellite datasets and the ability to analyse large areas at low cost. As some RS data sources are available for over 30 years (e.g. Landsat), historical changes in land cover and their characteristics can be analysed statistically and linked with known climatic conditions, changes in groundwater and surface water fluxes, as well as with historical land use practices. This analysis assists in development of the baseline for identification of likely GDEs/GDV and for understanding the potential impacts of mining activities on relevant riparian vegetation. Furthermore, future changes in riparian vegetation cover and persistence can be measured against the historical variability within the identified vegetation classes. This in turn helps to separate or contextualise changes due to natural climate variability from changes possibly caused by mining-related activities.

NDVI persistence mapping allows the identification of ground pixels where vegetation is most consistently dense throughout wet and dry seasons, with high persistence indicated by a high percentage of Landsat or Sentinel images having exceeded the chosen threshold at any point on the ground (for the relevant temporal period). It is thus inferred that high persistence vegetation (in the order of 70% persistent and greater) is likely to be accessing a water source other than incident rainfall and typical surface water flows, to maintain growth and productivity throughout the year. This inference generally implies that high persistence is potentially utilising stored groundwater (many potential sources) to satisfy at least part of its environmental water requirements.

Across the Study Area, Landsat remote sensing (RS) derived NDVI and NDMI (Normalised Difference Moisture Index) persistence mapping was reviewed to provide an indication of riparian zones. The persistence mapping highlighted zones with a low potential for the presence of GDV, the location and size of potentially groundwater dependent riparian features, as well as highlighting areas where varying degrees of mesic riparian habitats/communities occurred. This provided information for mapping refinements and an indication of the potential magnitude of groundwater dependence exhibited by relevant local riparian communities.

Trends observed in the Sentinel 2 NDVI persistence mapping, using the same methodology as Barron (2012 & 2017), were essentially the same as that observed in longer temporal period of the Landsat derived NDVI persistence mapping product. Given the finer scale resolution (three times higher resolution) of the Sentinel mapping product, this product was chosen as the primary tool (along with sampling data, vegetation mapping and associated mapping notes) for assessing the likely groundwater dependence of riparian vegetation units across the Study Area.

Sentinel 2 based NDVI persistence mapping is presented in Figure 2-5. NDVI persistence mapping (Sentinel imagery 2016-2021, NDVI threshold of 0.32) for the Greater Hope Downs locality identified some highly persistent areas, particularly around the “Ben’s Oasis” area (Figure 2-5). Note that some

areas of high persistence depicted in the map represent irrigated areas that are watered for substantial periods of the year.

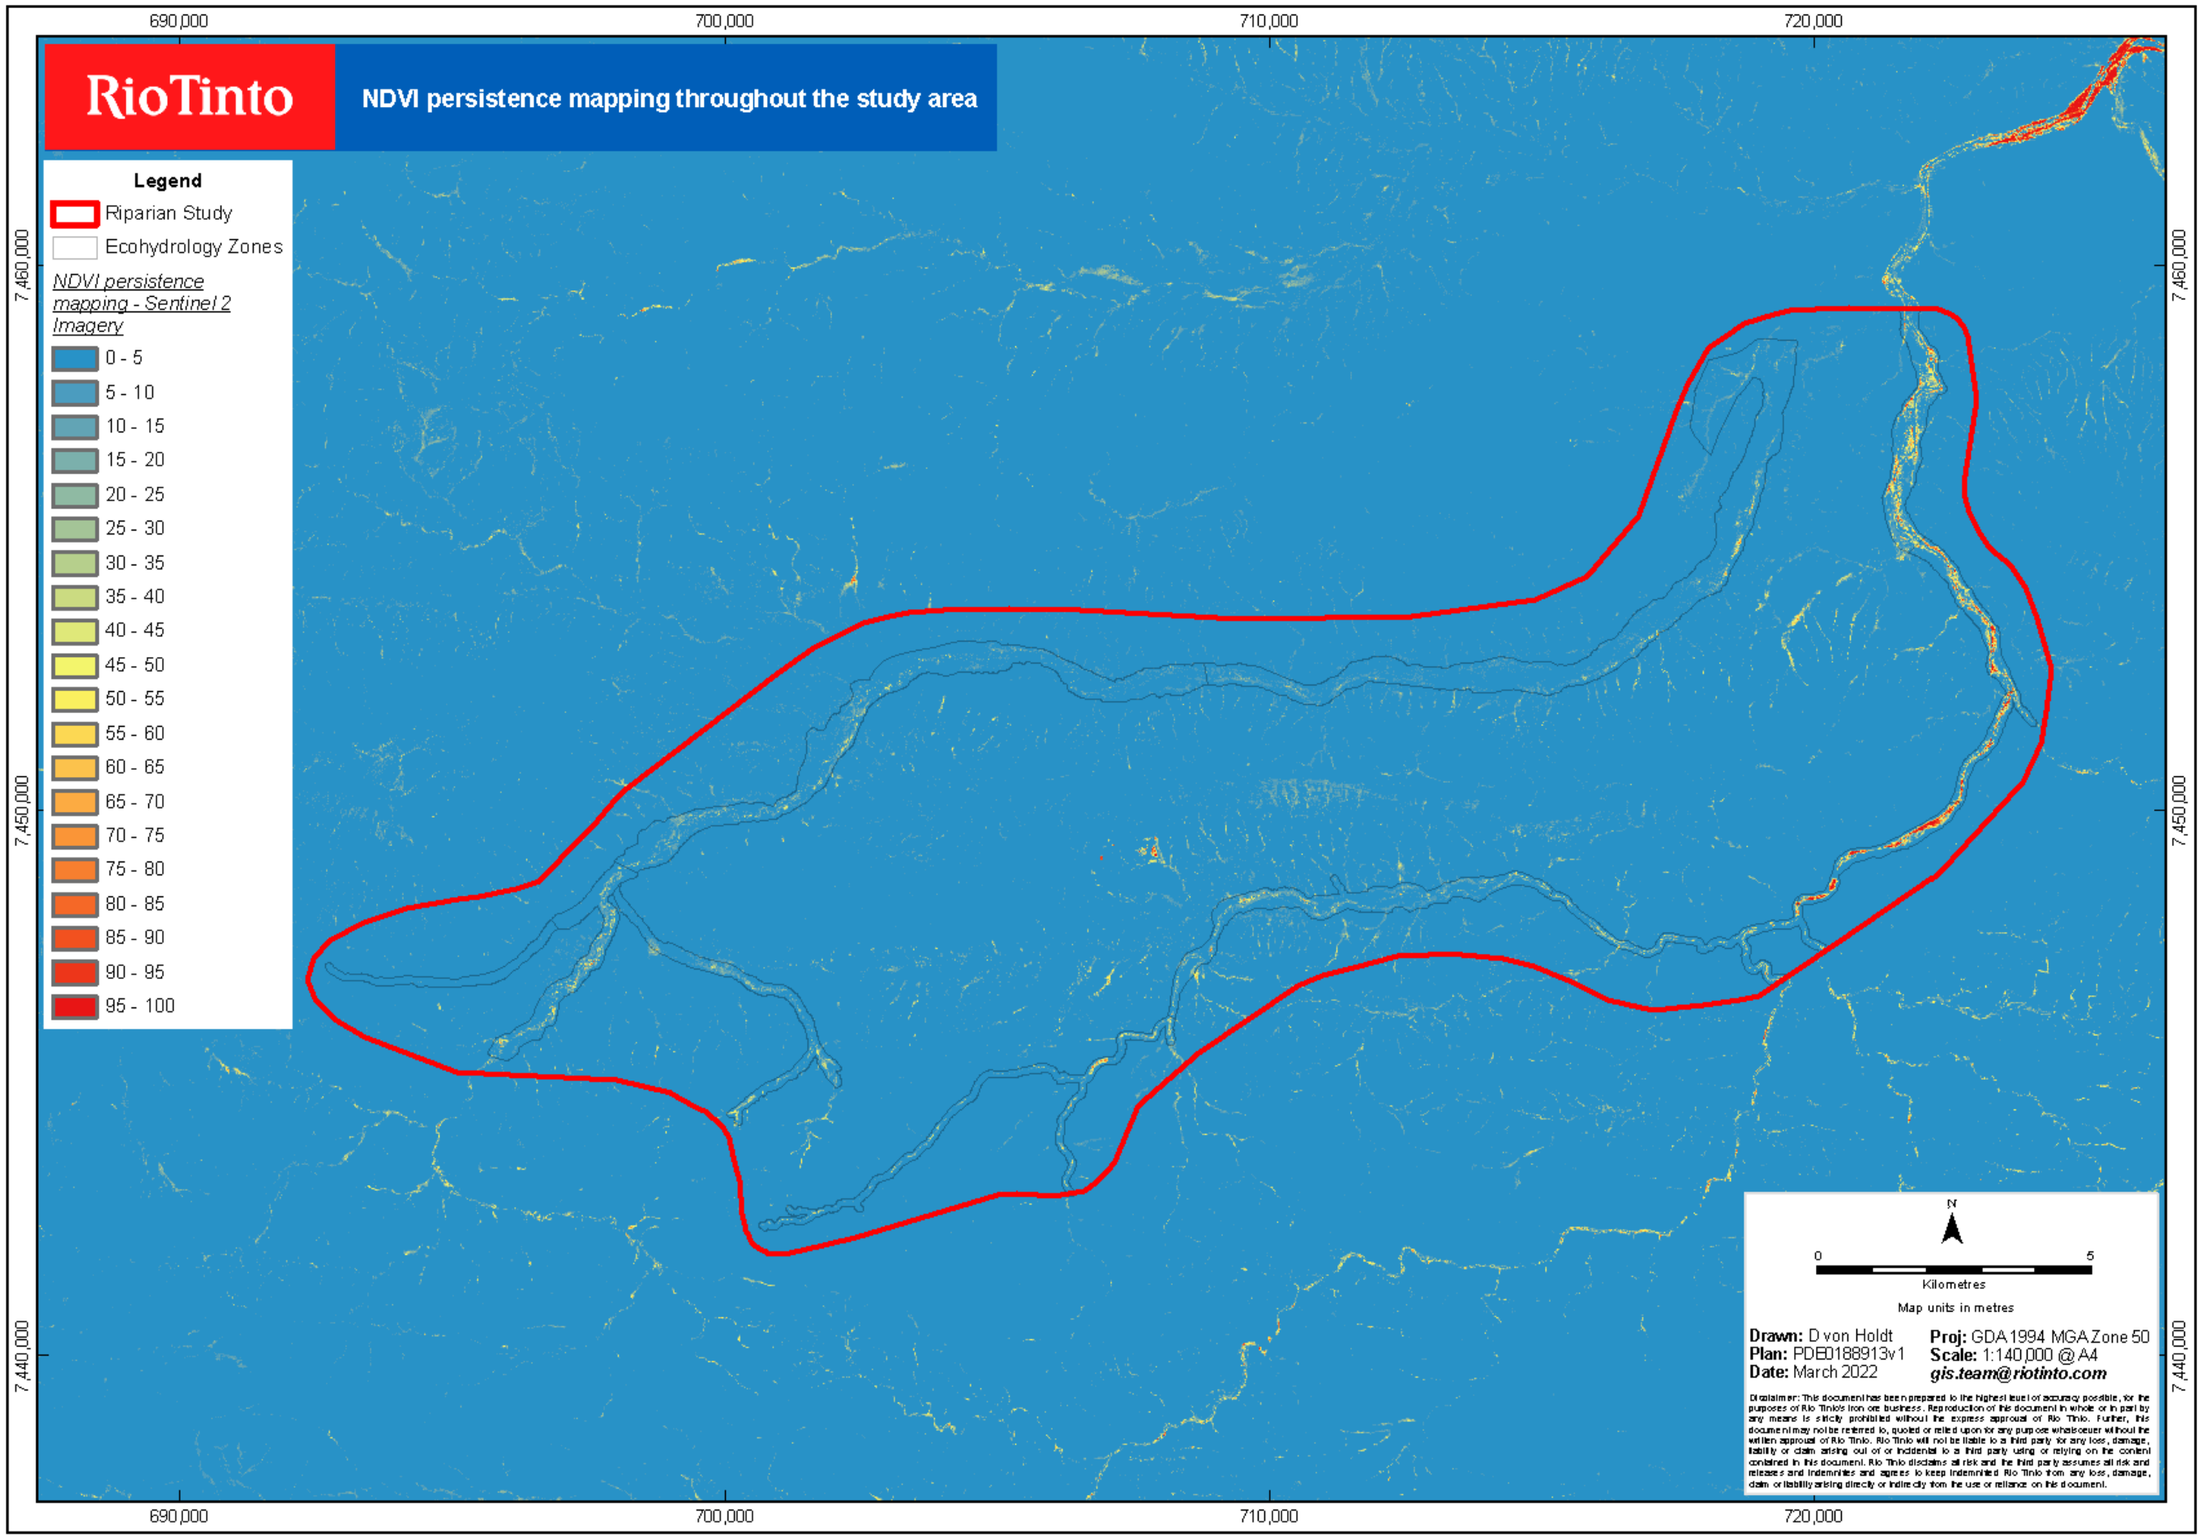

Figure 2-5: NDVI Persistence mapping using Sentinel 2 Imagery for the Greater Hope Downs locality

2.7. Bureau of Meteorology National GDE atlas

The Bureau of Meteorology (BoM) has developed the Groundwater Dependent Ecosystems Atlas (GDE Atlas) as a national dataset of Australian GDEs to inform groundwater planning and management (BoM, 2022). It is the first and only national inventory of GDEs in Australia.

The GDE Atlas web-based mapping application allows for visualisation, analysis and downloading of GDE information for an area of interest without needing specialised software.

The GDE Atlas contains information about three key types of ecosystems: Aquatic ecosystems, Terrestrial ecosystems, and Subterranean ecosystems (explained in Section 3.2). Importantly, the GDE Atlas also includes the national inflow-dependent ecosystems (IDE) layer which is derived from remotely sensed data. This layer indicates the likelihood that a landscape is accessing water in addition to rainfall (such as soil moisture, surface water or groundwater), and generally represents a potential GDE dataset for all areas not yet studied or investigated in any detail.

The GDE mapping in the GDE Atlas comes from two broad sources:

- National assessment – national scale analysis based on a set of rules that describe potential for groundwater/ecosystem interaction and available GIS data.
- Regional studies – more detailed analysis undertaken by various State and regional agencies using a range of different approaches including field work, analysis of satellite imagery and application of rules/conceptual models.

The BoM GDE Atlas indicates that there are numerous moderate to low (from national assessment) potential GDEs over the area of the Proposal and surrounds (Figure 2-6). There were no high potential (from national assessment) GDE sites noted within the Greater Hope Downs locality. Importantly, the sub-regionally significant Weeli Wolli Springs occurs in the mapped area of Figure 2-6, and occurs adjacent to the current Study Area. The absence of this feature highlights the gaps present in the atlas as it currently stands, however value is still placed in this resource as a first point of call.

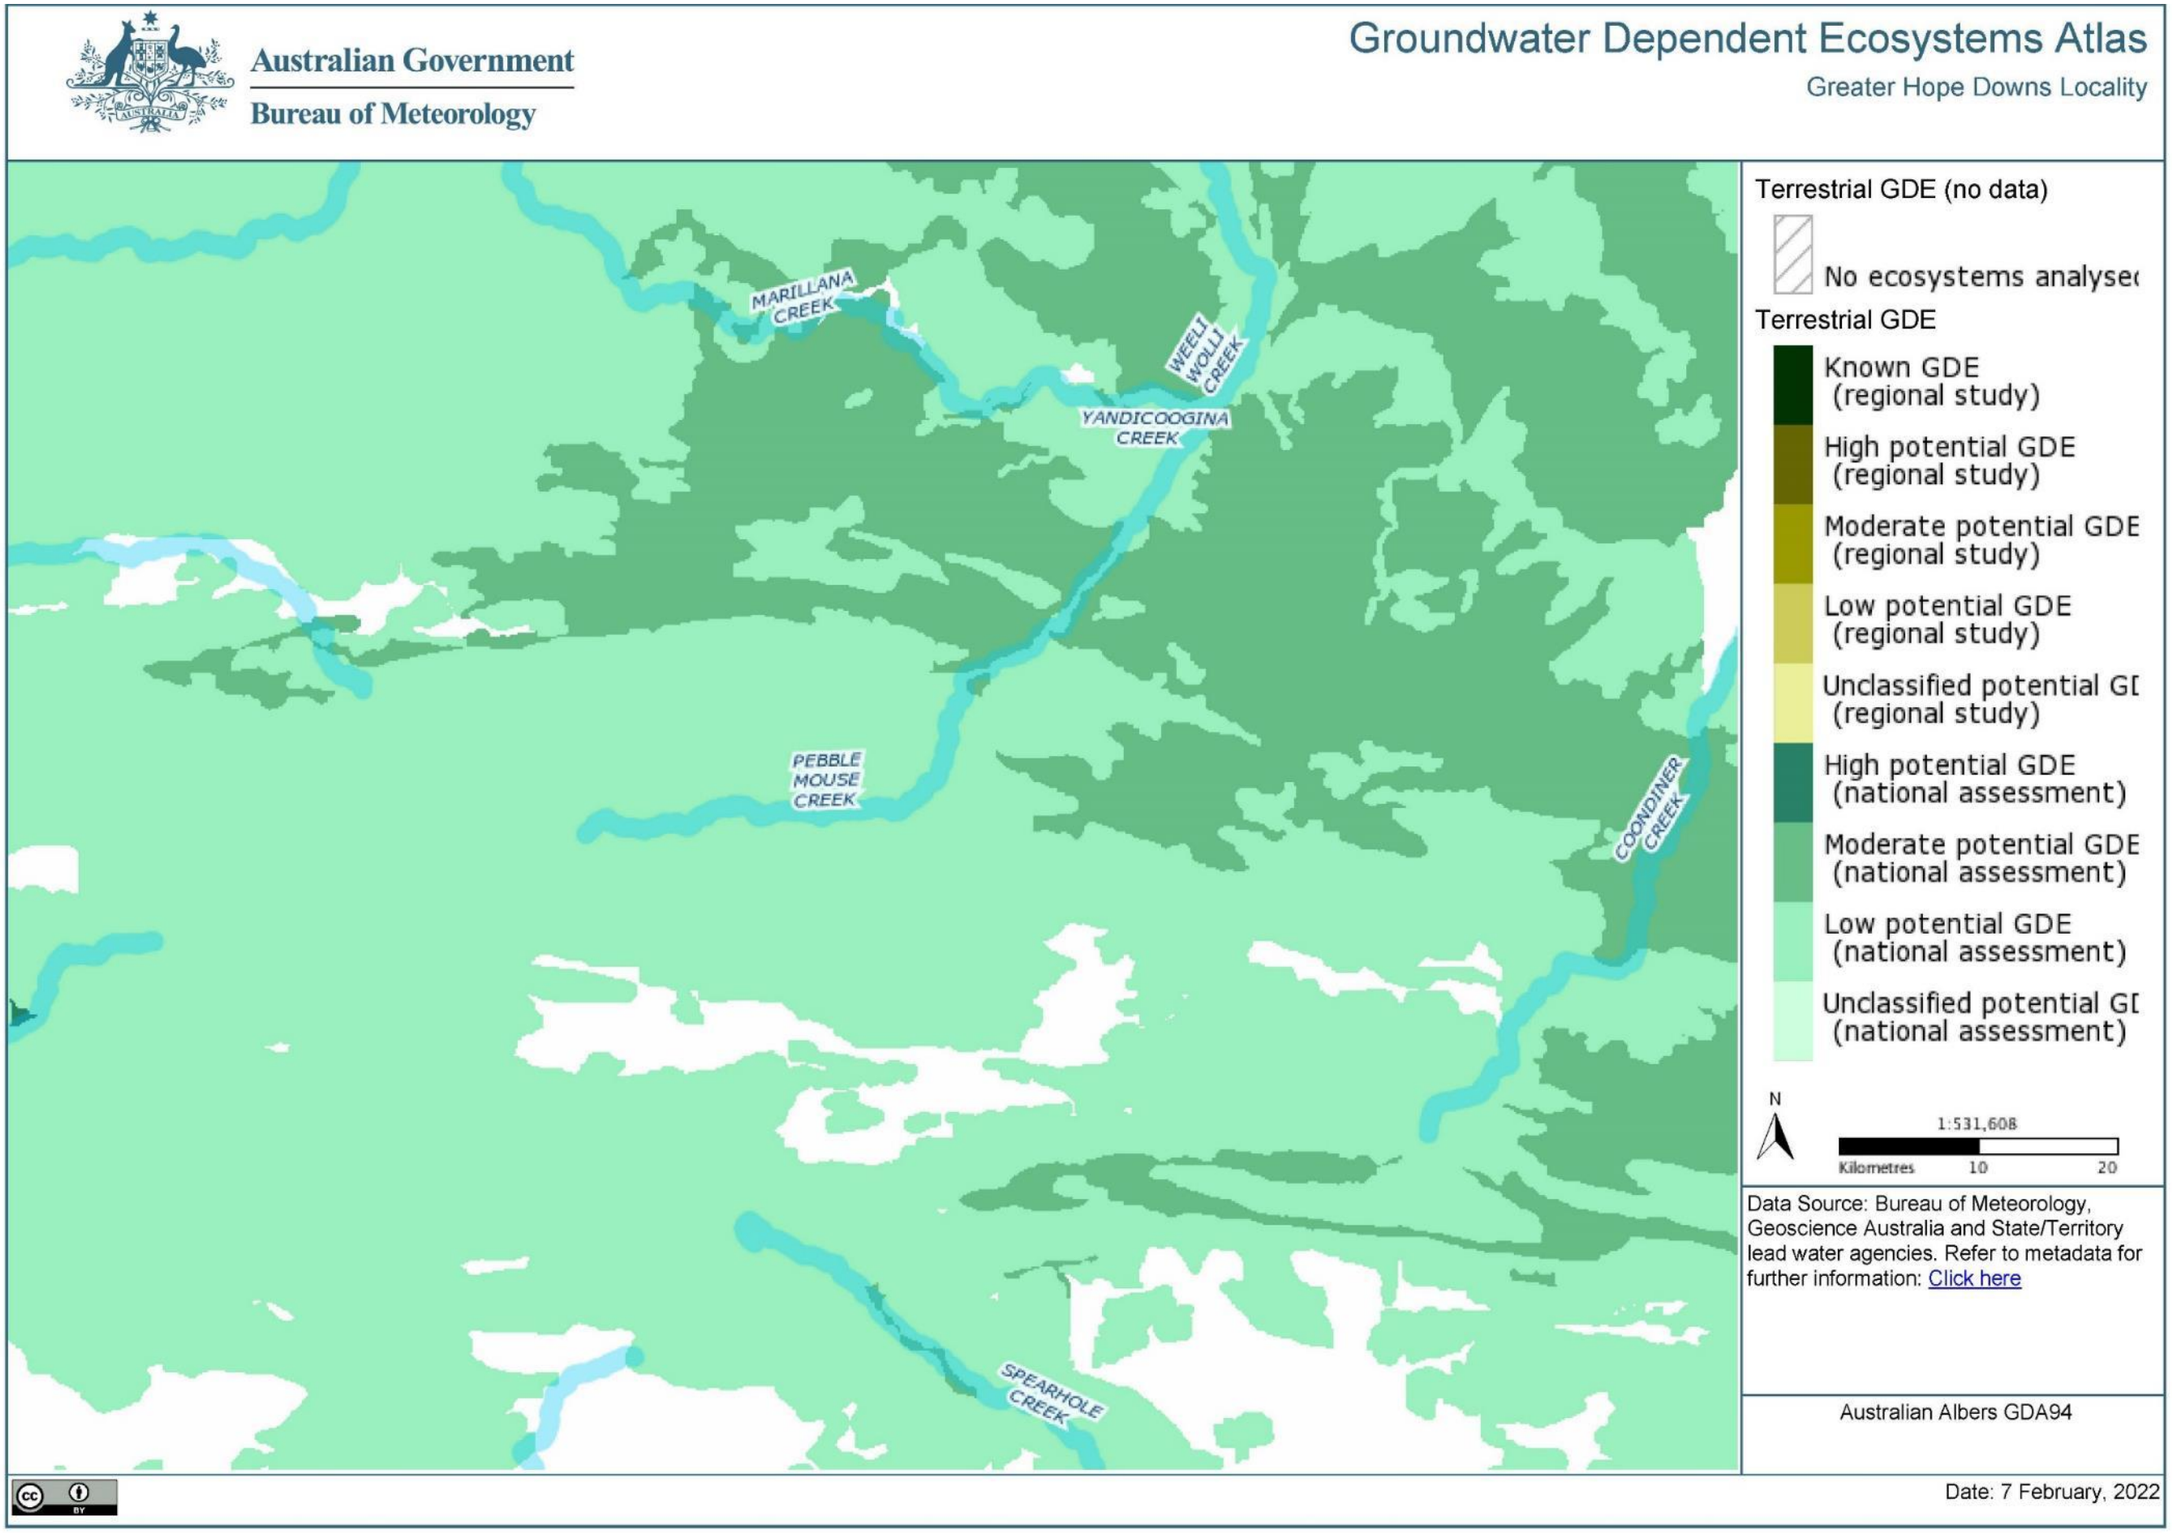

Figure 2-6: BoM GDE Atlas mapping for the Greater Hope Downs locality (Terrestrial GDE mapping Layer) (BoM, 2022).

3. Riparian & Groundwater Dependent Ecosystems

3.1. Protection

Initially, within the EIA process, riparian ecosystems and GDE's are detected and assessed via the "Flora and Vegetation" Environmental Factor Guideline (EPA, 2016a). This guideline allows provisions for survey work and biodiversity-based assessment of potential riparian values in a study area, particularly those features which may be dependent on groundwater and thus susceptible to hydrological change. However, following on from this process, Groundwater Dependent Ecosystems (GDEs) are protected under the Environmental Factor Guideline: Inland Waters (EPA, 2018b) when assessing any potential proposal that may impact GDEs. The objective of the Inland Waters Environmental Factor is "to maintain the hydrological regimes and quality of groundwater and surface water so that environmental values are protected" (EPA, 2018b). For the purposes of EIA, the Environmental Protection Authority (EPA) defines Inland Waters Factor as:

"The occurrence, distribution, connectivity, movement, and quantity (hydrological regimes) of inland water including its chemical, physical, biological, and aesthetic characteristics (quality)" (EPA, 2018b).

Inland Waters include both groundwater (such as superficial and confined aquifers) and surface water systems (such as waterways, wetlands and estuaries) (EPA, 2018b). Both permanent systems and those which hold water for part of the year or occasionally (seasonal and ephemeral systems), are included in the Inland Waters Factor. Waterways are any river, creek, stream or brook, including its floodplain and estuary or inlet and includes systems that flow permanently, for part of the year or occasionally (EPA, 2018b). In this instance, Weeli Wolli Creek is considered a waterway warranting assessment under the Inland Waters Factor guidelines.

Based on these definitions, while it's clear that GDE's are of increased environmental value and thus increased importance for being considered by both the 'Flora and Vegetation' as well as 'Inland Waters' factors, it's also clear that all larger scale riparian features should be considered as part of both guidelines. Being generally dependent upon either ground or surface water systems, larger scale riparian ecosystems are hydrologically sensitive ecosystems whose fostered diversity is predominantly linked to mesic/hydric habitats and the unique floral/faunal assemblages which they support. This highlights that not only does an assessment of their significance require a much more targeted approach, but that targeted assessments of riparian flora and vegetation values such as this are a critical step in underpinning and supporting EIA relating to the Inland Waters Factor.

Environmental value is defined under the EP Act as a beneficial use or an ecosystem health condition. Ecosystem health is the focus of this document (the EP Act) and generally includes the ability of Inland Waters to sustain vegetation, aquatic fauna and birdlife, and the ecological processes that support them (EPA, 2018b). For the purposes of EIA, the EPA focusses on 'significant ecosystems'. Significant ecosystems which relate to the Study Area will predominantly be defined based on the presence of terrestrial and aquatic GDEs and the communities/species they support.

3.2. Background

GDEs are ecosystems that rely upon groundwater for their continued existence (BoM, 2022). GDE's can be represented by many different assemblages of biota which rely on groundwater, and as a result come in many forms.

For terrestrial systems there are three key types of GDE (BoM, 2022);

1. **Aquatic ecosystems;** that rely on the surface expression of groundwater – this includes surface water ecosystems which may have a groundwater component, such as rivers, wetlands and springs.

2. **Terrestrial ecosystems;** that rely on the subsurface presence of groundwater–this includes all vegetation ecosystems.
3. **Subterranean ecosystems;** this includes cave and aquifer ecosystems.

Aboveground terrestrial GDE's are typically characterised by the presence of flora species that rely on groundwater (i.e. phreatophytes). Phreatophytes may be classified as either obligate or facultative phreatophytes depending on their reliance on groundwater (Eamus *et al*., 2016):

- Obligate phreatophytes are flora species confined to habitats with access to groundwater.
- Facultative phreatophytes are flora species that can utilise groundwater to satisfy a proportion of their ecological water requirement (EWR) when it is available. However, some individuals may also satisfy their EWR by relying solely on uptake from upper unsaturated soils layers where groundwater is inaccessible.

This study has adopted a novel approach to support the process of identifying, characterising and contextualising GDEs/GDV occurring within the Study Area. The novel approach, in simple terms, has utilised remote sensing analyses to guide the desktop identification of the presence, and importantly, absence of potential GDE's. The results of the remote sensing analyses were used to guide the distribution of field investigations and resultant confidence in the completeness of the associated findings.

Broadly this study focused on identifying and mapping riparian vegetation within the Study Area. Further to this, a focus on identifying and characterising significant 'mesic' representations of riparian vegetation (i.e. occurring in mesic habitats) helped the study to determine the value, extent and sensitivity of potential occurrences of GDV. For the purpose of this study, 'mesic' vegetation is defined as that vegetation with a composition (both overstorey and understorey components) indicative of the presence of riparian habitat possessing at least a moderately continuous (outside of drought) supply of soil moisture (and potentially surface moisture). Such habitats will typically be inhabited by species which are able to be classified as mesophytic or hydrophytic in their habitat/environmental preferences. This relatively continuous supply of moisture is typically indicative of the availability of at least intermittent groundwater sources of varying scale. In the arid Pilbara climate, such sources are of high importance to specific assemblages of 'mesic' riparian vegetation. The presence of mesic vegetation has been initially used to identify the presence of potentially significant GDV, which is then used as an indicator for the potential presence of:

- Groundwater Dependent Ecosystems (GDEs) – ecosystems which rely on permanent or intermittent access to groundwater to meet some or all their EWRs; or
- Inflow Dependent Ecosystems (IDEs)[1] – ecosystems likely to access a water source in addition to rainfall (e.g. surface water, water stored in the unsaturated zone or smaller groundwater sources).

In general, the structure and composition of creekline vegetation in the Pilbara tends to be driven by the inter and intra-annual availability of moisture. As such, the structure and composition of vegetation present is often the most reliable indicator of the longer term inter/intra-annual availability of moisture, often providing valuable insight into groundwater proximity (and consistency of access), surface water permanence and therefore the potential sensitivity of a riparian ecosystem to fluctuations in water availability.

[1] Refer to Section 2.7 for a modified definition of this term which is introduced by the Bureau of Meteorology as part of the Australian Groundwater Dependent Ecosystems Atlas (BoM, 2022).

In larger riparian systems of the Pilbara, groundwater can typically be contained within shallow, unconsolidated sedimentary aquifers close to the surface (Landman, 2001). These shallow aquifers often support riparian vegetation which can be classified as a GDE.

Ecosystems that rely on the presence or input of groundwater are associated with terrestrial vegetation complexes, river base flow systems, wetlands, and caves (Hatton & Evans, 1998). GDEs can have various levels of dependency on or utilisation of groundwater, ranging from complete dependence to occasional supplementary use. It is for this reason it is important to define the vegetation present and to estimate the likely dependence of such vegetation on groundwater and surface-water sources to contextualise the potential influence of local scale hydrogeological impacts.

Although GDEs only cover a comparatively small proportion of the land surface, they provide specific ecosystem functions supporting unique and important biological diversity at both local and regional scales (Boulton & Hancock, 2006; Humphreys, 2006; Murray *et al*., 2006; Thurgate *et al*., 2001). In addition to environmental benefits, GDEs often have significant social, economic, and spiritual values (Murray *et al*., 2006). Protection of GDEs is commonly considered an important criterion in sustainable water resource management, particularly when human water management is in competition with environmental water demands.

3.3. Groundwater Dependent species

Groundwater Dependent Ecosystems tend to support relatively dense and diverse vegetation communities. Such vegetation tends to contain an above average proportion of mesophytic or potentially hydrophytic species which often thrive in areas where groundwater proximity (or other sources of increased moisture) significantly increases the availability of moisture. It is these species, which are indicative of the presence of perennial to sub-perennial (and ephemeral) mesic conditions/habitats, which are typically quite restricted in their distribution and extent and therefore of elevated significance or conservation value. In an arid climate like the Pilbara, this elevated value is attributed to the restricted nature of such mesic conditions, and the functions provided by the moisture they harbor.

Species that broadly utilise groundwater are referred to as phreatophytes, and they may be classified as either obligate or facultative phreatophytes depending on their level of dependence on groundwater. Obligate phreatophytes are plants that are completely or highly dependent on groundwater. This dependence can be continual, seasonal or episodic. Obligate phreatophytes are often associated with surface expressions of groundwater rather than purely the subsurface presence of groundwater, and they are highly sensitive to large changes in groundwater regime and respond negatively to rapid groundwater drawdown. Not all phreatophytic species display the same degree of dependency on groundwater and the dependency within species has been shown to vary both spatially and temporally (Eamus & Froend, 2006). Obligate phreatophytes are those species for which access to groundwater is critically important to their presence in the landscape. Such species can only inhabit areas where they have access to groundwater in order satisfy at least some proportion of their EWR (Eamus *et al.,* 2006).

Facultative phreatophytes are plants that can access groundwater but are not totally reliant on groundwater to fulfil their water requirements. Rather, they utilise groundwater opportunistically, particularly during times of drought when moisture reserves in the unsaturated (vadose) zone of the soil profile become depleted. The framework for assessing 'Environmental Water requirements of Groundwater Dependent Ecosystems' published by REM, CSIRO and SKM (2007) defines facultative GDEs as plants that require access to groundwater in some landscapes, but in other landscapes can utilise alternate sources of water to maintain ecosystem function, i.e. the presence or absence of groundwater is not critical in determining ecosystem occurrence (compared with obligate GDEs).

Facultative phreatophytes may utilise groundwater to satisfy a proportion of their EWR but, if required, may also satisfy their total EWR via stored soil water reserves (Eamus *et al.*, 2006). Facultative phreatophytes are generally associated with the subsurface presence of groundwater rather than surface water. Most facultative phreatophytes are large woody trees and shrubs with deep root systems capable of accessing the capillary fringe of the water table which may occur at considerable depth within the soil profile.

Knowledge surrounding the groundwater use strategies of plants in the Pilbara is generally restricted to keystone trees species, and as a result there is limited knowledge in this space for understorey species. Table 3-1 presents the different classes of groundwater dependence (water use strategies) relevant to tree species in the Pilbara, and the most relevant species considered as being attributable to each. This table has been produced through the synthesis of a number of references on the subject along with the observations of species/groundwater height interactions across multiple sites in the Pilbara (Rio Tinto, 2018a, 2018b, 2019a, 2020).

Table 3-1: Tree species dependence on groundwater

Species dependence on Groundwater	Plant Physiology/water use strategy	Relevant Species in the Pilbara
Very High	Wetland Obligate Phreatophyte/Hydrophyte[2]	Obligate phreatophytes (i.e. *Melaleuca argentea*) plus presence of hydrophytic macrophytes (e.g. *Schoenus falcatus, Eleocharis geniculata, Cladium procerum*)
High	Obligate Phreatophyte	*Melaleuca argentea, Livistona alfredii*[3]
Moderate	Facultative Phreatophyte (in anomalous cases can be a vadophyte)	*Eucalyptus camaldulensis, Sesbania formosa*[4]
Low to Moderate	Facultative Phreatophyte/Vadophyte[5]	*Eucalyptus victrix, Eucalyptus xerothermica, Corymbia candida/aspera*
Low (virtually negligible)	Vadophyte/Xerophyte[6]	*Eucalyptus leucophloia, Corymbia hamersleyana, Corymbia deserticola and others*

It is generally recognised that obligate phreatophytes are those species with the highest degree of groundwater dependence (i.e. smallest acceptable depth to saturation which they will tolerate), and as such are often the best indicator within the Pilbara of consistently shallow groundwater tables, or permanent surface water presence. The structure and composition of creekline vegetation is generally considered to be heavily driven by the degree and consistency of moisture availability. As a result, the

[2] Hydrophytes are plants which live in waterlogged soil or partly or wholly submerged in water. Generally associated with aquatic flora.

[3] The groundwater use strategy of *Livistona alfredii* is not completely understood, however mature individuals are generally observed in situations that would suggest it is an obligate phreatophyte, requiring access to groundwater

[4] *Sesbania formosa* may be an obligate phreatophyte. Environmental data would suggest it is a phreatophyte, but there is some question as to whether its groundwater use strategy is obligate in nature.

[5] Vadophytes are plants commonly associated with drainage lines which rely on moisture in the soil surface profiles and are independent of groundwater.

[6] Xerophytes are plants which are adapted to dry environments. Xerophytic adaptations including waxy covering over the stomata, very few stomata, or stomata that only open at night, the development of a dense, hairy leaf covering, the ability to drop leaves during dry periods, the ability to reposition or fold leaves to reduce sunlight absorption all prevent water loss, while fleshy stems or leaves store water.

structure and composition of vegetation types present in a riparian system is an important longer-term indicator of groundwater proximity and surface water permanence. Furthermore, such insight into the degree of moisture permanency also provides insight into the associated values and significance of a riparian ecosystem. It is for these reasons that often the most reliable and effective indicator for moisture permanency and therefore inherent hydrological sensitivity is the composition and structure of vegetation present.

Such concepts underpin the basis for a potential conservation framework for terrestrial and aquatic GDE features in the arid zones of Australia's North. The concept relies on the fact that there is inevitably a suite of species in any region whose distributions are inherently restricted in the environment due to their sensitivity to variability in water access, i.e. which possess decreased ability to persist in areas which periodically dry out. In effect the presence of at least some of these species in a riparian habitat becomes a good indicator of increasing degrees of consistency in moisture availability (or high water permanence) and thus indicative of a hydrological refuge. By this logic, habitats possessing increasing numbers of species which are most indicative of high water permanence (and thus which cannot exist without perennial moisture availability) represent increasingly restricted, and important refugial habitats for mesophytic/hydrophytic diversity. These habitats invariably support restricted faunal assemblages who also need permanent access to moisture. By understanding which species indicate increasing degrees of moisture permanence and where they might sit on this scale, we can also use the presence, composition and relative abundance of these species to help quantify values, ecosystem services and ultimately riparian significance.

A recently listed (2018) Priority Ecological Community (PEC) by The Department of Biodiversity, Conservation and Attractions (DBCA), introduces some of these concepts in a conservation context and provides a description of some of the associated values. The PEC is titled "Riparian flora and plant communities of springs and river pools with high water permanence of the Pilbara". The PEC is described as including flora with restricted distributions or populations that are highly disjunct or are major range extensions from northern and eastern Australia (DBCA, 2021). Detail in its description indicates that in the Pilbara these taxa are almost exclusively restricted to the riparian zones of permanent wetlands with high soil moisture maintained by groundwater flows.

To help identify these values (and potential degrees of groundwater dependence) at a fine scale, and with increased detail it is important to understand the habitat specificity of different mesophytic/hydrophytic species and thus how reliant they may be on varying degrees of water availability/consistency. In the Pilbara, a non-exhaustive list of mesophytic/hydrophytic species indicative of sub-perennial to perennial moisture availability is likely to contain many of the taxa listed in Table 3-2 (in conceptual order of importance/usefulness and therefore decreasing reliance on consistent/elevated moisture availability; refer to Table 3-3 for further detail) (adapted from information provided by WAH (2022), ALA (2022), and Pilbara environmental observations by J. Naaykens (Rio Tinto)).

Riparian zones or water gaining sites which contain obligate phreatophytes (such as *Melaleuca argentea* and/or an abundance of facultative phreatophytes) and a few of the following species are considered to provide good evidence of high moisture availability and its degree of persistence/permanence.

Table 3-2: Pilbara mesophytic/hydrophytic species likely to indicate sub-perennial to perennial moisture availability.

Species	Lifeform	Indicator Guild Level
Melaleuca argentea	**Tree**	**Very High**
Cladium procerum	**Macrophyte/sedge**	**Very High**
Adiantum capillus-veneris	**Fern**	**Very High**
Pteris vittata	**Fern**	**High**
Imperata cylindrica	**Reed/Grass**	**Very High**
Various sedge spp. including *Schoenus* spp., *Baumea* spp., *Fimbristylis* spp., etc.	**Macrophyte/sedge**	**Moderate - Very High**
Sesbania formosa	**Tree**	**Very High**
****Phoenix dactylifera*** **(Date palm)**	**Palm**	**Standard Riparian**
Eucalyptus camaldulensis	**Tree**	**Very High**
Acacia ampliceps	**Shrub**	**High**
Cullen leucanthum	**Shrub**	**High**
Melaleuca bracteata	**Shrub**	**Moderate – High**
Lobelia **spp.**	**Herb**	**High**
Stylidium **spp.**	**Herb**	**Moderate - High**
Melaleuca linophylla	Shrub	Moderate - High
Melaleuca glomerata	Shrub	Moderate
Eucalyptus victrix	Tree	Very High
Atalaya hemiglauca	Tree	Moderate
Acacia coriacea subsp. *pendens*	Tree/shrub	Moderate
Eleocharis **spp. (Particularly *E. geniculata*)**	**Macrophyte/sedge**	**Moderate – High/High**
Potamogeton **spp.**	**Aquatic Macrophyte**	**High**
Fuirena ciliaris	**Macrophyte/sedge**	**Moderate - High**
Schoenoplectus subulatus	Aquatic Macrophyte	Moderate
Typha domingensis	Aquatic Macrophyte/sedge	Moderate
Cyperus iria	Macrophyte/sedge	Moderate - Low
Duma **spp.**	**Macrophyte/shrub**	**Moderate**
Cyperus vaginatus	Macrophyte/sedge	Moderate
Schoenoplectiella spp.	Macrophyte/sedge	Moderate
Marsilea spp.	Macrophyte/fern	Low
Gossypium sturtianum	Shrub	Moderate
Acacia citrinoviridis	Tree	Standard Riparian
Acacia sclerosperma	Shrub	Low
Peplidium sp. E Evol. Fl. Fauna Arid Aust. (A.S. Weston 12768)	Herb	Standard Riparian
Sesbania spp.	Shrub	Moderate
Sorghum spp.	Grass	Standard Riparian
Eragrostis surreyana	Grass	Moderate - High
Geijera salicifolia	Tree	Standard Riparian
Commelina ensifolia R.Br.	Herb	Standard Riparian
Trigonella suavissima Lindl.	Herb	Standard Riparian

Note: Species in **bold** identify some of the best upper level indicators of moisture availability/permanence

Outside of the list provided within Table 3-2, the following keystone Pilbara phreatophytes (and thus mesophytic/hydrophytic species) are well accepted as species indicating the potential presence of GDV and thus a GDE within the hot tropical regions of Australia's northwest.

3.3.1. *Melaleuca argentea*

In the Pilbara, *Melaleuca argentea* is thought to depend on groundwater almost exclusively and is therefore considered to be an obligate phreatophyte (Graham *et al.*, 2003; Lamontagne *et al.*, 2005; Landman *et al.*, 2003; McLean, 2014, O'Grady *et al.*, 2006).

Due to its dependence on groundwater, *Melaleuca argentea* is often the best indicator of consistently shallow groundwater tables or permanent (perennial) surface water presence and subsequently, this species is also widely considered the best available indicator for the presence of GDV and therefore a GDE.

3.3.2. *Eucalyptus camaldulensis*

Eucalyptus camaldulensis is a small to large tree (typically 5 to 20 m but can grow to more than 30 m) with smooth white bark and a generally spreading form. This species displays a great diversity in height, form, trunk and leaf morphology (WAH, 2022; Colloff, 2014) across the State and Australia.

Eucalyptus camaldulensis is one of the most iconic and broadly distributed *Eucalyptus* species in Australia and more is known about this species than nearly all others. Across its broad geographic distribution, *Eucalyptus camaldulensis* populations display high genetic diversity with regard to hydraulic architecture, water relations and salt tolerance, reflecting how different populations have evolved and adapted to local climates and hydrogeological regimes (Colloff, 2014). Furthermore, this diversity is also shown by the various sub-species (there are at least seven recognised sub-species) known to occur in Australia. In the Pilbara, *Eucalyptus camaldulensis* is typically represented by *Eucalyptus camaldulensis* subsp. r*efulgens*, and subsp. o*btusa* (as well as subsp. *arida* along the eastern boundary between the Pilbara and the Little Sandy Desert*)* and commonly occurs along water courses and riverbanks, growing in deep alluvial sand and sandy loams (WAH, 2022).

Trees in riparian zones exposed to flood events (often in more open areas subject to less competition) tend to have short, thick stems with irregular crowns or multiple stems diverging from a short trunk. Often stems sprout from epicormic buds in living tissue of the bole or root stock and new stems can arise from horizontal stems fallen by flood, fire or windstorms. In less dynamic environments, fast-growing trees can grow tall and straight with relatively even form similar to that seen in silvicultural plantations. *Eucalyptus camaldulensis* supports a large root system consisting of vertical tap roots with lateral roots branching off at right angles at several levels, and sinker roots extending downwards from laterals. Mature trees are thought to have a zone of water influence which will tend to extend at least 20 m and can often extend to more than 40 m around individuals (Colloff, 2014). A study by Hulme (2008) found examples of lateral root extensions in the order of 100 m. This extensive reach would suggest a significant reliance on soil pore water stored in the vadose zone.

Vertical sinker roots provide support for the aboveground part of the tree and deep penetration of soil over a wider area than would be possible via a single taproot. Extension of the root system also allows for access to oxygen from unsaturated portions of the soil profile during periods of inundation, thus enhancing flood tolerance. Mature trees are thought to have roots to depths of at least 9 to 10 m and possibly as deep as 30 m (Davies, 1953 cited in Colloff, 2014). Adventitious roots can grow out from boles or branches in response to flooding and as a way of increasing oxygen uptake and as a form of vegetative propagation. Woody roots of this species are known to have large xylem vessels for fast, efficient rates of water transport and rapid recovery following water stress (Heinrich, 1990 cited in Colloff, 2014).

Eucalyptus camaldulensis has the ability to utilise water from a range of different sources including rainfall, floodwater, stored soil water and groundwater and is therefore considered to be a facultative

phreatophyte (Mensforth *et al*., 1994). When conditions are favourable, *Eucalyptus camaldulensis* tends to employ a 'going for growth' strategy that involves vigorous growth rates and high rates of uptake and transpiration from a dependable water source, often provided by groundwater, river base-flow, or floodwaters that sustain groundwater recharge (Gibson, Bachelard, and Hubick, 1994; Marshall *et al*., 1997; Morris & Collopy, 1999). Consequently, *Eucalyptus camaldulensis* is generally regarded as being more reliant on groundwater than *Eucalyptus victrix*. When stressed, *Eucalyptus camaldulensis* reduces transpiration and water demand by shedding leaves and sometimes also whole branches (particularly lower limbs).

Where large *Eucalyptus camaldulensis* trees are present and common, groundwater is generally within the reach of the root zone, and in some environments depth to groundwater is a good predictor of the condition of *Eucalyptus camaldulensis* stands. Some studies have observed a sharp decline in tree health and stand condition below a threshold depth or around 10 to 12 m (England *et al*., 2009 cited in Colloff, 2014). However, some case studies have also shown reasonable resilience in vegetation health when access to groundwater is removed. What is often evident is that not all systems are equal and in certain sized catchments (generally larger ones) it appears that the frequency of replenishment of the vadose soil resource is great enough to maintain healthy populations of *Eucalyptus camaldulensis* without access to the broader water table. Conversely, there are times where drought may determine that the vadose soil resource is inadequate, and in turn fails to sustain local populations. In areas where *Eucalyptus camaldulensis* has established with groundwater depths at approximately 10 mbgl, susceptibility to impact from hydrological change may be significantly reduced.

3.3.3. *Eucalyptus* victrix

Eucalyptus victrix is a small to medium tree (typically 5 to 15 m but can grow to more than 20 m) with smooth white bark (sometimes with a box type stocking to 1 m) and a spreading form that typically occurs on red loamy or sandy soils and clay loams on floodplains, incised channel zones, and in low lying areas across the Pilbara and other areas in the north-west of Western Australia (WAH, 2022).

Mature *Eucalyptus victrix* trees commonly support a large dimorphic root system, consisting of a prominent tap root and a network of laterally expansive roots near the soil surface and in the top 1 to 2 m of the soil profile, which can extend to at least 10 to 20 m away from the main stem (and further). From the lateral roots, vertical sinker roots can also develop and potentially extend tens of metres to water table depth (Florentine 1999).

Eucalyptus victrix typically draws the majority of its water requirement from soil pore moisture (the vadose zone). During extended dry periods *Eucalyptus victrix* can also use groundwater opportunistically as required and are a facultative phreatophyte during these situations.

Previous studies have shown that when provided with access to groundwater, *Eucalyptus victrix* can maintain high leaf water potentials and high rates of tree water use during times of drought (O'Grady *et al.*, 2009; Pfautsch *et al*., 2011; Pfautsch *et al*., 2014). *Eucalyptus victrix* however, also demonstrates a strong ability to regulate water losses when water supplies are limited via regulation of stomatal conductance (Pfautsch *et al*., 2014) and structural modifications including leaf die-off, crown defoliation and adjustment of leaf area to sapwood area ratio. Such changes enable trees to maintain constant water use despite increasing evaporative demand if sufficient water is available (O'Grady *et al*., 2009). As a result, the water use strategy of *Eucalyptus victrix* appears to be highly plastic and opportunistic, enabling survival in a wide range of ecohydrological settings (Pfautsch *et al.*, 2014).

Work by Loomes (2010), assessing the range of depth to groundwater for a subset of Pilbara riparian species, found that in large Pilbara rivers, the mean minimum water level depth occurring under *Eucalyptus victrix* populations was somewhat greater than that for *Eucalyptus camaldulensis*, providing some support for the view that *Eucalyptus victrix* is found in slightly drier areas than *Eucalyptus camaldulensis* and may not be as responsive to water table fluctuations.

Despite being a relatively plastic species, major adjustments to hydraulic architecture in large trees takes time and as such *Eucalyptus victrix* growing over historically shallow groundwater exhibits much greater susceptibility to hydrological change than trees that have developed over historically deeper groundwater, as highlighted in a recent study by Pfautsch *et al.* (2014).

Mature *Eucalyptus victrix* trees display a moderate level of flooding tolerance and are able to tolerate temporary inundation in the range of weeks to months at most. The presence of adventitious roots and stem hypertrophy (the ability to increase the size of component cells) provides a level of tolerance to waterlogging in seedlings and saplings, allowing them to survive in flood-prone areas (Florentine 1999; Florentine & Fox, 2002a). In fact, flooding events are believed to play a major role in the reproductive cycle of *Eucalyptus victrix*, particularly for seedling establishment (Florentine & Fox, 2002b).

3.3.4. *Sesbania Formosa*

Sesbania formosa is a small tree, at times growing to 13 m in height, but more commonly in the 5 to 10 m height range. *Sesbania formosa* occurs across a variety of habitats, however most habitats are generally associated with creeks, rivers, and arid/tropical swamps (e.g. Dragon Tree Soak in the Great Sandy Desert). In the Pilbara, *Sesbania formosa* is commonly located along creeks and rivers with groundwater close to the surface.

Work completed by Loomes (2010) found that the mean minimum water level depth occurring under *Sesbania formosa* populations ranged from 1 to 4 m below the surface. This places it amongst other facultative phreatophytic trees (*Eucalyptus camaldulensis*) and mesophytic small trees/shrubs (e.g. *Atalaya hemiglauca, Melaleuca glomerata* and *Melaleuca bracteata*) (Loomes, 2010).

Sesbania formosa is less well studied than the other species discussed above, and as such its groundwater use strategy is less accepted. This species is clearly a phreatophyte, which at times behaves like a facultative phreatophyte, and in many cases occurs in habitats indicative of an obligate groundwater use strategy.

3.3.5. Other key potentially Groundwater Dependent Species (GDS)

Several other key woody shrub species which occur in the Pilbara and are either potentially groundwater dependent or are associated with GDE's are as follows (in decreasing order of importance):

- *Livistona alfredii* (Priority 4);
- *Acacia ampliceps;*
- *Melaleuca bracteata;*
- *Melaleuca glomerata;*
- *Melaleuca linophylla;* and
- *Acacia coriacea* subsp. *pendens.*

Compared to the phreatophytic tree species discussed above, significantly less is known about the groundwater dependence of these species. This may be linked to the shallower roots systems possessed by these species. These species have been recorded in areas with consistent water availability which could potentially indicate reliance on groundwater sources.

Further to the list of species provided in Table 3-2, RTIO have developed the "Pilbara Riparian Ecohydrological Framework (PREF)" which is a hierarchical list of defined and increasingly important guilds of riparian ecohydrological indicator species. These species are split into a hydrological hierarchy which provides insight into the quality and degree of long-term stability or variability of the hydrological habitat.

The species used in the PREF have been constructed by considering the degrees of spatial correlation between species presence/absence data with anomalously persistent vegetation and surface water using remote sensing (detected using NDVI persistence mapping; as per Barron *et al.* 2012). The validation work used in the inception of the PREF has been completed using a large dataset collected from on-ground work. This validation process for the PREF was outlined within a presentation by Jeremy Naaykens at the WBSI Biodiversity conference 2021; Resilient Landscapes (Rio Tinto, 2021). RTIO are currently in the process of seeking a peer review for this framework.

In the PREF, from left to right the species are listed in increasingly order of reliance on persistent moisture availability and are unlikely to maintain viable populations from year to year if the riparian habitat of interest experience dry periods either annually, interannually, or over decadal time scales. This plant guild provides valuable insights into the inter and intra-annual consistency of moisture and sensitivities of riparian ecosystems to fluctuations in water availability. The PREF will be used to map riparian community types and to provide some insight into how represented these community types are in the study area and surrounds.

Table 3-3: Draft (2022) Pilbara Riparian Ecohydrological Framework (PREF) table for interpreting increasing degrees of availability, consistency and permanence of moisture/water (i.e. consistently mesic/hydric conditions).

Pilbara Riparian Ecohydrological Framework (PREF)						
Key Riparian Habitat Type & Plant Guild		← Increasingly Mesophytic/ Hydrophytic Indicator Guilds				
		Very High Level i.e. soil moisture availability or surface water availability is perennial	**High Level** i.e. soil moisture availability or surface water availability is clearly perennial to sub-perennial	**Moderate - High Level** i.e. soil moisture availability or surface water availability is perennial to sub-perennial	**Moderate Level** i.e. soil moisture availability or surface water availability is sub-perennial	**Low Level** i.e. soil moisture availability or surface water availability is sub-perennial to ephemeral
Keystone Mesophytes	Terrestrial Habitats - Overstorey	*Melaleuca argentea* (mature and abundant)	*Sesbania formosa* (abundant)	*Sesbania formosa* (present)	*Eucalyptus camaldulensis* (open woodland to woodland)	*Eucalyptus victrix* (scattered trees to woodland)
		Sesbania formosa (abundant and mature)	*Melaleuca argentea* (present - either scattered or sporadic)	*Melaleuca argentea* (potentially present - generally only an associated species, typically immature)	*Eucalyptus victrix* (open forest)	*Eucalyptus xerothermica* (abundant)
		Eucalyptus camaldulensis & *E. victrix* (usually present but generally in a lower abundance or occurring more peripherally)	*Eucalyptus camaldulensis* (open forest & greater)	*Eucalyptus camaldulensis* (open forest & greater)	Potentially includes larger more abundant tree populations of the following species: *Acacia coriacea* subsp. *pendens, Eucalyptus xerothermica, Atalaya hemiglauca, Terminalia circumalata*	*Terminalia circumalata* (present)
	Keystone constituents		*Eucalyptus victrix* (usually present but generally a peripheral component)	*Eucalyptus victrix* (usually present but generally a peripheral component)		
Mesophytes	Terrestrial Habitats - understorey i.e. habitats with increasingly consistent subsurface soil moisture only	*Sesbania formosa*	*Acacia ampliceps*	*Melaleuca bracteata*	*Gossypium sturtianum*	*Melaleuca glomerata* (present-scattered)
		Samolus spp. (verging on aquatic)	*Cullen leucanthum*	*Gymnanthera cunninghamii* (common) (priority species)	*Melaleuca linophylla* (present-scattered) *Melaleuca lasiandra* (north/north east edge of Pilbara) *Melaleuca glomerata* (abundant/dominant)	*Acacia coriacea* subsp. *pendens* & *Acacia sericophylla*
		Imperata cylindrica (verging on aquatic)	*Myoporum montanum*	*Melaleuca alsophila* (present)	*Plumbago zeylanica* (becoming common/abundant)	*Atalaya hemiglauca* (present-isolated)
			Ficus virens & *F. virens* var. *dasycarpa*	*Melaleuca xerophila* (lake edges, brackish groundwater)	*Dodonaea lanceolata* (becoming common/abundant)	*Plumbago zeylanica* (present-isolated)
			Ficus aculeata (common abundance)	*Adriana tomentosa*	*Cyperus vaginatus* (abundant to highly abundant)	*Acacia sclerosperma*
			Melaleuca nervosa or potentially M. alsophila (abundant) (north to north east edge of Pilbara)	*Ficus aculeata* (scattered to isolated abundance)	*Kirganelia baccata* (previously *Phyllanthus baccatus*) (present-isolated)	*Cyperus vaginatus* (present-isolated)
				Melaleuca linophylla (abundant/dominant)	*Abutilon amplum*	*Typha domingensis* (present-isolated)
				Kirganelia baccata (previously *Phyllanthus baccatus*) (common)	*Gymnanthera cunninghamii* (present-isolated) (priority species)	*Eulalia aurea* (abundant)
				Lawrencia glomerata	*Duma florulenta* (soaks, alluvial features)	*Stylobasium spathulatum* (becoming common/abundant)
				Tinospora smilacina	*Muellerolimon salicorniaceum* (salt marshes, brackish floodplains)	*Rhynchosia bungarensis* (priority species)
				Eragrostis surreyana (priority species)	*Flueggea virosa subsp. melanthesoides*	*Sesbania cannabina* (present-scattered)
				Commicarpus australis	*Atalaya hemiglauca* (common)	*Enteropogon ramosus*
				Pseudoraphis spinescens	*Sesbania cannabina* (abundant)	
					Commicarpus australis	
					**Echinochloa colona*	
					Leptochloa digitata	
Hydrophytes	Aquatic Habitats i.e. surface water habitats (including situations where surface water may be ephemeral, but where saturated sub-surface moisture is typically perennial) Blue highlighted taxa represent species more commonly present in such habitats which appear to be good groundwater discharge indicators	*Phragmites karka*	*Imperata cylindrica*	*Potamogeton* spp. (potential initial groundwater discharge indicator)	*Schoenoplectus subulatus*	*Cyperus vaginatus* (abundant)
		Cladium procerum (priority species)	*Pteris vittata*	*Schoenus falcatus* (potential initial groundwater discharge indicator)	*Ammannia baccifera* (present) (or *Ammannia multiflora*)	*Typha domingensis* (present-isolated)
		Eriocaulon cinereum	*Schoenus falcatus* (abundant)	*Eleocharis geniculata* (potential initial groundwater discharge indicator)	*Chara* spp. (abundant)	*Ammannia baccifera* (present-isolated)
		Adiantum capillus-veneris (priority species)	*Fimbristylis littoralis*	*Stylidium fluminense*	*Typha domingensis* (abundant)	*Chara* spp. (present-isolated)
		Acrostichum speciosum	*Eleocharis spiralis*	*Samolus repens*	*Eleocharis pallens*	*Myriophyllum* spp. (and other similar aquatic taxa)
		Ampelopteris prolifera (priority species)	*Fimbristylis sieberiana* (present) (potential initial groundwater discharge indicator) (priority species)	*Sonchus hydrophilus* (moderate to high)	*Striga curviflora*	*Stemodia grossa* (becoming abundant)
		Machaerina rubiginosa (previously *Baumea rubiginosa*)	*Fimbristylis cephalophora* (basalt)	*Schenkia australis*	*Fimbristylis microcarya*	*Marsilea* spp.
		Machaerina juncea (previously *Baumea juncea*)	*Eleocharis dulcis* (north Pilbara)	*Ruppia polycarpa*	*Cyperus difformis*	*Wahlenbergia tumidifructa*
		Juncus kraussii (Millstream)	*Stylidium weeliwolli* (priority species)	*Ammania baccifera* (abundant)	*Najas* spp. (present)	*Elytrophorus spicatus*
		Livistona alfredii (priority species)	*Eleocharis sphacelata*	*Fuirena ciliaris*	*Myriophyllum verrucosum* (present)	*Schoenoplectiella laevis*
		Ceratopteris thalictroides	*Samolus* sp. Millstream (and potentially *Samolus junceus*)	*Pseudoraphis spinescens*		*Cyperus leptocarpus* (previously *Lipocarpha microcephala*)
		**Nymphaea pubescens* (Millstream)	*Schoenus punctatus*	*Cyperus polystachyos*		*Glinus oppositifolius*
		Nymphoides indica	*Potamogeton* spp. (abundant) (potential groundwater discharge indicator)	*Cyperus dactylotes*	Medium to Low (other uncommon Cyperus species): *Cyperus bifax, C. cunninghamii, C. hesperius, C. iria, C. squarrosus*	
		Fimbristylis ferruginea (Millstream)	*Lobelia arnhemiaca*	*Schenkia clementii*		
		Stuckenia pectinata [&]	*Vallisneria* spp. (potential groundwater discharge indicator)	*Ludwigia perennis*	Low (Poorly known, poorly collected Cyperus species): **Cyperus involucratus, C. ixiocarpus, C. nervulosus, C. pulchellus, C. pygmaeus, C. rigidellus*	
		**Arundo donax*	*Sporobolus virginicus* (inland settings - not coastal/saline)	*Najas* spp. (abundant)		
			Eragrostis elongata	*Diplachne fusca*		

Orange indicates Poaceae species

Note: In some cases, the abundance of a particular species is noted as the determinant for its inclusion in different indicator categories. Where only a genus is listed; includes all species in that genus.
[&] New taxa whose position within the guilds is not yet confidently understood (requiring further investigation).

3.4. GDE's concepts and relevant terminology

Groundwater comes in many forms and occurs on many scales (e.g. small (to micro scale) perched aquifers versus local alluvial aquifers (unconsolidated), versus broader local/regional aquifers (consolidated)), and as such there is often high uncertainty about the source(s) of groundwater which vegetation might depend on, and the ability of mining to influence these sources. Furthermore, all water used by plants comes from the ground, and so the complex interactions and interdependencies which occur between vadose ground water (sourced from direct rainfall and surface water flows) and the suite of micro, small and local and regional scale aquifers potentially supporting riparian communities, makes defining GDE's a difficult process. In most cases it requires detailed and resource-intensive work conducted at a fine scale to define their groundwater dependence and likely impact from proposed development. Importantly these types of investigations can be lengthy and expensive and don't integrate well with the risk-based assessment approach associated with traditional EIA methods.

The Bureau of Meteorology (BoM), who developed and manage the GDE Atlas of Australia (BoM, 2020) have dealt with this issue by using alternative terminology for features other than those ecosystems which are known to be GDE's. Ecosystems that could not be confidently identified or inferred as GDE's due to lack of data, but which may be using groundwater, are considered as potentially Inflow Dependent Ecosystems (IDE) (SKM, 2012). Inflow Dependent Ecosystems are defined in the Atlas as vegetation ecosystems that are likely to use a water source in addition to rainfall, such as water stored in the unsaturated zone, surface water or groundwater. In general, this terminology is applied in the Atlas because for much of the continent it's not yet clear whether riparian formations[7] represent GDE's; generally due to a lack of hydrological/ecological data or complexities around groundwater sources potentially being accessed. In the Atlas they are presented using likelihood mapping which infers some level of risk that GDE's may be present. Inflow Dependent Ecosystems layers (presented as GIS layers within the Atlas) allow the presentation of a more complete understanding of the likely water use of ecosystems analysed during development of the GDE Atlas.

Inflow Dependent Ecosystems terminology and logic can also be applied to 'mesic' riparian formations which are potentially groundwater dependent, but where it's not yet clear whether they represent GDE's due to; a lack of hydrological/ecological data or because they are likely dependent on aquifers stored in lithological or alluvial formations which are either small to micro in scale, or intermittent/seasonal in nature. Generally, these small to micro scale groundwater features are not clearly indicated in the hydrological data on account of their size/seasonality, and as such they fit more appropriately into the low-data/low-confidence category as an IDE. Alternatively, IDE features which generally possess lower abundances of known phreatophytes, but which occur on creeklines receiving surface water regimes of elevated magnitude/frequency, can also reasonably be considered to depend on seasonal surface water recharge events (i.e. inflow dependent) and associated residence times of vadose and micro scale groundwater sources. As a result the remainder of riparian features are classified as GDE's when they are either known/demonstrated to be GDE's (through hydrogeological or ecological data), or can realistically be inferred to be GDE's due to groundwater data indicating the presence of moderate to larger scale aquifers in reach of resident vegetation. For the purpose of the current study this will be the preferred definitions/distinctions relevant to the 'GDE' and 'IDE' terminology.

BoM GDE Atlas terminology for IDE defines it as:

[7] In this document the term "riparian formation" (or vegetation formation) is referring to a non-descript potentially unbounded section of riparian vegetation which is of interest/question for whatever reason. It is not necessarily representing a vegetation unit, but more often than not, is referring to a section of enhanced vigour, structure or density, or associated with a certain reach or fluvial profile of interest. In simple terms, it is purely a section/area of riparian vegetation of interest.

Ecosystems that are likely to be using another source of water in addition to rainfall. IDEs include groundwater dependent ecosystems as well as ecosystems which rely on sources of water other than rainfall (e.g., surface water, water stored in the unsaturated zone, irrigation) (SKM 2012).

In many cases, within arid tropical regions, riparian formations likely to be at least partially supported by groundwater or other inflows tend to exhibit and possess similar characteristics which can be more broadly described as being representative of a 'mesic' environment/habitat. One where specific overstorey and understorey components establish in increasing abundance (or proportion to 'ephemeral' biota) in response to increasing degrees of moisture availability. While the source of this moisture is often not yet clear, and in some cases could be purely from surface water inflows (but in more 'mesic' cases is likely to be linked to some type of aquifer), what's initially most important is identifying the presence, magnitude and characteristics of such 'mesic' vegetation communities. On the flip side, riparian representations not indicating the presence of moisture levels elevated above that expected in typical arid zone riparian formations can be appropriately termed as more 'ephemeral' in nature and thus of low to very-low risk of being groundwater dependent.

Establishing the presence and characteristics of 'mesic' communities and their distribution in an area can then form the inventory with which to further study, assess and thus predict potential for impact as a result of proposed hydrological change in the areas of elevated risk. For these reasons, the following assessment tends to favour the use of the concept of identifying and classifying 'mesic' riparian formations (as opposed to more ephemeral riparian communities), rather than the identification of GDV and GDE's. However, while the terminology is relatively interchangeable, the 'mesic' terminology is more appropriate for all representations identified given that work to understand the scale, connectivity and variability of the supporting water sources has not yet been done for all.

Given the potentially variable water use strategies of phreatophytic species in the Pilbara, it becomes important to distinguish between these lower sensitivity groundwater dependent ecosystems/vegetation, and those which are truly phreatophytic and therefore depend on groundwater almost exclusively to meet their water requirements. To address this disparity, the terms 'Facultative Phreatophytic Vegetation' (FPV) and 'Obligate Phreatophytic Vegetation' (OPV) are proposed to provide distinction between the facultative, often markedly less significant/sensitive phreatophytic vegetation and those high value communities possessing obligate phreatophytes. Note: these are not well-recognised terms and have been created for the purpose of this and other related studies from other associated, well accepted terms such as obligate phreatophytes and GDV.

For the purpose of this study, OPV is defined as representing communities which:

> *Encompasses vegetation associations and sub-associations, whose structure is at least co-dominated by one obligate phreatophyte, namely* Melaleuca argentea *(i.e. possesses vegetation described as being dominated by one or more species within the tree or tall shrub stratum and which includes the species* Melaleuca argentea *as one of these described dominant species).*

FPV is defined as representing communities which:

> *Encompasses vegetation associations and sub-associations, whose structure is at least co-dominated by one facultative phreatophyte (typically either* Eucalyptus camaldulensis *or* Eucalyptus victrix*) (i.e. possesses vegetation described as being dominated by one or more species within the tree or tall shrub stratum and which includes a facultative phreatophytic species as one of these described dominant species), but which is not co-dominated by any obligate phreatophytes and which typically does not possess obligate phreatophytes as an associated species.*

3.5. Factors contributing to biological significance

Riparian vegetation and Groundwater Dependent ecosystems involve both Environmental Protection Authority (EPA) factors Flora and Vegetation and Inland Waters. Therefore, the guidelines for significance for both factors have been considered for this targeted riparian survey assessment.

The EPA factor guideline for Flora and Vegetation (EPA 2016a) states that, vegetation may be considered significant for a range of reasons, including, but not limited to the following:

- being identified as threatened or priority ecological communities
- restricted distribution
- degree of historical impact from threatening processes
- a role as a refuge
- providing an important function required to maintain ecological integrity of a significant ecosystem.

The EPA factor guideline for Inland Waters (EPA 2018b) states that "For the purposes of EIA and in relation to ecosystem health, the EPA is focussed on impacts to significant ecosystems. Significant ecosystems include, but are not limited to:

- Ramsar sites. Wetlands of International Importance as listed under the Ramsar Convention, an international treaty on the conservation of important wetlands
- Conservation category or Resource enhancement management wetlands as mapped in the Geomorphic Wetlands of the Swan Coastal Plain dataset as managed by the Department of Biodiversity, Conservation and Attractions
- wetlands listed in the Directory of Important Wetlands in Australia
- wetlands protected by Environmental Protection Policies under Part III of the Environmental Protection Act 1986
- wild rivers, as identified by the Australian Heritage Commission and Department of Water and Environmental Regulation
- wetland types which may be poorly represented in the conservation reserves system
- springs and pools, particularly in arid areas
- ecosystems which support significant flora, vegetation and fauna species or

communities, including migratory waterbirds, bats, and subterranean fauna

- ecosystems which support significant amenity, recreation and cultural values
- saline lakes, estuaries and near shore ecosystems reliant on groundwater or surface water inputs
- downstream marine ecosystems."

3.6. Relevant high-value riparian vegetation communities within the Hamersley's and their associated distribution

The climate of the Pilbara is essentially classified as arid-tropical possessing an average precipitation to evaporation ratio of less than 0.2 (McKnight 2000). With annual precipitation generally falling within the range of 250 to 450 mm, the Pilbara can be mistaken for being semi-arid, but with high average

temperatures and an average evaporation rate in the vicinity of 2000 mm per year, the effective precipitation in the region is minimal and therefore classified as arid. Because of such climatic factors, water gaining sites which are exposed to surface water supply from larger catchments, and which can lock away significant amounts of water from evaporation, become quite important. Within the Hamersley Ranges and plateau, the rocky/rugged upland environments, eco-physical settings, and unique geological formations provide a suite of novel opportunities for surface water inputs to be stored and provided more consistently to biota in key fluvial locations. Such fluvial systems create riparian corridors which can provide refuge for a diversity of moisture loving species which wouldn't otherwise be present in areas possessing a similar climate classification. Consequently, these riparian features provide value to the region as custodians of biological diversity through their provision of ecological services and habitat diversity/complexity.

Beyond the general importance and functions of large creek systems in hot and often dry climates such as that of the Pilbara, drainage systems which provide the right catchment size and environmental conditions (generally related to underlying geology, elevation, slope, meander shape and creek profile etc.) to create surface or groundwater permanence are considered most valuable. This value is primarily a product of the restricted vegetation communities they can sustain, and by association the fauna assemblages they support. The permanence of the water present ensures the landforms ability to create and sustain communities such as OPV of a high structural and species diversity, and potentially support associated conservation significant fauna assemblages. These attributes in turn create value and therefore significance due to the restricted distribution of these perennial habitats. With respect to conservation significance, features such as this tend to possess elevated and potentially high conservation significance as they are generally few in number, restricted to small areal extents, and sensitive to perturbation.

4. Methods

Several methods were used to facilitate the aims of the current targeted flora and vegetation study. The aims focus on improving the understanding of riparian vegetation present, their distribution and associated ecohydrology, in moderate and greater sized drainage systems in and around the HD1 development area.

This broader focus led to the development of the following aims for which the described methods are relevant. These aims were to;

1. Complete survey tasks which enable the production of accurate and targeted riparian vegetation mapping.
    i. Increase the density and coverage of the systematic sampling site array
    ii. Compile appropriate targeted vegetation mapping notes and desktop mapping products which aid the mapping refinement process
2. Identify ecohydrological characteristics relevant to the different drainage reaches and riparian ecosystems present within the Study Area.
3. Assess local vegetation for the presence of relevant ephemeral, mesophytic and hydrophytic riparian indicator species of value to the riparian mapping and assessment process.
4. Gather evidence on the distribution and persistence of surface water features across the Study Area.
5. Provide updated and refined riparian vegetation mapping for the Study Area, as well as:
    i. Relevant ecohydrological zone mapping
    ii. GDV likelihood mapping
    iii. Persistent riparian surface water mapping
6. Provide findings on the types of riparian communities and degrees of representation across the Study Area and surrounds.

Given the low hydrological risk posed by the development on local drainage systems, one of the listed aims was the production of non-exhaustive GDV likelihood mapping. The aim of this mapping is for the purpose of providing a cursory assessment of the degree of potential GDV exposure present within the Study Area. Further to the GDV likelihood mapping, a systematic assessment of the presence of surface water features was conducted in order to map the presence of persistent surface water features in moderate and greater sized drainage across and directly adjacent to the Study Area.

The final aim listed above was one of the most important components of the whole study. This was to conduct a systematic assessment on each of the mapped vegetation units and in some cases (where relevant) on specific reaches of different vegetation units. This involved classifying units into a riparian hierarchy to determine the likely biodiversity values held by each of the riparian communities assessed.

4.1. Desktop Tasks and Investigations

For the broader riparian vegetation mapping process, the following key desktop tasks were conducted:

1. Consideration of historical and recent baseline flora and vegetation surveys conducted in the locality, including determination of the most relevant and up to date mapping units available for the Study Area.
2. Within riparian habitats of relevant moderate and greater sized drainage; assess the array of historical flora and vegetation sampling, and design an infill sampling program to support the study aims.
3. The development and use of Landsat and Sentinel derived NDVI persistence mapping for the locality (as per Barron et al., 2017) in order to guide targeted field traverses into relevant habitats and ecotypes.
4. Map out the presence of both low level and particularly moderate level Facultative Phreatophytic Species (FPS) in key reaches of WWC and particularly PMC in order to understand the relative

abundance of each and to help inform the mapped structure and dominance of keystone overstorey species within local riparian vegetation.

5. Development and upload of relevant mobile GIS layers for field validation and to support the field and desktop based riparian vegetation mapping processes.
6. Assess trends in remote sensing derived NDVI persistence mapping and available groundwater height monitoring (from monitoring bores) to help inform ecohydrological characteristics/zones and GDV likelihood within relevant Study Area drainage reaches.
7. Following field work; use various desktop resources, analyses, remote sensing, monitoring data and outputs in conjunction with field data to support the process of vegetation delineation and mapping.

   Steps 1 & 2 above are described in more detail within section 4.2 (namely section 4.2.1), with step 3 detailed in section 2.6 and further in section 4.1.1. Step 4 above is described in detail in section 4.3.1 & 4.3.2, while steps 5, 6 & 7 are described in section 4.2 and 4.2.1.

For the purpose of completing GDV likelihood mapping across the Study Area, the following key desktop tasks were conducted to help identify the presence of phreatophytes, 'Mesic' riparian assemblages and potential GDV:

1. Development and interpretation of Landsat and Sentinel derived NDVI persistence mapping (1987-2021 & 2016-2021 respectively) for the locality as per Barron *et al.* (2017) in order to help interpret ecohydrological characteristics and water-availability across the Study Area.
2. Consideration of GDE and IDE identification layers provided by the BoM GDE atlas (BoM, 2022), as well as height data from local groundwater monitoring bores.
3. Consideration of historical and recent baseline flora and vegetation surveys (particularly systematic sampling sites) conducted in the locality.
4. Development and upload of relevant mobile GIS layers for field validation and to support the field and desktop based GDV likelihood mapping tasks (including persistence mapping, desktop phreatophyte mapping, historical vegetation mapping and systematic sampling sites); and
5. Following field work and the creation of targeted riparian vegetation mapping for the Study Area; various desktop resources, analyses and outputs in conjunction with field data were used to support the process of GDV delineation and likelihood mapping.

The following section outlines the approach and application behind Step 1. The tools used in steps 2 and 3 are discussed in Sections 2.7 and 2.5 respectively. Step 5 involved the consideration and integration of all relevant data at a desktop level following field and desktop-based tasks.

,

The riparian ecotype hierarchy provided in PREC aims to provide a logical approach to classifying ecosystem gradients and degrees of community restriction based on the typical structural and compositional gradients which have been observed within riparian ecosystems of the Pilbara, and which are predominantly linked to moisture/ecohydrological gradients.

4.1.1. NDVI Persistence Mapping use – GDV likelihood identification and riparian mapping

Sentinel derived NDVI and NDMI (as well as Sentinel Water Mask (SWM)) persistence mapping was used to visually identify areas of persistent vegetation cover and canopy hydration (as well as surface water) as potential locations of GDEs, but also as indications of zones experiencing differing ecohydrological characteristics. Persistence mapping was produced over the locality using a web-based application (developed by NGIS in conjunction with Rio Tinto) which interfaces with the Earth Engine cloud based spatial data repository (Google© Product). Exported outputs from this web portal have been quality checked and thematically mapped by the Rio Tinto Biological assessments team (Jeremy Naaykens) following the methods of Barron *et al.* (2017) and Barron *et al.* (2012). The Sentinel aerial imagery utilised

all available imagery which spans a five-year period from 2016 to 2021 (10 m pixel size) and an NDVI or NDMI threshold of 0.32 and 0.1 respectively was also applied (Barron *et al.* 2017).

From the persistence mapping, groups of pixels returning mean NDVI/NDMI persistence values above 60-70 %, are indicating a relevant range of inter/intra-seasonal index persistence. Such a persistence range is indicative of imagery and thus vegetation exhibiting minimal drying signal in the drier months of the year such that additional water sources such as groundwater are likely to be implicated in the ongoing health/characteristics of the target riparian vegetation. The magnitude and spatial extent of NDVI/NDMI persistence, in combination with the landforms and vegetation visible in aerial imagery were used to help define likelihood of the presence of GDV for each of the mapped riparian communities or potential GDE features either known, sighted on imagery, or identified in persistence mapping. The broad range of persistence values attained across the sites was correlated with known and extensive GDE/GDV located along parts of WWC and particularly within and around Weeli Wolli Springs (WWS), directly to the northeast of the Study Area. GDV located within WWS has persistent, shallow access to ground and surface water throughout the year. The persistence ranges (generally informed by mean to maximum NDVI/NDMI values within an area of interest) utilised to inform riparian mapping trends and GDV likelihood ratings in this assessment included the following likelihoods:

- **90 – 100 %**: increased reliance on groundwater (larger scale aquifers) for ecosystem function likely; associated with dense *Eucalyptus camaldulensis* dominated (± *Melaleuca argentea*) communities; generally associated with areas of shallow groundwater and potential groundwater discharge such as the informally named “Ben’s Oasis” and associated features;
- **80 – 89 %**: reliance on groundwater (larger scale/small scale aquifers) for ecosystem function likely; associated with sparse to dense *E. camaldulensis* dominated (± *E. victrix*) communities; generally associated with areas of shallow groundwater, supportive basement morphology and some gorge/gully features;
- **60 – 79 %**: some to limited reliance on groundwater (small scale aquifers) for ecosystem function likely; generally associated with FPS dominated canopies on bends in creeks and increased canopy density of riparian vegetation, *E. victrix* (and *E. camaldulensis*) main phreatophyte present. Smaller scatterings or groupings of pixels in the order of 60-70% persistence may be indicative of reaches where vegetation represents an IDE, but where Eco physical characteristics are such that surface water has a higher residence time; and
- **40 – 59 %**: vegetation likely to be mostly representative of IDE riparian vegetation predominantly reliant on seasonal surface flows and factors which increase residence time of vadose recharge events.

Across the Study Area, Landsat and Sentinel derived Remote Sensing (RS) derived NDVI persistence mapping was used to:

1. Provide an indication of the temporal characteristics of moisture availability within riparian zones across the Study Area;
2. Provide an indication of riparian zones which showed low potential for the presence of GDV;
3. Indicate the location and size of potentially groundwater dependent riparian features; and
4. Provide an indication of the potential magnitude of groundwater or surface water dependence exhibited by of each identified feature.

As a result, NDVI persistence mapping combined with high resolution aerial photographic interpretation informed key areas of interest for field validation/investigation and the post field work GDV likelihood mapping process.

It was also recognised that there are limitations of NDVI persistence mapping. These limitations are primarily associated with the pixel size (30m) of Landsat derived imagery. This pixel size determines that riparian features no wider than 20-30m can be missed, or underrepresented (through pixel mixing) by Landsat derived persistence mapping. It is noted that for most drainage systems, such issues are uncommon and where it occurs, reduced patch size of potential GDE features typically determines reduced significance (and reduced risk), but also such features are often picked up by aerial photo interpretation and baseline surveys. Further to this the use and review of Sentinel 2 persistence mapping and the resulting 10m pixel which it provides, allows such limitations to be circumnavigated.

A secondary issue is that in some areas, vegetation can be purely represented by overstorey trees only (i.e. no understorey) and where the overstorey is relatively sparse, truly groundwater dependent riparian overstorey formations can fail to meet the applied 0.32 NDVI threshold producing a false negative in the mapping. This situation is uncommon, but importantly most often occurs in larger drainage systems where bed scour removes the understorey in key zones. Typically in such situations, adjacent un-scoured and similarly groundwater influenced areas return RS pixel values which help identify the presence of potential GDV and trigger field investigation of the area.

4.2. Field work

The primary field work completed for this study and described in this section occurred over 7 days from the 12th till the 17th of July 2021. The work was conducted by three Botanists (Jeremy Naaykens & Cassie Reynolds – Rio Tinto, and Carmel Winton – Biologic). Data and observations from five separate additional field trips in the Hope Downs 1 area (all conducted by Jeremy Naaykens – Principal advisor ecohydrology and Botanist RTIO) was also used for this study:

1. 26th of July 2017- Reconnaissance of “Ben’s Oasis” Spring and vegetation communities
   - Compositional observations,
   - Surface water presence and abundance observations and
   - *Melaleuca argente*a distribution observations
2. 13-14th of December 2018 – Further work at “Ben’s Oasis” & checks along Pebble Mouse Creek (PMC).
   - Collection of Compositional data in and around “Ben’s Oasis”,
   - Extensive traverses and data collection for the presence, age and distribution of *Melaleuca argentea*, both upstream and downstream of the main “Ben’s Oasis” pool over a 5km reach of Weeli Wolli Creek.
   - Phreatophyte abundance/dominance and general vegetation composition – spot checks at 4 locations along PMC for the purpose of ground truthing of aerial photo interpretations of Eucalyptus camaldulensis abundance.
3. 22 February 2020 – Priority flora Spot checks along pebble mouse creek
   - Spot checks in 4 locations on PMC, near operations, for the presence of *Aristida lazaridis* (along with phreatophyte abundance ground truthing).
4. 1st of October 2020 - Initial investigations of a small potential GDE on the upper tributaries of WWC
   - Foot traverse along WWC looking at phreatophyte abundance and mesophyte composition/abundance in the understorey from south of HD2 deposit to the highway.
5. 2-3rd of June 2021- Study Area Reconnaissance visit (J. Naaykens & C. Reynolds).
   - Included vegetation spot checks along parts of WWC and PMC.

4.2.1. Riparian vegetation mapping with a focus on ecohydrology and potential GDV characteristics and distribution

To achieve the riparian vegetation mapping aims of this study, a targeted survey was conducted as defined under the EPA Technical Guidance; Flora and Vegetation Surveys for Environmental Impact Assessment (EPA 2016). Targeted field investigations of features of interest and extent/locations were supported by NDVI persistence mapping described above. Persistence mapping was used to identify, prioritise and select areas requiring field validation. In addition, this mapping provided supporting information regarding the extent and type of riparian formations present. This type of mapping is particularly helpful in determining where more mesic communities as opposed to more ephemeral communities were distributed.

While the core focus of this study was to refine the baseline vegetation mapping to focus on riparian values while increasing the accuracy and detail of the resulting mapping, a secondary focus was to enable this mapping to inform the presence and distribution of potential and clear GDV. In order to do this, the study also focused on detecting and recording potentially groundwater dependent vegetation (GDV), as an indicator of the potential presence of GDE's and IDE's.

In order to appropriately refine the baseline mapping to highlight riparian values, the vegetation mapping traverses and investigations conducted focused on gathering information on the distribution and compositional characteristics of 'mesic' riparian vegetation (and potential GDEs) within Pebble Mouse and Weeli Wolli Creeks. This was primarily achieved primarily by gathering information about the structure, distribution and maturity of facultative phreatophytic species/vegetation, and where appropriate obligate phreatophytic species/vegetation. In addition, gathering information about the presence/absence and abundance of mesophytic and hydrophytic indicator species (as per the PREF) was also prioritised.

Given that relatively ephemeral FPV was thought to be dominant in the area, with Obligate Phreatophytic Species (OPS), namely *Melaleuca argentea*, likely rare; particular focus was made on understanding the distribution and abundance patterns exhibited by *Eucalyptus camaldulensis* (River Red Gums). Despite this, there was also a focus on making sure any OPV representations were detected. OPV vegetation incorporates species possessing the highest degree of sensitivity to changes in groundwater hydrology, potentially associated with mining. Furthermore, data on the age structure of communities dominated by OPS obligate phreatophytes was gathered as it tends to provide information about the longer-term stability and consistency of shallow groundwater access.

The above field survey techniques and associated survey effort were then used along with desktop and remote sensing mapping products/analyses to delineate and describe vegetation types encountered in the Study Areas. Vegetation types described and delineated as part of this targeted riparian study represent a "structural vegetation classification", as per the Technical Guidance for Flora and Vegetation Surveys (EPA 2016b). This approach was chosen (rather than using a floristic classification) as it is thought to be most relevant for riparian vegetation surveys focused on facilitating ecohydrological assessments and in particular in assessing the likely groundwater dependence of resident vegetation. Structural vegetation classification uses vegetation structure and consideration of patterns in the dominance of relevant species within each stratum to describe differences between vegetation units. Structural vegetation classification provides information on the height of key strata present, foliar cover and dominant species.

The vegetation mapping process and the resultant field survey effort attributed to the Study Area was generally focused on riparian units occurring within the major riparian habitats of the Study Area. As part of this process, a higher degree of survey effort was afforded to the riparian units in the main incised channel zone (low flow channels) of local drainage systems compared to the fringing communities of the terrace and outer floodplain communities. Mapping of the outer riparian habitats (and the riparian zone) along Pebble Mouse and Weeli Wolli Creeks has previously been completed by Astron (2020) and Mattiske (2008; 2010), so mapping in these low risk areas (from a both a significance and hydrological sensitivity sense) relied upon this previous mapping to increase the degree of community validation applied.

A total of 25 quadrats/relevés were sampled as part of the current study and including the historical sampling sites the available sampling array totalled was 62 sites. The location of sampling sites conducted

as part of the current study were designed to fill in identified gaps in key historical surveys. The location of current and historical sampling sites are presented in Figure 4-1.

It should be noted that a vegetation map is essentially a model, and as such the spatial validity of the boundaries and the vegetation associations depicted to lie within those boundaries, is only true a portion of the time. In general, the accuracy of the model is directly correlated to the amount of ground-truthing which is done per unit area of the model, and the scale of the community descriptions created. Another factor influencing the accuracy of the vegetation model is generally considered to be the complexity of environmental factors influencing vegetation ecology, but for the surveyor this is an uncontrolled factor and is therefore not generally considered in detail. Importantly, as aerial photo resolution increases, an increasing level of information, model accuracy, and canopy classification is being derived by using on ground data (particularly vegetation photos) to interpret and validate desktop classification of aerial imagery data.

All vegetation types mapped as part of this study, were described using Aplin's (1979) framework for "Vegetation Structural Classes" (Specht, 1970). This framework is presented in Appendix A:, along with vegetation condition scale used in this study (Trudgen, 1988). As such all communities established as part of this study are generally considered to represent sub-associations (equivalent to the NVIS classification). Community descriptions were created by identifying dominants (where present) for all relevant strata available, rather than restricted to the three traditional strata, such that they represent relatively detailed vegetation descriptions, approximately equivalent to level 5 mapping within the National Vegetation Information System (NVIS) (DoE, 2014b). Additional key (sub-dominant) phreatophytic species were included in brackets and represented by '+/-' to indicate relatively lower frequencies of occurrence in the vegetation type.

Given the focus of this study; some vegetation types mapped and described as part of this study are lacking some of the compositional differentiation which comes from sampling over multiple phases (as part of a detailed survey (EPA 2016b). Furthermore, some of the non-core riparian communities of the floodplain and high-flow riparian habitats are less adequately sampled and described/delineated throughout the Study Area as the focus of this study was on improving accuracy and detail in the core-riparian zone and supporting the delineation of potential groundwater dependent ecosystems. Given this focus; the reduced level of detail provided for such communities (which are generally of lower likely significance and potential groundwater dependence) is considered relatively inconsequential when considering the riparian values of the Study Area as well as potential hydrologically derived impacts.

4.2.2. Quadrat and Relevé Sampling

In both the WWC and PMC stretches of the Study Area it was determined that sampling additional quadrats/relevés to those historically established was required to supplement floristic composition data and improve mapping confidence in the area. This additional sampling occurred from the 11-17th of July 2021, along with some of the targeted mapping traverses and ground truthing tasks completed for the Study Area. However, leveraging historical vegetation mapping by Astron (2019) and Mattiske (2010), the position of quadrats/relevés were able to be chosen to confirm the vegetation structure and floristic composition initially mapped via these studies thus better informing the vegetation mapping refinement process.

Quadrats (flora sampling sites of a fixed area) were preferentially used as the primary method to gather quantitative data on floristic composition. Quadrat positions were initially chosen at the desktop level to ensure that the sampling array was appropriate and took into account previous sampling and historical vegetation mapping boundaries. While the spatial location of corner points were accurately recorded using an standard accurate GPS (1-4 m accuracy), none of the corners were permanently marked in the field, as re-sampling was not planned and the majority of corner posts were in the low flow zone and as such would not last long term. All quadrats established were of 2,500 m^2 in area and most were either 50 x 50 m or 25 x 100 m in dimension. This quadrat area of 2,500 m^2 is recognised as providing an adequate sample of species presence for Pilbara vegetation and is the standard quadrat size for botanical survey work in the region (Clarke 2009). Where the dimensions of a community did not allow a square quadrat, a rectangular

quadrat of equivalent area was established instead. Measuring tapes were used to ensure sampling was broadly confined to the boundaries of the quadrats.

In the remainder of cases relevés were used either to overcome spatial constraints or to more rapidly acquire additional sampling effort. A relevé is an unbounded flora sampling site with a similar area to a standard quadrat. In this survey relevés were sampled in a more traditional fashion where the same information is recorded as for a quadrat, and the degree of sampling effort dedicated to sampling of flora is similar, but the boundaries of the sampling unit are not confined. Relevé sampling was often undertaken if the vegetation type had a confined irregular shape (e.g. along creeklines), making establishment of a standard quadrat in a single vegetation type difficult. The following information (and more) was recorded for each quadrat and relevé:

- Location: Universal Transverse Mercator (UTM) coordinates recorded in GDA 94 datum in Zone 50 (to an accuracy of typically ±4 m), using a handheld GPS unit; coordinates were recorded for all four corners of a quadrat and for the centre point of a relevé;
- Vegetation description: a broad description based on the height and estimated cover value of dominant species in all relevant strata (Aplin 1979; see Appendix A:);
- Habitat description: a description of the landform and habitat;
- Broad soil type: a description of the soil colour, texture and any stony surface mantle;
- Fire history: approximate time since last fire, where applicable;
- Vegetation condition ranking: considering evidence of grazing, physical disturbance, weed invasion etc. (after Trudgen 1988; see Appendix A:);
- The estimated percent foliar cover and height of each flora species present within the relevant community which the quadrat/relevé is positioned to represent; and
- A set of four colour photographs of each site (usually taken in an North/East/South/West fashion from a position in the quadrat which allows representative views of the vegetation community being sampled.

Overall, a total of 25 systematic sampling sites were established, including 11 quadrats and 14 relevés sampled in the Study Area, as well as 10 vegetation points (detailed vegetation mapping data points) and 2 reference sites sampled outside of the Study Area. The location of the additional quadrats and relevés established in the survey area as part of this study is provided in Figure 4-1.

In terms of the historical systematic sampling sites which were used to support the vegetation mapping refinement process; an additional 10 quadrats/relevés sampled by Astron (2020) were considered along with 9 vegetation mapping data points. In addition, approximately 27 quadrats/relevés sampled by Mattiske in 2008 & 2010 were also utilised, which means that all up more than 60 quadrats and relevés were considered across the Study Area as part of the mapping refinement process. The raw quadrat data from these quadrats are provided in Appendix M: along with a table presenting coordinates for each site (MGA Zone 50, GDA 94). A list of all of the systematic sampling sites utilised in the current study are provided in Appendix N: and presented in Figure 4-1.

None of the additional quadrats and relevés sampled as part of this study were seasonally sampled, that is, surveyed over two seasonally favourable phases. In addition to the new and historical sampling sites which were utilised in this study, two riparian vegetation monitoring transects (both on WWC in the “Ben’s Oasis” area) and the embedded quadrat data from each was also considered in the vegetation mapping process (Mattiske 2019; from surveys from 2008-2019).

Identification of vascular flora specimens was conducted in the field or in the office following the field survey. In cases where a plant specimen was common and known to the botanist, the identification was confirmed and noted in the field. If the species was difficult to determine without microscopic examination, belonged to a recognised species complex, was poorly collected or otherwise unusual, a voucher specimen was collected.

All voucher specimens were identified by Steven Dillon from the WA Herbarium using flora keys, consulting appropriate publications and relevant experts, checking voucher reference collections, and comparing the specimens to the main herbarium. Nomenclature followed the current listing of scientific names recognised by the WA Herbarium (unless specified). All data were entered into a Microsoft Access Vegetation Database structure.

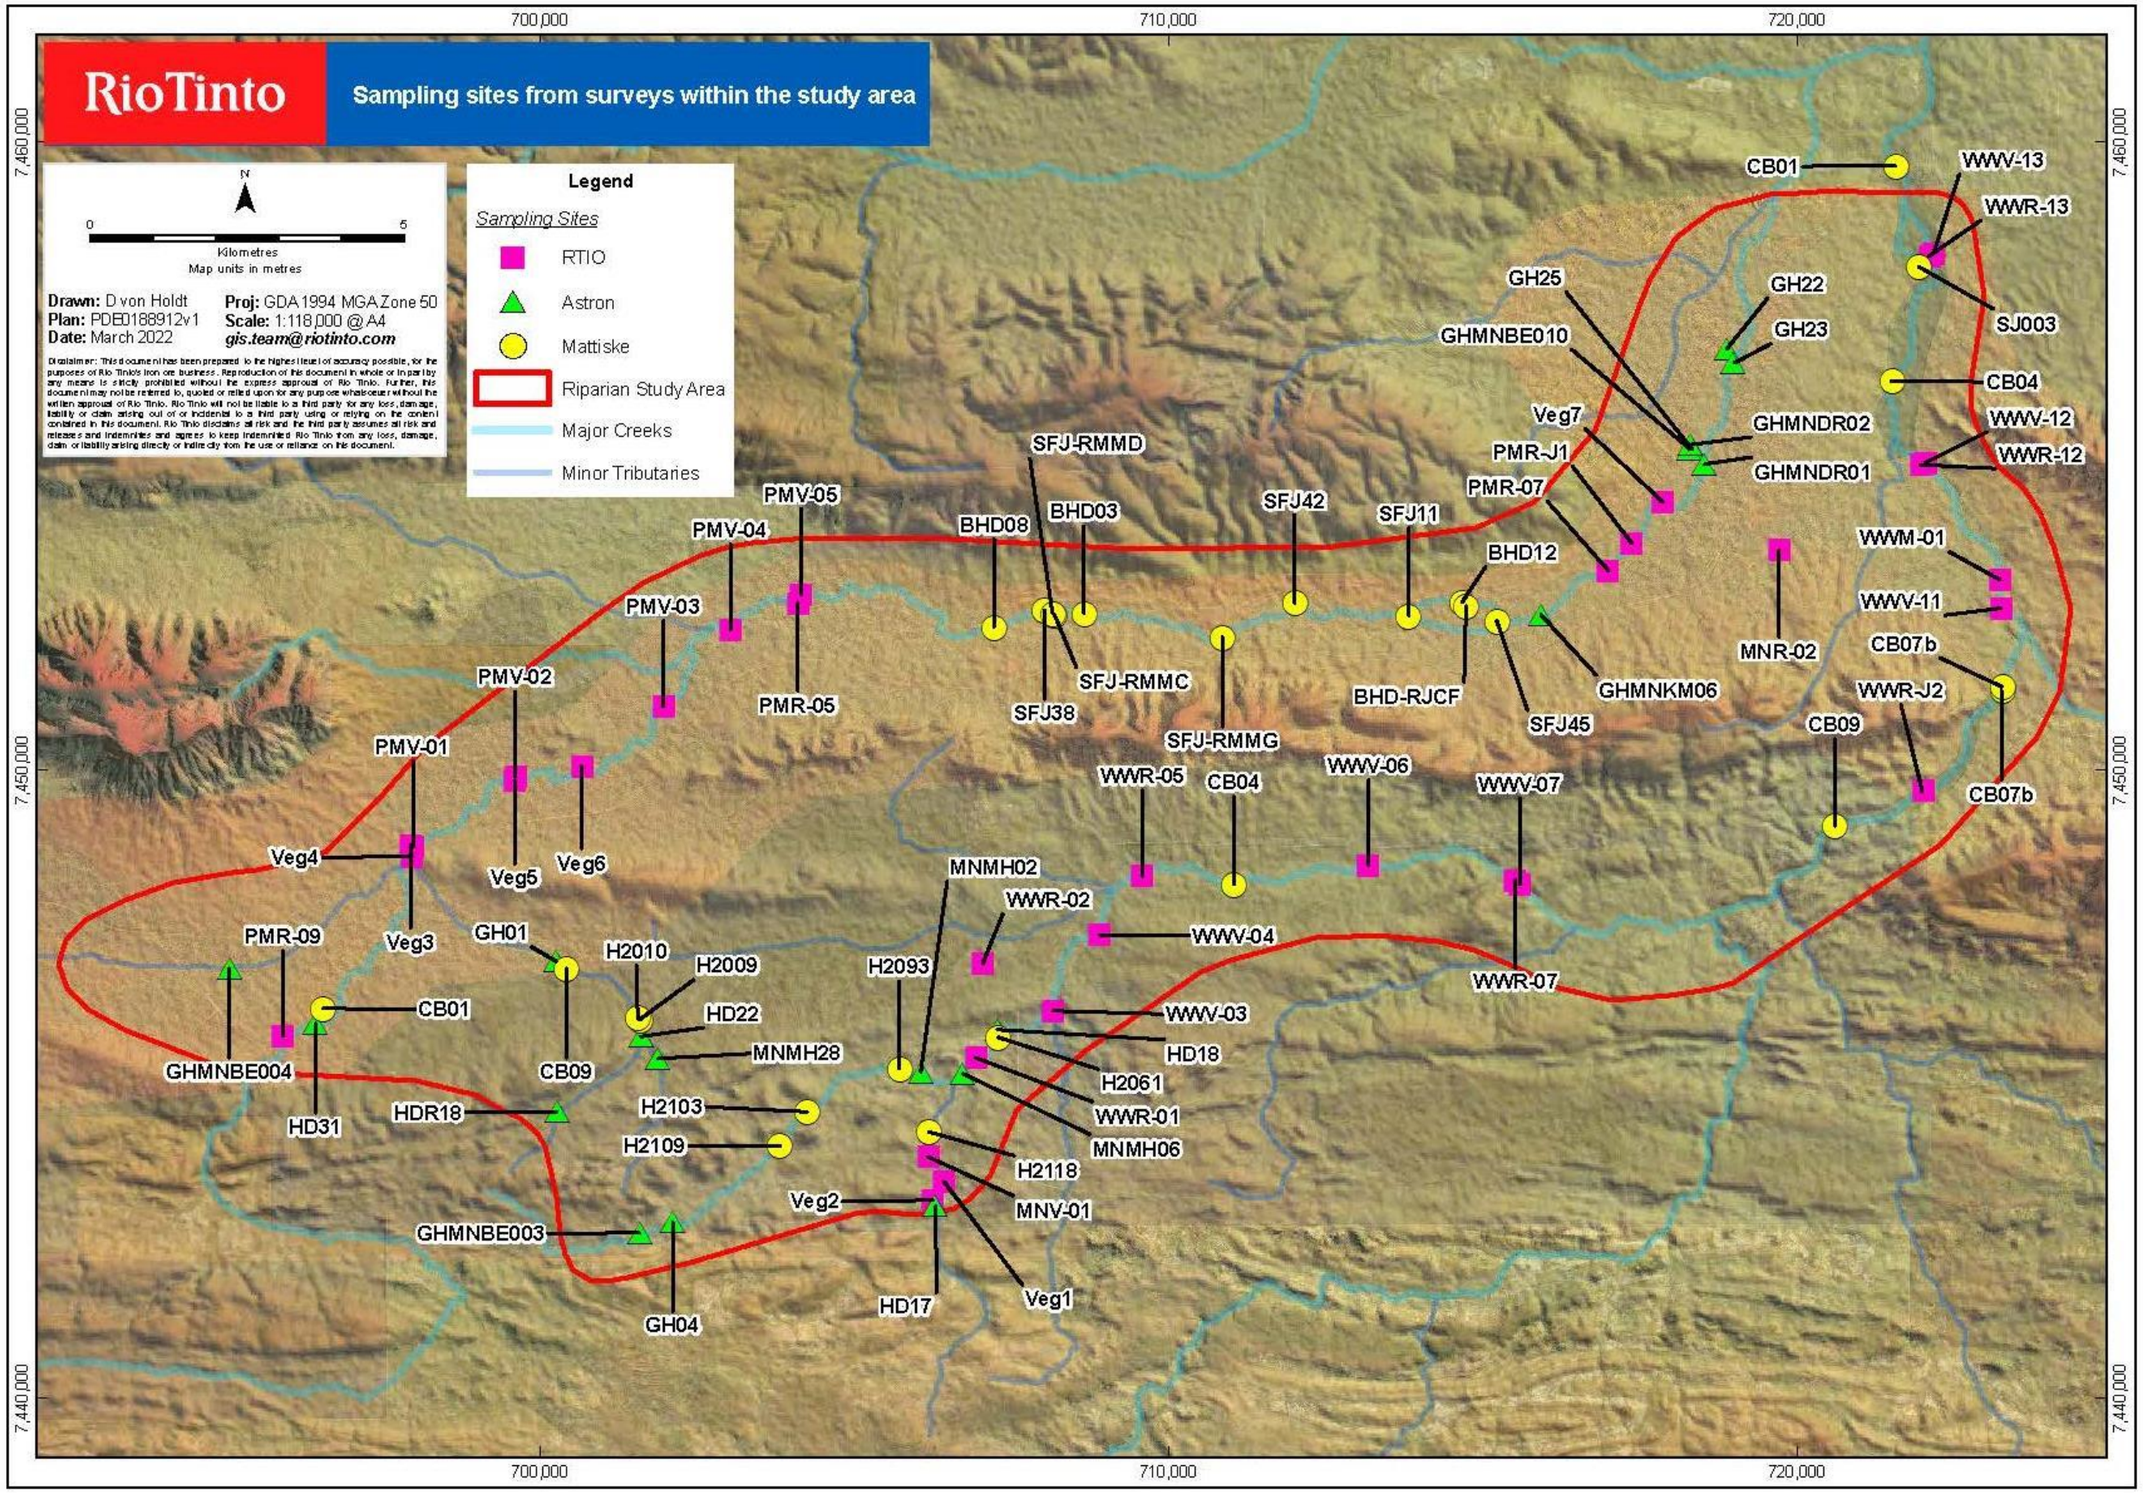

Figure 4-1: The location and spread of Quadrats and Relevés conducted by Rio Tinto (2021) (pink squares) as part of the current study, along with sampling sites conducted by Astron (2020) (green triangles) and Mattiske (2008; 2010; 2014) (yellow circles) also considered in this study.

4.3. Riparian mapping techniques utilised

A number of techniques were applied to the vegetation mapping process used in this targeted study. These techniques were utilised to help achieve the core study goal of both increasing the level of detail presented in the vegetation mapping while refining the mapping to be more relevant and focused on the riparian and ecohydrology disciplines.

The application of these techniques can be summarised in the following list of steps/tasks:

1. Leverage previous baseline vegetation mapping and associated vegetation units;
2. Utilise the Increased array of systematic sampling sites and mapping notes to refine the vegetation mapping to focus on informing riparian attributes and relevant trends in ecohydrology across the Study Area
3. Aim to provide an increased level of detail (low to moderate level gains) within the resulting vegetation mapping
4. When refining the vegetation mapping and associated vegetation descriptions:
    - Consider the distribution and abundance, but ultimately established structure of keystone overstorey species with particular focus on those keystone overstorey species which are broadly identified as potential phreatophytes.
    - Consider the compositional trends observed within riparian communities and the distribution of these trends with specific focus on both the broadly Ephemeral riparian taxa, as well as that of mesophytic and hydrophytic taxa across the Study Area.
    - Leverage the RTIO “Pilbara Riparian Ecohydrological Framework (PREF)” and included indicator guilds to inform which understorey constituents are more strongly associated with mesic (or conversely strictly ephemeral habitats) riparian habitats and relevant to informing relevant ecohydrological trends;
5. To improve vegetation mapping boundaries and associated trends;
    - Utilise aerial photography interpretation and resulting desktop mapping of the abundance/distribution of overstorey phreatophytes to improve vegetation descriptions and particularly mapping boundary accuracy.
    - Leverage improved overstorey mapping accuracy to also improve mapping and extrapolation of understorey assemblages more consistently associated with interpreted overstorey trends.
    - Review groundwater depth trends (from monitoring bores), broad geological and topographical trends and available evidence of surface water persistence across the Study Area to influence vegetation mapping where relevant and ultimately to confirm agreement with those trends described in the resulting riparian vegetation mapping.

Some of these tasks and techniques above are described in more detail in the follow section.

One of the core tasks of this study was to appropriately refine the riparian vegetation mapping across the Study Area, in order to provide more targeted and thus more detailed riparian mapping and community delineation. As a result of this requirement and of the relatively ephemeral nature of the majority of the drainage systems throughout the Study Area, the mapping process was heavily underpinned by the previous baseline vegetation mapping units and boundaries. Leveraging this resource, the core mapping tasks of the current study were to increase the longitudinal delineation of vegetation units in the riparian zone (with some increases in lateral delineation, i.e. the addition of floodplain units) via refinements in the composition and structure of the resulting mapping units. These refinements were predominantly facilitated by additional systematic sampling sites, targeted mapping notes in key focus areas, and desktop mapping of the distribution and abundance of key phreatophytes.

As stated in section 4, the mapping refinement process was supported by increasing the density and coverage of the systematic sampling site array. Following completion of the additional systematic sampling, all of the resulting sampling site data (including historical sites) were reviewed to identify

trends in overstorey structure and composition as well as specific patterns in the understorey composition and also the varying dominance of certain large riparian shrub species. In particular, a focus was placed on species which have been implicated as increasingly good indicators of elevated moisture stability via the PREF. However, in this case a secondary lens of focus was also placed on species which are either indicative of the highly ephemeral end of the ecohydrological spectrum, or whose abundance may be indicative of the presence of fine grained substrates such as clays which may not only inspire different community assemblages, but which also support extended residence time of surface water in the upper soil profiles.

In particular, the mapping refinement task was supported by desktop mapping (supported by ground-truthing of selected areas) of the presence and abundance of the keystone phreatophytes *Eucalyptus camaldulensis* (focus) and *E. victrix* (reduced effort). Methods used to relatively confidently map the presence (and alternatively absence) of these species at a desktop level are described in more detail below in sections 4.3.1 & 4.3.2. This technique has been successfully utilised by the author (aerial imagery quality allowing) in a number of locations within the Hamersley sub-region. In this case and in some of the previous use cases, ground-truthing of desktop mapping outcomes has only uncovered a very low error rate (approximately 1-5% error). In comparison, the error rate identified following ground truthing of traditional methods (i.e. extrapolation of abundances from systematic sampling sites and targeted mapping notes) seems quite high but variable, with some areas/practitioners producing low error rates and others being quite high. Ultimately traditional approaches are constrained by the large distances over which extrapolation is required, whereas the suggested desktop mapping approach is aided by low levels of extrapolation but does require appropriate imagery and interpretation abilities.

In a riparian setting, the abundance and distribution of key phreatophytes tend to reflect changing patterns in the temporal availability of surface and groundwater sources across the drainage systems being studied. Generally common riparian tree species present within the Pilbara, together form a hierarchy of likely water availability (among other eco-physical characteristics) across the drainage system continuum. As an example, this hierarchy might typically follows this general order;

1. *Melaleuca argentea* (OPS)
2. *Sesbania Formosa* (?OPS)
3. *Eucalyptus camaldulensis* (FPS)
4. *Eucalyptus victrix* (FPS)
5. *Eucalyptus xerothermica* (? Vadophyte)
6. *Corymbia hamersleyana* (Vadophyte)

With species at the bottom of this list being present and abundant or dominant in the driest drainage settings (or on the periphery/floodplain of wetter settings) and species at the top being abundant/dominant in the wettest of settings. As a result, the relative presence/abundance of each of these species can be observed and used to infer trends/patterns in water availability both from typical and concentrated surface water sources as well as groundwater sources, as species in the upper half of the list start to become abundant or dominant. It is for this reason that it is quite useful to have access to relatively accurate and comprehensive mapping of the abundance/distribution of local phreatophytes (and other relevant tree species) when refining riparian mapping. Particularly if that riparian mapping is also supporting assessments of the likelihood of GDV being present or making assertions around the ecohydrological characteristics of different drainage reaches. Alternatively, for the process of riparian mapping, it's quite useful to be able to review aerial imagery in areas where questions remain around the relative abundance of key overstorey components, or extrapolation of field data is required over longer distances. Regardless of the situation, such mapping and interpretation techniques are extremely useful for more enabling mapped boundaries to more accurately reflect the overstorey structure and relative abundance of species in described vegetation units. Ultimately these improvements in accuracy flow on to providing vegetation mapping boundaries which infer increasingly relevant patterns of water availability, particularly where they relate to phreatophyte distribution.

In this study, desktop mapping of the abundance of *Eucalyptus victrix* and particularly *Eucalyptus camaldulensis* was heavily relied upon to confirm proposed refinements to the vegetation mapping. In particular, these related to areas where *E. victrix* was observed to be dominant, rather than co-dominant, thus allowing better alignment with observed ecohydrological trends also utilised across the Study Area.

The same trends in vadophyte and phreatophyte abundance are also generally reflected in the presence/absence and diversity of mesophytic and hydrophytic understorey constituents. Sampling sites and mapping notes were used in the Study Area to confirm these associations and alignments between overstorey structure and phreatophyte abundance with mesic understorey composition. Following this process, desktop mapping and aerial photo interpretation of phreatophyte abundance/distribution can also be used to more accurately extrapolate the presence of key mesic and alternatively ephemeral understorey compositions in association with overstorey cues in aerial imagery which are able to be systematically assessed across the Study Area.

As the most hydrologically sensitive Pilbara vegetation communities are typically those with a significant component of *Melaleuca argentea*, an initial review was undertaken to identify desktop tools and resources suitable for helping identify the likely distribution of *Melaleuca argentea* dominated communities in the Study Area (i.e. OPV). Utilising observations from previous field work it was concluded that *Melaleuca argentea* was generally absent in the Study Area except in an approximately 4 km stretch of Weeli Wolli Creek surrounding the "Ben's Oasis" spring feature in the south-eastern portion of the Study Area. To make sure the distribution of this species, and particularly areas where mature populations were present, was adequately captured, a field plan capable of ground-truthing the predicted and potential spatial distribution markers for OPV and FPV communities in this area was developed. This plan predominantly leveraged extensive field traverses in the areas upstream and downstream of "Ben's Oasis" area during the main field trip for this study. On two separate occasions "Ben's Oasis" was visited and field traverses and observations were completed which were also utilised in this study (26th of July 2017 and 3-14th of December 2018).

Field traverses were set up in such a way that they regularly intersected lateral vegetation boundaries across the creek profile. As well as collecting data on the presence of this species, vegetation boundaries where mature, well-established populations of this species occurred were consistently marked with a GPS. Aerial photo interpretation techniques relevant to the canopy signature of this species were utilised at the desktop level to extrapolate the ground points in a highly accurate fashion, in order to provide high confident boundary delineation for this important community. By allowing both young "more transient" populations of *M. argentea* as well as long term mature and dominant/co-dominant populations of to be delineated, the resulting vegetation mapping provided a way of contextualising and assessing the potential for hydrological changes to impact the more sensitive and likely obligate phreatophytic riparian communities of the Study Area.

Together, the above described techniques were found to be appropriate for the purpose of achieving the core study goal of both increasing the level of detail presented in the vegetation mapping while refining the mapping to be more relevant and focused on the riparian and ecohydrology disciplines.

4.3.1. Aerial photographic interpretation of over storey phreatophyte species composition

To support identification, delineation and mapping of GDEs within the Study Area, aerial photographic interpretation and classification of the extent and relative abundance of groundwater dependant phreatophytes in the overstorey was undertaken. With respect to the GDE mapping process this is a critical task which substantially increases the power of the resultant riparian map and GDE classification it supports. In most cases one of the key tasks in this process is to spatially delineate FPV communities with a tree stratum either dominated by *Eucalyptus camaldulensis*, co-dominated by *Eucalyptus camaldulensis* and *Eucalyptus victrix*, or dominated by *Eucalyptus victrix* alone. *Eucalyptus camaldulensis* is the more groundwater dependent of the riparian eucalypts (at times potentially representing an obligate phreatophyte), which commonly occur in the Study Area. For this

reason, mapping the presence, distribution and dominance of *Eucalyptus camaldulensis* (outside of OPV) is an important step in the process of mapping varying degrees of potential community related groundwater dependence. This is particularly relevant for GDE identification where true obligate phreatophytes are absent. In such cases, FPV with a canopy dominated by *Eucalyptus camaldulensis* alone is that community most likely to represent a GDE (broadly speaking).

Traditionally, *Melaleuca argentea, Eucalyptus camaldulensis* and *Eucalyptus victrix* distribution (and thus vegetation community data) mapping requires regular field notes (along with quadrat and relevé sampling) on the presence/absence and abundance of these species on the ground to facilitate extrapolation throughout the relevant mapped areas. Within the many riparian formations in the Pilbara; it is noted that canopy, stem and reproductive material which often allow relatively confident differentiation between the two eucalypt species; are either not present or are insufficient to aid bulk differentiation during the field survey. The variable reflection of light off respective tree canopies which is provided to a botanist on the ground; substantially influences their ability to record meaningful amounts of data from canopy cues to classify canopies when later conducting the desktop mapping. Furthermore, it is relatively impossible (due to field time constraints) to capture adequate on ground data to accurately map the canopy abundance/presence of the three key phreatophytic species. For this reason, where possible, aerial photo interpretation is often the best tool for mapping the distribution of *Eucalyptus camaldulensis* and *Eucalyptus victrix*. Only with the more recent advent of extensive capture of high-resolution aerial imagery (sub 0.2 m) has the aerial photo differentiation of typical Pilbara riparian eucalypts been possible in a consistent and relatively confident manner. Up until now this type of imagery has not allowed the differentiation of *Melaleuca argentea*; with it typically exhibiting a very similar canopy signature to that of *Eucalyptus victrix* in aerial photography. Now with the ability to capture sub 0.1 m aerial imagery the differentiation of *Melaleuca argentea* become possible. Using a 0.05 m resolution aerial image, validated with adequately detailed ground data it has been confirmed that this type of canopy classification can be achieved.

Overall, the use of this methodology (in combination with on-ground data) to classify canopy composition via the riparian vegetation map enables accurate identification and mapping of GDE's and potential GDE's. This process was aided significantly using recent high resolution (0.05 m) true colour aerial imagery. Furthermore, where available, 7-band Worldview imagery further assisted identification (by improving the clarity of visual cues) of individuals/stands of *Eucalyptus camaldulensis* and *Eucalyptus victrix*. The use of Worldview imagery allowed more accurate mapping of communities as possessing dominant or co-dominant overstorey populations of these species. Worldview imagery also provides a useful alternative view to vegetation which provides increased visual differentiation between overstorey and understorey vegetation. This in-turn helps to inform the process of interpreting vegetation structure/density which further increases the power of the riparian map to interpret groundwater access and dependence.

In order of relative usefulness for basic aerial photo interpretation (and similar for worldview) of dominant Pilbara riparian eucalypt trees; Individuals or groups of *Eucalyptus camaldulensis* within the riparian environment were distinguished on aerial photography from *Eucalyptus victrix* on the basis of:

1. Darker green canopy colour signature of *Eucalyptus camaldulensis* (as opposed to quite grey canopies of the alternative species);
2. Denser canopy cover signature of *Eucalyptus camaldulensis*;
3. Different branch signature of *Eucalyptus camaldulensis* canopy architecture; and
4. Larger (spatial extent) canopy footprint of *Eucalyptus camaldulensis*.

On worldview imagery, there are also visual cues which can be utilised which generally relate to canopy vigour, but also to the associated understorey (particularly that of grass layers) signature which tends to accompany the larger more (biologically) productive *Eucalyptus camaldulensis* stands.

The available aerial photography and worldview imagery was considered to be of a high quality suitable for the application of the visual assessment described above and was found to be robust when ground-truthed using field data. Rio Tinto (2015, 2018a, 1018b) have previously proven the use of aerial imagery to accurately locate *Eucalyptus camaldulensis* trees from Weeli Wolli Creek (Yandicoogina Operations) and from the Robe River in the Western Pilbara.

Examples of the aerial signature of *E. camaldulensis* trees from Weeli Wolli Creek (Yandicoogina Operations) are provided below in Plate 4-1. The examples presented in Plate 4-1 were chosen due to their location on an open floodplain, where canopy density is reduced and as such surrounding canopy species don't inhibit the display of the above described characters, providing a clear example of the application of the species differentiation process. Plate 4-2 shows similar examples of key Eucalypt aerial signatures from the Robe River in the Western Pilbara.

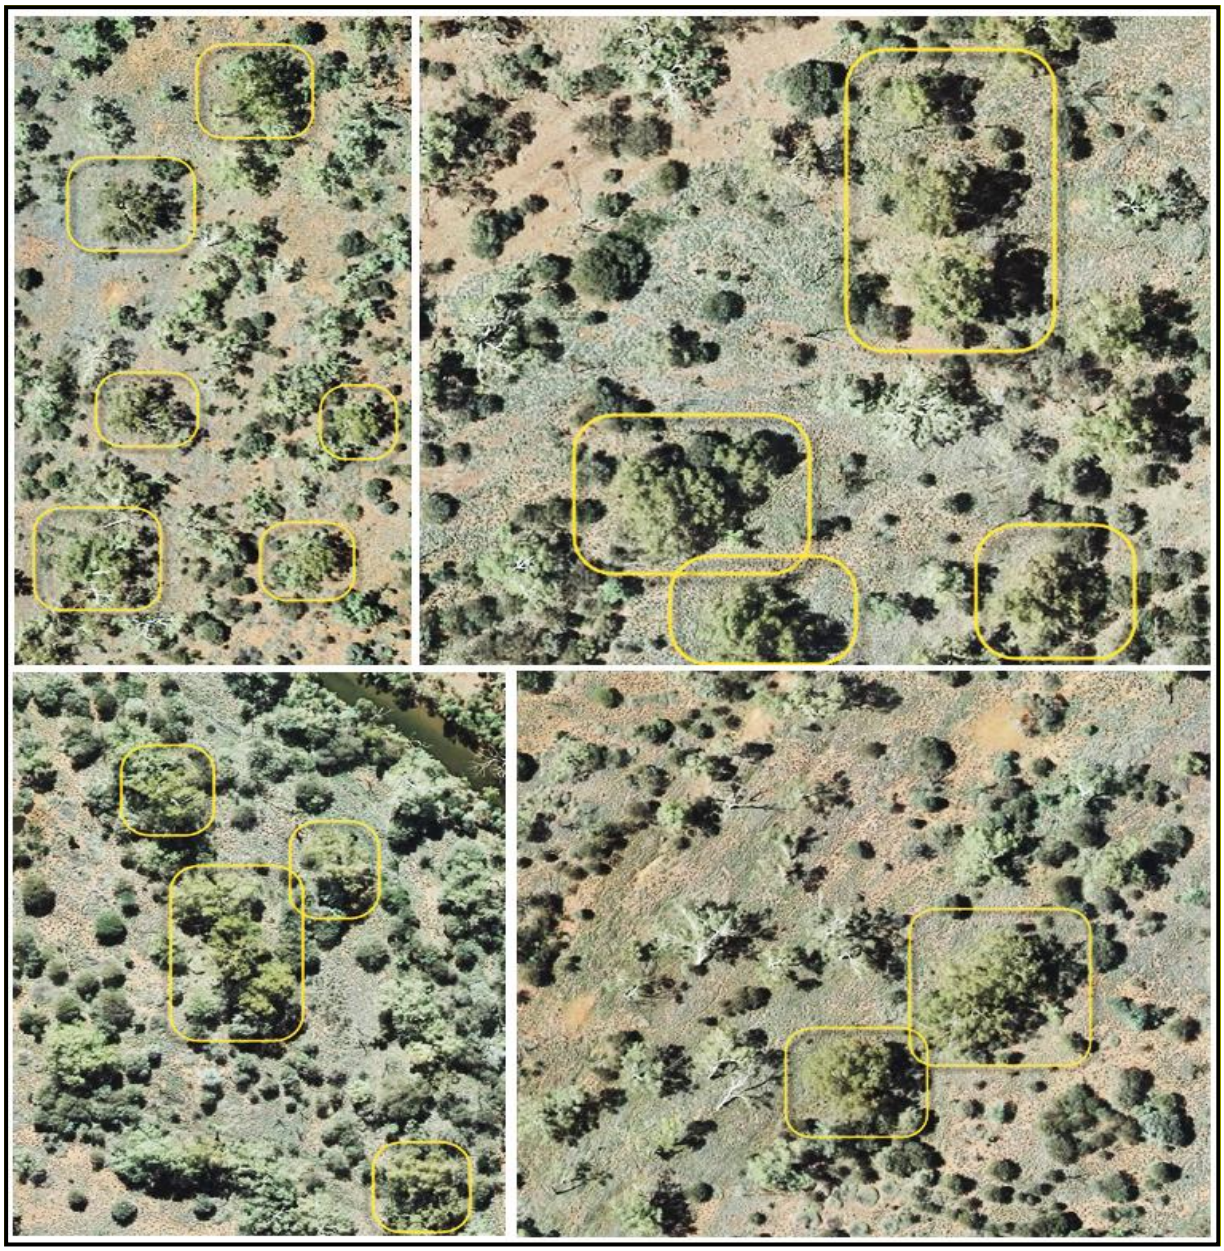

Plate 4-1: Aerial photos showing examples of *Eucalyptus camaldulensis* canopies (inside orange polygons) on high resolution aerial photography (Weeli Wolli Creek)

Note: Beyond the more obvious shrub features, the majority of the remaining eucalypt canopies present in these plates are considered to be *E. victrix* as indicated by the relatively obvious white branch and trunk colouration, open branching habit and lighter foliage colour.

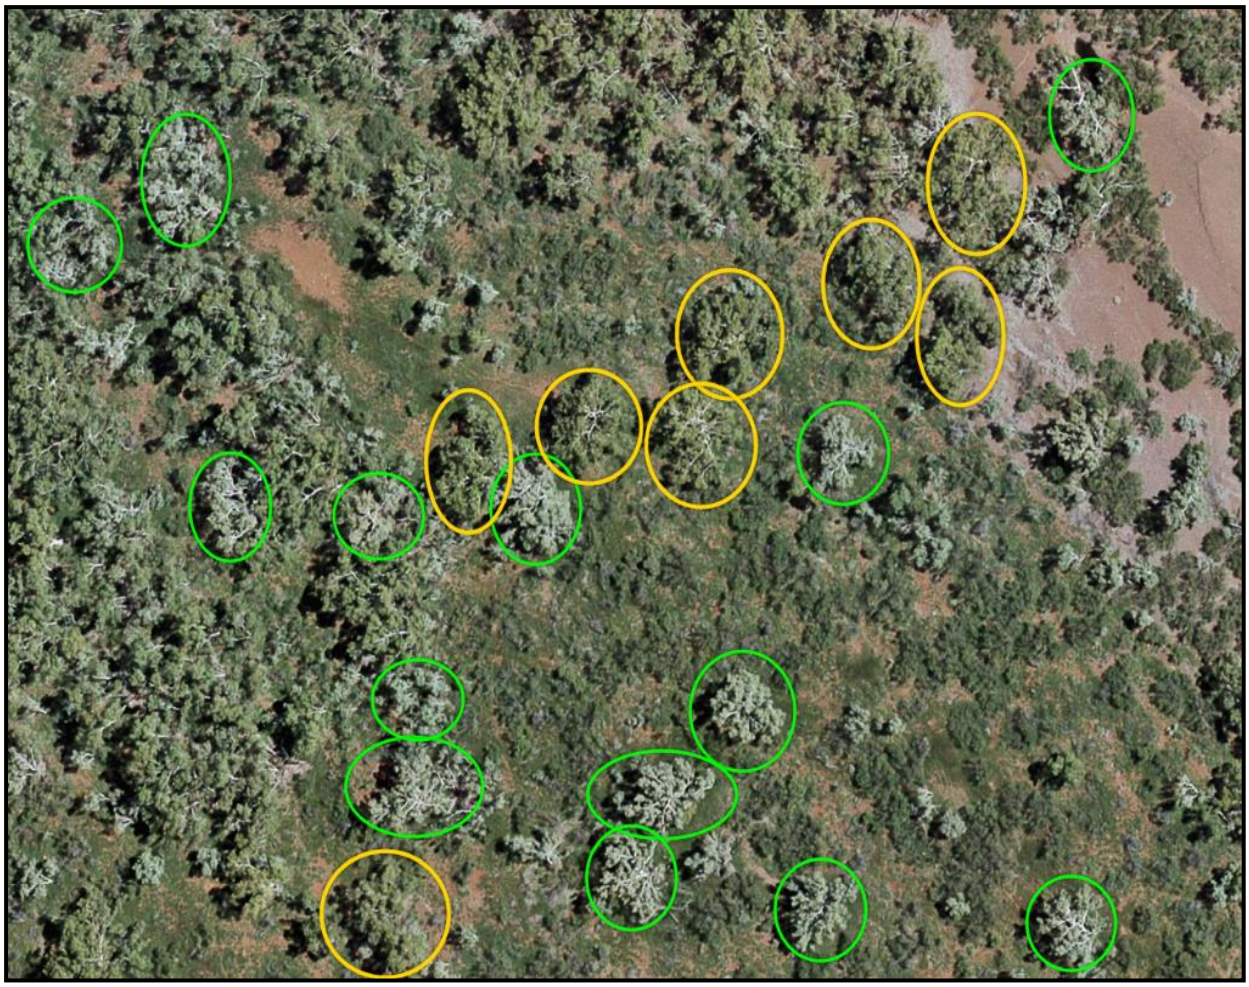

Plate 4-2: Aerial photos showing examples of *Eucalyptus camaldulensis* canopies (inside orange polygons), and *E. victrix* (inside green polygons), on high resolution aerial photography within the Robe River (April 2017)

The other core riparian vegetation canopy constituent of ecohydrological importance whose presence/absence can potentially be interpreted at the desktop level with some ground-truthing assistance is *Melaleuca argentea*. This is done using aerial imagery based interpretation of the presence of canopies consistent with *Melaleuca argentea* surrounding low flow channels. The canopy cue which is utilised leverages the grey/silvery component of mature canopies of *Melaleuca argentea* as compared to the darker more vigorous green of the canopy of *Eucalyptus camaldulensis*. Outside of low flow channels, and particularly outside of the core riparian zone, relevant canopy signatures are likely to be confused with *Eucalyptus victrix*. This canopy cue is not as relevant for stands of young *M. argentea* whose canopy is much more similar in colour to *E. camaldulensis*.

This approach is significantly supported by the use of ARC-GIS World imagery (ArcGIS 2021) high resolution imagery archives. At the appropriate scale, this imagery source provides relatively consistent spectral characteristics such that ground reflection properties and exposure/contrast is much more consistent and the generally more silver canopies of *Melaleuca argentea* can be differentiated from Eucalypts on most occasions. There are caveats on this interpretation; in particular, away from the low flow channels in areas where vegetation persistence is low, or where the accuracy of persistence signatures is reduced by bed-scouring (such as within river channels); silver canopies are not consistently able to be interpreted (often actually representing *E. victrix*). As a result the interpretive power of this approach is restricted, and in general its use needs to be confined to around low flow/high flow channels or areas of high vegetation persistence. Examples of how ARC-GIS World Imagery (and other google imagery sources) can be used to differentiate canopies of riparian Eucalypts from that of mature *Melaleuca argentea* canopies are presented in Plate 4-3 to Plate 4-5. In

these plates, green shapes are indicating Eucalypt spp. canopies (most likely *E. camaldulensis*) and orange shapes are *Melaleuca argentea* canopies; all examples confirmed by on-ground data.

Plate 4-3: *Melaleuca argentea* canopy differentiation - Example 1

Plate 4-4: *Melaleuca argentea* canopy differentiation - Example 2

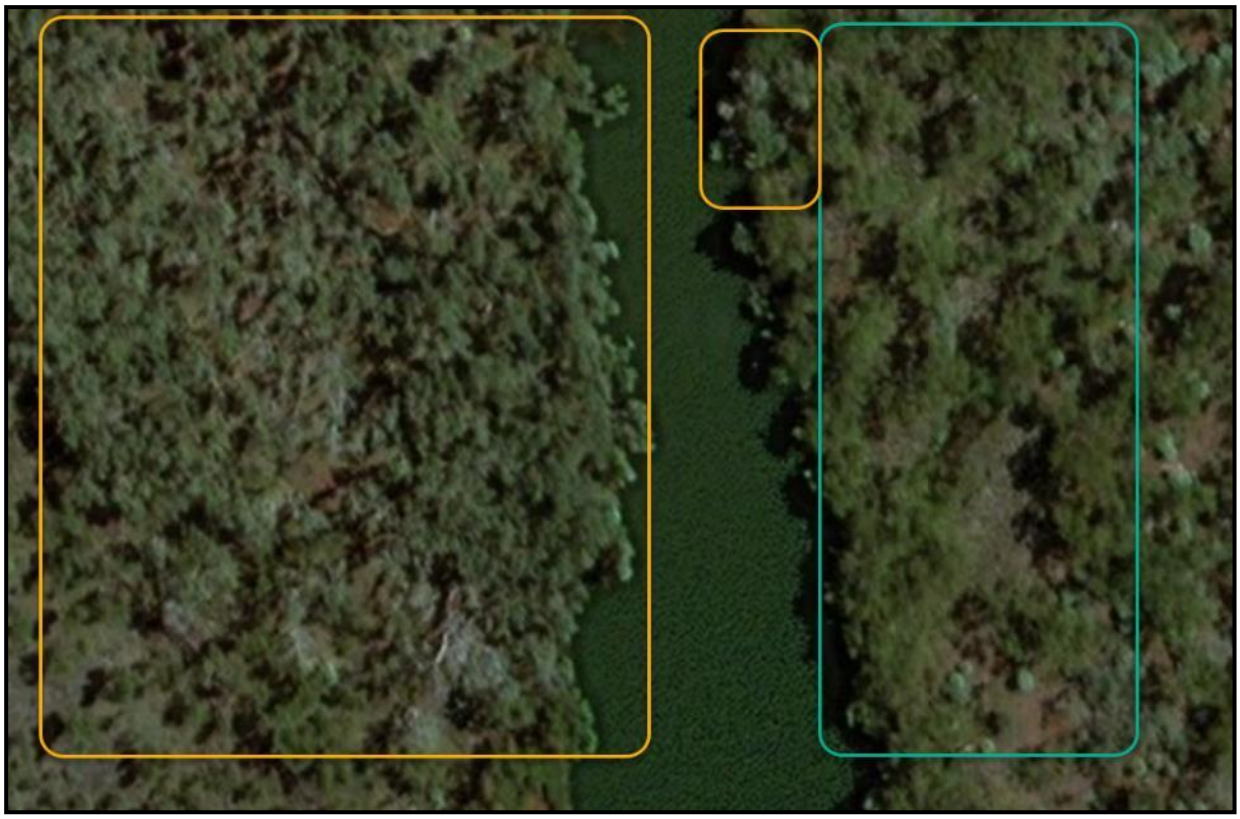

Plate 4-5: *Melaleuca argentea* canopy differentiation - Example 3

4.3.2. Use of aerial photo phreatophyte interpretation to support riparian mapping

As outlined in section 4.3.1, it is possible to conduct desktop interpretation of aerial photography to provide mapping of the distribution and abundance of the key phreatophyte species which tend to dominate riparian overstorey's in the Pilbara. This technique is particularly appropriate once adequate ground-truthing of the resulting desktop mapping is completed to ensure that the cues being provided by the imagery used are relatively accurate and consistent. Furthermore, this approach has been utilised successfully (aerial imagery quality allowing) by the author in a number of locations within the Hamersley sub-region, where ground-truthing has only uncovered a very low error rate (approximately 1-5% error).

However, when considering this error rate, the error rate of the on-ground survey alternative should also be considered. On-ground field validation by the author (using hand lens-based leaf checks along with other character suites) of the respective abundance placed on both *E. camaldulens*is and *E. victrix* yielded from quadrat sampling by other botanical practitioners, has indicated much higher error rates. This error rate is quite variable, depending on site conditions and practitioners, but is likely to be in the order of 2-50% based on initial indications and a relatively low validation sample size. The source of this error, and the associated variability is most likely to be partly due to site selection biases, and also due to inaccurate extrapolation of close quarters ID's to the other individuals in the wider quadrat and surrounds. With extrapolation throughout the site strongly influence by differing viewing angles and associated solar artefacts.

However, rather than question the validity of this result; both the relatively low rate of error in the aerial interpretations as well as the potentially high error rates in quadrat data, it appears more logical to consider the merits of the two different approaches. Looking at canopy characteristics from the sky perspective, normalises the solar conditions and colour palates/contrasts which are available to be utilised in the identification of dominance/abundance data for the respective target species. While the

resolution of these traits are heavily reduced when compared to on ground sites, this technique also has the advantage of a much larger range of gaze and thus is less biased by clusters of varying abundance which can be hard to look past when on the ground. By comparison, when on the ground looking out and up at trees, this perspective determines that in every direction you are looking, different solar irradiance conditions are being experienced, both influencing the colour of leaf, stem and bark characters, but also the degree of reflection from these surfaces. Furthermore, these complications are significantly greater in the early and late parts of the day. In particular; for *E. camaldulensis*, the degree of leaf shine or reflectance is highly variable on the ground, depending on the direction and time of day, but this trait also represents an important and influential character trait for this species which has a very shiny cuticle as opposed the waxy cuticle of *E. victrix*.

In general, the advantages of looking at patterns in dominance/abundance of overstorey canopy composition from the sky are quite clear, and so assuming aerial photography is of an appropriate resolution and colour/contrast then this approach can be quite superior for gathering data to support vegetation mapping. This is especially true in the riparian space, where the relative abundances of overstorey species can effectively be leveraged to interpret varying degrees of water availability and parallel potential increases in hydrological risk. Therefore, where appropriate, it seems clear that utilising both on-ground and aerial approaches and continuing to ground-truth the adequacy of the aerial images used, is a better approach than using on-ground data alone. Even if it's done for a sample area of differing vegetation units to make sure that both the scale of the mapping project, associated mapping descriptions/boundaries, on ground data and aerial interpreted data all generally agree.

4.4. An assessment of riparian vegetation communities across the Study Area

An assessment of the riparian vegetation and representation across the Study Area was completed as part of this study.

Riparian ecosystem diversity and representation is primarily driven by moisture availability patterns. It is therefore acknowledged that riparian flora of increasing habitat specificity to restricted mesic/hydric habitats are likely to be important indicators of riparian community representation and thus importance. An evaluation of the representation of these vegetation units locally and regionally were completed for the purpose of EIA.

To do this the study will rely on completing and conducting 6 different steps and assessment processes; the first 4 of which are conducted in order to create appropriately targeted riparian vegetation mapping and the final four of which focus on assessing and classifying each riparian unit in order to provide significance ratings:

1. Adequate sampling of riparian vegetation communities to allow a commensurate assessment of local riparian values.
2. Consideration of compositional trends observed within riparian communities and the distribution of these trends with specific focus on both the broadly Ephemeral riparian taxa, as well as that of mesophytic and hydrophytic taxa across the Study Area.
3. Consideration of the distribution and abundance, but ultimately established structure of keystone overstorey species with particular focus on those keystone overstorey species which are broadly identified as potential phreatophytes.

4. Using this information, conduct targeted riparian vegetation mapping which gives insight into the riparian values and different ecohydrological processes occurring within larger drainage systems (i.e. broadly Moderate[8] and above sized drainage) covered by the Study Area.
5. Identify which mesophytic and hydrophytic species are typically present in each of the mapped vegetation units, what ecohydrological indicator guild they fit in based on the "RTIO Pilbara Riparian Ecohydrological Framework" (PREF) (for externally draining riparian features) (See Table 3-3), and where relevant what's their likely abundance.
6. Use the info gathered in steps 2, 3 and 5 to map and classify each riparian vegetation unit into Ecotypes (see Table 4-1). For ecotype classifications, in some cases riparian units will not fit into the classification perfectly, or simply that additional factors of relevance need to be incorporated.
    a. the following factors might influence the final classification: Consideration of any relevant state conservation listings which the community may be associated with or representative of;
    b. The associated composition of mesophytic/hydrophytic taxa, and particularly the presence/absence of some of the more highly restricted and relictual hydrophytes from the 'High' to 'Very-High' level indicator guilds (Table 3-3);
    c. Consideration of the presence and nature of relevant surface water features, including monitoring data which supports assertions around the persistence/permanence of relevant features;
    d. Consideration of the relevance of the eco-physical setting/characteristics of the landscape or lithology which riparian communities have established upon,
    e. Consideration of the distribution and therefore degree to which the community in question is spatially restricted in the environment, the degree of representation outside of the Study Area of the community, and potential rarity of this feature within local, sub-regional, and regional scales;
    f. Consideration of whether the community in question provides any atypical ecosystem services which should be highlighted/incorporated; and
    g. Consideration of the condition and inherent resilience to perturbation/s of the community in question. This should consider those potential hydrological influences which may not be traditionally considered, such as disturbance provided by surface flows, altered flow patterns, fluvial weed abundance, exposure to surplus mine water discharge, reductions to catchment size etc.

Step 5

The RTIO developed "Pilbara Riparian Ecohydrological Classification" and the relevant indicator guild lists (PREF) is presented in Table 3-3. By surveying a riparian feature & assigning presence/absence data to the framework table, an assessment of restriction is facilitated via the presence of increasing diversity both;

- Vertically down the framework through successive ecological plant groups;
- And horizontally across the frameworks ecohydrological plant guilds.

Where communities possess increasing diversity at the 'High' and Very High' indicator guild end of the scale, such communities are inferred to possess habitats which support increasingly stable long term hydrological conditions. These diversity gradients are thus used to infer:

- increasing availability and stability of moisture;
- increasing habitat quality &
- increasing hydrophytic biodiversity & rarity of riparian assemblage.

[8] Broadly moderate and above sized drainage refers to drainage typically greater than 25 km^2 (and up to, or greater than, 2000 km^2) and is likely to have GDV present. See table in Appendix E: for detailed drainage classification information.

This ecotype classification has been developed based on a broad analysis and ongoing observations of the spectrum of riparian communities present within the Pilbara. This classification attempts to deal with both externally draining features (the focus of the classification) as well as lightly dealing with more internally draining type features.

Substantial efforts were made to identify relevant ‘mesic’ riparian formations and their associated mesophytic and hydrophytic constituents of moderate to high potential significance within the Study Area. This identification process was greatly assisted by assessing NDVI persistence mapping for the presence of vegetation persistence anomalies in the order of 70% persistence and greater. Such information is thought to be critical in this process as these assemblages and their constituents typically represent highly restricted communities of increasing significance.

In addition, with respect to assessing condition; the current condition of riparian vegetation at the time of consideration will have an influence on its significance. Therefore, it is important to also incorporate the historical anthropogenic impacts into the resultant significance. This process is important as it helps to contextualise the traditional condition ranking attributed to local vegetation as part of baseline surveys. Often the condition attributed to vegetation as part of baseline surveys is significantly skewed by the presence of weeds typically common/abundant within most Pilbara/North-West drainage systems. The proliferation of weeds in these types of habitats (once they have arrived) are linked to natural disturbance processes which fluvial environments provide. As a result, it is important to contextualise their presence and abundance and acknowledge that weeds are proliferating in these environments due to natural processes and not necessarily directly due to anthropogenic disturbance. This third step attributes a more landform based and locally relevant consideration of condition and degree of modification into the significance attributed to any riparian community being assessed.

Table 4-1: Pilbara Riparian Ecotypes used for mapping

	Broad Riparian/GDE Type and key Characters	Subtype	Detailed structural descriptions & Keystone species notes	Alternative/additional keystone constituents characteristics	Typical Mesophyte Hydrophyte composition characteristics	Typical surface water conditions/characteristics
Type 1 - Aquatic GDE	**Generally Aquatic GDE's & associated obligate Terrestrial GDV** · Typically including permanent groundwater fed pools · Including obligate Terrestrial GDV Generally coinciding consistently with shallow Groundwater (Permanently* 0-4 m below ground level). · Typically associated with open forest scale overstorey riparian formations	1A	Aquatic & terrestrial GDE type riparian formations of varying size, generally in excellent condition and often occurring in an A class Reserve. Generally, always possessing Obligate Phreatophytic species (OPS) and Obligate Phreatophytic Vegetation (OPV). In some cases, Rights reserved sites, heritage values and multiple conservation listings can lead to classification to this tier without being in an A class reserve. Example: Millstream, some of the Karijini Gorge formations.		Generally possessing multiple 'Very High' and 'High' Level Hydrophytic indicator species suggesting a Very High degree of moisture permanence in the associated habitats. Multiple 'High' and 'Moderate-High' (Likely also 'Very High' examples) Mesophytic indicator species generally common in associated terrestrial GDE habitats.	Typically including multiple permanent groundwater fed pools and an array of Semi-permanent and persistent pool surface water features
		1B	Aquatic & terrestrial GDE type riparian formations of moderate to large scale, generally in excellent to good condition. Generally, always possessing substantial mature OPV (Obligate Phreatophytic Vegetation) formations and a series of permanent aquatic pool environments with associated interconnected pools systems of differing permanence (i.e. semi-permanent and persistent pool)			
		1C	Terrestrial type GDE with varying Aquatic formations (less substantiated) of at least moderate scale, generally in good condition. Generally possessing OPV (Obligate Phreatophytic Vegetation) formations.		Generally possessing multiple 'High' and 'Moderate-High' (and likely an occasional 'Very High' level) Level Hydrophytic & likely Mesophytic indicator species suggesting a high to very high degree of moisture permanence in the associated habitats.	Typically including permanent groundwater fed pools and likely an array of potentially Semi-permanent and Persistent pool surface water features
Type 2 - Obligate Terrestrial GDE	**Broadly Obligate Terrestrial GDV /GDE's** · At times Including some semi-permanent to permanent aquatic habitats · Generally coinciding with groundwater of various sources typically occurring less ≤ 5 m from the surface · Typically including persistent pool aquatic habitats. · Typically associated with woodland to open forest scale overstorey riparian formations	2A	Typically, moderate to large scale Terrestrial type Riparian GDE formations. Always possessing riparian formations co-dominated by mature OPS (Melaleuca argentea) and OPV (or other well accepted species with obligate groundwater use patterns). Generally, possess semi-permanent and persistent pool pool formations in key locations (permanent pools also present, but uncommon). May be small to moderate scale, but if so, typically possessing demonstrated permanent surface water formations.		Generally possessing multiple 'High' and 'Moderate-High' (potentially an occasional 'Very High' example) level Mesophytic indicator species, as well as multiple 'Moderate-High' and occasional 'High' level hydrophytic indicator species. These assemblages indicate a high level of permanency of moisture availability.	Likely to possess a permanent aquatic habitat, but small in extent/restricted. Generally, possess semi-permanent and persistent pool formations in key locations.
		2B	Typically, moderate to large scale Terrestrial type Riparian GDE formations. Generally possessing relatively obligate phreatophytic vegetation dominated by keystone species typically classed as moderate level FPS (Facultative Phreatophytic Species) at times with mature or at least transient-young outcrops of known OPS. As such community has relatively obligate groundwater requirements, either via a high-density FPS overstorey, or via the presence of OPS or potential OPS species. Small scale versions generally associated with outcrops of Mature OPS.		Generally possessing occasional 'High' level and multiple 'Moderate-High' to 'Moderate' level Mesophytic indicator species, as well as some 'Moderate-High' level and multiple 'Moderate' level hydrophytic indicator species. These assemblages indicate a moderate to high level of permanency of moisture availability.	Typically associated with multiple persistent pool to semi-permanent pool formations in key locations.
		2C	Small to Moderate scale (but lower significance) Terrestrial type Riparian GDE formations. Often possessing relatively obligate phreatophytic vegetation (in terms of water use) which is always dominated by keystone species typically classed as FPS (Facultative Phreatophytic Species – predominantly moderate level). Potential for a single OPS flora species to be present as an associated species only. Often represented by smaller scale formations occurring in upland gorge features, often with multiple receptors occurring sporadically at locations within the relevant landform and associated with small scale structural features impeding groundwater flow and/or increasing permeability.		Generally possessing occasional 'Moderate-High' level and multiple 'Moderate' to 'Low' level Mesophytic indicator species, as well as multiple 'Moderate' level (and the occasional 'Moderate-High' level) hydrophytic indicator species. These assemblages indicate a moderate to high level of permanency of moisture availability.	Typically associated with some persistent pool to semi-permanent pool formations in key locations.

IDE: Inflow dependent Ecosystem. i.e. features most likely dependent on the inflow and accumulation, above the surface and in the vadose zone (potentially including very small scale seasonal groundwater sources) of seasonal (and potentially inter-seasonal) surface water flows.

OPV: Obligate phreatophytic vegetation; i.e. vegetation whose water requirements are likely obligate (but not necessarily because they possess obligate phreatophytic species such as Melaleuca argentea, i.e. may only possess FPS) such that removal of or changes to access is likely to lead to significant changes in structure and/or composition of the vegetation in question.

* Significance ratings are a broad guide relating to the classifications provided. Not all features will fit well into their classification, so in such cases ratings should be revised based on the feature characteristics. Further factors should generally be considered including drainage size classification, terrestrial and aquatic fauna info where available/applicable and other biotic and ecophysical characteristics; to gain a final significance rating.

4.5. GDV likelihood mapping

The deposits associated with the Proposal, are proposed to be restricted to above water table mining, and as a result the only groundwater abstraction proposed as part of the development is low volume abstraction to support mining infrastructure and processing. Given the low hydrological risk posed by the development on local riparian ecosystems and drainage systems, one of the listed aims of the riparian study was the production of non-exhaustive Groundwater Dependent Vegetation (GDV) likelihood mapping across the Study Area scope. The aim of this mapping is for the purpose of providing a cursory assessment of the degree of potential GDV exposure present within the Study Area. This rating is to be applied to riparian vegetation units, and where relevant to specific reaches or portions of mapped vegetation units.

The rating being applied is most equivalent to determining where riparian communities might sit on the scale of groundwater dependence, rather than whether they are explicitly groundwater dependent. For this reason, the term GDE Likelihood is avoided, as it has a higher potential to confuse the conversation. Therefore, the key question summarised by the rating being applied is:

> Based on biological and physical lines of evidence, what is the likelihood of groundwater access/reliance and if so, how clear and consistent might that access be, and what's the potential for meaningful change to riparian vegetation if that access is reduced/removed.

Riparian communities determined to sit at the 'negligible' GDV likelihood end of the ratings scale, are unlikely to be groundwater dependent and vegetation characteristics exhibited, are a result of the accumulation of other water sources. However, it's also acknowledged that riparian habitats which tend to accumulate surface water can support riparian vegetation with characteristics (enhancement, persistence, presence of FPS, elevated density etc.) similar to vegetation with low degrees of access to groundwater. For this reason, features occurring at the low end of the GDV Likelihood rating scale can be both an IDE, or represent low likelihood GDV. However, in the case of features with low degrees of access to groundwater, the potential for meaningful changes to vegetation if that access is removed is also low. I.e., most likely to lead to reduced condition/density, but not necessarily changes in structure, with changes in composition being highly unlikely, particularly with respect to dominant/co-dominant constituents. This is important for two reasons; not only is the potential for a significant impact low, but also these fairly ephemeral types of riparian vegetation are generally very well represented. As a result, low level impacts to such riparian examples are comparatively more acceptable than to those which are more clearly representative of GDV and additionally represent more restricted community types.

Features generally attracting determinations of low GDV likelihood are inherently complicated, as at this end of the scale, its increasingly unclear whether groundwater access is available and meaningful, and whether instead the feature is just benefiting from the accumulation of surface water or positioned where micro scale seasonal groundwater sources may be forming. However, because significant impact to such communities are both highly unlikely, and comparatively more acceptable, determinations at this end of the scale become less critical, and relatively inconsequential with respect to the EIA process. Despite this, the identification of riparian communities with low GDV likelihood ratings, remains important, as it allows them to be considered later in the EIA process, particularly if for other reasons the potential for significant impact is increased or because the value of the feature becomes atypically elevated due to other factors such as heritage etc.

The data collected in the field, as well as the desktop tasks (see section 4.1) provide the platform for completing the GDV likelihood assessment and mapping process. To interpret and attribute Groundwater Dependent Vegetation (GDV) likelihood ratings to riparian vegetation within the Study Area; the following qualitative factors were considered where appropriate:

- water use strategy (i.e. obligate phreatophyte, facultative phreatophyte (low and moderate level), etc.) and associated potential groundwater dependence associated with the dominant species in the overstorey (and in some cases understorey);
- obligate phreatophyte age structure (particularly noting the presence of a mature component);
- obligate phreatophyte structural dominance (i.e. whether it is dominant or co-dominant in the tree strata); distribution within the creek bed profile;
- vegetation cover/structure (i.e. stand density);
- consideration of depth to groundwater and stability in adequately monitored areas;
- consideration of NDVI persistence mapping anomalies and patterns;
- proximity to surface water flow paths as well as ephemeral and persistent surface water bodies;
- consideration of the catchment size and likely surface water flow regime provide to the area in question; and
- in relation to landforms being dissected by drainage systems, consider the influence of topography, dominant lithology, the presence of basement outcropping and the general proximity of basement lithology to the drainage surface, and;
- consideration of inherent significance; broadly as a measure of the degree of restriction of these vegetation types in the landscape, the magnitude of associated values, and thus the degree of conservatism required for likelihood ratings.

The resulting rating applied by this process is thought to provide an interpretation of the likelihood that riparian communities are dependent on groundwater and importantly to what degree.

Of the factors considered above, catchment size is quite important in relation to features at the lower end of the scale of GDV likelihood. Consideration of the size and frequency of the surface water contribution which might report to riparian habitats is important. This helps to perceive how likely it is that specific vegetation types could rely predominantly on this source of moisture both annually and intra-annually. This also allows consideration of how the baseline composition of riparian communities might respond to changes in surface water availability and changes in the stability of moisture availability. Finally, and where available, groundwater monitoring data is ultimately used to validate and finesse outcomes based on the quality and temporal span of the data available.

As riparian vegetation in the Pilbara tends to rely on both surface water and groundwater sources; any determination of GDV likelihood is uniquely influenced by what proportion of a communities EWR is met by each of these sources. Furthermore, it must also be considered how floristic composition influences community requirements for minimum levels of moisture abundance and stability. Such factors also influence how important groundwater access might be and thus the GDV likelihood potentially attributed to a community.

4.6. Systematic riparian surface water mapping

In order to add value and give context to the riparian vegetation mapping, associated riparian significance assessment and the GDV likelihood mapping; it was determined that a relatively robust surface water mapping process should be conducted for the moderate to major scale drainage systems present throughout the Study Area scope and immediate surrounds. However, the scope of this surface water assessment would not cover minor drainage systems, and in particular it would not cover surface water features occurring in minor incised gully systems present in the rugged range systems occurring in the Study Area and surrounds. Systematic and relatively accurate detection of such surface water features is inherently constrained by the typical size of these features and the issues faced by their occlusion by topography, vegetation and shading.

The surface water mapping task was proposed in order to give an indication of the likely abundance and nature of surface water within and directly surrounding the riparian mapping Study Area. Areas directly around the Study Area were also considered in this process as not only was surface water relatively absent in the Study Area (beyond “Ben’s Oasis”), at least in terms of persistent surface water formations, but it was deemed that there was value in contextualising this result further afield.

The surface water mapping process utilised a number of evidence lines to establish the presence of surface water bodies which exhibited atypical residence times in the environment. This was done with the aim of identifying surface water bodies which behaved distinctly different from those truly ephemeral water bodies in terms of being more consistent in their position, and in their persistence beyond the core surface water flow season. Truly ephemeral water bodies can be both extensively distributed in the wet season and relatively random as to where they occur from year to year. Such surface water features are common and of low value, whereas more consistently located and persistent surface water features provide more valuable services and benefits for local biota.

Initially the surface water mapping process utilised a persistence based analysis of the temporal trends in a water mapping index called Sentinel Water Mask (SWM). The important distinction to note with the SWM index is that it is more appropriate for surface water persistence analyses. This is because the spectral characteristics are such that hydrated canopy and surface water present on different zones of the index such that surface water alone can be identified alone by utilising a threshold in a persistence analysis. In this case that threshold is a SWM index of 0.59/0.6, such that SWM indices returning for ground pixels of Sentinel 2 imagery, of approximately 0.59-1.0, are likely to be indicative of surface-water bodies in the realm of 8-10m wide or greater. See Plate 4-6 for a depiction of the location on the index where both hydrated canopy and surface water typically present in the Pilbara.

A Sentinel 2 imagery based persistence analysis of the SWM index for top of atmosphere imagery from March 2016 to March 2021 was utilised for the remote sensing component of the mapping process. Persistence mapping was systematically searched for persistence pixels returning over low-flow channels within the riparian zone of the Study Area. Either single pixels and their persistence value were recorded or clusters of pixels, their number of pixels and the maximum persistence value returned for that cluster was recorded for potential surface water features.

Following the systematic use of remote sensing to detect the size and temporal nature of potential water features, aerial orthophoto imagery was scanned for the presence of surface water in winter and dry season periods across the drainage systems in the study scope. The key part of this process was checking for surface water features which also occurred in approximately 1-3 (typically at least 2) appropriately timed and appropriately detailed/contrasting aerial image sources from Google earth and ESRI. Ultimately imagery captured in the period of august to November was ideal. For the majority of the Study Area, imagery timed in December, May, June, July, and 2 September images were generally available.

Scanning aerial imagery was firstly done to validate the remote-sensing data where persistent surface water anomalies were detected in remote sensing. Then following that, the remaining parts of the Study Area were scanned for surface water formation visible on the aerial photo. By checking the temporal changes in presence and extent of detected surface water features on progressively later (i.e., later in the year and the dry season) aerial photography, interpretations were able to be made about how persistent those features may be but also why they didn’t feature in the remote sensing data. Generally surface water features which didn’t present in the remote sensing data were either partially occluded by vegetation/topography, or generally of a small spatial extent (i.e. <8 m wide).

These data sources (remote sensing and aerial photo interpretation) were combined with recent and historical field observations of surface water presence and extent (particularly those gathered in the “Ben’s Oasis” area, as well as some ephemeral pools observed near systematic sampling sites). In addition, relevant groundwater monitoring data was reviewed to round out the process and provide a

combined list of ephemeral, persistent pool, and higher rated surface water features for the Study Area.

Pool Classifications

Permanent Pools and Semi-Permanent Pools are groundwater fed (typically from regional groundwater). Permanent pools are permanently connect to the groundwater and represent surface expressions of groundwater and rely on the groundwater interacting with the surface. They can be either a continuous expression of the groundwater table at the surface or result from groundwater discharge at a specific point or zone of groundwater impedance.

In some cases, "permanent" pools may experience short periods of low to no groundwater contribution, typically late in the year, or during drought periods, but in general despite such periods of evaporation are rarely completely emptied.

For habitat purposes and biological value, a permanent pool will not necessarily need to meet traditional hydrological size and depth criteria. Instead, it should consistently contain surface water, even if only of a very small spatial extent, and during droughts, at least moist sediments should be evident at the base of the pool. In the arid Pilbara climate, genuinely permanent pools are rare, with many initially considered permanent turning out to be semi-permanent. At a minimum, permanent pools will typically be accompanied by the facultative phreatophyte *Eucalyptus camaldulensis*, and in many cases (but not always) will be associated with populations of obligate phreatophytes such as *Melaleuca argentea* (and at times *Sesbania formosa*). Other useful indicators for interpreting pool permanence include restricted/refugial and relictual submerged and emergent macrophytes, along with key perennial mesophytic shrubs.

Ideally, the determination of pool permanence should be made utilising appropriate groundwater data or modelling. Alternatively, pool permanence can be interpreted from the outcomes of regular late season visits over multiple years, combined with aerial imagery or remote sensing analyses. In addition, interpretations of permanence can be supported by the use of key hydrophytic and hyporheic indicator species.

Semi-permanent pools are surface water features with seasonal or intermittent connectivity to a groundwater table or source. They are typically present when the groundwater table is above the surface at a location, persisting for a period after the groundwater drops below the surface (annually), either slowly evaporating or quickly disappearing upon disconnection from the groundwater source. Confirming intermittent or seasonal groundwater contribution is important for the identification of this pool type.

The following pools are seasonally fed by rainfall; persistent pools are ephemeral pools with extended hydroperiods and ephemeral pools.

Persistent pools are derived from ephemeral rainfall-driven surface water flows but resist quick dissipation or drainage into underlying sediments/lithology or evaporation to the atmosphere. This pool type typically perches over sediments or basement rock and exhibits prolonged existence without rapid evaporation. They persist above the ground surface for extended periods, often throughout and beyond the wet season, and potentially into or throughout winter. In some settings, increasingly persistent examples of this pool type may have some temporary alluvial baseflow contribution.

Persistent ephemeral pools tend to remain present due to; consistent shading, impervious sediments supporting prolonged perching, presence over relatively impermeable basement lithology, favourable basement morphology encouraging seasonal perching, location at the base of incised rocky gullies or gorges with topographical and aspect-related shading, and various other topographic or ecophysical circumstances that reduce evaporation and infiltration.

In some years and settings, persistent pools can remain throughout the year, but where they are wholly rainfall or surface-flow derived, but sustained by volume and reduced evaporation and infiltration, these pools should continue to be categorised as persistent, as evaporation occurs, these pools will deplete in the absence of contributions from groundwater. However, it is important to record these pools with extended hydroperiods as these areas could support other biotic and abiotic values.

Ephemeral pools are short lived and can be widely dispersed after rainfall and surface flows, with their locations often varying unpredictably from year to year. Typically, these features either rapidly infiltrate/evaporate or are sustained by sub-surface flows for a short period, with their presence limited to the wet season months (December to March) or a few months following winter rainfall events.

5. Results

5.1. Identified Ecohydrology zones

During the field survey, broad ecological and hydrological patterns were observed within both Pebble Mouse and Weeli Wolli Creeks. Key mesophytic, hydrophytic and ephemeral understorey floral assemblages, along with other structural cues in vegetation distribution and the abundance of keystone overstorey species and phreatophytes; were observed to occur in discrete parts of the Study Area. Patterns in the presence/absence, abundance and persistence of surface-water features and associated habitats were also observed. In addition, topographical characteristics of the landscape, the proximity (depth) of basement rock types to the alluvial surfaces of drainage and the broad geological characteristics of different lithologies have been considered throughout the Study Area. All of these factors were considered in order to be able to map out relevant ecohydrological zones within the Study Area Figure 5-1.

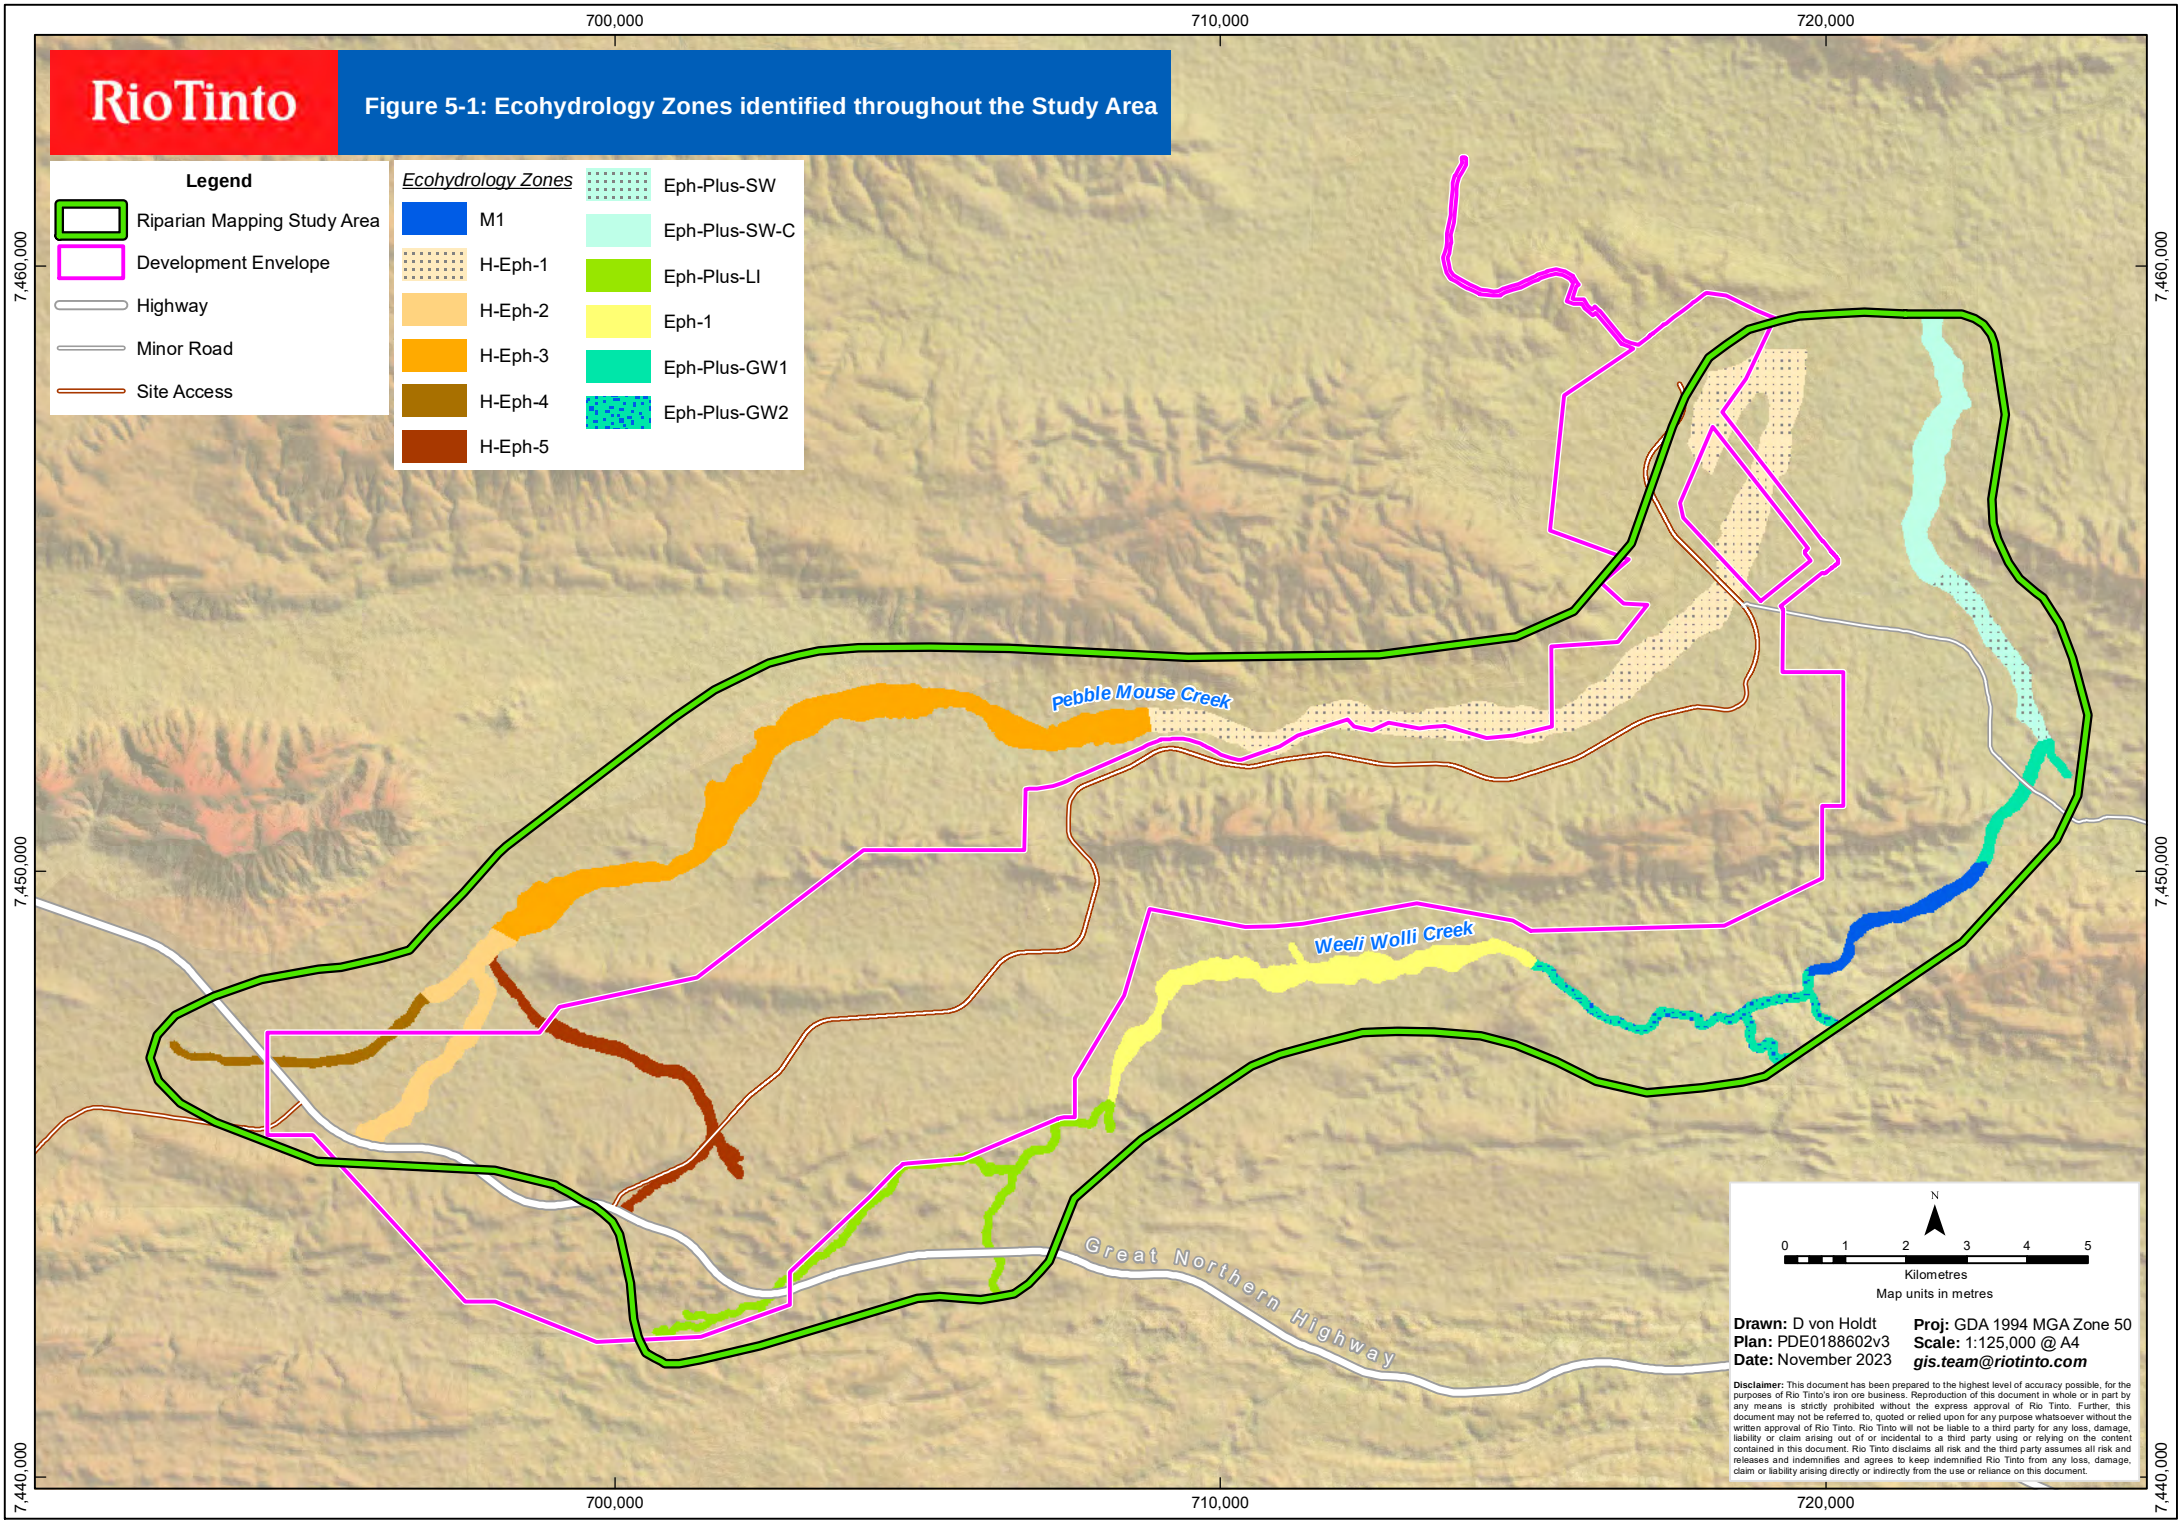
The codes, names, descriptions, groundwater conditions and notes relating to each of the zones is provided in Table 5-1.

Both the ecological and surface/subsurface hydrology patterns observed were thought to impart relevant information on the distribution of different hydrological/hydrogeological regimes as well the likely distribution and magnitude of biodiversity values. These observations are summarised in the following ecohydrological zonation developed for the Study Area.

Four broad ecohydrological classifications were applied: Mesic, Ephemeral Plus, Broadly Ephemeral and Highly ephemeral. The highly ephemeral zones generally represented those areas where the creek reaches in question occurred in broader valley habitats and as such the core riparian zones were flanked by broad (in some cases up to +600 m wide) fine grained floodplains and high flow channel profiles. Both due to the generally inaccessible groundwater conditions and the broad nature of the creek profile in these ecohydrological zones; riparian vegetation, even in the core riparian zone of the low flow channel and banks, was generally quite sparse and low in stature. As a result the structure, composition and productivity of these zones was highly ephemeral in nature and as such, the overstorey of the more productive zones was predominantly dominated by low level FPS.

The “Broadly Ephemeral” classification represents those creek reaches which were generally quite ephemeral in nature (i.e. predominantly supported by wet season surface flows alone), but also possessed a more typical density of riparian vegetation and were overstorey density was elevated and Moderate level FPS were also typically co-dominant with low level FPS. The one example of this zone mapped was also present in relatively topographically confined country such that the riparian zone was relatively narrow and as such, surface flows were also focused in a small riparian zone, helping to support a denser vegetation and slightly more mesic composition.

The “Ephemeral Plus” classification represents those zones with similarly ephemeral type vegetation and hydrological processes, but for various reasons (increased surface water, shallow groundwater, geological factors etc.) hydrological conditions are partly enhanced and as a result water availability to riparian vegetation is higher.



The final “Mesic” classification relates to spring type ecohydrological scenarios, in this case the informally named “Ben’s Oasis” area, where shallow groundwater and associated groundwater discharge in key areas supports a much more mesic (and at times Hydrophytic) assemblage of riparian habitats with moderate to high water availability and reliance on groundwater access.

Details of the characteristics of each of the differing zones identified in the Study Area, which have been assigned to these broader ecohydrological classifications are presented in Table 5-1. Where zones are referred to as confined, this identifies that the breadth of the respective creek reach is topographically confined and as such the riparian zone is laterally compressed, focusing surface water into a smaller area. The alternative is for the creek reach to be broad and thus laterally unconfined leading to surface water flows feeding a much larger riparian zone. For each of the identified zones,

changes in composition, both in the dominance and abundance of overstorey components, but particularly in the understorey composition and the diversity/magnitude of understorey mesophytic taxa. For specific information about mesophyte/hydrophyte composition of each zone, refer to the information provided for each of the vegetation units within Table 5-11.

Table 5-1: Ecohydrology zones identified throughout the Study Area

FID	Code	Ecohydrology Classification/Label	Formation, Position, Geology	Ecohydrology Zone Notes	GW Access
7	M1	Mesic - Shallow groundwater & surface discharge	Confined Moderate drainage. Predominantly Basalt (Fortescue formation)	Reach generally occurs over areas of shallow groundwater/basement lithology and some GW discharge zones. Supports one broadly permanent pool and GW discharge zone and other persistent pool to Semi-permanent pools in the downstream outflow zone.	Broader aquifer generally accessible i.e., 2-5 mbgl near west boundary, 0-1m through "Ben's Oasis", and approximately 2 mbgl at east boundary (vegetation not necessarily reflective of this depth at east boundary - basement shallow). Shallow Basement may also mean that practically speaking, vegetation may find it hard to access GW in some areas.
8	Eph-Plus-GW1	Ephemeral Plus - partially* GW Enhanced - 1	Confined Moderate drainage - Some apparent Spring influence. Predominantly Basalt (Fortescue formation)	Reach generally contains sections of elevated vegetation persistence and accompanying low to moderate level mesic species composition. Likely due to basement proximity, shallow GW at South-west end and influence of outflow from adjacent spring.	Broader aquifer generally accessible in the south-west but trending towards inaccessibility in the north-east i.e., 2-5 mbgl near west boundary, getting deeper as the creek moves north-east reach 25 mbgl at the North-East boundary.
6	Eph-Plus-GW2	Ephemeral Plus - partially* GW Enhanced - 2	Confined Moderate drainage. Predominantly Basalt (Fortescue formation)	Reach quite topographically confined. Groundwater becomes potentially accessible at east end of reach (within 5m), however basement remains shallow through this area, (likely less than 5m deep) which potentially restricts access.	Broader aquifer trending into accessibility i.e., 30 mbgl in west, 10 in east and approximately 5 mbgl at east boundary (vegetation not necessarily reflective of this depth at east boundary - basement shallow and likely restrictive)
10	Eph-Plus-SW-C	Ephemeral Plus - SW & Calcrete Enhanced	Broad Major drainage. Calcrete over Hamersley Formation	Creek reach occurring over substantial calcrete formations prior to Weeli Wolli Springs. Ecohydrology already influenced by adjacent mining abstraction.	Broader aquifer generally inaccessible 30-40 mbgl (40 mbgl in the south and approximately 30 mbgl at the north boundary). (Historically, this area possessed GW 10-20 mbgl - dewatering has reduced this).
9	Eph-Plus-SW	Ephemeral Plus - SW Enhanced	Confined Major drainage - Some Mesic outcropping. Hamersley Formation	Reach contains outcrops of elevated vegetation persistence and accompanying low level mesic species composition. Structure and composition in area likely from increased surface water input regime due to reporting catchment increases.	Broader aquifer generally inaccessible (25-50 mbgl - 25 mbgl in the south, and approximately 40 mbgl at the north boundary).
4	Eph-Plus-LI	Ephemeral Plus - Lithology enhanced	Confined Moderate sized drainage - Upper. Basalt (Fortescue formation))	Reach directly overlying basalt basement which generally supports minimal infiltration, leading to higher surface water persistence in low points and fractured/weathered basement below low flow channels. Composition somewhat reflects this.	Broader aquifer clearly inaccessible 30-50 mbgl, basement lithology likely implicated in the presence of more frequent perched small scale groundwater sources.
5	Eph-1	Broadly Ephemeral - 1	Broad Moderate sized drainage. Hamersley Formation	Reach moderately broad, and floodplain soils quite fine due to upstream basalt influence.	Broader aquifer clearly inaccessible (40-50 mbgl)
11	H-Eph-1	Highly Ephemeral (low density veg) - 1	Broad Moderate drainage - Lower. Hamersley Formation	Very broad nature of the creek profile and floodplain determines that the established riparian formations are highly ephemeral, and support relatively low vegetation densities in the low flow and floodplain habitats.	Broader aquifer clearly inaccessible 30-50 mbgl
2	H-Eph-2	Highly Ephemeral (low density veg) - 2	Broad Moderate sized drainage - Upper. Basalt influence in Hamersley formation	Broad creek profile and floodplain leading to sparse highly ephemeral vegetation. However, reach directly downstream from Fortescue formation and influence of basalt sediment outflow leading to increased seasonal moisture persistence in terraces.	Broader aquifer clearly inaccessible 50-70 mbgl
3	H-Eph-3	Highly Ephemeral (low density veg) - 3	Broad Moderate sized drainage - Upper. Hamersley Formation	Minor Basalt influence in sediment compositions. Very broad creek profile & floodplain determines that the established riparian formations are highly ephemeral, and support relatively low vegetation densities in the low flow and floodplain habitats.	Broader aquifer clearly inaccessible 40-50 mbgl
0	H-Eph-4	Highly Ephemeral (low density veg) - 4	Upper Tributary - minor to moderate sized drainage. Basalt influence in Hamersley formation	Broad creek profile and floodplain leading to sparse highly ephemeral vegetation.	Broader aquifer clearly inaccessible 50-70 mbgl
1	H-Eph-5	Highly Ephemeral (low density veg) - 5	Upper Tributary - minor to moderate sized drainage. Basalt influence in Hamersley formation	Broad creek profile and floodplain with some Basalt influence leading to sparse highly ephemeral vegetation.	Broader aquifer clearly inaccessible 50-70 mbgl

5.2. Riparian vegetation units and associated mapping

Fifteen vegetation units were described in the Greater Hope Downs area. Summary information for these units is presented in Table 5-2. Detailed descriptions for all 15 units are presented in Appendix C:.

Previous vegetation mapping by Astron (2020) mapped four vegetation units; D4, D5, D7 and D8, across the larger drainage units covered by the Astron study (See section 2.5 for full coverage of this Study Area). Vegetation mapping in the current study leveraged these baseline vegetation units where relevant, making minor modifications as well as adding new vegetation units in order to provide an adequately detailed complement of vegetation units across the moderate to major sized drainage systems the current Study Area. To do this the current study utilised vegetation observations from multiple reconnaissance field visits, and collected targeted riparian mapping notes, ground-truthing data, and Quadrat/Relevé data from 2021 survey work. These data sources were considered along with relevant historical flora and vegetation surveys in order to provide a more focused riparian scope, and higher level of detail required for the task of providing a targeted riparian vegetation mapping and an assessment of their values/significance.

As an example of the level of detail provided, the previously mapped D4 unit (Astron 2020), was mapped across most of the riparian zone for moderate to major sized drainage in the greater Hope Downs 1 area. In the current study, the important D4 vegetation assemblage was modified and split into seven vegetation units along Pebble Mouse and Weeli Wolli Creeks, with the vegetation description of D4 being slightly modified and assigned to the area most closely related to the original description. Changes to the differentiation of the previous D4 unit was done to increase riparian mapping accuracy and context. This was based on both current and historical vegetation mapping and quadrat data (Astron, 2020; Mattiske, 2008; 2010) as well as finer scale consideration of the distribution and abundance of keystone species (particularly overstorey phreatophytes) throughout Pebble Mouse and Weeli Wolli Creeks. Areas previously mapped as D4 along Pebble Mouse Creek were assigned to either C4B, C4Bx-2 or C3C along Pebble Mouse Creek, or C2B, CB4x-1 or C3A along Weeli Wolli Creek.

Floodplain units previously mapped as D7 (Astron, 2020) or ATC-M2 (Mattiske 2008; 2010) were split into three vegetation units; CF-X3, CF-X1 and CF-X2, associated with varying floodplains adjacent to Pebble Mouse Creek and Weeli Wolli Creek.

Vegetation units mapped and assessed across the study area (Table 5-2) are all considered to occur within the riparian zone of the moderate to major sized creek systems within the study area. However, not all of the vegetation units mapped in the study area are considered to possess the elevated environmental value representative of “riparian vegetation”. For the purpose of this study (and successive similar studies), the Rio Tinto Ecohydrology team have defined those vegetation communities/habitats which possess an adequate structural complexity, appropriately elevated biodiversity and ecohydrological value and suite of fluvial and riparian characteristics deemed to warrant the riparian vegetation classification and receive appropriate management. For this purpose the Rio Tinto Ecohydrology team have defined this adequately elevated riparian vegetation type as ‘core riparian vegetation’. The remainder of vegetation occupying the riparian zone, but of reduced value and complexity has been defined as ‘floodplain & associated riparian vegetation’. Within the study area and across the riparian zone (Table 5-2 and Appendix C:), all mapped vegetation units, except for the three floodplain units (CF-X1, CF-X2 and CF-X3), were considered likely to be classed as ‘core riparian vegetation’. Only the C1A vegetation unit of ‘Ben’s Oasis’ was considered to represent the ‘core riparian vegetation – riverine’ definition which highlights increasingly elevated riparian biodiversity values.

To further clarify the key riparian zones (see Appendix D for ‘riparian zone’ definition) of relevance in this space, riparian definitions, ‘core riparian vegetation’ (including riverine) and ‘floodplain & associated riparian vegetation’, have been formed to outline the approach applied to come to these conclusions. The main distinction proposed is that while the ‘riparian zone’ and associated riparian vegetation communities are considered to more broadly cover the floodplain habitats (where water flows much less frequently), it is within the low flow channel and bench/bank complex that core riparian vegetation will generally establish and meet specific characteristics worthy of the classification. Vegetation defined as ‘core riparian vegetation’ (see Appendix D for full definition) is what the Rio Tinto Ecohydrology team propose to define as riparian vegetation worthy of increased management provisions.

Broad floodplain units have been excluded from the 'core riparian vegetation' definition as these formations are typically flanking the core riparian zone where such characteristics are clearly and significantly reduced in value. Floodplain units can be defined under the 'floodplain & associated riparian vegetation' definition (see Appendix D for full definition).

One of the core tasks conducted in respect to the process of increasing the detail and ecohydrological relevance of riparian mapping in the Study Area, was the process of accurately assessing the distribution of keystone phreatophytes. To do this, all detectable mature *Eucalyptus camaldulensis* individuals were identified at a desktop level using high resolution aerial photography within representative reaches of the target drainage systems within the Study Area. This process was also done for *E. victrix*, but in a smaller number of representative areas across the Study Area to that of *E. camaldulensis*. The reduced coverage for *E. victrix* was on account of the fact that in areas where *E. camaldulensis* is not present, it is more easily assumed that *E. victrix* is the replacing keystone species, and this assumption was also ground-truthed. This was done in order to accurately determine the relevant abundance and dominance of both *E. camaldulensis* and *E. victrix*. This in turn allowed better delineation of vegetation units whose description reflected the varying degree of dominance exhibited by these two species. Main keystone species differences for which this technique was aimed at supporting accurate delineation for were:

- Locations where *E. camaldulensis* were dominant
- Locations where *E. camaldulensis* and *E. victrix* were consistently co-dominant, and;
- Locations where *E. victrix* were consistently dominant
- Locations where other keystone species were dominant in the overstorey.

Examples of this mapping are presented in Figure 5-2 to Figure 5-5 for various reaches and vegetation units within the Study Area.

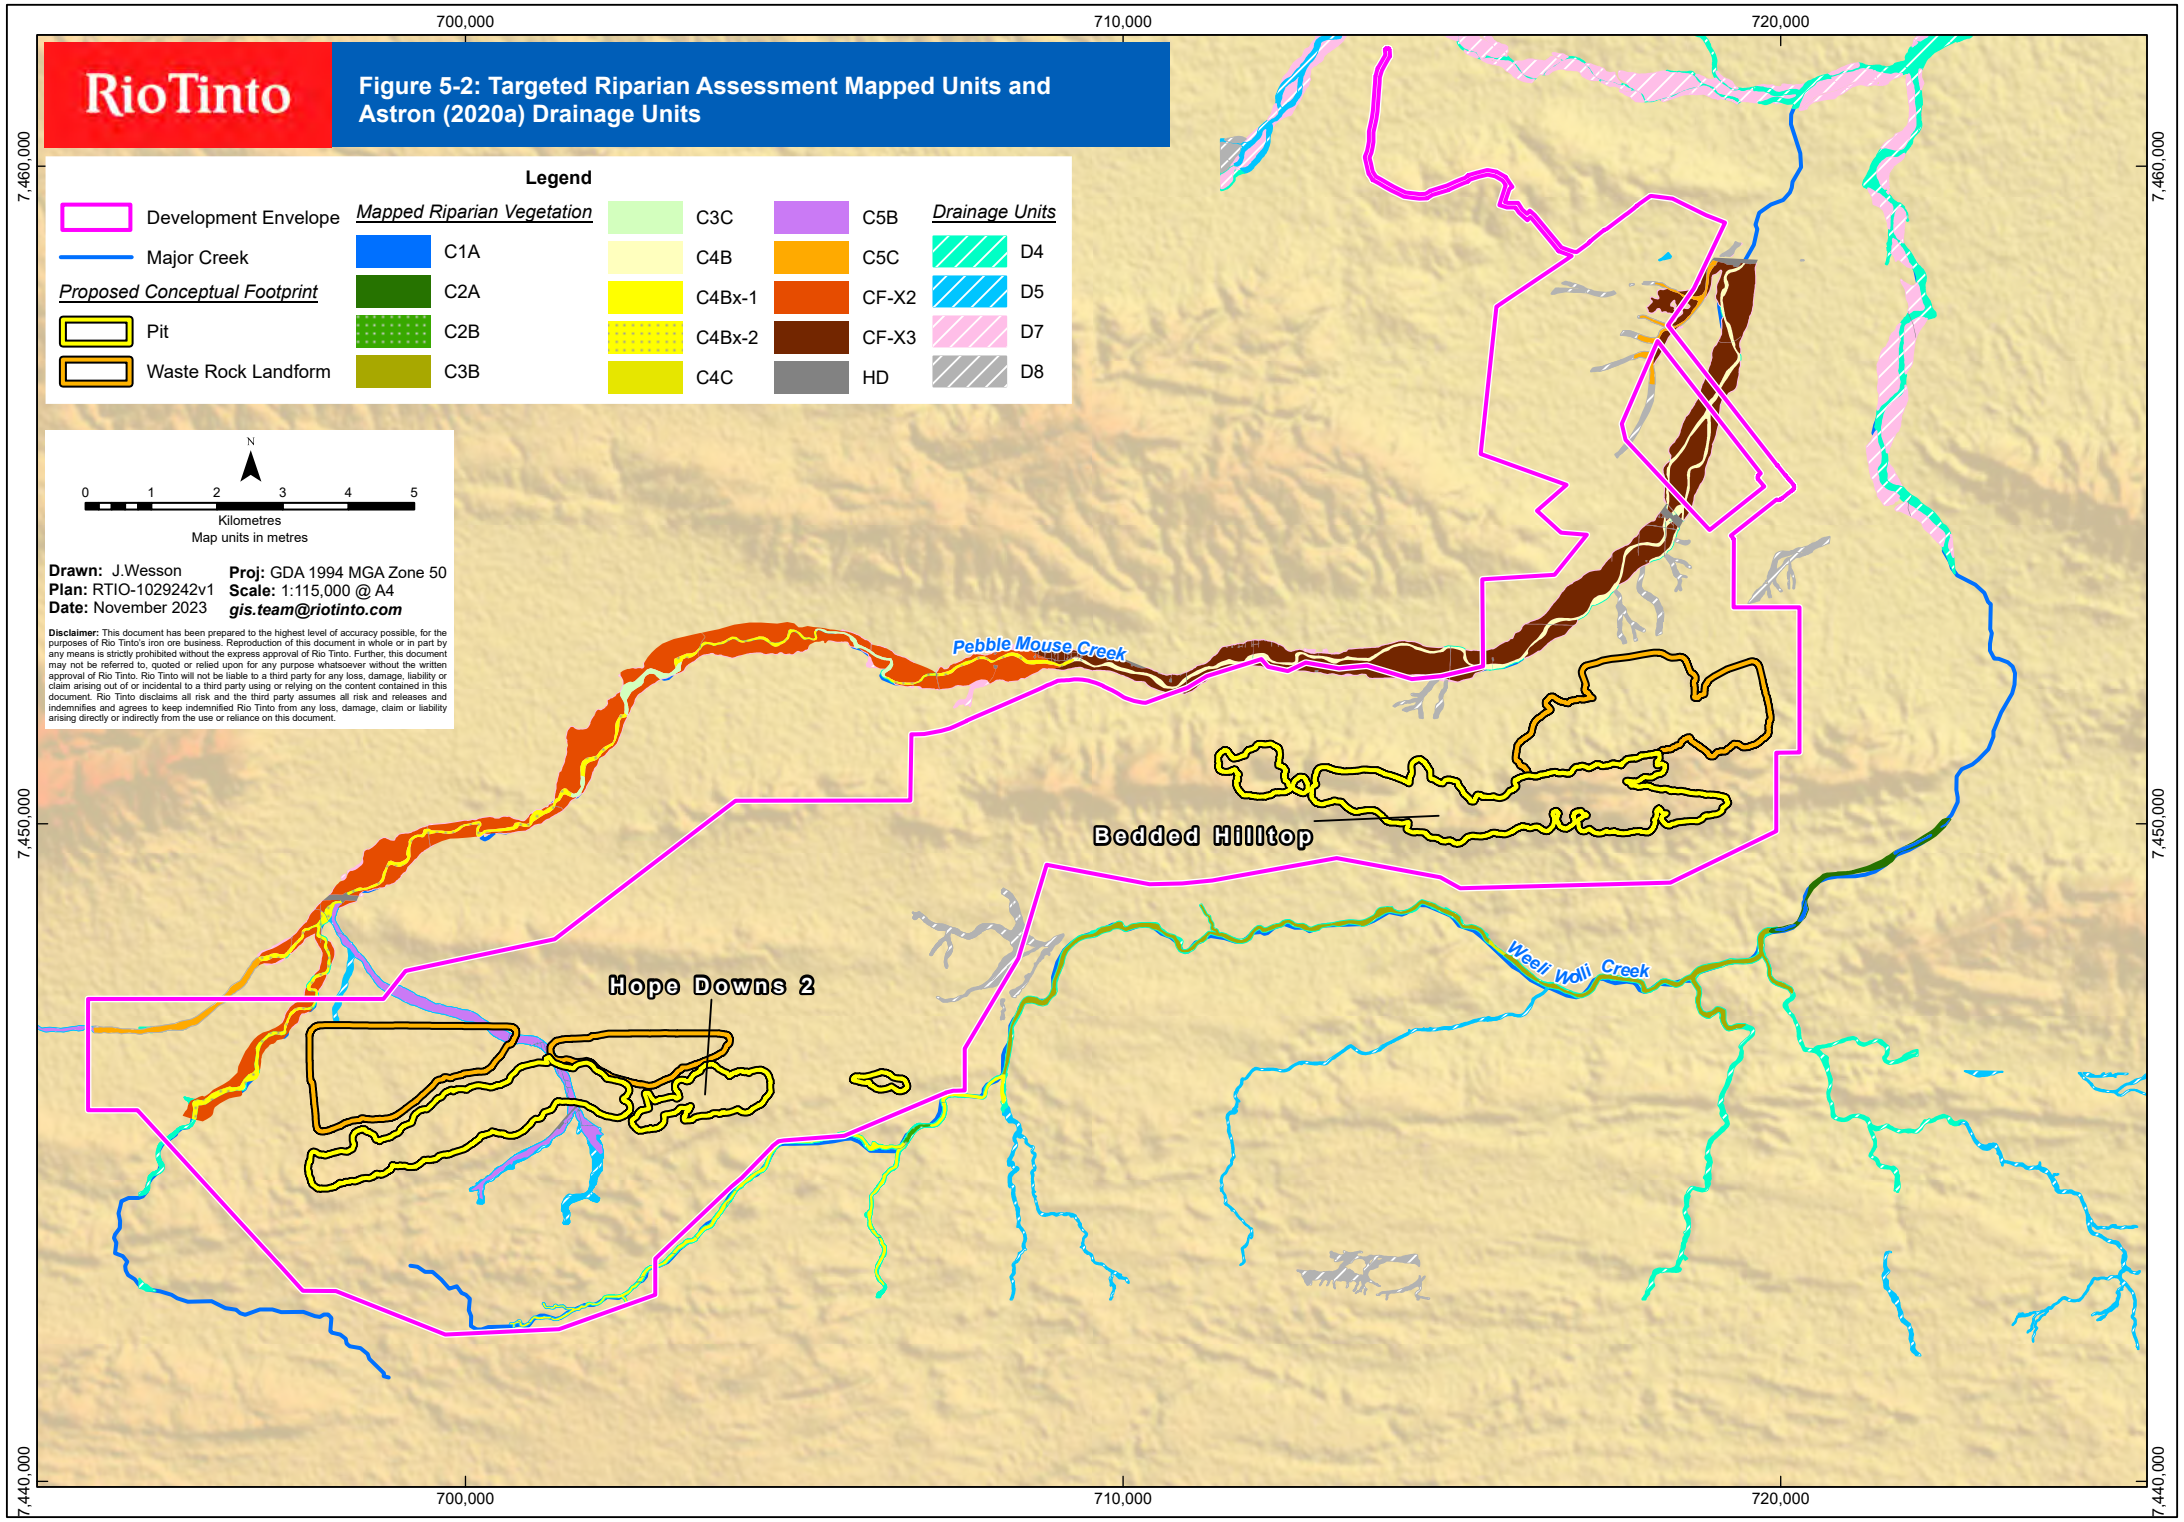
Previous vegetation mapping in various studies for the area generalised the dominance of these key species across the majority of larger drainage systems in the area. In most cases this was in the form of a vegetation unit which mapped *E. camaldulensis* and *E. victrix* as codominant in the overstorey. The consequence of such generalisations is that for creeks and reaches where this is inaccurate, the significance of the riparian features and also the likelihood that they support GDV is typically overestimated. The alternative is also true where creeks may support riparian vegetation of a greater density and also greater abundance of *E. camaldulensis*. Furthermore such vegetation is often accompanied by a uniquely mesic understorey composition which is also likely to miss representation in standard baseline vegetation mapping of riparian areas. For these reasons, accurate mapping of the abundance and dominance of keystone overstorey species and phreatophytes, not only allows for a complement of riparian vegetation units which accurately delineate vegetation with key overstorey differences, but it also typically aligns with and allows for those units to reflect key compositional changes in the understorey. Changes which not only allow for a detailed reflection of compositional change, but which also speak to changes in ecohydrology and potential for communities to rely on alternative water sources like groundwater.

The other factors which the resulting riparian vegetation mapping takes into consideration is topography, and the relevant broad geological groups. Across the Study Area, riparian corridors are broadly contained in broad alluvial valleys, low undulating range systems, and occasionally in incised gully/gorge type settings. These three topographical settings have both an effect on the vegetation which has established, but also on the presence/absence of adjacent floodplain landforms, which in turn influences vegetation and productivity.

Geology is also influential in the Study Area. PMC and WWC both dissect both Hamersley and Fortescue geological groups. These two geological groups broadly possess different hydraulic properties. Infiltration within Fortescue group lithology is typically quite low, whereas within Hamersley group it is generally much higher. Following rainfall, this typically leads to Fortescue catchments shedding surface water via drainage quite quickly, and Hamersley less so. Faster shedding equals more frequent effective surface water flows within Fortescue group creeks. Where basement is shallow, it can lead to small groundwater sources more often being perched over favourable basement morphology and within weathered basement lithology. Within local creeks flowing over Fortescue geology, on average we tend to see a greater abundance of *E. camaldulensis*, more examples of persistent pool surface water features, and an abundance of some moderate to high level mesophytic shrub species such as *Melaleuca bracteata* and *M. glomerata*. These are all signs that surface water

flows and potentially small, perched groundwater sources are providing a more persistent source of water available for riparian vegetation. An example of such vegetation within the Study Area is vegetation unit C4Bx-1 and C2B.

Another characteristic of Fortescue lithology is that a portion of the sediment which weathers from this lithology is very fine. The fine nature of this weathered sediment often leads to the formation of clay soils where it accumulates adequately. These fine-grained sediments not only accumulate in broad valleys, typically on terraces and adjacent floodplains, but they also flow on and accumulate in the adjacent Hamersley group valleys. Creek terraces and floodplains with a substantial proportion of these fine such clay sediments not only support clay loving species and at times diverse ephemeral communities, but they also tend to hold water near the surface for longer periods post wet season, than other more typically loamy soils derived from Hamersley group lithology. In turn this can lead to the provision of different ecohydrological habitats and associated vegetation assemblages. Within the Study Area vegetation units C5B, C5C C4Bx-2 and CF-X2 are examples of riparian units which occur on fine-grained sediments likely to have accumulated following weathering of Fortescue group lithology.



Alternatively, Hamersley group creeks tend to flow less frequently that Fortescue group creeks, but their typically greater rates of infiltration can also more often lead to the provision of accessible alluvial aquifers and increased recharge to regional aquifers. This can in turn lead to the establishment of a range of differing riparian vegetation types from highly ephemeral, such as the C4B unit (and corresponding CF-X3 floodplain unit) to the enhanced ephemeral C3A unit, to the increasingly mesic C2A and ultimately C1A OPV unit which occurs where the regional Hamersley aquifer appears forced to the surface by Wittenoom basement material.

Table 5-2: Summary of riparian vegetation units within the Study Area

Final Unit (Standardised riparian classification)	Initial Vegetation Unit	Area (Ha)	Vegetation Label	Vegetation Summary Description	Creek Profile position	Drainage classification (i.e. reporting catchment estimate)	Mapping confidence notes
C1A	D14a	6.48	"Ben's Oasis" Core Riparian unit (WWC)	*M. argentea* & *Eucalyptus camaldulensis* open forest over mixed mesic shrublands	Low Flow Channels and banks (and Permanent to Semi Permanent Pools)	Moderate Drainage* (< 450km2)	Mapping Confidence High
C2A	D14b	23.74	"Ben's Oasis" Fringing riparian unit (WWC)	*E. camaldulensis* Woodland (to open forest) over open mesic shrublands (Scattered young *Melaleuca argentea* present in some locations)	Low Flow Channels and banks	Moderate Drainage* (< 450km2)	Mapping Guided by vegetation mapping from Multiple Mattiske Surveys from 2009 and earlier. Mapping confidence reduced but considered adequate.
C2B	D12	2.88	West WWC - Basalt & Calcite bend	Small *E. camaldulensis* Woodland over mixed open shrubland with *Melaleuca bracteata*.	Low Flow Channels and banks	Moderate Drainage (< 150km2)	Mapping Guided by vegetation mapping from Mattiske 2009 Survey. Mapping confidence reduced but considered adequate.
C3A	D15	106.84	Lower WWC Main (Pre Weeli-Wolli Springs)	*Eucalyptus camaldulensis* subsp. *obtusa, E. victrix* woodland over open Semi-Mesic Shrublands with *Triodia longiceps*	Low Flow Channels and banks	**Major Drainage* (< 500-750km2)**	Mapping Confidence Moderate
C3B	D04	98.94	Middle WWC West confined	*E. camaldulensis* & *E. victrix* Woodland (variable) over mixed open shrubland with *Petalostylis labicheoides*	Low Flow Channels and banks	Moderate Drainage (< 200-400km2)	Mapping Guided by vegetation mapping from Multiple Mattiske Surveys from 2009 and earlier. Mapping confidence reduced but considered adequate.
C4C	D18	1.41	WWC west - small, incised gorge/gully	*Corymbia ferriticola* and *Eucalyptus victrix* low open woodland over mixed open shrubland with rocky influence.	Low Flow Channel and fringing rocky banks	Moderate Drainage (< 200-400km2)	Mapping Guided by vegetation mapping from Multiple Mattiske Surveys from 2009 and earlier. Mapping confidence reduced but considered adequate.
C4Bx-1	D13	49.58	Upper WWC West Basalt	*Eucalyptus victrix, E. xerothermica* woodland	Low Flow Channels and banks	Moderate Drainage (< 150km2)	Mapping Confidence High
C3C	D11	21.15	Middle Pebble Mouse Creek - Less ephemeral bends (slightly mesic)	*Eucalyptus victrix, E. xerothermica* and *E. camaldulensis* woodland	Low Flow Channels and banks	Moderate Drainage (< 150-300km2)	Mapping Confidence Low-Moderate
C4B	D09	86.66	Lower Pebble Mouse Creek broad	*Eucalyptus victrix* low open woodland over *Acacia citrinoviridis* tall open shrubland.	Low Flow Channels and banks	Moderate Drainage (< 250-350km2)	Confidence in mapping is High
C4Bx-2	D10	88.31	Upper Pebble Mouse Creek broad	*Eucalyptus victrix, E. xerothermica* low open woodland over variable tall open shrubland of *Acacia aneura* complex.	Low Flow Channels and banks	Moderate Drainage (< 100-300km2)	Confidence in mapping is High
C5B	D05	80.98	Lower Pebble Mouse Creek East tributary (fine grained)	*Eucalyptus xerothermica* low open woodland over mixed tall open shrubland with *Petalostylis labicheoides* and *Triodia longiceps* hummocks	Low flow channels bank and terrace	Moderate Drainage (< 100km2)	Mapping Confidence High
C5C	D08	40.42	Lower Pebble Mouse Creek West tributary (fine grained)	*Eucalyptus xerothermica* scattered low trees over variable tall open shrubland of *Acacia aneura* complex.	Low flow channels bank and terrace	Moderate Drainage (< 100km2)	Mapping Confidence High-Moderate
CF-X1	DF16	284.09	WWC Floodplain (variable) - Lower (and middle)	*Eucalyptus xerothermica* & *E. victrix* (+/-) scattered trees over mixed Acacia spp. tall open shrublands with *Acacia citrinoviridis*.	Floodplain (and High flow Channels)	Major Drainage* (< 500-750km2) to Moderate Drainage (< 100-400km2)	Mapping Guided by vegetation mapping from Multiple Mattiske Surveys from 2009 and earlier. Mapping confidence reduced but considered adequate.
CF-X2	DF17	450.6	Floodplain – Upper Pebble Mouse Creek	*Eucalyptus xerothermica* scattered low trees over scattered tall shrubs and *Triodia longiceps* hummocks	Floodplain (and High flow Channels)	Moderate Drainage (< 150-300km2)	Mapping Confidence Low-Moderate
CF-X3	DF7	494.9	Floodplain – Lower Pebble Mouse Creek	*Eucalyptus xerothermica* scattered low trees over scattered tall shrubs with *Acacia citrinoviridis* and *Triodia longiceps* hummocks	Floodplain (and High flow Channels)	Moderate Drainage (< 250-350km2)	Mapping Confidence High

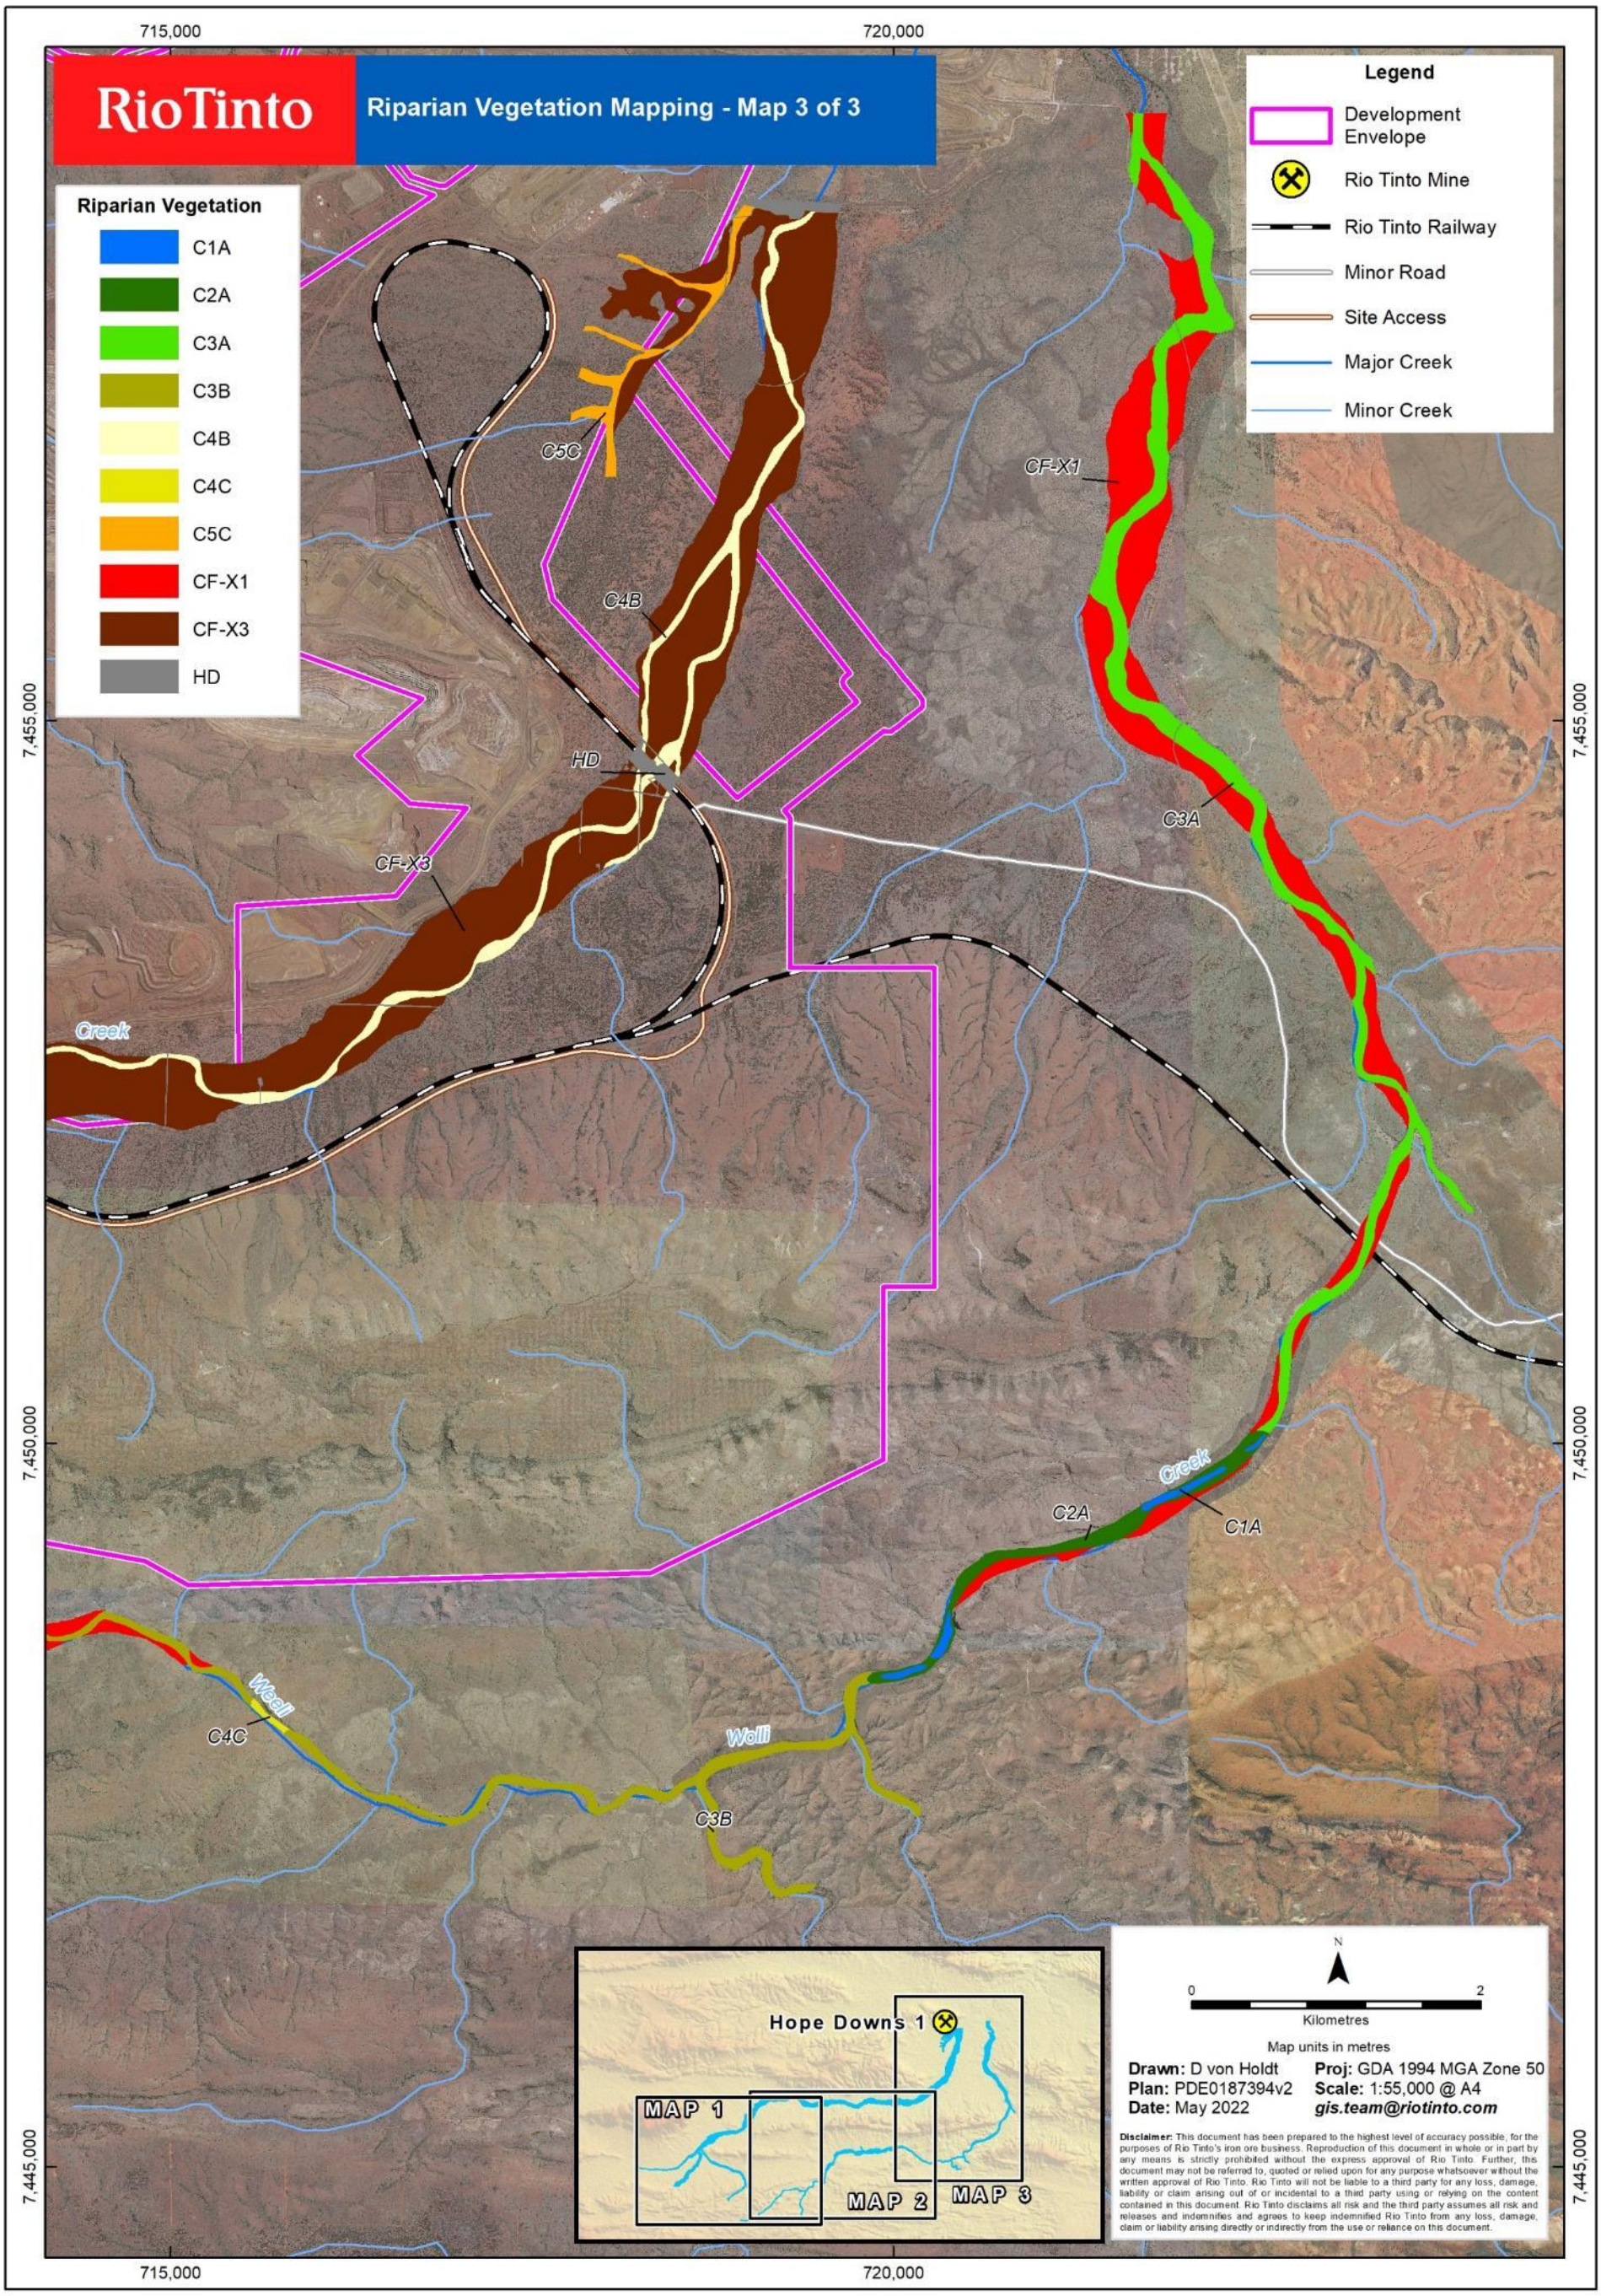

Figure 5-5: Riparian vegetation mapping in the east of the Study Area (Map 3 of 3).

5.3. Riparian Flora

A total of 207 species from 120 genera and 47 families were recorded from sampling conducted in riparian areas during the Rio Tinto (2021) riparian survey (Appendix K:). Additional data from surveys by Astron (2020) and Mattiske (2008, 2010) increased the total number of species recorded in the area to 418 species from 163 genera and 57 families (Appendix L:). Importantly, the current survey was able to detect new riparian taxa, with sampling in the current study detecting 63 new taxa not detected or identified in the previous Astron (2019) and Mattiske (2008, 2010) surveys.

5.3.1. Key Riparian Flora Species

Of the species recorded both in this current study and historical surveys/sampling, certain riparian taxa can often be of use/value for interpreting various aspect of the riparian ecosystem they occur in.

Table 5-3 lists the riparian species of note which assisted this study in the determination of the following attributes;

- Riparian vegetation descriptions and unit boundaries;
- Ecohydrological characteristics (including potential for vegetation to have some/no dependence on groundwater access);
- Unique riparian understorey compositions (particularly those which might infer presence/absence of stable mesic riparian habitats);
- Relevant soil characteristics which might influence broader vegetation trends and;
- Riparian significance/value attributed to each vegetation unit mapped.

Blue shading in the cells within Table 5-3 indicate where taxa were generally influential in the area of ecohydrology and the detection of mesic habitats and increasing moisture stability, with blue text indicating the more influential of the taxa in this space. Green shaded cells indicate those taxa which both were involved in the detection of the lower end of the mesic habitat scale, but also in the nature of the ephemeral habitats being considered as well as the persistence of any ephemeral surface water features likely present or detected. Such taxa can also be used to interpret the presence of riparian habitats or soil and geological conditions which were more likely to facilitate accumulation and post wet season persistence of ephemeral surface water. Grey shaded cells indicate species which were specifically used to interpret soil/geology based ecohydrological characteristics of some of the ephemeral habitats as well as significance/condition ratings outside of commonly considered taxa.

Within cells of Table 5-3, red highlighted text indicates priority flora, while purple highlighted text indicates introduced species of relevance to riparian habitats.

Table 5-3: Key riparian flora species recorded from the Study Area

Overstorey	Understorey	Less mesic: Sedges/Grasses/Herbs	Submerged/emergent macrophytes and aquatic/fine Herbs
Melaleuca argentea	*Cullen leucanthum*	*Cyperus cunninghamii & C. cunninghamii subsp. cunninghamii*	*Stylidium weeliwolli*
Eucalyptus camaldulensis subsp. *obtusa*	*Acacia ampliceps*	*Cyperus iria*	*Eleocharis geniculata*
Eucalyptus victrix	*Melaleuca bracteata*	*Cyperus squarrosus*	*Sonchus hydrophilus*
Corymbia aspera	*Melaleuca glomerata*	*Cyperus difformis*	*Schoenoplectus subulatus*
Eucalyptus xerothermica	*Tinospora smilacina*	*Cyperus vaginatus*	*Schoenoplectiella laevis*
Acacia coriacea subsp. *pendens*	*Gossypium sturtianum*	*Eulalia aurea*	*Ammannia baccifera & A. multiflora*
Atalaya hemiglauca	*Dodonaea lanceolata*	*Stemodia grossa*	*Chara* sp.
Clerodendrum floribundum	*Abutilon amplum*	*Aristida lazaridis*	*Typha domingensis*
Corymbia ferriticola	*Stylobasium spathulatum*	**Melinis repens & *Sigesbeckia orientalis*	*Marsilea hirsuta*
Ficus brachypoda	*Denhamia cunninghamii*	*Commelina ensifolia*	*Wahlenbergia tumidifructa*
	Olearia fluvialis	*Rostellularia adscendens var. latifolia*	
	Dodonaea viscosa	*Bothriochloa ewartiana & Dichanthium sericeum subsp. Humilis & Eriachne benthamii*	
	Pittosporum angustifolium	*Sorghum plumosum*	
	Ehretia saligna var. saligna	**Urochloa mosambicensis & *Chloris virgata*	

5.3.2. Conservation Significant Flora

A total of four Priority listed flora species were recorded from the riparian zone of Weeli Wolli Creek, Pebble Mouse Creek and their associated tributaries within the Study Area. The four Priority listed species and their locations are detailed below and in Figure 5-6.

Aristida lazaridis (Priority 2)

Aristida lazaridis was recorded in ten locations and from five vegetation units (Table 5-4). Astron (2020) conducted extensive targeted searches for this species in key habitats and as a result recorded *A. lazaridis* in two locations. Together, this data, along with the targeted searches conducted for this species in the current study allowed *A. lazaridis* population abundance mapping to be provided for this species within Figure 5-6. This mapping is designed to help inform significance assessments for each of the riparian vegetation unit by adding information to inform the likelihood of the presence of Priority flora in different riparian units. *Aristida lazaridis* population abundance mapping in Figure 5-6 suggests that while it is not restricted to these units, in general this species was common within and therefore preferred the habitats provided by vegetation units C4Bx-2 (and the flanking CF-X2 floodplain unit), and C4Bx-1. In addition, this species had a scattered to isolated distribution within the C3B unit and the CF-X1 floodplain unit which flanks it.

Table 5-4: Locations of *Aristida lazaridis* recorded from the Study Area

5.3.3. Flora of 'Other' Significance

The Study Area supports a diverse array of flora that can be considered to be of 'other' significance as defined by EPA (2016). This includes range extensions, unusual/unique flora, relictual flora and flora that are representative of GDE.

Three flora species of 'other' significance were recorded during the current study and by Astron (2020) as occurring within the riparian zone of Weeli Wolli Creek and Pebble Mouse Creek. These flora species and their locations are detailed below and in Figure 5-6.

Eulalia sp. 'Three River Station'

The current study recorded *Eulalia* sp. 'Three River Station' at one location (Table 5-8). This taxon is currently not recognised by the Western Australian Herbarium (WAH), though it continues to present in the field as a different *Eulalia* species to those recognised in WA, forming continuous mats of rhizomatous grass beds. The species is distinct and appears well represented in the Pilbara, but it remains a potential species of interest requiring further taxonomical investigation.

Table 5-8: Location of *Eulalia* sp. 'Three River Station' recorded from the Study Area

Transect	Vegetation Unit	Easting	Northing
Veg4	C4Bx-2	721993	7449670

**Urochloa mosambicensis*

*The current study recorded *Urochloa mosambicensis* at three locations within the Study Area (Table 5-9). These records are a substantial range extension for this introduced weed taxon. **Urochloa mosambicensis* is an African native that has become naturalised throughout Queensland, the Northern Territory, and is currently restricted to the Kimberley region of Western Australia. There are no previous records of this taxon in the Pilbara region, though the climate is likely able to support the species spread into the region (tropical/hot climate).

Table 5-9: Locations of **Urochloa mosambicensis* recorded from the Study Area.

5.4. Assessment of riparian vegetation communities across the Study Area

A core objective of the current study, apart from producing targeted and appropriately detailed Riparian vegetation mapping, was to determine the degrees of restriction for all the mapped riparian vegetation units and their associated habitats. Approximately eight different steps were undertaken to complete the current significance assessment (see Section 4.4). This included steps such as:

- Considering the likelihood of the unit representing GDV as well as the mapped ecohydrological zone which is falls within.
- mapping the reporting catchment to each vegetation unit and classifying its drainage size.
- Determining the suite of relevant mesophytic and hydrophytic indicator species present in each and their abundance.
- Providing notes on relevant indicator species, as well as overstorey keystone species and structure as well as any other taxa which were of relevance to the assessment.
- Discuss mapped riparian units and their representation in the study area and surrounds

Within the study area, 15 vegetation units have been mapped. Vegetation units C1A and C2A may be sub-regionally significant as it is currently mapped as part of the occurrence of the Weeli Wolli Springs PEC. The rest of the units are discussed in more detail in section 6.1.Table 5-11 below provides detailed descriptions of riparian vegetation throughout the Study Area.

Table 5-10: Table of riparian vegetation units and their representation throughout the Study Area

Vegetation Units	Drainage Size Classification	Representation
C1A	Moderate	Restricted
C2A	Moderate	Restricted
C2B	Moderate	Restricted
C3A	Major	Restricted
C3B	Moderate	Well represented
C4C	Moderate	Restricted
C4Bx-1	Moderate	Restricted
C3C	Moderate	Restricted*
C4B	Moderate	Well represented
C4Bx-2	Moderate	Restricted*
C5B	Moderate	Well represented
C5C	Moderate	Well represented
CF-X1	Major to Moderate	Well represented
CF-X2	Moderate	Well represented
CF-X3	Moderate	Well represented

Restricted* based on the comparison of targeted and detailed mapping completed compared to database records which contains broader baseline vegetation mapping units.

5.4.1. Influence of the Major Drainage classification

The term “Major Drainage” can typically be applied to drainage systems in a very ad-hoc fashion when attempting to classify their size as part of baseline studies. As a result, any nominal biodiversity significance ratings which are linked to such a classification are often disproportionately applied to the drainage systems in question.

The automatic assertion of ‘High’ significance, which is often applied to drainage systems classed as “Major” drainage systems via baseline surveys, is quite simplistic and is predominantly linked to the Hamersley subregion based ‘Ecosystems at Risk’ (EAR) listings provided as part of the 2002 biodiversity audit of WA (DEC 2002). Not only is this audit relatively out of date, but the “Other Ecosystems at risk” component referred to here is considered to be made relatively redundant by the proceeding PEC listings process which was introduced after the audit, and thus is likely defunct. This guidance continues to be used as the basis for considering the significance of other potentially lower significance communities not captured by the TEC and PEC listings, and still has some merit. However the EAR list does not provide any detailed descriptions, and as such is poorly guided. Furthermore, while this list calls out “All major Ephemeral watercourses” as an EAR, it does not provide a definition for major drainage/watercourses, leading to the term being inconsistently applied. As mentioned, this approach is quite simplistic, and generally counterproductive to a proper assessment of significance which takes into account the flora and vegetation values of the drainage in question. While previous biodiversity studies in the area did map a number of major drainage features, this study utilised a drainage classification (Appendix E) which instead classified some of those systems as clearly moderate in size and reporting catchment. In addition, the automatic rating of ‘High’ significance for major drainage systems was not found to be consistent with the on-ground survey findings and alternative, more measures approaches to assigning significance were utilised.

Table 5-11: Descriptions of riparian vegetation throughout the Study Area

New Riparian code	Vegetation Label	GDV likelihood Rating	Drainage size classification	Position within creek Profile	Mesophyte/hydrophyte indicator species presence/abundance	Mesic Indicator Species – Relevant Notes	Notes relevant to degrees of restriction
C1A	*M. argentea* & *Eucalyptus camaldulensis* open forest over mixed mesic shrublands	High to Very High	Moderate Drainage* (< 450km2)	Low Flow Channels and banks (and Permanent to Semi Permanent Pools)	**High:** *Cullen leucanthum, Stylidium weeliwolli* **Moderate-High**: *Eleocharis geniculatus, Tinospora smilacina, Sonchus hydrophilus, Ammannia baccifera* (A) **Moderate:** *Gossypium sturtianum* (A), *Dodonaea lanceolata* (A), *Abutilon amplum, Schoenoplectus subulatus* **Low:** *Acacia coriacea* subsp. *pendens, Atalaya hemiglauca, Eulalia aurea* (A), *Stemodia grossa* (A), *Cyperus vaginatus* (A), *Typha Domingensis* (A), *Chara* spp. (A) **Keystone**: *Melaleuca argentea* (A-Mature) plus *Eucalyptus camaldulensis* (A) & *E. victrix* (I)	Reduced diversity of hydrophytes, and some question marks as to how permanent the surface water features are at this feature may reduce the overall significance of the feature. Reduced hydrophyte diversity likely a product of consistent cattle disturbance in and around the permanent water feature.	Small-Moderate scale GDE feature, which supports a known *permanent pool, plus some potentially semi-permanent pools. Restricted as it possesses a relatively permanent aquatic habitat. Indicators: 0 very high 2 High.
C2A	*E. camaldulensis* Woodland (to open forest) over open mesic shrublands (Scattered young *Melaleuca argentea* present in some locations)	High	Moderate Drainage* (< 450km2)	Low Flow Channels and banks	**High**: *Cullen leucanthum* (U). **Moderate-High:** *Tinospora smilacina* (U), *Sonchus hydrophilus, Ammannia baccifera* (A). **Moderate**: *Gossypium sturtianum* (A), *Dodonaea lanceolata* (A), *Abutilon amplum, Schoenoplectus subulatus.* **Low:** *Acacia coriacea* subsp. *pendens, Atalaya hemiglauca, Eulalia aurea* (A), *Stemodia grossa* (A), *Cyperus vaginatus* (A), *Typha Domingensis* (U), *Chara* spp. (U). **Keystone:** *E. camaldulensis* (A) *E. victrix* (S), *M. argentea* (U)		Small-Moderate scale feature; potentially supports a semi-permanent pool and persistent pool pools, Classified as a PEC due to link with WWS. Indicators: 0 very high 1 High.
C2B	Small *E. camaldulensis* Woodland over mixed open shrubland with *Melaleuca bracteata*.	Moderate	Moderate Drainage (< 150km2)	Low Flow Channels and banks	**Moderate-High:** *Melaleuca bracteata* (A). **Moderate:** *Gossypium sturtianum*. **Low:** *Cyperus vaginatus* (C), *Eulalia aurea* (C), *Melaleuca glomerata* (C). **Keystone:** *Eucalyptus camaldulensis* (woodland) plus *E. victrix* (S).	Associated with a significant Heritage site/artefact scatter. Substantial calcite precipitation present on the western terraces adjacent to	Low number of mesophytes

New Riparian code	Vegetation Label	GDV likelihood Rating	Drainage size classification	Position within creek Profile	Mesophyte/hydrophyte indicator species presence/abundance	Mesic Indicator Species – Relevant Notes	Notes relevant to degrees of restriction
						the creek, as well as indications that GW seepage from the accent slopes is likely.	
C3A	*Eucalyptus camaldulensis* subsp. *obtusa*, *E. victrix* woodland over open Semi-Mesic Shrublands with *Triodia longiceps*	Moderate + To Moderate-Low (variable)	**Major Drainage* (< 500-750km2)**	Low Flow Channels and banks	**Moderate**: *Abutilon amplum, Atalaya hemiglauca*, **Low:** *Acacia coriacea* subsp. *pendens*, *Cyperus vaginatus, Dodonaea lanceolata*. **Keystone Species:** *Eucalyptus camaldulensis*, *Eucalyptus victrix* (woodland).	Some impact already experienced in this area due to dewatering of HD1 - Some reduced mesic diversity likely already experienced.	Moderate - due to position on WWC main and position on Major drainage
C3B	*E. camaldulensis* & *E. victrix* woodland (variable) over mixed open shrubland with *Petalostylis labicheoides*	Low TO Low + (variable) Phreatophytes likely to part relate to small seasonal Fractured rock aquifers	Moderate Drainage (< 200-400km2)	Low Flow Channels and banks	**Moderate-High***: *Tinospora smilacina* **Moderate-Low:** *Abutilon amplum, Atalaya hemiglauca, Gossypium sturtianum* var. *sturtianum*, *Cyperus cunninghamii* subsp. *cunninghamii* (S), *Cyperus iria* (S), **Low**: *Stemodia grossa* (C), *Cyperus vaginatus* (C), **Keystone Species:** *Eucalyptus camaldulensis, E. victrix* (woodland).		Increased due to position on WWC, topographic confinement of channel (increasing structural complexity) and position on Moderate + drainage

New Riparian code	Vegetation Label	GDV likelihood Rating	Drainage size classification	Position within creek Profile	Mesophyte/hydrophyte indicator species presence/abundance	Mesic Indicator Species – Relevant Notes	Notes relevant to degrees of restriction
C4C	*Corymbia ferriticola* and *Eucalyptus victrix* low open woodland over mixed open shrubland with rocky influence.	Low + - Persistent pool Pool	Moderate Drainage (< 200-400km2)	Low Flow Channel and fringing rocky banks	**Moderate:** *Tinospora smilacina* (I), **Moderate-Low:** *Atalaya hemiglauca* (C), *Cyperus cunninghamii* subsp. *cunninghamii* (I), **Low**: *Eulalia aurea* (A), **Low (-)**: *Clerodendrum floribundum* var. *floribundum* (I), *Gossypium sturtianum* var. *sturtianum* (C), **Keystone:** *Corymbia ferriticola* (C) & *Eucalyptus victrix* (C) (open woodland)	Tier 3C based on structure and keystone species, 3B+ based on mesophyte diversity and presence of Persistent pool waterbody.	Increased due to position on WWC, topographic confinement of channel and position in incised valley, position on Moderate + drainage and presence of persistent pool water body and associated ephemeral aquatic fauna assemblages.
C4Bx-1	*Eucalyptus victrix, E. xerothermica* woodland	Low +	Moderate Drainage (< 150km2)	Low Flow Channels and banks	**High:** *Acacia ampliceps* (I), **Moderate-High**: *Melaleuca bracteata* (C), **Moderate-Low**: *Abutilon amplum, Gossypium sturtianum* var. *sturtianum* (C), *Dodonaea lanceolata*, *Typha domingensis*, **Low (-):** *Acacia coriacea* subsp. *pendens*, *Cyperus vaginatus* (C), *Eulalia aurea* (C), *Melaleuca glomerata* (C), *Stemodia grossa* (C), *Stylobasium spathulatum* (C-A), **Keystone Species:** *Eucalyptus victrix* (A) & *E. xerothermica* (A) (Woodland), plus *E. camaldulensis* (S-I)	Keystone species structure alone, potentially 3A based on elevated mesic diversity and common presence of *M. bracteata* in the system, Tier Class reflects combination of structure and Mesophyte diversity. EC also common	Increased due to position on lower WWC, but predominantly the elevated persistence of water within the creek channel and substrates due to basalt basement geology and the associated elevated/cryptic mesophyte diversity and structure which comes with this hydrology.
C3C	*Eucalyptus victrix, E. xerothermica* and *E. camaldulensis* woodland	Low +	Moderate Drainage (< 150-300km2)	Low Flow Channels and banks	**Low (-)**: *Eulalia aurea* (C), **Keystone Species:** *E. victrix*. (A - Woodland), plus *E. camaldulensis* (S)	Others likely present - Only one sampling site for this unit	Increased due to position on Moderate drainage and increased local abundance of E. camaldulensis.

New Riparian code	Vegetation Label	GDV likelihood Rating	Drainage size classification	Position within creek Profile	Mesophyte/hydrophyte indicator species presence/abundance	Mesic Indicator Species – Relevant Notes	Notes relevant to degrees of restriction
C4B	*Eucalyptus victrix* low open woodland over *Acacia citrinoviridis* tall open shrubland.	Very Low	Moderate Drainage (< 250-350km2)	Low Flow Channels and banks	**Moderate - Low:** *Atalaya hemiglauca*, *Cyperus iria* (S), *Cyperus squarrosus* (S), *Schoenoplectiella laevis* (S), **Low (-):** *Stemodia grossa* (C), *Eulalia aurea* (C), **Keystone Species:** *Eucalyptus victrix* (A - Woodland), Plus *E. camaldulensis* (S-I)		Nominally attributed well represented due to riparian classification
C4Bx-2	*Eucalyptus victrix, E. xerothermica* low open woodland over variable tall open shrubland of *Acacia aneura* complex.	Low -	Moderate Drainage (< 150-300km2)	Low Flow Channels and banks	**Moderate:** *Gossypium sturtianum* var. *sturtianum* (C), **Moderate-Low:** *Cyperus difformis, Cyperus iria, Abutilon amplum,* **Low (-):** *Cyperus vaginatus, Eulalia aurea* (C), Stemodia grossa (S), **Keystone:** *Eucalyptus victrix* & *E. xerothermica* (A) (Woodland) plus *E. camaldulensis* (S)		Nominally attributed well represented due to riparian classification

5.5. GDV likelihood mapping

For the current development proposal, mine pit dewatering (to allow safe mining) is not required, and groundwater abstraction volumes will be relatively small and limited to supporting some of the operational requirements of the development. For this reason, a non-exhaustive assessment of GDV likelihood was completed for the riparian vegetation units and relevant creek reaches mapped across the Study Area. This involved completing an assessment of the likelihood that both; individual mapped vegetation units, or specific reaches within units, would support vegetation with a potential for dependence on groundwater. While this was predominantly guided by the depth to water recorded for the broader aquifers monitored across the Study Area (see Table 5-1 for supporting groundwater info), it was also guided by structural and floristic vegetation characteristics, particularly where communities possessed an elevated diversity and abundance of mesophytic and hydrophytic indicator species (as per the Riparian ecohydrological assessment framework presented in (Table 3-3). Furthermore, where these two evidence streams have partially or completely contradicted each other, the likelihood rating was moderated based on the likelihood that alluvial aquifers or small scale generally perched groundwater sources may be helping to support vegetation. While such situations generally determine that there is low likelihood of developmental abstraction influencing vegetation, they remain included in the process as catchment changes or similar can be influential in such groundwater sources and thus ongoing vegetation condition.

Generally speaking, particularly within the development envelope area (i.e., on PMC and upper reaches of WWC) the likelihood that creek reaches and their associated mapped vegetation units would support GDV or potential GDV was quite low. This is not only because of the average depth to groundwater for the broader aquifers in the locality was beyond 30m, but also because the riparian vegetation density was generally quite sparse. Noting that the GDV ratings were not always purely linked to the boundaries of vegetation units, but that in many cases they were attributed to specific reaches of mapped units, a summary of the ratings or range of ratings applied to different vegetation units is provided in Table 5-12. As a result, to get a more complete comprehension of the distribution of GDV likelihood, these ratings are best viewed via the GDV likelihood mapping. The results of the GDV likelihood mapping are presented in Figure 5-7 to Figure 5-10.

Table 5-12: Summary of GDV likelihood ratings for each vegetation unit in the Study Area

Vegetation Unit	Relevant Notes	GDV likelihood Rating
C1A	Groundwater discharge known to occur; broader aquifers shallow here.	'High - Very High'
C2A	Broader aquifers shallow here.	'High'
C2B	Extensive calcite deposition on west banks/terrace, basalt basement relatively shallow. Evidence of somewhat persistent surface water pools here.	'Moderate'
C3A	Rating variable depending on reach.	'Moderate +' & 'Moderate-Low'
C3B	Rating variable depending on reach. Phreatophytes likely to be partly related to small seasonal perched or fractured rock aquifers, particularly in the east where basement is shallow.	'Low' & 'Low +'
C3C		'Low +'
C4C	Persistent pool pool present.	'Low +'
C4Bx-1	Basalt basement generally shallow.	'Low +'
C4Bx-2		'Low -'
C4B		'Very Low'
C5B		'Very Low -'
C5C		'Very Low'
CF-X1	Rating variable depending on reach. *Higher rating where on "Major Drainage" in the east of the Study Area, lower where on moderate drainage in the west of the Study Area. Floodplain unit, GDV potential typically low.	'Moderate', 'Moderate - Low' & 'Low-Very Low'
CF-X2	Floodplain unit - GDV potential generally low.	'Very Low'
CF-X3	Floodplain unit - GDV potential generally low.	'Very Low -'

* In many cases this higher rating occurring on the floodplain is due to the proximity of the floodplain to the core riparian zone and lateral simplification of the likelihood polygons when mapping. However, where vegetation is associated with major drainage or similar this can also be due to the presence of high flow channels with increased likelihood of access to relevant groundwater sources.

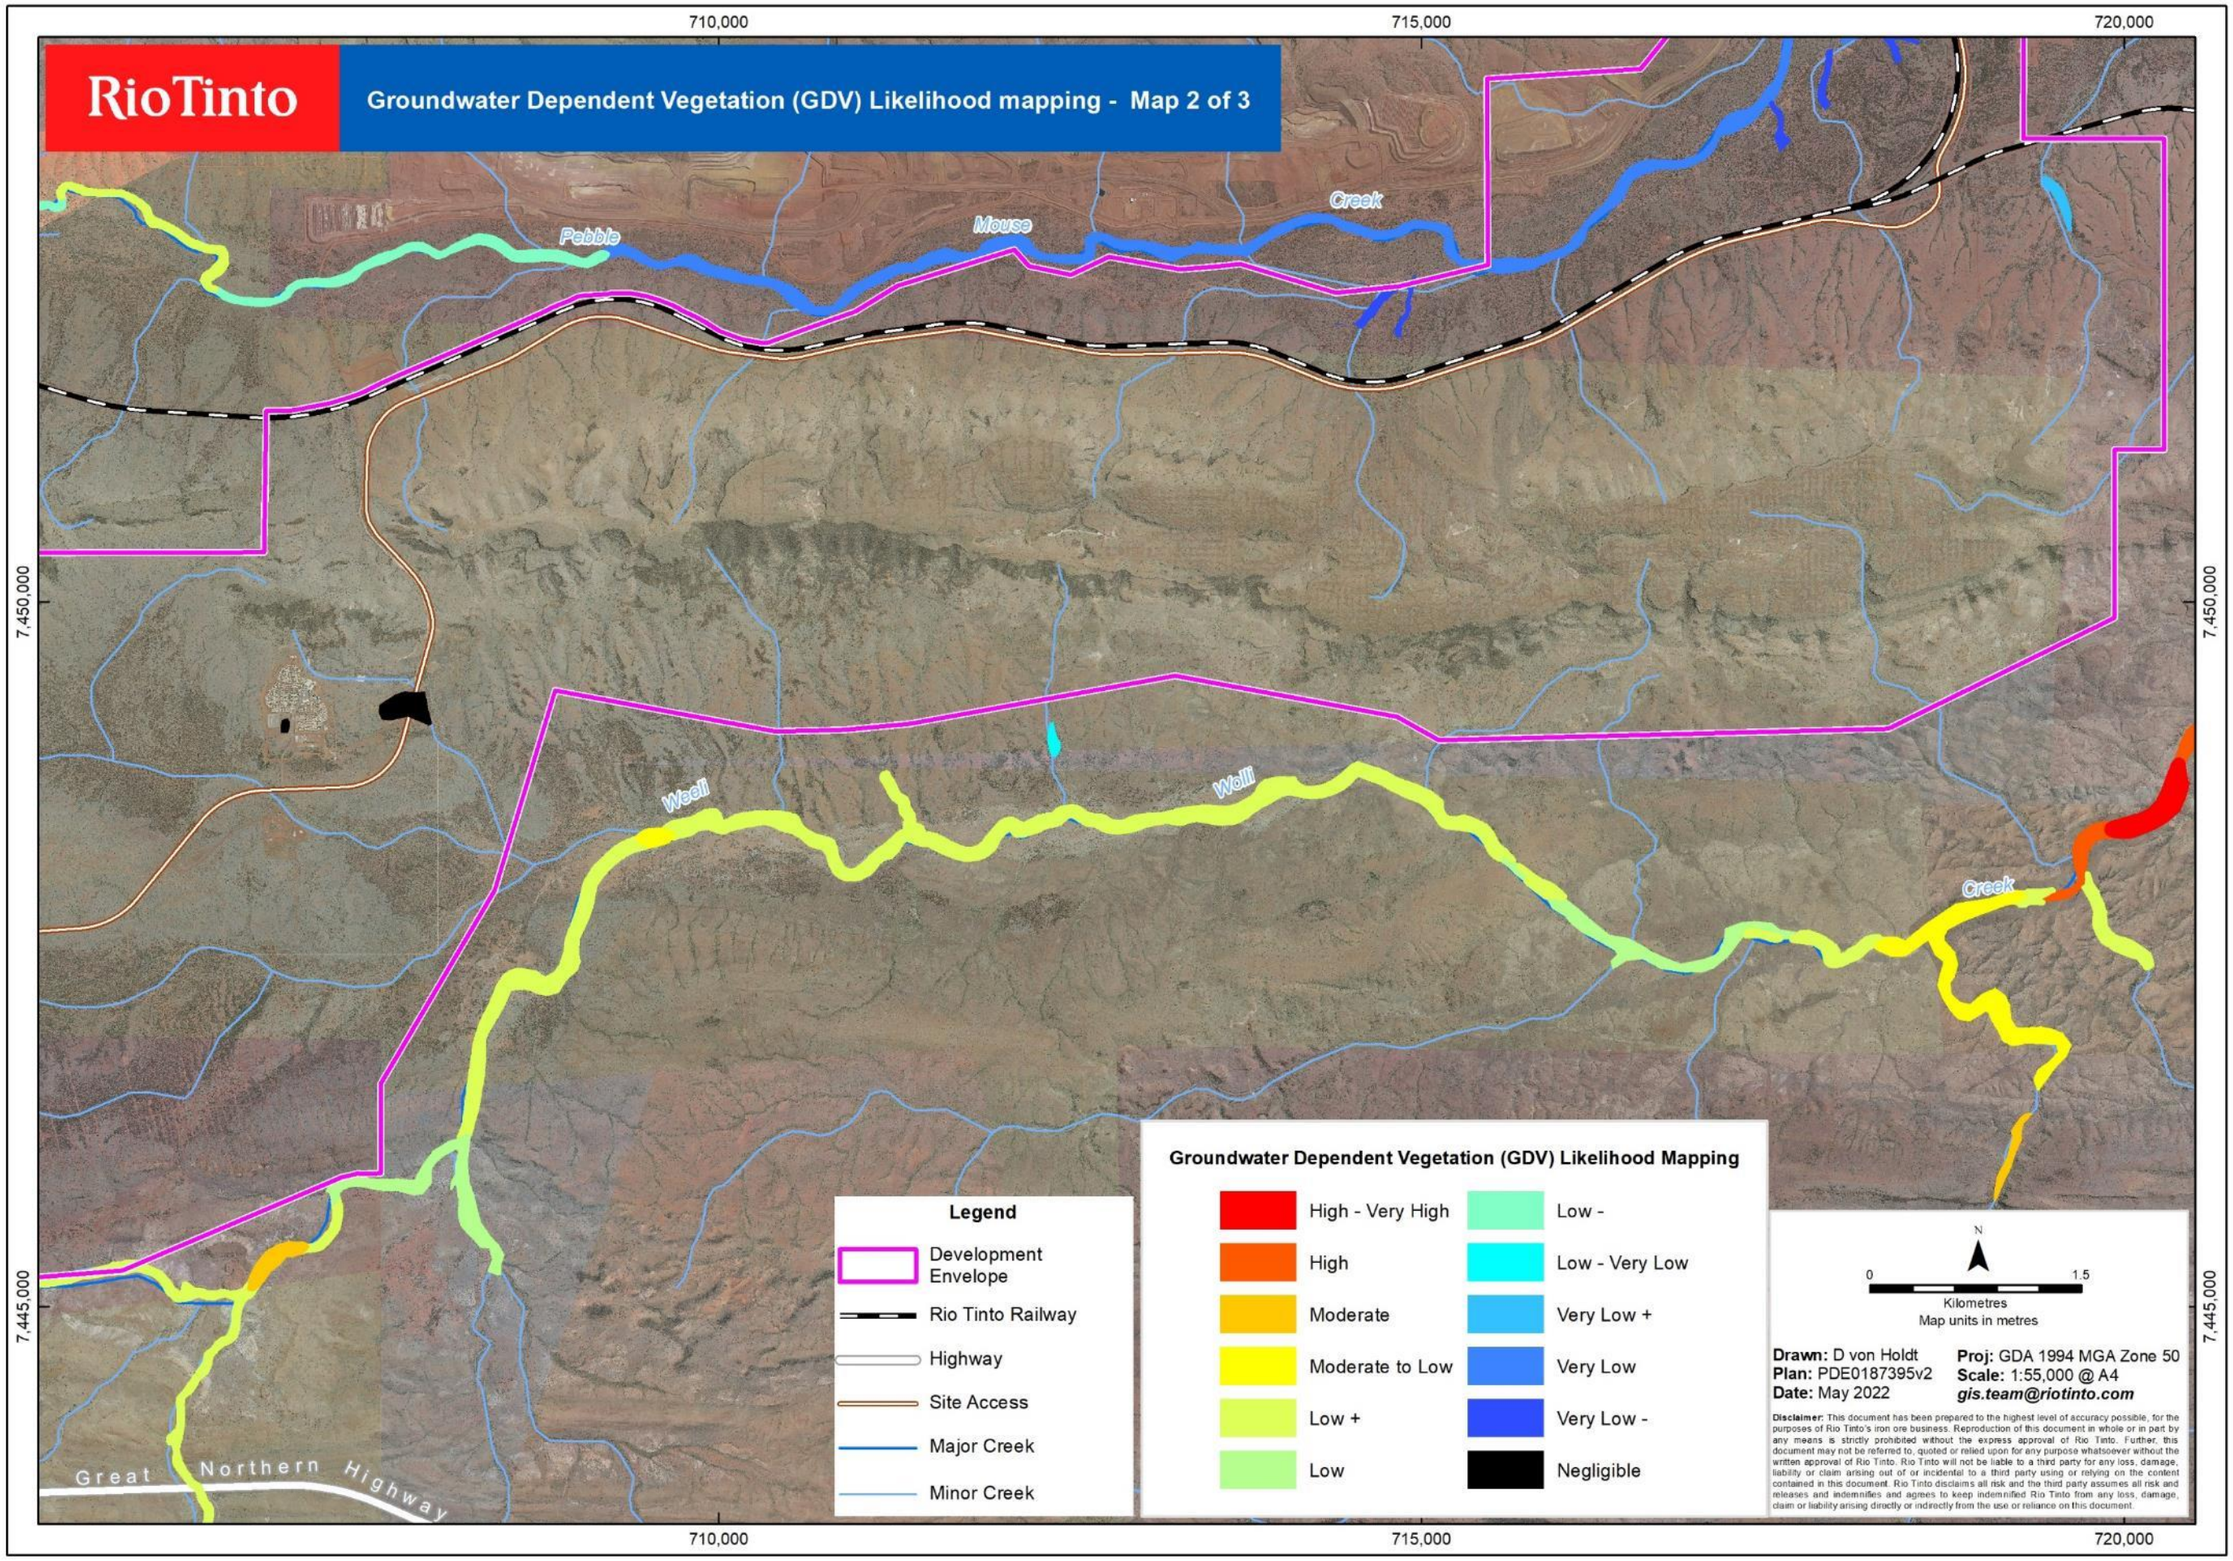

Figure 5-9: Groundwater Dependent Vegetation (GDV) likelihood mapping in the central area of the Study Area (Map 2 of 3)

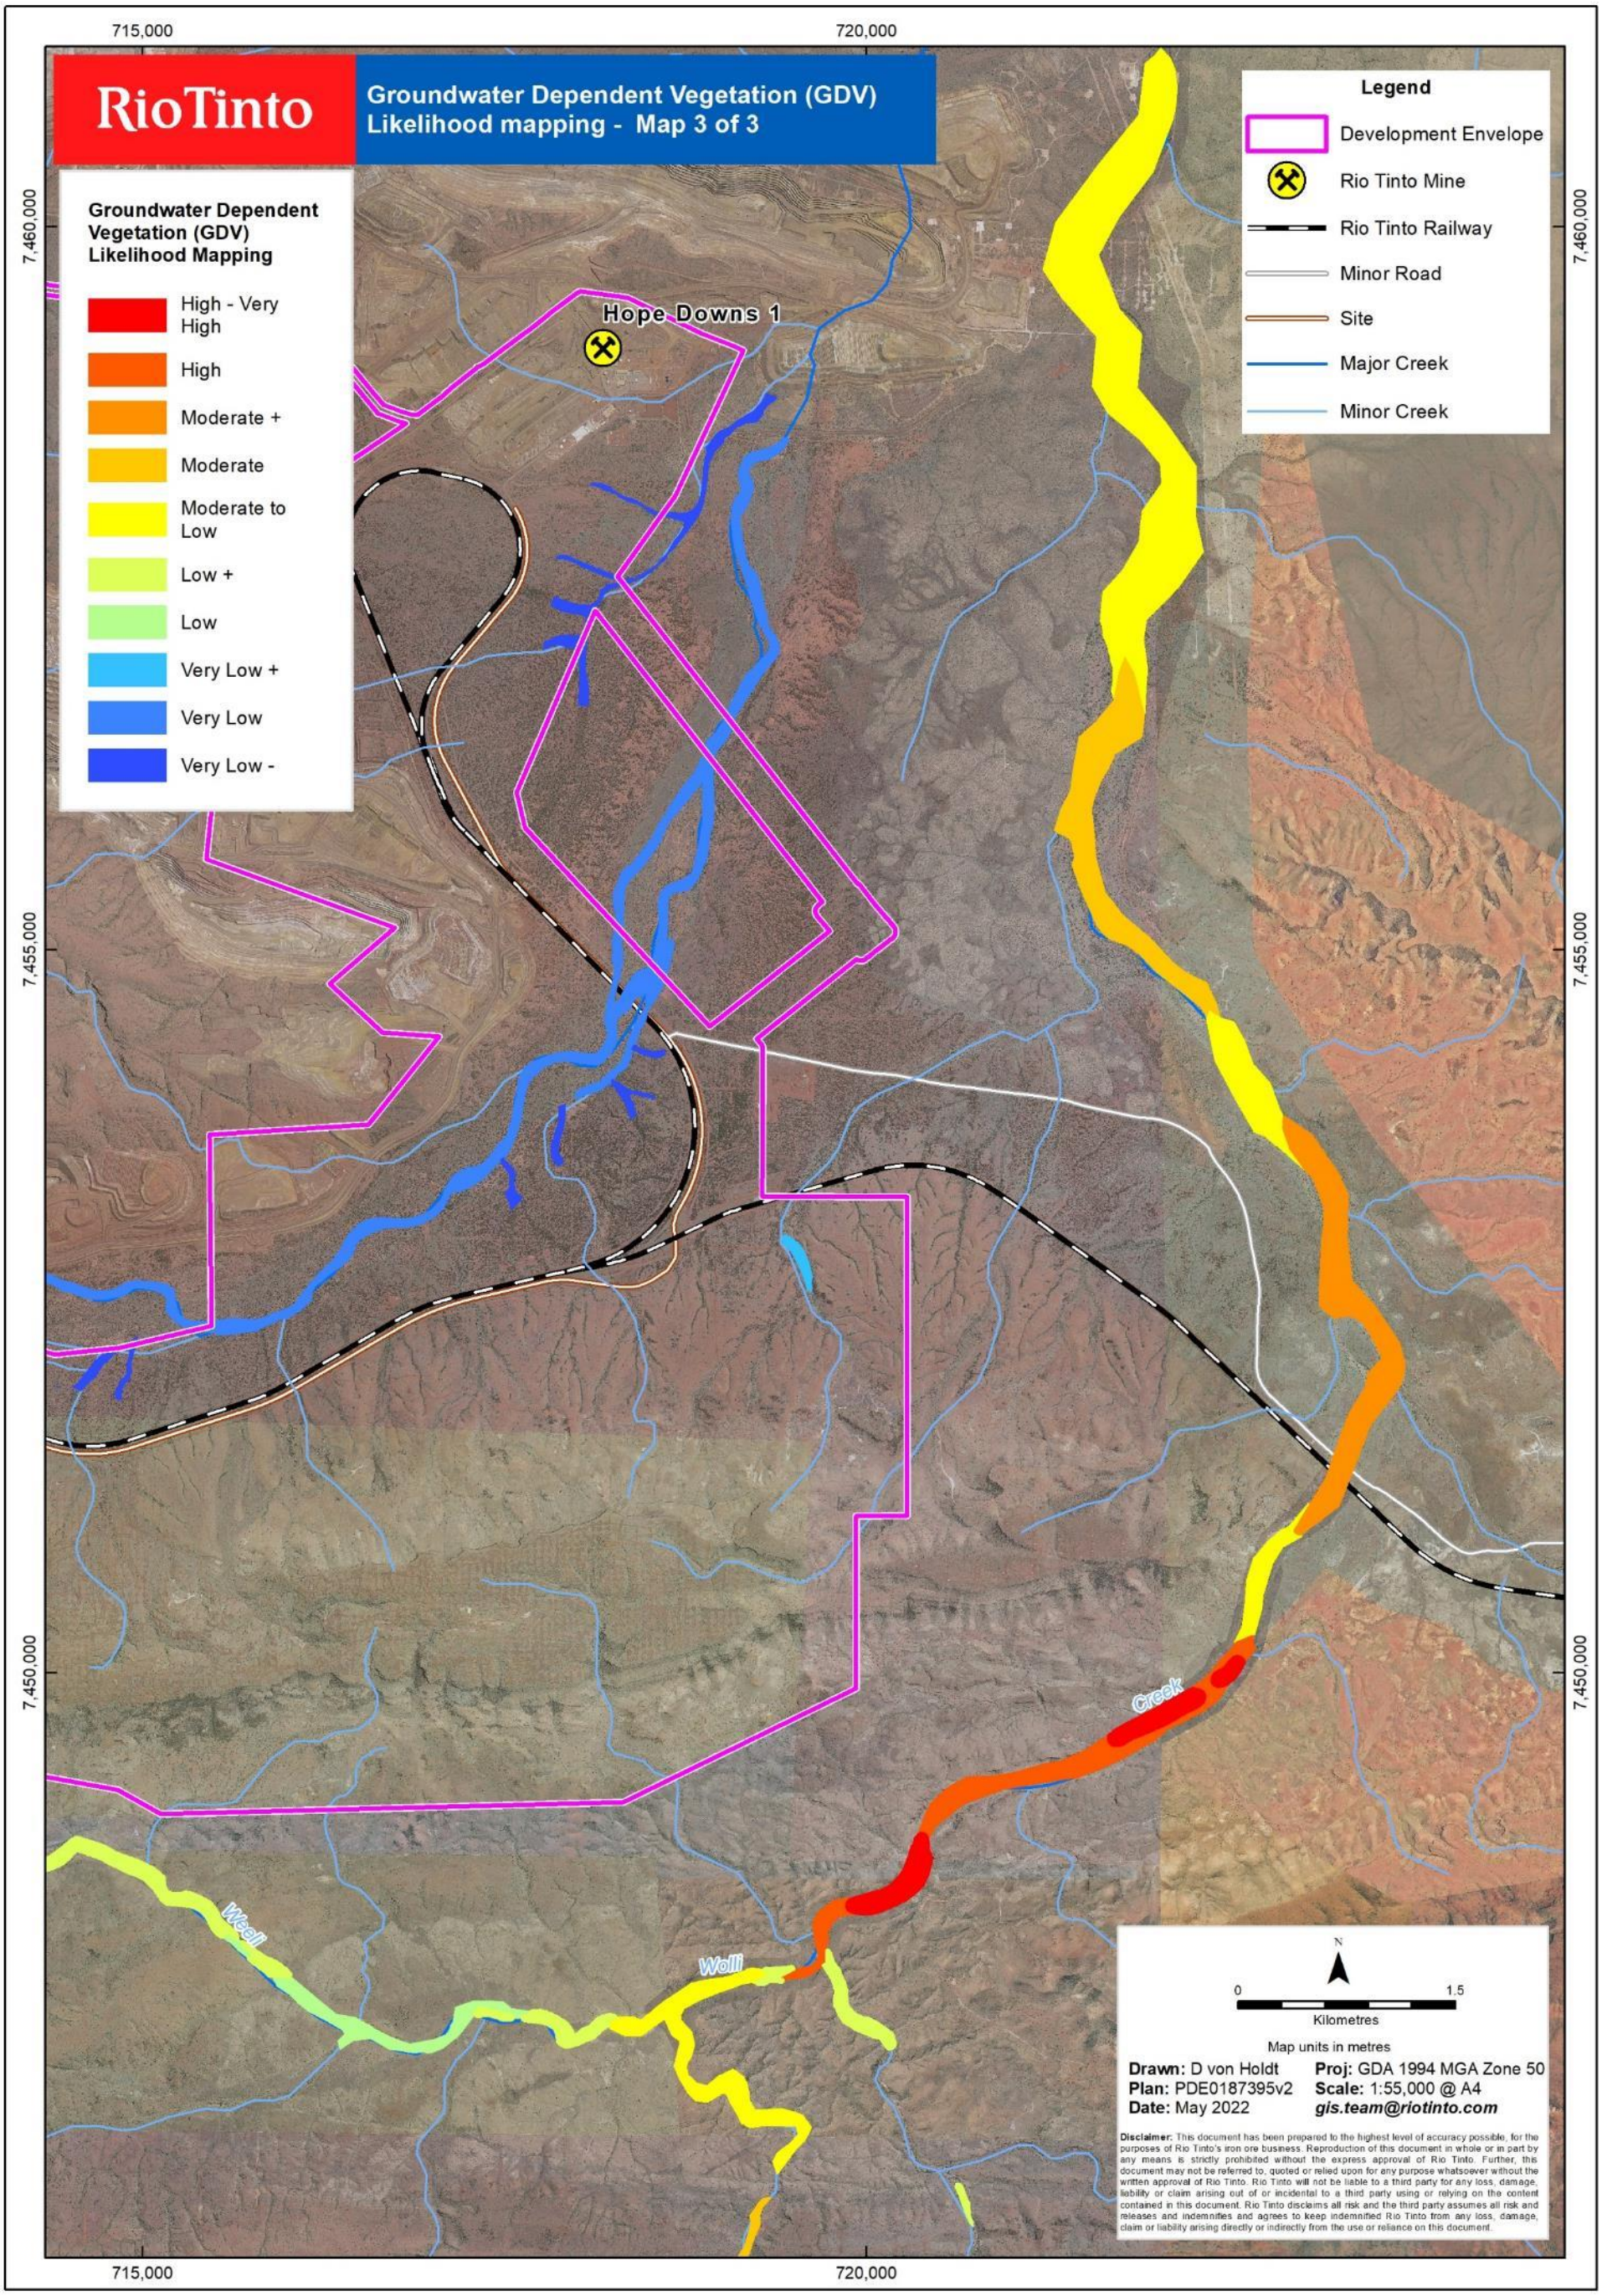

Figure 5-10: Groundwater Dependent Vegetation (GDV) likelihood mapping in the east of the Study Area (Map 3 of 3).

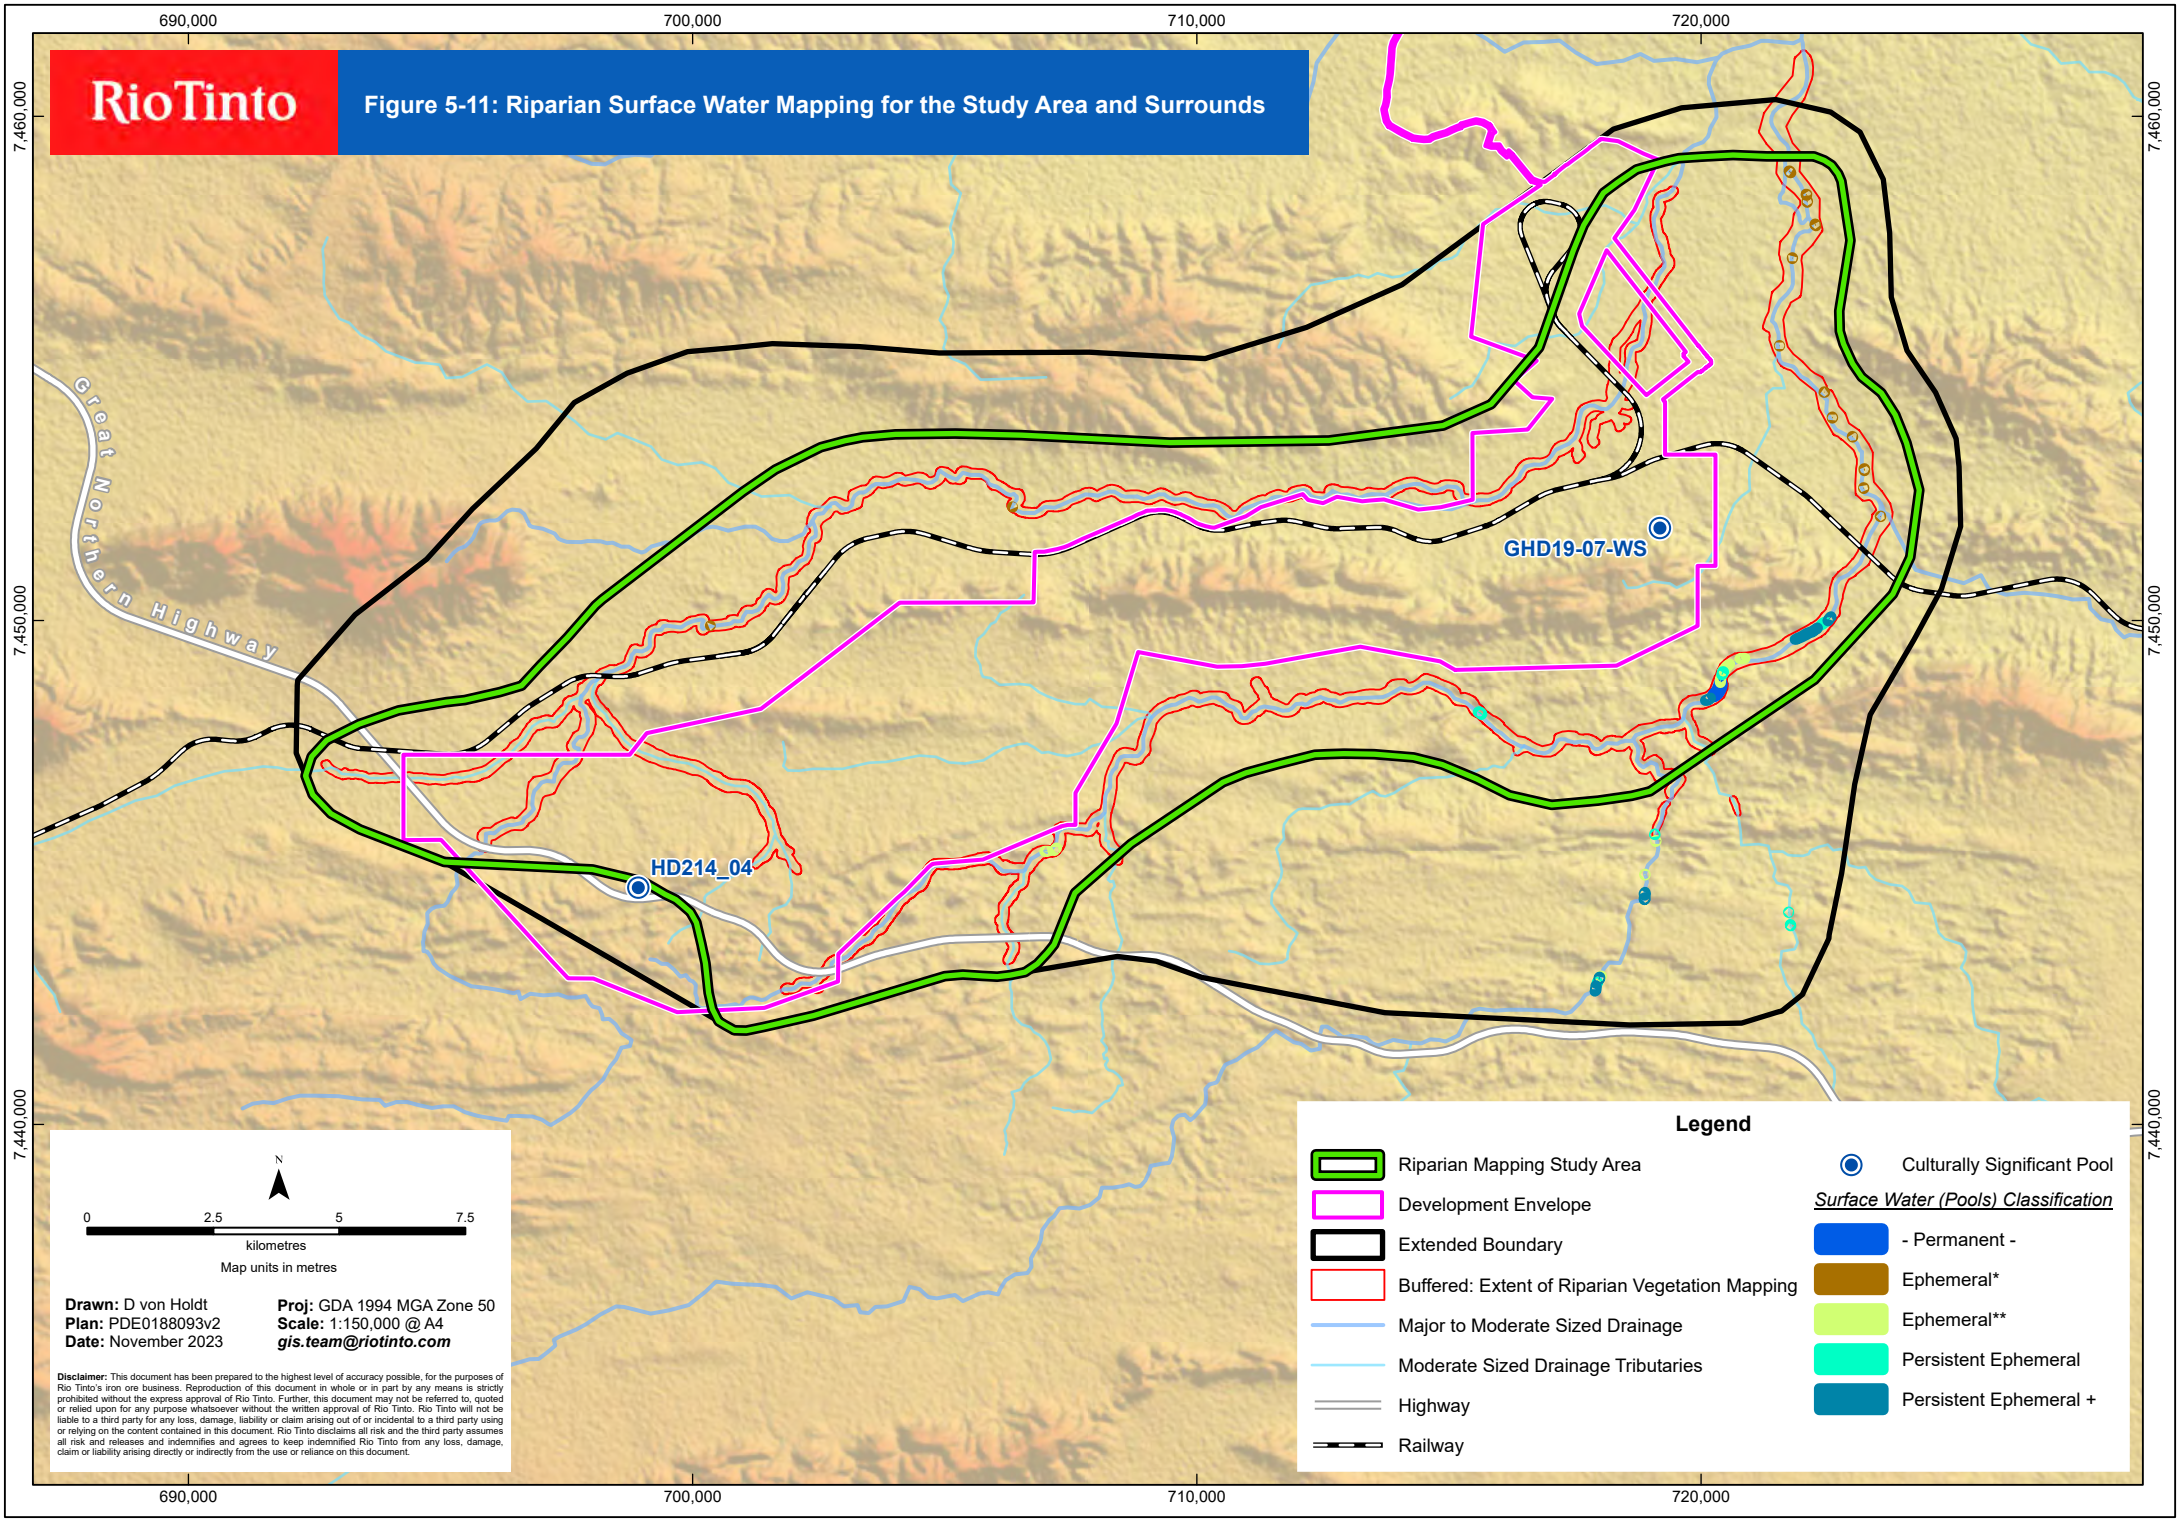

5.6. Surface water mapping

To give context to the riparian vegetation mapping, associated values/degrees of restriction and the GDV likelihood mapping; it was determined that a relatively robust surface water mapping process should be conducted. This was done to give an indication of the likely abundance and nature of surface water within and directly surrounding the riparian mapping Study Area. Areas directly around the Study Area were also considered in this process as surface water was relatively absent in the Study Area (beyond “Ben’s Oasis”), at least in terms of persistent surface water formations.

The surface water mapping process used a persistence map which utilised a water mapping index called Sentinel Water Mask (SWM), as well as multiple (generally 2-3) appropriately timed and appropriately detailed/contrasting aerial image sources from Google earth and ESRI. These data sources were combined with recent and historical field observations, as well as relevant groundwater monitoring data to provide a combined picture of the likely distribution of areas where surface water more persistently accumulates in the environment. While the terminology ephemeral and persistent pool features quite consistently in the results for the Study Area, the terms shouldn’t be thought about too literally. Ultimately ephemeral surface water could be everywhere at the right time of the year, and so the ephemeral and persistent pool terms are referring to areas more likely to support surface water outside of the wet season (and potentially early winter), or well into and potentially beyond the winter period in the case of Persistent pool surface water. Technically semi-permanent pools are classified as pools which intermittently or seasonally have connection to the groundwater table, and permanent pools most likely have effective permanent connection with or discharge from the groundwater table. It should be noted that this study did not consider ephemeral and greater classed pools which occur in minor drainage systems; particularly those surface water features which occur in incised drainage within the surrounding ranges. These types of features are not capable of being detected by such a combination of data sources as they are typically too small and too hidden within unfavourable topography to be able to be confidently detected and assessed.

A more detailed description of the methods used is provided in Section 4.6 along with relevant details surrounding the different surface water/pool classifications. The resulting surface water mapping is presented within Figure 5-11 and the detailed data to support this mapping is presented in Appendix H:. The extended area of consideration (outside of the riparian mapping Study Area) with respect to surface water mapping is also indicated in Figure 5-12, in order to show the full scope of this mapping product.

In general, there was a relative dearth of persistent surface water within the Study Area, with even the lower class “ephemeral” type pools being generally absent within the proposed development areas on larger drainage systems focused on by this study. The majority of locations typically supporting persistent or greater surface water pools being present in the “Ben’s Oasis” area. In this area the broader groundwater table becomes shallow and is seemingly forced over, or discharges out of the outcropping Wittenoom Formation which occurs in the area. Outside of this area, persistent surface water occurred where drainage passed through larger incised gully/gorge type formations. This is particularly true in the Wonmunna area, just southeast of the Study Area, but included in the surface water mapping area. In this area several features occur where tributaries of WWC repeatedly cross Hamersley/Fortescue geological group boundaries, through incised range formations. The resulting conditions mean that at several locations, persistent surface water pools occur over favourable basement outcropping. These features are not only clearly visible late in the dry season on multiple aerial photographs and as well as some being know aquatic fauna sampling sites; but some are also known to support traditional engravings, likely testament to their value as water sources.

6. Discussion

6.1. Restricted riparian flora and vegetation values within the Study Area

Restricted riparian flora and vegetation values within the current Study Area are generally restricted to the “Ben’s Oasis” area (C1A, and C2A units)This is predominantly due to “Ben’s Oasis’s” relatively permanent aquatic and hyporheic habitats, and elevated diversity of mesophytic and hydrophytic taxa, which are supported by the shallow groundwater system present in the area.

In addition, vegetation on those reaches of WWC which are classed as major drainage which support major drainage habitats/vegetation with elevated productivity and slightly mesic understory compositions (C3A vegetation unit) have been classified as limited in extent., and so too. Importantly a substantial part of this vegetation unit and drainage area, has experienced significant groundwater drawdown since the inception of mining at the HD1 mine site. Fortunately, the portions of this area which historically benefited from some level of groundwater access (still relatively low at ~10-15 mbgl pre-mining) also occur on a significantly large and deep calcrete formation. Tree health monitoring and systematic FPS investigations in this area have so far indicated no significant decline in tree health or increase in tree mortality, and as such the more obvious conclusion has been 2 fold;

1. Continual rehydration of calcrete formations in the area has ensured sufficient stored water availability for local GDV and FPS; and
2. For riparian vegetation on major drainage, groundwater in the realm of 10+mbgl typically wont form a meaningful portion of environmental water requirements, and as such seasonal flow regimes and related vadose recharge and temporary surficial aquifers will be more influential.

To a lesser degree the C4C, C2B, C3A and C4Bx-1 units on moderate drainage of WWC also warrant consideration to be limited in extent. Units C3C and C4Bx-2 have been delineated as restricted due to comparison to database records which contain broader baseline vegetation mapping units (Appendix ,B). The remainder of the vegetation in the Study Area is relatively well represented in the locality and broader sub-region.

“Ben’s Oasis”

The “Ben’s Oasis” spring area is currently mapped as a small representation of the “Weeli Wolli Spring Community” PEC (Priority Ecological Community). A detailed description of this PEC is provided in Appendix I:. The main Weeli Wolli spring occurrence is listed based on the associated riparian woodland and forest associations being unusual as a consequence of the composition of the understorey. Specifically, the sedge and herb-field communities that fringe many of the pools and associated water bodies along the main channels of WWC are highly restricted within Pilbara riparian Communities. The spring and creekline are also noted for their relatively high diversity of stygofauna and because it supports a very rich microbat assemblage including a threatened species.

With respect to the riparian flora values of WWS, a number of key, highly restricted hydrophytes are unique and important components of the WWS riparian community. These are:

- *Cladium procerum*;
- *Stylidium weeliwolli*;
- *Fimbristylis sieberiana*;
- *Imperata cylindrica*;
- *Fimbristylis oxystachya*;
- *Fimbristylis rara*; and others.

Furthermore a number of restricted understorey mesophytes are abundant in the midstorey of this community; These are:

- *Acacia ampliceps*;

- *Cullen leucanthum*;
- *Atalaya hemiglauca*; and
- *Gossypium sturtianum*.

While the broader Weeli Wolli Springs (WWS) have been listed as a PEC for many reasons, including stygofauna, aquatic invertebrates, ant/spider/beetle, and bat assemblages, it's likely that the diversity of highly restricted and hydrologically sensitive hydrophytes recorded at the spring are potentially the most important indicators of long-term hydrological stability at the site and thus the quality of riparian habitats it supports. The riparian flora diversity known to occur in the WWS area is likely to be a reliable indicator for the provision of riparian habitats capable of supporting similarly diverse/restricted faunal assemblages.

Importantly, in comparison to the WWS area, the "Ben's Oasis" area only supports one of the key hydrophytes listed above; *Stylidium weeliwolli*. Based on the riparian classification presented and used in this study, the C1A vegetation dominated zones of "Ben's Oasis" are considered to be restricted.

The significantly reduced hydrophyte diversity present at "Ben's Oasis" suggests that the site may not be a good quality representation of the Weeli Wolli Springs PEC. More accurately, the reduced hydrophyte diversity of "Ben's Oasis" casts doubts around the long term stability of the aquatic habitats of the spring and ultimately the reliability of the groundwater discharge at the site. This doubt is also partly supported by initial remote sensing analyses (mean monthly aggregate NDVI trends across the full Landsat catalogue) which focus on the insights which can be gained from the long term seasonal phenometrics of vegetation-cover/hydration at the "Ben's Oasis" aquatic GDE. In addition, the aquifer system and associated hydrogeological conceptualisation which "Ben's Oasis" is dependent upon is different to the WWS aquifer system. Detailed work is currently being undertaken to better understand the conceptualisation of the site and the characteristics of the groundwater system and associated discharge. The outcomes of this work will be important for enabling a better understanding of the nature of the riparian habitats present at the spring.

6.2. Significant riparian flora and vegetation values within the greater Hope Downs 1 Area

Weeli Wolli Springs

Outside of the Study Area and more broadly within the Greater Hope Downs 1 locality, significant riparian flora and vegetation values predominantly occur in the Weeli Wolli Springs area. Weeli Wolli Springs represents a large scale aquatic GDE formation which also supports substantial obligate terrestrial GDV formations and refugial and relictual flora throughout the springs.

6.3. Significant riparian vegetation values in the broader locality

The distribution of significant riparian vegetation aquatic GDE features in the broader locality are Mindy Mindy Springs which is approximately 25 km ENE of "Ben's Oasis", and 21 km ESE of WWS, Munjina Gorge Springs feature which lies approximately 75 km NW of "Ben's Oasis" and 65 km NW of WWS. Both of these features are sub-regionally and likely regionally significant features with some of the highest diversity of restricted and likely relictual/refugial hydrophytic and mesophytic taxa in the Pilbara.

For other limited features (i.e., broadly obligate riparian vegetation) the following are likely to possess some relatively permanent aquatic GDE type habitats within proximity to the Study Area:

- Yandicoogina gorge springs occur approximately 11.5 km northwest of WWS, and 25 km north of "Ben's Oasis";
- west of Yandicoogina gorge are two other, less well known features occurring 12 and 20 km, located further along the northern edge of the Hancock Range which these features are positioned along.
- Similar quality features (some of which are generally larger) occur approximately 19km to the east of WWS on a number of the tributaries of Mindy Mindy Creek. Some other similar quality, but now impacted features occur on parts of Marillana Creek to the northwest of WWS, next followed by a small scale but significant feature on an unnamed creek approximately 30 km's to the east of WWS.

- Finally, to complete the list of upper Tier 2 features in a 50 km radius of the Study Area, the lower reaches of Coondiner creek support significant aquatic GDE's along with some of the smaller tributaries to Coondiner in that area also supporting somewhat lower quality but poorly known features.

6.4. Key findings of the study

The majority of the riparian communities in the Study Area well represented and highly ephemeral riparian ecosystems, occurring on moderate to occasionally major sized drainage and supporting open woodlands to woodlands of mixed facultative phreatophytic species. Within the development envelope, riparian communities are primarily restricted to moderate sized and highly ephemeral drainage systems supporting open woodlands (predominantly low stature) of the low level facultative phreatophyte *Eucalyptus victrix*. Within the Study Area, the spring, aquatic GDE and supported riparian communities at the unofficially named "Bens Oasis" represent the only high value riparian features. Despite this, the value of this area is likely to be significantly lower than that of the nearby WWS's, regardless of the changes realised there in recent years.

Across the Study Area, significant riparian flora was generally lacking outside of a group of mesophyte/hydrophyte species detected in the "Ben's Oasis" area. Instead, riparian habitats across the Study Area generally only supported relatively well represented, low abundance populations of low to moderate level mesophytes. Within the development envelope, only low-level riparian indicator species were detected and in general this was coupled with a dominance of ephemeral riparian taxa, particularly within PMC. Instead, the P2 flora species *Aristida lazaridis* was the significant riparian flora species of the development envelope, and its presence in the area is likely connected to the delivery of fine basaltic origin sediments from the upstream Fortescue Group lithologies which is has a demonstrated affinity with.

Vegetation mapped by this study as representing GDV of moderate to high likelihood was also lacking within the Study Area outside "Ben's Oasis". In fact, all the vegetation units mapped to occur within the development envelope were classed as 'Low' GDV likelihood and lower. These conclusions find support in the existing groundwater monitoring data within the area. Consequently, the applied likelihoods and the trends they indicate are reasonable.

In terms of restriction, mapped vegetation communities (C1A, and C2A units) in the Study Area were found to be restricted, and as such confirms that the "Ben's Oasis" area clearly supports the most significant riparian ecosystems of the Study Area. Furthermore, this feature and particularly the extent of the C1A vegetation unit and more specifically where this unit occurs around the only permanent pool confidently recorded in the Study Area; represents the only clear aquatic GDE occurrence in the Study Area. Other vegetation communities with may be locally restricted are C4C, C4Bx-1, C3c and C4Bx-2, this could be attributed to detailed nature of the targeted mapping completed for purpose of the Riparian Values Assessment.

The remainder of the riparian vegetation units mapped in the Study Area are well represented, containing highly ephemeral and sparsely vegetated units.

The riparian surface water mapping exercise which was conducted provided insight into restricted habitats. In general, outside the cluster of features present in the "Ben's Oasis" area, significant and persistent surface water was generally lacking from the riparian Study Area. Furthermore, while some persistent pool water bodies are mapped in the Study Area (outside "Ben's Oasis"), they are both outside of the Development Envelope and likely to be supported by surface water or very small scale and seasonal flow derived surficial aquifers which are highly unlikely to be influenced by the proposal.

None of the riparian ecosystems and communities mapped within the development envelope as part of this study possess features/characteristics which are consistent with them representing 'Major Drainage'. The previous guidance, which has often led to major ephemeral drainage features automatically being assigned at least high local significance ratings (Section 5.4.1), is deemed inappropriate for the level of rigour and detail which this assessment applies. Instead, catchment characteristics, ecohydrological trends and flora and vegetation survey data was considered when classifying the drainage and allocating ecotypes and representation of these units in the area. .

7. Conclusions

The riparian ecosystems and associated vegetation communities distributed throughout the Study Area, and particularly within the development envelope, are generally well represented locally and sub-regionally. They are well represented and possess 'Low' to Very-Low' potential to represent GDV/GDE's.

The "Ben's Oasis" area supports an aquatic GDE and is a restricted ecosystem in the Study Area, and likely possessing sub-regional significance. This feature sits outside the development envelope and hydrogeological modelling suggests it is disconnected from the hydrological influence of the proposal. The resulting hydrological risk posed to this riparian system is considered to be very low. While the "Ben's Oasis" feature is linked to WWS through its PEC status, the floristic composition present is substantially different to that at WWS's in key life-forms, particularly with respect to highly sensitive aquatic macrophytes and hydrophytes. This fact may determine that the risk faced by changes to the aquatic habitats there is significantly reduced.

Persistent surface water is generally absent from the development envelope and apart from various water bodies and a permanent pool in the "Ben's Oasis" area, they are highly restricted within the Study Area.

Based on these conclusions and distribution of riparian vegetation in the Study Area, the activities associated with the proposal do not appear to pose a significant risk to riparian ecosystems and values in the Hope Downs 1 area. Indirect risks to riparian ecosystems in the area are predominantly restricted to weed incursion, dust deposition and disturbance related fine sediment transport/deposition. These risks are considered low within the Study Area, but dust and particularly sediment deposition should be considered where infrastructure is placed close to tributaries of WWC which occur upstream of "Bens Oasis".

Appendix A: Vegetation structure and condition scale used for vegetation description and mapping formulated within this study.

Vegetation Structure and Condition Scale

Vegetation Structural Classes*

Stratum	Canopy Cover (%)				
	70-100%	**30-70%**	**10-30%**	**2-10%**	**<2%**
Trees over 30 m	Tall closed forest	Tall open forest	Tall woodland	Tall open woodland	Scattered tall trees
Trees 10-30 m	Closed forest	Open forest	Woodland	Open woodland	Scattered trees
Trees under 10 m	Low closed forest	Low open forest	Low woodland	Low open woodland	Scattered low trees
Shrubs over 2 m	Tall closed scrub	Tall open scrub	Tall shrubland	Tall open shrubland	Scattered tall shrubs
Shrubs 1-2 m	Closed heath	Open heath	Shrubland	Open shrubland	Scattered shrubs
Shrubs under 1 m	Low closed heath	Low open heath	Low shrubland	Low open shrubland	Scattered low shrubs
Hummock grasses	Closed hummock grassland	Hummock grassland	Open hummock grassland	Very open hummock grassland	Scattered hummock grasses
Grasses, Sedges, Herbs	Closed tussock grassland / bunch grassland / sedgeland / herbland	Tussock grassland / bunch grassland / sedgeland / herbland	Open tussock grassland / bunch grassland / sedgeland / herbland	Very open tussock grassland / bunch grassland / sedgeland / herbland	Scattered tussock grasses / bunch grasses / sedges / herbs

Leeper). Melbourne.

Vegetation Condition Scale*

E = Excellent (=Pristine of BushForever) Pristine or nearly so; no obvious signs of damage caused by the activities of European man.
VG = Very Good (= Excellent of BushForever) Some relatively slight signs of damage caused by the activities of European man. For example, some signs of damage to tree trunks caused by repeated fire, the presence of some relatively non-aggressive weeds such as **Sonchus oleraceus* or **Cucumis* spp., or occasional vehicle tracks.
G = Good (= Very Good of BushForever) More obvious signs of damage caused by the activities of European man, including some obvious impact on the vegetation structure such as that caused by low levels of grazing or by selective logging. Weeds as above, possibly plus some more aggressive ones such as **Cenchrus* spp.
P = Poor (= Good of BushForever) Still retains basic vegetation structure or ability to regenerate to it after very obvious impacts of activities of European man, such as grazing, partial clearing (chaining) or frequent fires. Weeds as above, probably plus some more aggressive ones such as **Cenchrus* spp.
VP = Very Poor (= Degraded of BushForever) Severely impacted by grazing, very frequent fires, clearing or a combination of these activities. Scope for some regeneration but not to a state approaching good condition without intensive management. Usually with a number of weed species including very aggressive species such as **Prosopis* spp.
D = Completely Degraded (= Completely Degraded of BushForever) Areas that are completely or almost completely without native species in the structure of their vegetation; ie. areas that are cleared or 'parkland cleared' with their flora comprising weed or crop species with isolated native trees or shrubs.

* Based on Trudgen M.E. (1988). A Report on the Flora and Vegetation of the Port Kennedy Area. Unpublished report prepared for Bowman Bishaw and Associates, West Perth.

Appendix B: Area calculations for Riparian Vegetation Units mapped inside and outside of the Development Envelope.

Riparian Vegetation Units	Astron Vegetation Unit	Degrees of Restriction	Vegetation Extent Inside the Development Envelope (ha)	Vegetation Extent Outside Development Envelope in Study Area (ha)	Total Area (ha)	Amount of similar vegetation in RTIO regional database (ha)
C1A	-	Restricted	0	6.48	6.48	2616.81
C2A	-	Restricted	0	23.74	23.74	1,466.58
C2B	-	Restricted	0	2.89	2.89	392.11
C3A	-	Restricted	0	106.85	106.85	140.3
C3B	-	Well represented	0	98.95	98.95	7,556.01
C4C	-	Restricted	0	1.41	1.41	1.41
C4Bx-1	D5	Restricted	10.29	39.29	49.58	2537.63
C3C	-	Restricted*	0	21.15	21.15	381.94
C4B	D4	Well represented	28.24	58.42	86.66	14,996.45
C4Bx-2	D4	Restricted*	18.34	69.97	88.31	381.94
C5B	D5	Well represented	63.72	17.27	80.98	20,253.46
C5C	-	Well represented	24.5	15.92	40.43	14,428.97
CF-X1	-	Well represented	284.09	284.09	284.09	1408.87
CF-X2	D7	Well represented	46.53	404.07	450.60	9561.37
CF-X3	D7	Well represented	185.16	309.74	494.90	9,782.50

Restricted* based on the comparison of targeted and detailed mapping completed compared to database records which contains broader baseline vegetation mapping units.

Appendix C: Restriction ratings of mapped riparian units

Vegetation unit	In/Out of proposed Development Envelope	Occurrences	Drainage Size Classification	PREC ecotype	Representation of PREC type & community	Notes to support determination of restriction
C1A	**Outside**	**1**	**Moderate**	**Type 2**	**Restricted**	**A spring community (PREC type 2A) mapped occurrence of the Weeli Wolli Springs PEC and supports a GDE.**
C2A	**Outside**	**1**	**Moderate**	**Type 2**	**Restricted**	**Associated with a spring (PREC type 2C), associated with a mapped occurrence of the Weeli Wolli Springs PEC, supports GDV.**
C3A	Outside	1	Major	**Type 3**	**Restricted***	Major Drainage, associated with the main tributary of Weeli Wolli Creek.
C2B, C4C	Outside	2	Moderate	**Type 3**	**Restricted***	Restricted communities, C2B: restricted riparian assemblage associated with a heritage site and supports atypical ecohydrology, C4C: restricted riparian assemblage associated with a deeply incised gully, and an uncommon riparian vegetation assemblage.
C4Bx-1	Inside	1	Moderate	**Type 3**	**Restricted***	Moderate drainage dissecting basalt ranges which increase residence time of surface water flows. Additionally, riparian assemblages with an abundant cover of *Melaleuca bracteata* in the understorey are uncommon in the Pilbara.
C3B		1	Moderate	**Type 3**	Well Represented	Common riparian unit on moderate drainage dissecting Hamersley group geology
C3C	Outside	1	Moderate	**Type 3**	Well Represented	Common riparian unit on moderate drainage dissecting Hamersley group geology
C4B, C4Bx-2	Inside	2	Moderate	**Type 3**	Well Represented	Common riparian unit on moderate drainage dissecting Hamersley group geology
C5B, C5C	Inside	2	Moderate	**Type 4**	Well Represented	Common riparian unit on moderate drainage dissecting Hamersley group geology
CF-X1	Outside	1	Major to Moderate	**Type 4**	Well Represented	Common floodplain unit on moderate drainage dissecting Hamersley group geology
CF-X2, CF-X3	Inside	2	Moderate	**Type 4**	Well Represented	Common floodplain unit on moderate drainage dissecting Hamersley group geology

Appendix D: Vegetation units, descriptions and mapping notes for all Riparian vegetation types mapped as part of the current study. Note: Sites from historical surveys are indicated by: [1] Astron (2020), [2] Mattiske (2008), [3] Mattiske (2010), [4] Mattiske (2019).

Final Unit (Standardised riparian classification)	Initial New Vegetation Unit	Previous Unit (Astron or Mattiske)	Landscape Position	Vegetation Description			Sites	Notes
				Upper Strata	Middle Strata	Lower Strata		
C1A	D14a	MR-C4 /STC-C1[2]	Creekline	*Eucalyptus camaldulensis* subsp. *obtusa*, and *Melaleuca argentea* open forest	*Acacia citrinoviridis, A. coriacea* subsp. *pendens, Melaleuca glomerata* tall open shrubland over *Dodonaea viscosa* subsp. *mucronata*, *Gossypium sturtianum* var. *sturtianum*, *Stylobasium spathulatum* shrubland	**Cenchrus ciliaris*, *Themeda triandra* tussock grassland and *Cyperus vaginata* isolated sedges	WWJ2 WW22[4], WW23[4]	Represents the key areas supporting clearly obligate terrestrial GDE/GDV vegetation (i.e., OPS dominated/co-dominated) fringing areas of permanent to persistent-ephemeral surface water associated with the feature informally named "Ben's Oasis" (and the associated outlier occurrence of the Weeli Wolli springs PEC), and its associated on-flow areas. Also represents areas where mature *Melaleuca argentea (*OPS) *populations form the* dominant overstorey species.
C2A	D14b	MR-C4 /STC-C1[2]	Creekline	*Eucalyptus camaldulensis* subsp. o*btusa* woodland (variable - at times open wood/open forest)	*Acacia citrinoviridis*, *A. coriacea* subsp. *pendens*, *Melaleuca glomerata* tall open shrubland over *Dodonaea viscosa* subsp. *mucronata*, *Gossypium sturtianum* var. *sturtianum, Stylobasium spathulatum* open shrubland	*Cyperus vaginata* isolated sedges and **Cenchrus ciliaris*, *Eulalia aurea, Themeda triandra* isolated tussock grasses	CB09[2]	Represents dense likely obligate phreatophytic GDE/GDV vegetation (i.e., FPS dominated) fringing and associated with "Ben's Oasis" (and its broader on-flow areas) and locally shallow groundwater, but generally not possessing *Melaleuca argentea* or possessing it purely as an associated species (generally young). Instead FPS species generally dominate the overstorey.
C2B	D12	D4[1] and MF-C5[3]	Creekline	*Eucalyptus camaldulensis* subsp. *obtusa* woodland	*Melaleuca bracteata, Acacia bivenosa, Gossypium sturtianum* var. *sturtianum* open shrubland	**Cenchrus ciliaris, Eulalia aurea*, *Themeda triandra* tussock grassland	WW1 MNMH06[1]	Represents a small section of Weeli Wolli Creek adjacent to a significant heritage site, possessing some persistent pool pools, an increased abundance of Eucalyptus camaldulensis and an area possessing *Melaleuca bracteata as a* dominant understorey species
C3A	D15	D4[1] and STC-C1[2]	Creekline	Eucalyptus camaldulensis subsp. obtusa, E. victrix woodland	*Acacia citrinoviridis, A. coriacea* subsp. *pendens*, *Atalaya hemiglauca* tall open shrubland over *Corchorus crozophorifolius, Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186), *Acacia pyrifolia* low open shrubland	*Themeda triandra, *Cenchrus ciliaris, Bothriochloa ewartiana* open tussock grassland to tussock grassland and *Triodia longiceps* open hummock grassland	WW11, WW12-V&R, WW13-V&R, WWM1 CB01[2], CB04[2], CB07b[2], HC069[2]	Represents the north-east extent of Weeli Wolli Creek in the Study Area, where several tributaries of WWC combine and the riparian zone receives more than 500km2 of catchment such that the creek represents Major Drainage.
C3B	D4	STC-C1 / ATA-C2[2]	Creekline	*Eucalyptus camaldulensis* subsp. *obtusa*, *E. victrix* woodland (+/- Open woodland)	*Petalostylis labicheoides, Androcalva luteiflora, Gossypium sturtianum* var. *sturtianum* open shrubland	*Themeda triandra, Eulalia aurea*, (**Cenchrus ciliaris*) tussock grassland	WW3, WW4, WW5, WW6, WW7-R	Central reaches of the western arm of Weeli Wolli Creek within the Study Area and occurring on the downstream side of the Fortescue formation catchment boundary.
C3C	D11	D4[1]	Creekline	*Eucalyptus victrix* (*E. camaldulensis* subsp. *obtusa*), *E. xerothermica* woodland (to open woodland)	Mulga (*Acacia aneura* complex) tall open shrubland over *Acacia pyrifolia, Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186), *Petalostylis labicheoides* open shrubland	*Bothriochloa ewartiana, Cymbopogon ambiguus, Eulalia aurea* tussock grassland	PM4	Represents reaches of the south-western extent of Pebble Mouse Creek within the Study Area where *Eucalyptus camaldulensis* subsp. *obtusa* occurs more commonly but still doesn't represent a dominant overstorey species (*E. victrix* remains dominant). Also includes some sections of this creek not previously mapped or that were previously mapped as a combined floodplain without a separate core riparian zone unit identified
C4B	D9	D4[1]	Creekline	*Eucalyptus victrix* low open woodland (to woodland)	*Acacia citrinoviridis* (*Atalaya hemiglauca*) tall open shrubland over *Corchorus crozophorifolius, Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) low open shrubland	*Themeda triandra, Eulalia aurea*, **Cenchrus ciliaris* tussock grassland	PM7, Veg7 GH23[1], GHMNBE010[1], GHMNDR01[1], GHMNDR02[1], GHMNDR06[1], BHD-RJCF, SFJ-RMMG	Represents the downstream reaches and north-east extent of Pebble Mouse Creek within the Study Area. Most of this reach of pebble mouse creek generally possesses quite a broad floodplain (500-700m wide) and more braided low-flow/high-flow channel assemblages such that the riparian community in the low-flow channels being quite sparse and strongly ephemeral such that E. victrix is generally dominant but sparse and of low stature in the overstorey.
C4C	D18	STC-C1 / ATA-C2[2]	Gorge	*Corymbia ferriticola* and *Eucalyptus victrix* low open woodland	*Acacia pruinocarpa, A. citrinoviridis* and *Atalaya hemiglauca* tall shrubland over *Dodonaea pachyneura* open shrubland	*Eulalia aurea, Themeda triandra, Aristida burbidgeae* very open tussock grassland	WW7-V	Represents an approximately 300m stretch of Weeli Wolli Creek which dissects a ridgeline (Hamersley formation) such that the creekline is within an incised-gully/gorge for a short distance. In the most incised portion of the gully a persistent-ephemeral pool is supported over the rocky basement and associated boulder field. Presence of *Cyperus cunninghamii* and *Tinospora smilacina are indicative of the somewhat mesic conditions in the gully.*

Final Unit (Standardised riparian classification)	Initial New Vegetation Unit	Previous Unit (Astron or Mattiske)	Landscape Position	Vegetation Description			Sites	Notes
C5B	D5	D5[1]	Creekline	*Eucalyptus xerothermica* low open woodland	*Petalostylis labicheoides, Acacia maitlandii, A. pyrifolia* tall open shrubland to tall shrubland over *Androcalva luteiflora* scattered shrubs	*Triodia longiceps* very open hummock grassland to open hummock grassland with *Themeda triandra, Eulalia aurea* open tussock grassland to tussock grassland and **Bidens bipinnata* scattered herbs	GH01[1], SC002[2], H20093, H20103, HD22[1], HDR18[1], MNMH28[1]	Vegetation mapping consistent with Astron (2020). Represents vegetation on smaller tributaries (lower end moderate sized drainage) of the upper reaches (eastern tributary) of Pebble mouse Creek, where low flow channels are not well defined and as such a broad floodplain/channel assemblage is mapped as a combined riparian vegetation unit.
C5C	D8	D8[1]	Creekline	*Eucalyptus xerothermica* scattered low trees to low open woodland	*Acacia aptaneura, A. catenulata* subsp. *occidentalis* tall open shrubland to tall open scrub	*Triodia pungens* scattered hummock grasses to very open hummock grassland with *Themeda triandra* very open tussock grassland to open tussock grassland		Vegetation mapping consistent with Astron (2020). Represents vegetation on smaller tributaries (lower end moderate sized drainage) of the upper reaches (western tributary) of Pebble mouse Creek, where low flow channels are not well defined (or possess similar vegetation) and as such a broad floodplain/channel assemblage is mapped as a combined riparian vegetation unit.
C4Bx-1	D13	D4 /D5[1] and MF-C5[3]	Creekline	*Eucalyptus victrix, E. xerothermica* woodland (to open woodland)	*Petalostylis labicheoides, Gossypium sturtianum* var. *sturtianum, Androcalva luteiflora* (*Melaleuca bracteata* +/-) open shrubland	*Eulalia aurea, Bothriochloa ewartiana, Themeda triandra* tussock grassland	MN01, Veg2 HD17[1], HD18[1], MNMH02[1], GH04[1], H2061[3], H2093[3], H2103[3], H2109[3], H2118[3]	Represents the south-west extent of Weeli Wolli Creek in the Study Area where *Melaleuca bracteata* sporadically occurs as a dominant understorey species. Also contains *Melaleuca glomerata*
C4Bx-2	D10	D4[1]	Creekline	*Eucalyptus victrix, E. xerothermica* low open woodland (to woodland)	Mulga (*Acacia aneura* complex) tall sparse shrubland over *Acacia pyrifolia, A. dictyophleba, *Vachellia farnesiana, Petalostylis labicheoides* low open shrubland	*Themeda triandra, Bothriochloa ewartiana, Eulalia aurea* tussock grassland	PM1, PM2, PM3, PM5, PM9, Veg4 BHD03, BHD08, HD31[1]	Represents the south-west extent of Pebble Mouse Creek in the Study Area where *Eucalyptus camaldulensis* subsp. *obtusa* sporadically occurs. Also includes some sections not previously mapped or that were mapped as floodplain without a separate creekline unit identified
CF-X1	DF16	D7[1] and ATC-M2[2]	Floodplain	*Eucalyptus xerothermica* (*E. victrix* +/-) scattered trees	Mulga (*Acacia aneura* complex), *A. pruinocarpa* and *A. citrinoviridis* (*A. coriacea* subsp. *pendens* +/-) tall open shrubland (variable)	*Themeda triandra* open tussock grassland and *Triodia pungens* sparse hummock grassland	HC036[2], SJ003[2]	Includes additional areas where no floodplain was previously delineated (middle WWC). Now represents floodplains associated with Weeli Wolli Creek. In the lower areas (Major Drainage), Eucalyptus camaldulensis is a common addition in and around the high flow channels.
CF-X2	DF17	D7[1]	Floodplain	*Eucalyptus xerothermica* scattered low trees	*Acacia aptaneura, A. pruinocarpa* scattered tall shrubs to tall shrubland	*Triodia longiceps* open hummock grassland to hummock grassland and *Themeda triandra*, *Bothriochloa ewartiana*, *Chrysopogon fallax* open tussock grassland to tussock grassland	PM5-R, Veg3, Veg5, Veg6 HC007[2], SFJ38, SFJ-RMMC, SFJ-RMMD	Represents the floodplain associated with Pebble Mouse Creek in the south-west of the Study Area. Differs in the reduced occurrence of *Acacia citrinoviridis*. Some sections not previously mapped within the current targeted area
CF-X3	DF7	D7[1]	Floodplain	*Eucalyptus xerothermica* scattered low trees	*Acacia citrinoviridis, A. aptaneura, A. pruinocarpa* scattered tall shrubs to tall shrubland	*Triodia longiceps* open hummock grassland to hummock grassland	PMJ1 GH22[1], GH25[1], SFJ11, SFJ45, BHD12, SFJ42	Vegetation mapping consistent with Astron (2020), although a restricted distribution of the previous extent confined to the floodplain associated with Pebble Mouse Creek in the north-east of the Study Area. Contains *Acacia citrinoviridis* as a dominant middle strata species

Appendix E: Defining riparian vegetation

The following definitions represent a wholistic approach to defining the riparian zone, key types of riparian vegetation, and particularly riparian vegetation formations of increasingly elevated value which are worthy of increased management and potentially indicative of habitats supporting fauna/biodiversity values of even higher value. The proposed definitions would be appropriate for informing and guiding flora and vegetation surveys, informing Environmental Impact Assessment (EIA), and for inclusion within environmental approval documentation, as they are clear, prescriptive and serve multiple purposes/contexts. For the management of EIA considering clearing limits, it is proposed that riparian vegetation possessing elevated values which should be conditioned is likely to align with the definition of 'riverine' and 'riparian vegetation'.

Riparian zone

The riparian zone within drainage systems generally supports vegetation of increasing structural complexity as compared to surrounding landscapes. A series of drainage profile positions/features are generally present within the riparian zone. The location and characteristics of these profile features relate to fluvial processes such as surface flow regimes and are responsible for establishing key profile positions within the riparian zone. These drainage profile features typically occupy the following positions/zones:

- the bank-to-bank zone, which includes the low flow channel, immediate banks and any internal bench formations.
- the broader bank and adjacent terrace zones which occur beside and away from the main channel, which often support denser vegetation (i.e., riparian vegetation, which may extend beyond the bank).
- the floodplain zone beyond the terrace/bank - where vegetation density clearly transitions to a lower density), which includes:
- the broader floodplain.
- other high flow channels (these features can support higher density riparian vegetation).
- smaller channelised features (e.g claypans, braided channels) which may occur on the floodplain and support differing vegetation.

Internally draining features

These features are characterised by closed topography which generally do not drain externally (to the sea). These internally draining features form floodplain like areas where there is generally a lack of larger channelised fluvial habitats. Higher density vegetation will tend to occur in low points of these internally draining floodplain. In such habitats, where inundation occurs more regularly, ephemeral wetlands or similar can form. The vegetation in these areas can either be classed as 'floodplain and associated' or even 'riparian', depending on the complexity and density of flora species present.

Key types of riparian vegetation

Riverine vegetation

Riverine vegetation are typically highly complex and contain hydrophytic riparian vegetation. Riverine vegetation is likely dependent on either surface water flow regimes or groundwater sources of an elevated frequency or accessibility to provide an elevated level of water availability and persistence. These hydrological regimes help to establish flora diversity, structural complexity, and increased habitat quality, which in-turn supports valuable biotic assemblages such as fauna.

Riverine riparian vegetation will likely support mature stands of obligate phreatophytes such as *Melaleuca argentea* and/or *Sesbania formosa* or other stands of obligate riparian vegetation typically in the form of an open forest of *Eucalyptus camaldulensis*, over a mesic/hydric understorey assemblage. Within riverine vegetation, areas with persistent surface water will possess elevated biodiversity values often including refugial or relictual species, a high diversity of hydrophytic flora comprised of submerged and emergent macrophytes, herbs, and tussock grasses.

Within the Pilbara, this type of riparian vegetation is likely to occur within larger fluvial systems supporting scattered semi-permanent to permanent surface water features, broad multi-channel fluvial profiles, and

broader floodplains. Riverine vegetation is mostly likely to occur in regional drainage features with greater than 1500 km^2 of reporting catchment i.e., rivers or upper-order creek systems. At a minimum, riverine vegetation is likely to occur on major drainage with greater than 500 km^2 of reporting catchment (inclusive of large creeks and above). However, equivalent vegetation formations can also occur on smaller drainage systems, where shallow groundwater sources are responsible for abundant and stable moisture sources.

It is important to note that the riverine equivalent of riparian vegetation will not always be present in larger drainage systems, or other sized drainage systems. More typically, drainage systems will support 'riparian vegetation' and 'floodplain and associated vegetation', these are described below.

Riparian vegetation

In general, riparian vegetation includes vegetation which possesses an elevated degree of structural complexity and value. An annual to intra-annual hydrological regime which supports the establishment, at a minimum* of an open woodland density of approximately 2-10% cover of keystone overstorey riparian species. These keystone species include *Melaleuca argentea* (MA), *Eucalyptus camaldulensis* (EC), *Eucalyptus victrix* (EV), and potentially** *Corymbia candida* or *Eucalyptus xerothermica* over an understorey assemblage typically dominated by mesic perennial riparian species (i.e., at least a selection of species listed in the Pilbara Riparian Ecological Framework (PREF)) over at least a tussock grass co-dominated grass/herb layer.

Riparian vegetation will typically occupy the low flow channel and associated habitats, including both bank, internal benches, and inner terrace positions. As vegetation does not generally grow within the confines of sharp boundaries, blended vegetation or ecotones can occur. In areas where alluvial substrates are highly favourable or where groundwater is shallow or associated with rivers, riparian vegetation as described, can extend to the terrace, high flow channels and even parts of the floodplain. Within larger drainage systems, riparian vegetation can occur on high flow channels dissecting the floodplain, more often occurring when the associated vegetation is aligned with a clearly defined channel or bank formation.

Internally draining settings

In such habitats and where there is generally an absence of larger channelised fluvial habitats, while uncommon, riparian vegetation is most likely to occupy catchment low points which support higher inundation frequencies. These areas can support a higher density of vegetation along with ephemeral wetland flora assemblages due to increased water availability in the landform.

Floodplain & associated vegetation

These vegetation types occur on the floodplain and are much sparser, less complex and are less hydrologically sensitive than drainage derived vegetation. Floodplain and associated vegetation types generally occur on broad floodplain landforms which receive overland surface water flow or standing water accumulation approximately every two or more years. The vegetation assemblage in these areas will generally possess an overstorey component of a much lower density compared to vegetation in the low/high flow channel zones.

The overstorey of these vegetation units will generally be dominated by a lower density of less clearly defined riparian tree species other than MA, EC and EV, such as other *Corymbia* & *Eucalyptus* species, *Corymbia hamersleyana and Eucalyptus xerothermica* and *Acacia citrinoviridis* as well as *Hakea* and other *Acacia* species. This can include a low abundance of less than 2% cover of key riparian species which may also include *E. victrix* and occasionally *E. camaldulensis*. The understorey of these vegetation units will typically include ephemeral to xerophytic perennial species over mixed ephemeral tussock/hummock grassland and/or herblands.

Functionally, vegetation which occurs on floodplains do not typically represent 'riparian vegetation'. However, these areas should still be considered as part of the riparian zone and consequently floodplain vegetation should be considered as 'associated vegetation'.

*In general, riparian vegetation is typically represented by higher density overstorey vegetation (i.e., woodland and above), however this is dependent on the fluvial characteristics of the drainage system being considered. The definition provided in this document aims to include the complete spectrum of riparian vegetation which typically establish on larger drainage systems. Moderate and minor sized drainage systems have been included despite not typically supporting riparian vegetation. In addition, varying density of overstorey

vegetation such as open woodland have been included in this definition as these lower vegetation densities can still possess elevated riparian zone biodiversity values.

**As either co-dominant constituents along with the EC, EV, or MA. Where these species are singularly dominant, they could potentially be representative of riparian vegetation where a clear open woodland (or greater) are associated with surface water channelling or ponding features. There are other keystone mesophytic species listed in the PREF which possess similar characteristics, which could be considered to represent an assemblage of riparian vegetation.

Appendix F: Drainage Classification and Characteristics

Relevant Terms/definitions/References:	*GDV presence (i.e. vegetation clearly representing Groundwater Dependent Vegetation) is typically determined by considering the presence of obligate phreatophytes, obligate phreatophytic vegetation, complex vegetation structure, consideration of surface water regime, and likely proximity of groundwater.
	**Potential GDV presence is generally determined purely by establishing the presence of known keystone Phreatophytes in the drainage system.
	***Focus area is the general portion of the drainage system in question which occurs in the Study Area/area of interest.
	See relevant references below to drainage size classes used here from the surface hydrology discipline.

Drainage Size Ranking	Catchment characteristics		Drainage size criteria & characteristics	
	Headwaters Local /Non-local	Catchment size reporting to focus area***.	Species based Criteria	Presence of 'GDV'* **Or** 'Potential GDV'**
Major Drainage - Regional - (Generally rivers, but can include very large Creeks)	Derived Regionally Upstream catchment distributed regionally (i.e. crossing multiple localities) before reporting to focus area.	~ >1500 km^2 (generally >2000 km^2)	Key indicator species of Major Drainage (i.e. rivers, major creeks, and their associated persistent pools) are present and dominant. Obligate phreatophytes (namely *Melaleuca argentea*) are common and intermittently dominant.	The associated vegetation is almost always representative of potential GDV or possessing reaches clearly representative of GDV.
Major Drainage	Derived Non-locally Headwaters of catchment clearly positioned outside Study Area and locality (i.e. derived non-locally) before reporting-to/intersecting focus area.	~ 400 km^2 - 1500 km^2 (generally >500 km^2 and up to 2000 km^2)	Key indicator species of Major Drainage (i.e. rivers, major creeks, and seasonally wet locations and their associated persistent pools) are present and dominant in at least bed/bank/bench fluvial positions. Typical intermediate-level riparian indicator species are also common.	The associated vegetation is almost always representative of potential GDV, and commonly possesses extensive portions of vegetation clearly representative of GDV.
Moderate drainage	Typically derived locally Headwaters of catchment generally positioned locally (i.e. arising in or in the vicinity of the Study Area) or in some cases extending into areas directly adjacent to the locality.	~ 25 - 400 km^2 (potentially up to 500 km^2)	Typical intermediate-level riparian indicator species are generally dominant. Key indicator species of major drainage are often still present but are generally not dominant and are more typically exhibit a scattered to rare distribution in the riparian zone.	The associated vegetation is often representative of potential GDV and can possesses small portions of vegetation clearly representative of GDV.
Minor Drainage	Derived Locally Headwaters of catchment clearly positioned locally (i.e. arising in the vicinity of the Study Area).	~ <25 km^2 (generally <10 km^2)	A combination of low-level riparian taxa and species typically associated with more xerophytic (to vadophytic) habitats (i.e. hills and/or plains) are generally co-dominant. Typical intermediate-level indicator species are at times present but dominant. Species indicative of major drainage are generally rare to absent.	The associated vegetation is rarely representative of potential GDV. – (While increasingly rare, minor drainage can possess very small portions of vegetation clearly representative of GDV - typically where drainage interacts with variable topography and basement lithology).

Appendix G: Pool Classifications

Water source characteristics		Pool Type	Definition and characteristics
Water source	**Temporal characteristics**		
Groundwater (GW) fed pools (typically regional groundwater)	***Permanently* connected to GW**	**Permanent Pools**	Permanent pools represent surface expressions of groundwater and rely on the groundwater interacting with the surface. They can be either a continuous expression of the groundwater table at the surface or result from groundwater discharge at a specific point or zone of groundwater impedance. In some cases, "permanent" pools may experience short periods of low to no groundwater contribution, typically late in the year, or during drought periods, but in general despite such periods of evaporation are rarely completely emptied. For habitat purposes and biological value, a permanent pool will not necessarily need to meet traditional hydrological size and depth criteria. Instead, it should consistently contain surface water, even if only of a very small spatial extent, and during droughts, at least moist sediments should be evident at the base of the pool. In the arid Pilbara climate, genuinely permanent pools are rare, with many initially considered permanent turning out to be semi-permanent. At a minimum, permanent pools will typically be accompanied by the facultative phreatophyte *Eucalyptus camaldulensis*, and in many cases (but not always) will be associated with populations of obligate phreatophytes such *as Melaleuca argentea* (and at times *Sesbania formosa*). Other useful indicators for interpreting pool permanence include restricted/refugial and relictual submerged and emergent macrophytes, along with key perennial mesophytic shrubs. Ideally, the determination of pool permanence should be made utilising appropriate groundwater data or modelling. Alternatively, pool permanence can be interpreted from the outcomes of regular late season visits over multiple years, combined with aerial imagery or remote sensing analyses. In addition, interpretations of permanence can be supported by the use of key hydrophytic and hyporheic indicator species.
	Seasonally connected to GW	**Semi-Permanent Pools**	Semi-permanent pools are surface water features with seasonal or intermittent connectivity to a groundwater table or source. They are typically present when the groundwater table is above the surface at a location, persisting for a period after the groundwater drops below the surface (annually), either slowly evaporating or quickly disappearing upon disconnection from the groundwater source. Confirming intermittent or seasonal groundwater contribution is important for the identification of this pool type.
Seasonal rainfall derived surface water (SW) pools	**Temporally persistent rainfall derived surface water pools**	**Persistent Pools** **(ephemeral pools with extended hydroperiods)**	Persistent pools are derived from ephemeral rainfall-driven surface water flows but resist quick dissipation or drainage into underlying sediments/lithology or evaporation to the atmosphere. This pool type typically perches over sediments or basement rock and exhibits prolonged existence without rapid evaporation. They persist above the ground surface for extended periods, often throughout and beyond the wet season, and potentially into or throughout winter. In some settings, increasingly persistent examples of this pool type may have some temporary alluvial baseflow contribution. Persistent pool pools tend to remain present due to; consistent shading, impervious sediments supporting prolonged perching, presence over relatively impermeable basement lithology, favourable basement morphology encouraging seasonal perching, location at the base of incised rocky gullies or gorges with topographical and aspect-related shading, and various other topographic or ecophysical circumstances that reduce evaporation and infiltration.

			In some years and settings, persistent pools can remain throughout the year, but where they are wholly rainfall or surface-flow derived but sustained by volume and reduced evaporation and infiltration, these pools should continue to be categorised as persistent, as evaporation occurs, these pools will deplete in the absence of contributions from groundwater. However, it is important to record these pools with extended hydroperiods as these areas could support other biotic and abiotic values.
	Temporary, rainfall derived Surface water pools which typically persist for short periods after rainfall events	**Ephemeral Pools**	Ephemeral pools are short lived and can be widely dispersed after rainfall and surface flows, with their locations often varying unpredictably from year to year. Typically, these features either rapidly infiltrate/evaporate or are sustained by sub-surface flows for a short period, with their presence limited to the wet season months (December to March) or a few months following winter rainfall events.

Appendix H: Classifications of surface water mapped across the Study Area

Mapped Surface water Classification	Detailed surface water classification/Interpretation	Data source for surface water mapping and permanence interpretation	Relevant Notes	Notes relating to Remote sensing product - Sentinel Water Mask (SWM) Index persistence map (pixel values relate to the percentage of images where the 0.6 index threshold is met. Each pixel 10x10m).	Centroid - Easting	Centroid - Northing
Permanent Pool *	Permanent Pool - “Ben’s Oasis” main pool	Aerial photo interpretation, Field Observation, and groundwater monitoring	*Relatively Permanent pool, supported by monitoring with Mature Melaleuca argentea woodland to open forest. Essentially permanent, but not "Clearly Permanent". Some potential for pool to no longer receive groundwater discharge and dry out following an extended drought period.	No persistent pixels detected - pools clearly shrouded by vegetation. Some elevated SWM persistence here, patchy and influenced by vegetation (max 66%)	720349	7448634
Persistent pool +	Persistent pool Pool	Aerial photo interpretation, Field Observation, and groundwater monitoring	Showing signs of groundwater influence. Upstream of “Ben’s Oasis” permanent main pool - Mature MA woodland here	No persistent pixels detected - pools either too small or shrouded by vegetation - Elevated SWM persistence	720141	7448430
Persistent pool +	Persistent pool Pool (to semi-permanent)	Remote sensing, aerial photo interpretation & Field Observation	Basement (Hamersley Group) outcropping here	Max Pixel value 48 (6 pixels) - Elevated SWM persistence (max 75%)	718882	7444481
Persistent pool +	Persistent pool Pool (potentially greater)	Remote sensing, aerial photo interpretation & Field Observation	Basement (Hamersley Group) outcropping here	Max Pixel value 30 (9 pixels) - Elevated SWM persistence (max 73%)	718885	7444578
Persistent pool +	Persistent pool Pool (to semi-permanent)	Remote sensing, aerial photo interpretation & Field Observation	Basement (Hamersley Group) outcropping here	No persistent pixels detected - pools either too small or shrouded by vegetation - Minor Elevated SWM persistence	717983	7442899
Persistent pool +	Persistent pool Pool (to semi-permanent)	Remote sensing, aerial photo interpretation & Field Observation	Basement outcropping here	No persistent pixels detected - pools either too small or shrouded by vegetation - Minor Elevated SWM persistence	717915	7442705
Persistent pool +	Persistent pool Pool	Aerial photo interpretation and field observations	Basement outcropping here (? Wittenoom) - Some young Melaleuca argentea here	No persistent pixels detected - pools either too small or shrouded by vegetation - Minor Elevated SWM persistence	722547	7450034
Persistent pool +	Persistent pool Pool (parts potentially semi-permanent)	Remote sensing, aerial photo interpretation & Field Observation	Area showing groundwater influence. Mature Melaleuca argentea woodland here. Vegetation cover Constrains classification	No persistent pixels detected - pools shrouded by vegetation - Minor Elevated SWM persistence (vegetation clearly shrouding)	722097	7449729
Persistent pool	Persistent pool Pool	Remote sensing, aerial photo interpretation & Field Observation	Basement (Hamersley Group) outcropping here	Max Pixel value 8 (1 pixels) - Minor Elevated SWM persistence	717946	7442813
Persistent pool	Persistent pool Pool	Aerial photo interpretation and field observations	Basement (Hamersley Group) outcropping here	No persistent pixels detected - pools either too small or shrouded by vegetation -? Minor Elevated SWM persistence	715620	7448164
Persistent pool	Persistent pool Pool (To Ephemeral)	Remote sensing, aerial photo interpretation & Field Observation	Some young Melaleuca argentea here	No persistent pixels detected - pools either too small or shrouded by vegetation - Minor Elevated SWM persistence	722424	7449941
Persistent pool	Persistent pool Pool (To Ephemeral)	Remote sensing, aerial photo interpretation, groundwater monitoring & Field Observation	Downstream of “Ben’s Oasis” permanent main pool - More consistent end of Pool	Max Pixel value 33 (20+ pixels) - Elevated SWM persistence (max 72%)	720431	7448956
Persistent pool	Persistent pool Pool	Aerial photo interpretation and field observations	Basement outcropping here	No persistent pixels detected - pools either too small or shrouded by vegetation - Minor Elevated SWM persistence	719084	7445756
Persistent pool	Persistent pool Pool	Aerial photo interpretation and field observations	Basalt (Fortescue Group) basement outcropping here	No persistent pixels detected - pools either too small or shrouded by vegetation - Elevated SWM persistence (max 45%)	721739	7444210
Persistent pool	Persistent pool Pool	Remote sensing, aerial photo interpretation & Field Observation	Basalt (Fortescue Group) basement outcropping here	No persistent pixels detected - pools either too small or shrouded by vegetation - Some Elevated SWM persistence (max 33%)	721775	7443957

Mapped Surface water Classification	Detailed surface water classification/Interpretation	Data source for surface water mapping and permanence interpretation	Relevant Notes	Notes relating to Remote sensing product - Sentinel Water Mask (SWM) Index persistence map (pixel values relate to the percentage of images where the 0.6 index threshold is met. Each pixel 10x10m).	Centroid - Easting	Centroid - Northing
Ephemeral**	Ephemeral to Persistent pool Pool (Potentially Greater)	Remote sensing, aerial photo interpretation, groundwater monitoring & Field Observation	Downstream of “Ben’s Oasis” permanent main pool - Less consistent end of Pool - Variable presence	Max Pixel value 40 (32 pixels) - Strong SWM persistence signal (72% maximum upstream end of pool)	720492	7449056
Ephemeral**	Ephemeral to persistent pool Pool	Aerial photo interpretation and field observations	Substantial calcite precipitation here on banks and terrace - Adjacent HS	No persistent pixels detected - pools either too small or shrouded by vegetation - No Elevated SWM persistence pixels	707016	7445420
Ephemeral**	Ephemeral to persistent pool Pool	Aerial photo interpretation and field observations	Substantial calcite precipitation here on banks and terrace - Adjacent HS	No persistent pixels detected - pools either too small or shrouded by vegetation - No Elevated SWM persistence pixels	707197	7445465
Ephemeral**	Ephemeral to persistent pool Pool	Remote sensing, aerial photo interpretation & Field Observation; however, vegetation cover constrains classification.	Vegetation cover Constrains classification. Potentially greater persistence.	No persistent pixels detected - pools either too small or shrouded by vegetation -? Minor Elevated SWM persistence	720827	7449244
Ephemeral**	Ephemeral to persistent pool Pool	Remote sensing, aerial photo interpretation & Field Observation	Some young Melaleuca argentea here	Max Pixel value 11 (2 Pixels) - Minor Elevated SWM persistence	718888	7444959
Ephemeral**	Ephemeral to persistent pool Pool	Aerial photo interpretation and field observations	Basalt (Fortescue Group) basement outcropping here	No persistent pixels detected - pools either too small or shrouded by vegetation - Minor Elevated SWM persistence	718022	7442941
Ephemeral**	Ephemeral to persistent pool Pool	Aerial photo interpretation and field observations	Basement (Hamersley Group) outcropping here)	No persistent pixels detected - pools either too small or shrouded by vegetation - Some Elevated SWM persistence (max 29%)	719104	7445627
Ephemeral**	Ephemeral to persistent pool Pool	Remote sensing, aerial photo interpretation, groundwater monitoring & Field Observation	Downstream of “Ben’s Oasis” permanent main pool - Post main pool outflow zone over Wittenoom outcropping. Quite exposed to evaporation due to minimal vegetation cover, which may influence variability of surface water expression. *Stylidium weeliwolli* common here.	No overly persistent pixels detected - Minor Elevated SWM persistence- pools likely too narrow/shallow	720387	7448818
Ephemeral*	Ephemeral Pool (Potentially to persistent pool Pool)	Remote Sensing, plus some aerial photo interpretation.	Lower Weeli Wolli Creek - Pools not generally visible late in the dry season (i.e. post winter) on aerial imagery - likely relatively ephemeral	Max Pixel value 6 (3 pixels) - Elevated SWM persistence (relatively low)	721765	7458898
Ephemeral*	Ephemeral Pool (Potentially to persistent pool Pool)	Remote Sensing, plus some aerial photo interpretation.	Lower Weeli Wolli Creek - Pools not generally visible late in the dry season (i.e. post winter) on aerial imagery - likely relatively ephemeral	Max Pixel value 11 (1 pixels) - Elevated SWM persistence (relatively low)	722091	7458445
Ephemeral*	Ephemeral Pool (Potentially to persistent pool Pool)	Remote Sensing, plus some aerial photo interpretation.	Lower Weeli Wolli Creek - Pools not generally visible late in the dry season (i.e. post winter) on aerial imagery - likely relatively ephemeral	Max Pixel value 11 (2 pixels) - Elevated SWM persistence (relatively low)	722106	7458310
Ephemeral*	Ephemeral Pool (Potentially to persistent pool Pool)	Remote Sensing, plus some aerial photo interpretation.	Lower Weeli Wolli Creek - Pools not generally visible late in the dry season (i.e. post winter) on aerial imagery - likely relatively ephemeral	Max Pixel value 8 (2 pixels) - Elevated SWM persistence (relatively low)	722270	7457847
Ephemeral*	Ephemeral Pool (Potentially to persistent pool Pool)	Remote Sensing, plus some aerial photo interpretation.	Lower Weeli Wolli Creek - Pools not generally visible late in the dry season (i.e. post winter) on aerial imagery - likely relatively ephemeral	Max Pixel value 6 (1 pixels) - Elevated SWM persistence (relatively low)	721813	7457187
Ephemeral*	Ephemeral Pool (Potentially to persistent pool Pool)	Remote Sensing, plus some aerial photo interpretation.	Lower Weeli Wolli Creek - Pools not generally visible late in the dry season (i.e., post winter) on aerial imagery - likely relatively ephemeral	Max Pixel value 8 (1 pixels) - Elevated SWM persistence (relatively low)	721557	7455448
Ephemeral*	Ephemeral Pool (Potentially to persistent pool Pool)	Remote Sensing, plus some aerial photo interpretation.	Lower Weeli Wolli Creek - Pools not generally visible late in the dry season (i.e., post winter) on aerial imagery - likely relatively ephemeral	Max Pixel value 6 (1 pixels) - Elevated SWM persistence (relatively low)	722447	7454529
Ephemeral*	Ephemeral Pool (Potentially to persistent pool Pool)	Remote Sensing, plus some aerial photo interpretation.	Lower Weeli Wolli Creek - Pools not generally visible late in the dry season (i.e., post winter) on aerial imagery - likely relatively ephemeral	Max Pixel value 10 (3 pixels) - Elevated SWM persistence (relatively low)	722605	7454024

Mapped Surface water Classification	Detailed surface water classification/Interpretation	Data source for surface water mapping and permanence interpretation	Relevant Notes	Notes relating to Remote sensing product - Sentinel Water Mask (SWM) Index persistence map (pixel values relate to the percentage of images where the 0.6 index threshold is met. Appendix I: Weeli Wolli Spring PEC

Weeli Wolli Spring – DBCA info

Extract of the "Nomination of a Western Australian ecological community for listing as threatened, priority, change of status or delisting" for Assemblages of Weeli Wolli Spring and Creek (Pilbara) (Priority 1).

Description

Weeli Wolli is the aboriginal term for running water.
Weeli Wolli Spring appears superficially to be a typical spring site in the Pilbara. However, the site is an area of high floristic richness as a result of the varied geology and landscape, and the system is a good representation of Pilbara riparian habitat.

The vegetation associations present at Weeli Wolli Spring resemble riparian vegetation found throughout the Hamersley Range and inland Pilbara, and are dominated by an open to moderately dense woodland of *Eucalyptus camaldulensis* (River Red Gum) over scattered *E. victrix* (Coolabah) and *Acacia citrinoviridis* (Black Mulga). In areas of surface water expression or near surface water tables a forest community comprising *E. camaldulensis* and *Melaleuca argentea* (Silver Cadjeput) over *Atalaya hemiglauca* (White Wood) dominates. In terms of vegetation associations, the spring's riparian woodland and forest associations are unusual because of the composition of the understorey (Van Leeuwen 2000).

The sedge and herbfield communities that fringe many of the pools and associated water bodies along the main channels of Weeli Wolli Creek have not been recorded from other wetland sites in the Pilbara, probably because of difference in the hydrological processes, streambed gradients, water flow rates and because of the deleterious impacts of trampling and grazing by livestock elsewhere (Van Leeuwen 2000).

Biota (2006) noted that the relatively high diversity of stygofauna in the Weeli Wolli Spring and creekline area was probably attributed to the large-scale calcrete and alluvial aquifer system associated with the creek (Biota 2006; DEC preliminary Pilbara Biological Survey data). The Pilbara Biological Survey has also revealed that the valley of Weeli Wolli Spring supports the richest microbat assemblage recorded during this survey.

Biological Components

In summary, the flora and the stygofauna are the two main groups of biota that are considered to distinguish the assemblage of Weeli Wolli Spring and Creek. However, the microbat fauna were also found to be unusual, diverse and regionally significant in the preliminary Pilbara Biological Survey data (see below). Other groups of biota associated with site are also described below.

Flora and Vegetation

(Personal communication S. Van Leeuwen)
Riparian tree species that occur in the spring include *Melaleuca argentea, Eucalyptus camaldulensis* and *E. victrix*. Species richness probably similar to Millstream wetlands and other riparian habitat in the Pilbara.

Flora of conservation significance that occur in the spring (from van Leeuwen 2000) include:

- *Stylidium weeliwolli*
  Endemic to northwestern Australia and known from only three locations. The population at Weeli Wolli Spring is the largest known comprising several thousands of plants in ephemeral herbfields fringing spring outflows and associated waterbodies.

- *Fimbristylis sieberiana*
  Sedge is known from 11 localities in northern WA, of which four are in the Pilbara. At Weeli Wolli, this species is common in the herbfields that fringe pools.

Plant taxa recorded from Weeli Wolli Spring that are biologically significant (from van Leeuwen 2000) include:

- *Fimbristylis oxystachya*
  Tropical taxon known from Kimberley, Weeli Wolli Spring and three other Pilbara sites.

- *Fimbristylis rara*
  Tropical taxon known from the Kimberley, Weeli Wolli and three other Pilbara sites.

- *Gossypium sturtianum*
  Typically from central Australia and Exmouth - Cape Range area.
  The Weeli Wolli occurrence is the only population known in the Pilbara. At the spring, this taxon grows sympatrically with *G. robinsonii* and at some sites forms a 'hybrid swarm', which is of significant biological interest with respect to conservation of genetic diversity.

Elytrophorus spicatus, Mollugo cerviana, Rotala diandra and *Rotala mexicana* are also of biological interest as they represent disjunct outliers from distributions that are either predominantly tropical or concentrated in the central Australian deserts. The occurrence of such disjunct outlying populations for tropical species is indicative of the Weeli Wolli Spring area being a refugial/relictual habitat. Further evidence of this is the fact that the nearest relative taxonomically to *S. weeliwolli* is *S. calcaratum*, a southwest Australian species (from van Leeuwin 2000).

Flora recorded in Florabase, or during survey of the site by CALM staff in 1998 for Weeli Wolli Spring include: *Abutilon dioicum, Acacia bivenosa, Acacia citrinoviridis, Acacia coriacea* subsp. *pendens, Acacia tumida* var. *tumida, Ammannia baccifera, Atalaya hemiglauca, Clerodendrum floribundum* var. *angustifolium*, *Eucalyptus camaldulensis, Eucalyptus victrix, Gastrolobium grandiflorum, Gossypium robinsonii, Jasminum didymum* subsp. *lineare, Lobelia quadrangularis, Melaleuca argentea, Melaleuca leucadendra, Melaleuca eleuterostachya, Plumbago zeylanica, Ptilotus calostachyus, Sesbania cannabina, Stylidium weeliwolli* (P2), *Tephrosia rosea, Triumfetta leptacantha* (P3), *Stemodia grossa, Santalum lanceolatum*.

Aquatic invertebrates

"*Wandesia* sp. P1 (nr glareosa) (PSW)", interstitial water mite, known from three localities in eastern Pilbara (Weeli Wolli, Cangan Pool on Cangan Creek and Miningarra Creek). Note that only two other species of Australian *Wandesia* are described and both are restricted to south-eastern Australia. "*Austraturus* P1", a water mite known only from Weeli Wolli and Millstream so far. "*Guineaxonopsis* sp. P1 (PSW)", an un-named water mite known only from Weeli Wolli and Miningarra Creek so far. Mark Harvey lists an undescribed species from north-west WA so this may be the same species.

Stygofauna

Stygofauna have been recorded in the interstitial gravel habitat of Weeli Wolli Spring where discharge dewatering is occurring. The stygofauna included Crustacea belonging to the groups *Amphipoda*, *Copepoda*, *Bathynellacea*, *Ostracoda*, and *Isopoda*. Eberhard and Humphreys (1999) considered that these stygofauna are significant and vulnerable to even slight drawdown effects.

Biota (2006) provides a table of stygofaunal taxa, and notes their status and wider distribution. However, the aim of the report was to indicate the status and wider distribution of fauna that occurred within the drawdown impact zone for Hope Downs mine, and therefore does not provide much information about the status of animals located in Weeli Wolli Spring, which was considered at that time to be outside of the direct impact zone for primary drawdown impacts. The report does however contain information about the genetic status of amphipod groups located in the 'drawdown impact zone' and within Weeli Wolli Spring and creek (Finston 2006, reported in Biota 2006). Finston noted that combined information from allozyme and DNA analyses for amphipods indicated the presence of five genetic groups representing a likely four or five species. Finston noted the need for further morphological work to confirm the genetic studies.

The five groups of amphipods represented were as follows (Finston 2006):
Group A: quite widespread, probably a good species. Located in bores in the adjacent Hope Downs Impact Zone, Weeli Wolli Spring and creek.

Group B: Likely single status species. Located in two bores within Weeli Wolli Spring and one in the Impact Zone.

Group C: Requires more detailed morphological work to clarify single species status. Located in one Weeli Wolli Spring site, and three Impact Zone sites.

Group D: 'Species' only located in Weeli Wolli Spring bore, and 'taxon' with similar profile located in Ethel Gorge region.

Group E: Located in 'Impact Zone' only, taxonomic status uncertain.

Preliminary data from Pilbara Biological Survey for Weeli Wolli Spring and Creek (reports in preparation)

Stygofauna (personal communication S. Halse)

- *Arrenurus* sp. nov.

One recorded only from Weeli Wolli. It may be more widespread in samples.

- *Pygolabis weeliwolli*

Occurs in the upper Fortescue west of Newman – Weeli Wolli, Fortescue Marsh, Area C sites.

- *Notacandona boultoni*

Has been recorded only from Weeli Wolli.

- *Notocandona modesta*

Has been recorded only from Weeli Wolli and Pebble Mouse Creek, north of Weeli Wolli.

- *Ainudrilus* sp. WA26

Known only from Weeli Wolli.

- 'Maarka wolli' ms

Name is known only from Weeli Wolli and Pebble Mound Creek, although a similar species occurs around Newman.

The other species are all more widespread.

Aquatic Invertebrates (personal communication A. Pinder)
The surface water list for Weeli Wolli is higher than average for Pilbara sites (at 186 taxa, cf average for 2 sampling occasions of 147 taxa) but the lists contain nothing that is restricted to this site or vicinity. In multivariate analyses Weeli Wolli grouped within a large group of sites dominated by springs or spring-fed pools.

Ground Ants (personal communication B. Durrant)
The site is quite rich with 21 species and although there were no singletons the species *Opisthopsis haddoni* Emery was only found at 2 PBS sites (both in the SE corner), but the species is actually found throughout Australia. Main thing to take from ant data is that there was a low number of true eremaean species, with most being either Australia wide species or torresian. However *Leptogenys centralis* appears confined to the central south of the Pilbara but according to CSIRO Ants Online it is distribution is South Australia (Lake Eyre Basin).

Ground Spiders (personal communication B. Durrant)
Weeli Wolli (RHNC10) is an unusual site for the spiders. There were 8 species collected there but 4 were *Salticids* and 4 were *Zodariids*. None of these species were singletons but it is unusual to have such a poor higher taxonomic richness at a site.

Scorpions (personal communication B. Durrant)
Weeli Wolli (RHNC10) and site NW11 were the only two sites that recorded 5 scorpion species out of the 17 from the Pilbara Biological Survey. All five species were widespread through the survey. So it was the equal richest scorpion site in the Pilbara Biological Survey (304 sites sampled).

Ground Beetles (personal communication N. Guthrie)

- Carabids - all are fairly widespread or found at more than 10 sites, really not restricted in any sense
- Tenebrionids - bear in mind *Chalcopteroides* is a large and difficult group requiring revision. The other we simply couldn't get anywhere with it, may occur in other collections from other areas.
- Scarabids- *Automolius* sp. mainly an eastern high rainfall genus- 2 described species known to occur in the north west and south west WA plus 5 described species known from the south west WA only. Currently this taxon is considered to be probably new- no species of the genus recorded from interior deserts.
- Three new species of *Heteronyx*, no other known material present in other collections. *Heteronyx tepperi* is widespread (arid zone thru to east of Murray-Darling River) so not restricted in any sense
- Weevils- *Cyphicerini* gen.indet sp.indet.

In the Beetle community analysis Weeli Wolli comes out by itself or is it with other wetland/riparian sites or Hamersley Range sites.

Reptiles (personal communication A. Burbidge)
Recorded 8 reptile species at the Weeli Wolli site (RHNC10), plus two frogs. The reptiles were mostly common and widespread, but *Carlia munda* is at or close to its southern limit of distribution here, and *Lerista neander* is at or near its northern limit. The frogs were the common and widespread *Litoria rubella* and an as yet unidentified frog from a wet pit.

Birds (personal communication A. Burbidge)
Recorded 36 bird species and a total of 70 species have been recorded from within a few km of the spring; so for the Pilbara, the area is rich in bird species. Again, most are common and widespread, but the Grey Honeyeater is rare (but not threatened) and was only recorded at one of the Pilbara survey sites (but not this one). The Grey Fantail is rare in the Pilbara, normally only occurring at a few sites like Weeli Wolli and Millstream. The Western Gerygone is uncommon in the Pilbara. The record of Azure Kingfisher is one of only three from the Pilbara – i.e. it is a vagrant. Barking Owls are not rare, but in the Pilbara they are restricted to sites like Weeli Wolli – i.e. with large cadjeputs.

Mammals (personal communication L. Gibson)
Nothing of significance at Weeli Wolli.

Bats (personal communication N. McKenzie)
Data collected during the Pilbara Biological Survey has revealed that the richest assemblages of microbats found in the Pilbara are associated with well developed, continually productive riparian site set in ranges country, and that the regional populations of two species are confined to these riparian environments (*Nyctophilus bifax daedalus* and *Chalinolobus mo*rio). Loss of complexity in riparian vegetation, reduced permanence of pools and loss of suitable cave roosts, are all likely to reduce this microbat richness. There is a need to ensure that highly developed riparian sites in ranges country, such as Weeli Wolli, are included in conservation reserves (Weeli Wolli, Cattle Gorge, Turee Creek etc).

The valley of Weeli Wolli Spring appears to be regionally unique from a microbat viewpoint. It supports the richest microbat assemblage recorded during our survey, and is also the only area in northern WA known to support a population of *Chalinolobus morio*, a species elsewhere restricted to southern Australia (van Dyke and Strahan 2008). In fact, Weeli Wolli has every species of microbat known from the region's landward environments. Additionally, it is the only location known in northern Western Australia where *Tadarida australis* can persist through the hot and humid summer months (see Bullen and McKenzie 2005). We speculate that occasional cool air floods through the Weeli Wolli valley during summer nights may reduce atmospheric enthalpy to levels in which these two, otherwise temperate-adapted species, can forage for long enough to meet their metabolic requirements.
Survey

This spring is the only one known that contains this particular suite of flora (Van Leeuwen 2000). No other similar springs were located during the three years of the DEC Pilbara Biological survey, or during routine flora and vegetation surveys listed above, or as undertaken by survey effort. Dr Stephen Van Leeuwen worked in the Pilbara Region for 15 years and does not know of another similar spring in the Pilbara.

Other surveys of the area include:

- Weston and Trudgen (1995) undertook a vegetation and flora survey of Marillana/Weeli Wolli Creeks and Paleochannel.
- Ecologia (1996) - flora and fauna survey of Weeli Wolli Creek
- A brief report by S. Van Leeuwen, S (2000). 'Vegetation and Flora of the Weeli Wolli Spring Area' provided a summary of botanical characteristics of the area.
- Biota (2006) - survey of invertebrate fauna of Weeli Wolli Spring and Creek and some adjacent areas.
- The three-year Pilbara Biological Survey by DEC included aspects of invertebrate, mammal and flora survey for the Pilbara region as a whole (surveys completed 2007, some preliminary results above).

Riparian flora and plant communities of the Pilbara – DBCA info

Extract of the "Nomination of a Western Australian ecological community for listing as threatened, priority, change of status or delisting" for Riparian flora and plant communities of springs and river pools with high water permanence of the Pilbara Region (Priority 2).

Description

A subgroup of river pools and springs identified by Lyons (2015) included sites which had the highest mean permanence of water of all site groups sampled across the Pilbara, coupled with the highest mean annual rainfall.

The soil of the sites contained the highest percentage of gravel and were otherwise typically sandy. There were also high levels of exchangeable calcium reported in the soil, likely to reflect the contribution of calcium-rich groundwater to the riparian zone substrate.

The distribution is restricted to sites in Hamersley Range from Millstream to Karijini National Park and Munjina Gorge. The location of the springs are confined to the mesic rocky gullies in the Pilbara IBRA Region including the Chichester and Hamersley sub regions.

Occurrences of this community are disjunct with sites typically associated with groundwater discharge in gorge and valley wetlands that are often couples with significant shading.
The hydrological conditions that support the groundwater dependent overstorey trees and moisture dependent understorey taxa are potentially threatened from a combination of groundwater drawdown, dewatering and surface water diversion associated with mining activities. The effects of the hydrological change on this community are unknown, however has the potential to cause significant change based on changes that have occurred at Weeli Wolli Spring. There is also potential for wholescale catchment change relating to mining activities. Additional threatening processes include inappropriate/altered fire regimes and weed invasion (*Cenchrus ciliaris)* and deleterious impacts of trampling and grazing by livestock.

Biological components:

Flora and Vegetation

The vegetation present at springs and river pools with high water permanence are differentiated from other riparian vegetation found throughout the Hamersley Range and inland Pilbara owing to the presence of significant indicator species.

In areas of surface water expression or near surface water tables, a forest community comprised of *Melaleuca argentea* and *Eucalyptus camaldulensis* subsp. *refulgens* dominate trees over shrubs grasses and sedges. There were also *Acacia ampliceps, Typha domingensis* and *Cyperus vaginatus* fringing many of the pools and associated water bodies.

Significant in this subgroup was the presence of relictual taxa and outliers of the Kimberley and eastern Australia. Including *Livistona alfredii* (P4) (Millstream fan-palm) occurred at Palm pool, Millstream; *Cladium procerum* occurred at both Millstream, Karijini National Park and recently identified (Jeremy Naaykens pers comm.) at Munjina Gorge; *Adiantum capillus-veneris* (P2) occurs at Fortescue Falls. This fern has a scattering of localised populations across much of Australia. *Imperata cylindrica* sampled at Millstream and Karijini National Park, Caves Creek and at Munjina Gorge; and *Fimbristylis sieberiana* P3 and *Schoenus falcatus* occur at a number of sites

The mean species richness (18.4 taxa) is believed to be similar to Millstream wetlands and other riverine riparian habitats in the Pilbara. *Melaleuca argentea* and *Eucalyptus camaldulensis* subsp. *Refulgens* were present in the dominant riparian forest community occurring across majority of the sites.

Indicator species used to assist with defining the community include:

- *Fimbristylis sieberiana* P3
  Distribution Pilbara/Kimberley
- *Schoenus falcatus* (not threatened)
  Distribution Pilbara/Kimberley/Gascoyne
- *Cladium procerum* P2
  Distribution Pilbara population is major disjunction from SE Australian distribution.
- *Imperata cylindrica* (not threatened)
  Distribution Kimberley/Pilbara
- *Adiantum capillus-veneris* P2
  Distribution: Pilbara – scattered locations in Australia.
- *Phragmites karka* (not threatened)
  Distribution Kimberley/Pilbara

No information on fauna or stygofauna was provided in this TEC/PEC nomination form.

Non-biological components

Rocky gully mesic habitats of the Pilbara bioregion. Areas of sheltered gorges, upland creeks and rocky gullies/gorges. Floors of some gorges contain permanent wetlands and support unusual riverine species.

Extensive aquifer systems of the Pilbara discharge groundwater to form permanently flowing creeks, or contribute to permanent pools within river channels. Springs and spring fed river pools with high water permanence and associated gorges provide an important mesic refuge.

Processes

Maintenance of the spring and pools would be dependent on the hydrologic regime that has been established over many millennia. Uninterrupted flow of springs and creeks with sustained high-water permanence maintains the endemic and relictual flora. Changes to the hydrologic regime, including increased inundation or drying are likely to result in changes to flora populations and communities.

The permanent springs and associated vegetation are important habitats for a large number of species. The habitats may be susceptible to trampling by feral stock and other disturbance (KNPMP).

Uniqueness

Most springs in the Pilbara tend to show similar species composition to many permanent (probably groundwater fed) river pools, however, the riparian flora and plant communities of springs and river pools with high water permanence sites are unique given the presence of restricted taxa and outliers from the Kimberley and eastern Australia.

The following have described how the community is unique and how it differs from any other ecological community:
Lyons, M.N. (2015). The riparian flora and plant communities of the Pilbara region of Western Australia.
Eight major wetlands groups were defined by classifying 98 wetlands in terms of species presence /absence data. Site group 6.1 showed distinct separation in both composition and abiotic parameters. Site group 6.1 showed the highest water permanence and soil exchangeable Calcium (consistent with groundwater discharge) of all floristic groups identified in the survey.
Studies of springs elsewhere in Australia confirm that the springs of the Pilbara are floristically distinct from the remainder of Australia.

Gibson et al. (2000) sampled a small number of springs in the Carnarvon Basin IBRA in a study of 58 ephemeral and permanent wetlands. Springs were small scale and along with other Carnarvon Basin wetlands were dominated by taxa with Eremaean and Southwestern distributions in contrast to Pilbara wetlands that capture elements of the Eremaean and Tropical flora.

Kenneally et al (1991); Russell-Smith (1991)
Studies conclude the spring flora in the Kimberley and Northern Territory contained a majority of rainforest elements.

Fensham and Fairfax (200); Fensham and Price (2004)
Detailed studies of springs of the Great Artesian Basin show a completely distinctive flora from that of Pilbara riparian zones.

Survey Effort

Lyons (2015) - undertook site classification of 103 survey sites based on species presence/absence. Classification at 8-group level. Group 6 Springs and river pools with high water permanence with subgroup 6.1. Ninety-eight wetlands were selected to capture the diversity of wetland types present in each of the five major drainage basins of the Pilbara. The selected wetlands were part of an integrated survey that covered and examined how the major geographic and site environments correlate with floristic composition, and included a sample Rudall River (Great Sandy Desert IBRA). Data sets for this study were linked with studies of aquatic invertebrates by Pinder et al (2010)

Regional survey: Prior to Lyons (2015), only two previous studies of the riparian flora of the Pilbara have been undertaken by Masini (1998) and Masini and Walker (1989).
Localised studies have been undertaken for the purpose of environmental impact assessment for proposed mining.

With additional surveys, it is likely that other gorges in Karijini National Park for example Dales may fit within this subset. A spring in the upper reaches of Munjina Gorge (east branch), located on Juna Downs Pastoral lease may also fit into the subset (awaiting data), however “indicator” species are present.

Distinctiveness/detectability of the community

Lyons (2015) - Eight major groups were defined by classifying wetlands in terms of species presence /absence data. Floristic patterning strongly aligned with major wetland types (geomorphic /hydrological) groups.

Threats

Hydrological change:
The greatest threat to the riparian springs and rivers pools relates to potential hydrological change from cumulative impact owed to a combination of groundwater drawdown due to mine dewatering and surface water diversion activities. There is also potential for wholescale catchment changes relating to associated mining activities relating to changes in surface water regimes in terms of magnitude and frequency of runoff as a result of diversion or catchment interception by planned mining activities resulting in groundwater recharge to the alluvial aquifer of reinjection bores. Planned injection of surplus water has the potential to result in groundwater mounding, thereby changing the water balance and potential to impact riparian communities
Cattle grazing:
Increases weed invasion; selectively graze species, erode banks, eutrophic water.
Fire:
Too frequent, increase in weed invasion; favours fire tolerant species, leaves banks bare of vegetation and prone to erosion.
Weed invasion:
Competing with natives; increase in fire risk, altering structure. Buffel-grass (*Cenchrus ciliaris*) does occur in springs, but its extent is limited by the absence of suitable sandy substrate.
Recreational activities:
Increase in vegetation disturbance, littering, campfires, tracks

	Urochloa occidentalis	
	Urochloa occidentalis var*. ciliata*	
	Urochloa piligera	
Portulacaceae	*Portulaca oleracea*	
Proteaceae	*Hakea lorea* subsp*. lorea*	
Pteridaceae	*Cheilanthes sieberi* subsp*. sieberi*	
Rubiaceae	*Psydrax suaveolens*	
Santalaceae	*Anthobolus leptomerioides*	
	Santalum lanceolatum	
Sapindaceae	*Atalaya hemiglauca*	
	Dodonaea lanceolata	
	Dodonaea pachyneura	
	Dodonaea viscosa subsp*. mucronata*	
Scrophulariaceae	*Eremophila ?compacta*	
	Eremophila forrestii subsp*. forrestii*	
	Eremophila longifolia	
Solanaceae	*Nicotiana occidentalis* subsp*. obliqua*	
	Solanum chippendalei	
	Solanum cleistogamum	
	Solanum lasiophyllum	
	Solanum nigrum	
Stylidiaceae	*Stylidium weeliwolli*	P3
Surianaceae	*Stylobasium spathulatum*	
Violaceae	*Afrohybanthus aurantiacus*	
Zygophyllaceae	*Roepera iodocarpa*	
	Tribulus astrocarpus	

Appendix L: Combined species list from sampling conducted as part of this study and riparian quadrats and relevés from relevant riparian habitats sampled by Astron (2019) and Mattiske (2008, 2010, 2014) (418 species in total).

Family	Species	Current	Astron	Mattiske
Acanthaceae	*Dicladanthera forrestii*	x	x	x
	Dipteracanthus australasicus			x
	Dipteracanthus australasicus subsp. *australasicus*	x		x
	Rostellularia adscendens var. *clementii*	x		
	Rostellularia adscendens var. *latifolia* (P3)	x		
Amaranthaceae	*Achyranthes aspera*	x		
	Alternanthera denticulata		x	x
	Alternanthera nana	x	x	x
	Alternanthera nodiflora	x		x
	Amaranthus cuspidifolius			x
	Amaranthus mitchellii			x
	Gomphrena canescens	x		
	Gomphrena cunninghamii	x		x
	Ptilotus aervoides			x
	Ptilotus astrolasius		x	x
	Ptilotus auriculifolius	x		x
	Ptilotus exaltatus	x	x	x
	Ptilotus exaltatus var. *exaltatus*			x
	Ptilotus helipteroides	x	x	x
	Ptilotus nobilis			x
	Ptilotus obovatus	x	x	x
	Ptilotus obovatus var. *obovatus*			x
	Ptilotus polystachyus	x		x
Apocynaceae	*Cynanchum floribundum*			x
	Cynanchum ?pedunculatum	x		
	Marsdenia sp. (indet.)		x	
Asteraceae	**Bidens bipinnata*	x	x	x
	Brachyscome ciliaris	x		
	Centipeda minima	x		x
	Centipeda minima subsp. *macrocephala*		x	
	Chrysocephalum apiculatum			x

Family	Species	Current	Astron	Mattiske
	Chrysocephalum apiculatum subsp. *pilbarense*	x	x	
Asteraceae	*Chrysocephalum gilesii*			x
	**Erigeron bonariensis*		x	
	**Flaveria trinervia*	x	x	x
	**Lactuca ?saligna*	x		
	Leiocarpa semicalva			x
	Olearia fluvialis	x		
	Peripleura arida	x	x	
	Pluchea dentex	x	x	x
	Pluchea rubelliflora	x	x	
	Pluchea sp. (indet.)		x	
	Pterocaulon serrulatum			x
	Pterocaulon serrulatum var. *velutinum*		x	
	Pterocaulon sp. (indet.)		x	
	Pterocaulon sphacelatum	x	x	x
	Pterocaulon sphaeranthoides			x
	Rhodanthe margarethae			x
	Rutidosis helichrysoides			x
	Rutidosis helichrysoides subsp. *helichrysoides*			x
	**Sigesbeckia orientalis*	x	x	x
	Sonchus hydrophilus	x		
	**Sonchus oleraceus*	x	x	x
	Streptoglossa decurrens			x
Araliaceae	*Trachymene oleracea*			x
Boraginaceae	*Ehretia saligna* var. *saligna*	x		
	Heliotropium cunninghamii	x		x
	Heliotropium inexplicitum			x
	Heliotropium tanythrix		x	
	Heliotropium tenuifolium		x	
	Trichodesma zeylanicum	x		x
	Trichodesma zeylanicum var. *zeylanicum*		x	x
Brassicaceae	*Lepidium echinatum*			x
	Lepidium phlebopetalum	x		x
	Lepidium sp. (indet.)		x	
	Stenopetalum decipiens			x

Family	Species	Current	Astron	Mattiske
Campanulaceae	*Wahlenbergia tumidifructa*	x	x	x
Capparaceae	*Capparis lasiantha*	x	x	x
	Capparis spinosa			x
Caryophyllaceae	*Polycarpaea corymbosa*			x
	Polycarpaea corymbosa var. *corymbosa*		x	
	Polycarpaea holtzei			x
	Polycarpaea longiflora	x		x
Celastraceae	*Maytenus* sp. Mt Windell (S. van Leeuwen 846)		x	
Characeae	*Chara* sp. (indet.)	x		
Chenopodiaceae	*Dysphania kalpari*		x	x
	Dysphania melanocarpa forma *melanocarpa*	x		
	Dysphania rhadinostachya	x		x
	Dysphania rhadinostachya subsp. *rhadinostachya*		x	x
	Dysphania sp. (indet.)			x
	Enchylaena tomentosa			x
	Enchylaena tomentosa var. *tomentosa*	x	x	
	Maireana planifolia			x
	Maireana villosa			x
	Rhagodia eremaea	x	x	x
	Rhagodia sp. Hamersley (M. Trudgen 17794) (P3)		x	
	Salsola australis	x	x	x
	Sclerolaena cornishiana	x	x	x
Cleomaceae	*Arivela viscosa*	x	x	x
Commelinaceae	*Commelina ensifolia*			x
Convolvulaceae	*Bonamia pilbarensis*		x	
	Convolvulus angustissimus			x
	Convolvulus clementii		x	x
	Convolvulus remotus	x		
	Duperreya commixta	x	x	x
	Evolvulus alsinoides			x
	Evolvulus alsinoides var. *decumbens*	x	x	
	Evolvulus alsinoides var. *villosicalyx*	x	x	
	Ipomoea muelleri	x		
	Ipomoea plebeia			x
	Ipomoea polymorpha			x

Family	Species	Current	Astron	Mattiske
	Polymeria ambigua	x		x
Cucurbitaceae	*Cucumis melo*		x	
	Cucumis variabilis	x	x	x
Cyperaceae	*Bulbostylis barbata*			x
	Bulbostylis turbinata		x	x
	Cyperus bulbosus			x
	Cyperus cunninghamii			x
	Cyperus cunninghamii subsp. *cunninghamii*	x		
	Cyperus iria	x		x
	Cyperus squarrosus			x
	Cyperus vaginatus	x	x	x
	Fimbristylis microcarya			x
	Schoenoplectiella laevis			x
Elatinaceae	*Bergia pedicellaris*	x		x
Euphorbiaceae	*Adriana tomentosa* var. *tomentosa*			x
	Euphorbia australis			x
	Euphorbia australis var. *subtomentosa*	x	x	
	Euphorbia biconvexa	x	x	x
	Euphorbia boophthona	x	x	x
	Euphorbia coghlanii	x	x	x
	Euphorbia sp. (indet.)		x	x
	Euphorbia tannensis			x
	Euphorbia trigonosperma		x	x
Fabaceae	*Acacia adsurgens*	x		
	Acacia ampliceps hybrid	x		
	Acacia aneura	x		
	Acacia aneura var. *aneura*			x
	Acacia aptaneura	x	x	x
	Acacia aptaneura x *paraneura*	x		
	Acacia bivenosa	x	x	x
	Acacia citrinoviridis	x	x	x
	Acacia colei var. *colei*	x		
	Acacia coriacea subsp. *pendens*	x		x
	Acacia dictyophleba	x	x	
	Acacia hamersleyensis			x

Family	Species	Current	Astron	Mattiske
	Acacia inaequilatera			x
Fabaceae	*Acacia incurvaneura*	x		
	Acacia macraneura	x		
	Acacia maitlandii	x	x	x
	Acacia monticola			x
	Acacia pachyacra	x		x
	Acacia paraneura			x
	Acacia pruinocarpa	x	x	x
	Acacia pteraneura			x
	Acacia pyrifolia	x	x	x
	Acacia sibirica		x	
	Acacia sp. (indet.)		x	
	Acacia tenuissima			x
	Acacia tetragonophylla		x	x
	Crotalaria cunninghamii			x
	Crotalaria medicaginea			x
	Crotalaria medicaginea var. *neglecta*	x	x	
	Crotalaria novae hollandiae			x
	Cullen ?leucanthum	x		
	Cullen leucochaites			x
	Cullen pogonocarpum			x
	Glycine canescens	x	x	x
	Indigofera fractiflexa			x
	Indigofera georgei	x	x	x
	Indigofera linnaei	x		
	Indigofera monophylla		x	
	Isotropis forrestii	x		x
	Isotropis iophyta	x	x	
	Petalostylis labicheoides	x	x	x
	Rhynchosia minima	x	x	x
	Senna artemisioides			x
	Senna artemisioides subsp. *filifolia*	x		
	Senna artemisioides subsp. *Helmsii*		x	
	Senna artemisioides subsp. *oligophylla*		x	
	Senna artemisioides subsp. *oligophylla* x *helmsii*			x

Family	Species	Current	Astron	Mattiske
	Senna artemisioides subsp. x *artemisioides*	x	x	x
Fabaceae	*Senna artemisioides* subsp. x *sturtii*			x
	Senna glaucifolia			x
	Senna glutinosa			x
	Senna glutinosa subsp. *chatelainiana*			x
	Senna glutinosa subsp. *glutinosa*		x	
	Senna glutinosa subsp. ×*luerssenii*	x		
	Senna notabilis			x
	Senna pleurocarpa var. *pleurocarpa*	x		
	Senna stricta		x	
	Senna venusta			x
	Swainsona maccullochiana			x
	Tephrosia rosea			x
	Tephrosia rosea var. *clementii*			x
	Tephrosia rosea var. Fortescue creeks (M.I.H. Brooker 2186)	x	x	x
	Tephrosia sp. (indet.)			x
	**Vachellia farnesiana*	x	x	x
	Vigna lanceolata			x
	Vigna lanceolata var. *lanceolata*		x	
	Vigna sp. Hamersley Clay (A. A. Mitchell PRP 113)			x
Goodeniaceae	*Goodenia lamprosperma*	x	x	
	Goodenia microptera			x
	Goodenia muelleriana			x
	Goodenia prostrata	x		x
	Goodenia sp. (indet.)		x	
	Goodenia stellata	x	x	x
	Goodenia stobbsiana			x
	Scaevola amblyanthera			x
	Scaevola amblyanthera var. *centralis*	x	x	
	Scaevola browniana		x	
	Scaevola parvifolia subsp. *Pilbarae*		x	
Haloragaceae	*Haloragis gossei*		x	x
	Haloragis gossei var. *gossei*	x		
	Haloragis odontocarpa		x	
	Haloragis sp. (indet.)			x

Family	Species	Current	Astron	Mattiske
Hemerocallidaceae	*Tricoryne* sp. Hamersley Range (S. van Leeuwen 915)		x	x
Lamiaceae	*Clerodendrum floribundum*	x		x
	Clerodendrum floribundum var. *angustifolium*		x	
	Clerodendrum floribundum var. *floribundum*	x		
	Prostanthera albiflora			x
Lauraceae	*Cassytha* sp. (indet.)		x	
Loranthaceae	*Amyema miquelii*	x		
Lythraceae	*Ammannia baccifera*	x		
	Ammannia multiflora			x
	Rotala diandra			x
Malvaceae	*Abutilon amplum*	x	x	
	Abutilon fraseri			x
	Abutilon fraseri subsp. *fraseri*	x		
	Abutilon otocarpum	x	x	x
	Abutilon oxycarpum			x
	Abutilon sp. Dioicum (A.A. Mitchell PRP 1618)	x	x	
	Androcalva luteiflora	x	x	x
	Corchorus crozophorifolius	x	x	x
	Corchorus lasiocarpus subsp. *lasiocarpus*		x	
	Corchorus lasiocarpus subsp. *parvus*		x	
	Corchorus tridens	x	x	x
	Corchorus walcottii			x
	Gossypium australe		x	x
	Gossypium robinsonii	x	x	x
	Gossypium sturtianum var. *sturtianum*	x	x	
	Hibiscus burtonii			x
	Hibiscus coatesii		x	
	Hibiscus sp. Mt Robinson (G. Byrne 3537)			x
	Hibiscus sturtii		x	x
	Hibiscus sturtii var. *campylochlamys*		x	
	**Malvastrum americanum*	x	x	x
	Melhania oblongifolia	x	x	x
	Sida arenicola			x
	Sida echinocarpa		x	x
	Sida ectogama			x

Family	Species	Current	Astron	Mattiske
	Sida fibulifera	x	x	x
Malvaceae	*Sida rohlenae*			x
	Sida sp. Articulation below (A A. Mitchell PRP 1605)		x	
	Sida sp. L (A.M. Ashby 4202)	x		
	Sida sp. Shovelanna Hill (S. van Leeuwen 3842)			x
	Sida sp. spiciform panicles (E. Leyland s.n. 14/8/90)	x	x	x
	Sida sp. (indet.)			x
	Triumfetta clementii			x
	Waltheria indica		x	x
Marsileaceae	*Marsilea hirsuta*	x		x
Menispermaceae	*Tinospora smilacina*	x		
Molluginaceae	*Trigastrotheca molluginea*		x	
Moraceae	*Ficus brachypoda*	x		x
Myrtaceae	*Corymbia aspera*			x
	Corymbia ferriticola	x		
	Corymbia hamersleyana			x
	Corymbia hamersleyana (sens lat.)		x	
	Eucalyptus camaldulensis	x		x
	Eucalyptus camaldulensis subsp. *obtusa*	x	x	
	Eucalyptus gamophylla	x		x
	Eucalyptus ?kingsmillii	x		
	Eucalyptus leucophloia			x
	Eucalyptus leucophloia subsp. *leucophloia*		x	
	Eucalyptus socialis subsp. *eucentrica*		x	
	Eucalyptus trivalva	x		
	Eucalyptus victrix	x	x	x
	Eucalyptus xerothermica	x	x	x
	Melaleuca argentea	x		x
	Melaleuca bracteata	x	x	x
	Melaleuca glomerata	x	x	x
	Melaleuca lasiandra			x
Nyctaginaceae	*Boerhavia burbidgeana*			x
	Boerhavia coccinea	x	x	x
	Boerhavia sp. (indet.)			x
Oleaceae	*Jasminum didymum*			x

Family	Species	Current	Astron	Mattiske
	Jasminum didymum subsp*. lineare*	x	x	x
Papaveraceae	**Argemone ochroleuca*			x
Phrymaceae	*Peplidium muelleri*			x
	Peplidium sp. C Evol. Fl. Fauna Arid Aust. (N.T. Burbidge & A. Kanis 8158)	x		
Phyllanthaceae	*Notoleptopus decaisnei*			x
	Phyllanthus erwinii		x	x
	Phyllanthus maderaspatensis	x	x	x
Pittosporaceae	*Pittosporum angustifolium*	x		x

Executive Summary

Rio Tinto is evaluating the potential development of additional iron ore deposits at Hope Downs 2 (HD2) in the Pilbara region of Western Australia. Astron Environmental Services was commissioned to undertake a Level 2 fauna and Short Range Endemic assessment of the HD2 Development Envelope (the survey area, which is 10,817.7 hectares) over three separate phases of fauna surveying.

Vertebrate Fauna

Eight broad fauna habitat types were recorded in the survey area: Minor Drainage, Gorge/Gully, Breakaway, Rocky Hill, Low Hill and Slopes, Alluvial Plain, Mulga Woodland and Stony Plain. Areas of cleared habitat were present within the HD2 and Bedded Hilltop areas where exploration drilling had occurred in the form of drill pads and drill access tracks. The Gorge/Gully and Breakaway habitats in the survey area were considered important for fauna due to the microhabitats they provide such as caves and the potential for semi-permanent water pools. These areas contained a high diversity of microhabitats representing important sites of refuge and habitat for conservation listed fauna, such as the Northern Quoll, Pilbara Leaf-nosed Bat and Ghost Bat.

There were 174 vertebrate fauna species recorded within the survey area, comprising two amphibians, 55 reptiles, 84 birds and 33 mammals (including seven introduced mammal species). The fauna species assemblage recorded during the survey is considered typical of the Hamersley subregion.

Seven vertebrate species of conservation significance were recorded during the survey: Northern Quoll (*Dasyurus hallucatus*) (EN; EN); Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) (VU; VU); Ghost Bat (*Macroderma gigas*) (VU; VU); Oriental Plover (*Charadrius veredus*) (IA; IA); *Lerista macropisthopus remota* (P2); Letter-winged Kite (*Elanus scriptus*) (P4); and Western Pebble-mound Mouse (*Pseudomys chapmani*) (P4). Three of these species (Northern Quoll, Pilbara Leaf-nosed Bat and Ghost Bat) are classified under the *Environment Protection and Biodiversity Conservation Act 1999* as Matters of National Environmental Significance.

The Northern Quoll was recorded 14 times in the form of motion camera detection images (10 records), scat recordings (three records) and a solitary individual captured during the Phase 2 fauna survey. The seemingly large number of recordings, relative to the local vicinity and the micro-niches found in the preferred fauna habitats at Bedded Hilltop, suggests a resident population exists within the survey area.

The Pilbara Leaf-nosed Bat was recorded at three of the 23 bat detector locations. Recordings at all three locations were deemed to indicate low activity levels. The Pilbara Leaf-nosed Bat records were from foraging individuals in Gorge/Gully and Breakaway fauna habitats with all calls at least three hours after dusk and not consistent with the presence of a permanent roost cave nearby.

The Ghost Bat was recorded on nine occasions within the survey area through acoustic recordings (calls), scats recorded in nocturnal feed caves and an individual sighted during spotlighting within the HD2 area. Seven caves (two Category 3 roost caves with occasional occupancy and five Category 4 nocturnal roost caves) were recorded within the survey area. Based on regional records, this species has a strong presence in the vicinity of the survey area. The survey results are consistent with the Ghost Bat foraging in low numbers on the HD2 and Bedded Hilltop ridges.

Short Range Endemic Invertebrate Fauna

Five habitats were considered more conducive to relictual Short Range Endemic invertebrates: Breakaway, Mulga Woodland, Minor Drainage, Gorge/Gully and Rocky Hill. Most of these latter habitats are associated with an isolated ridge running in an east-west direction, so most of the breakaways and rocky slopes are south-facing and therefore conducive to Short Range Endemic invertebrates.

The field surveys generated a total of 202 samples (comprising 358 individuals) from Short Range Endemic target taxa representing 66 different taxa. Seventeen of these species were known to be widespread, 48 were potential Short Range Endemics and one was a confirmed Short Range Endemic, *Karaops banyjima*. Of these Short Range Endemic category taxa, 32 were identified to the level of species or morphospecies:

- seven spiders: *Karaops banyjima*, *Karaops* sp. 'ARA001', *Aurecocrypta* 'MYG315', *Aurecocrypta* 'sp. indet. (AESHD1)', *Synothele* 'MYG309', *Synothele* 'MYG311' and *Yilgarnia* 'MYG197'
- nine pseudoscorpions: *Tyrannochthonius* 'sp. indet. (AESHD1)', *Tyrannochthonius* 'sp. indet. (AESHD2)', *Austrohorus* 'sp. indet. (AESHD5)', *Beierolpium* 'sp. indet. (AESHD1)', *Beierolpium* 'sp. indet. (AESHD2)', *Euryolpium* 'sp. indet. (AESHD6)', *Euryolpium* 'sp. indet. (AESHD7)', 'Genus 7/4 PSE118' and '*PSEAAA* sp. indet. (AESHD4)'
- four scorpions: *Lychas* 'bituberculatus complex', *Lychas* 'hairy tail complex', *Lychas* 'multipunctatus complex' and *Urodacus* 'HD1'
- seven centipedes: *Sepedonophilus* 'HD1', *Sepedonophilus* 'HD2', *Mecistocephalus* 'HD1', *Mecistocephalus* 'HD2', *Mecistocephalus* 'HD3', *Cryptops* 'HD1' and *Orphnaeus* 'HD1'
- three millipedes: *Antichiropus* 'wonmunna', *Austrostrophus* 'Clade A' and *Austrostrophus* 'Clade E'
- two isopods: *Buddelundia* '10ma' and *Buddelundia* '77'.

Seventeen Short Range Endemic taxa sampled represented ambiguously identified groups:

- three spiders: *Synothele* sp., *Aname* sp. and Nemesiidae sp.
- five pseudoscorpions: *Anatemnus* sp., *Sundochernes* sp., *Euryolpium* sp., *Indolpium* sp. and Olpiidae sp.
- two centipedes: *Sepedonophilus* sp. and Geophilomorpha sp.
- two millipedes: *Antichiropus* sp. and *Austrostrophus* sp.
- five isopods: *Buddelundia* sp., Buddelundiinae sp., *Pseudodiploexochus* sp., *Troglarmadillo* sp. and Philosciidae sp.

Several Short Range Endemic category invertebrates were found in multiple habitat types, suggesting that they may be less specialised with respect to their habitat preferences:

- *Lychas* 'bituberculatus complex', from Stony Plain, Alluvial Plain and Low Hills and Slopes
- *Sepedenophilus* 'HD1', from Gorge/Gully and Mulga Woodland
- *Mecistocephalus* 'HD1', from Rocky Hills, Gorge/Gully and Mulga Woodland
- *Austrostrophus* 'Clade E', from Stony Plain, Alluvial Plain and Mulga Woodland

- *Antichiropus* 'wonmunna', from Mulga Woodland in the survey area, but from gully slopes and riparian vegetation outside of the survey area.

These species are likely to be found outside of the limits of the survey area.

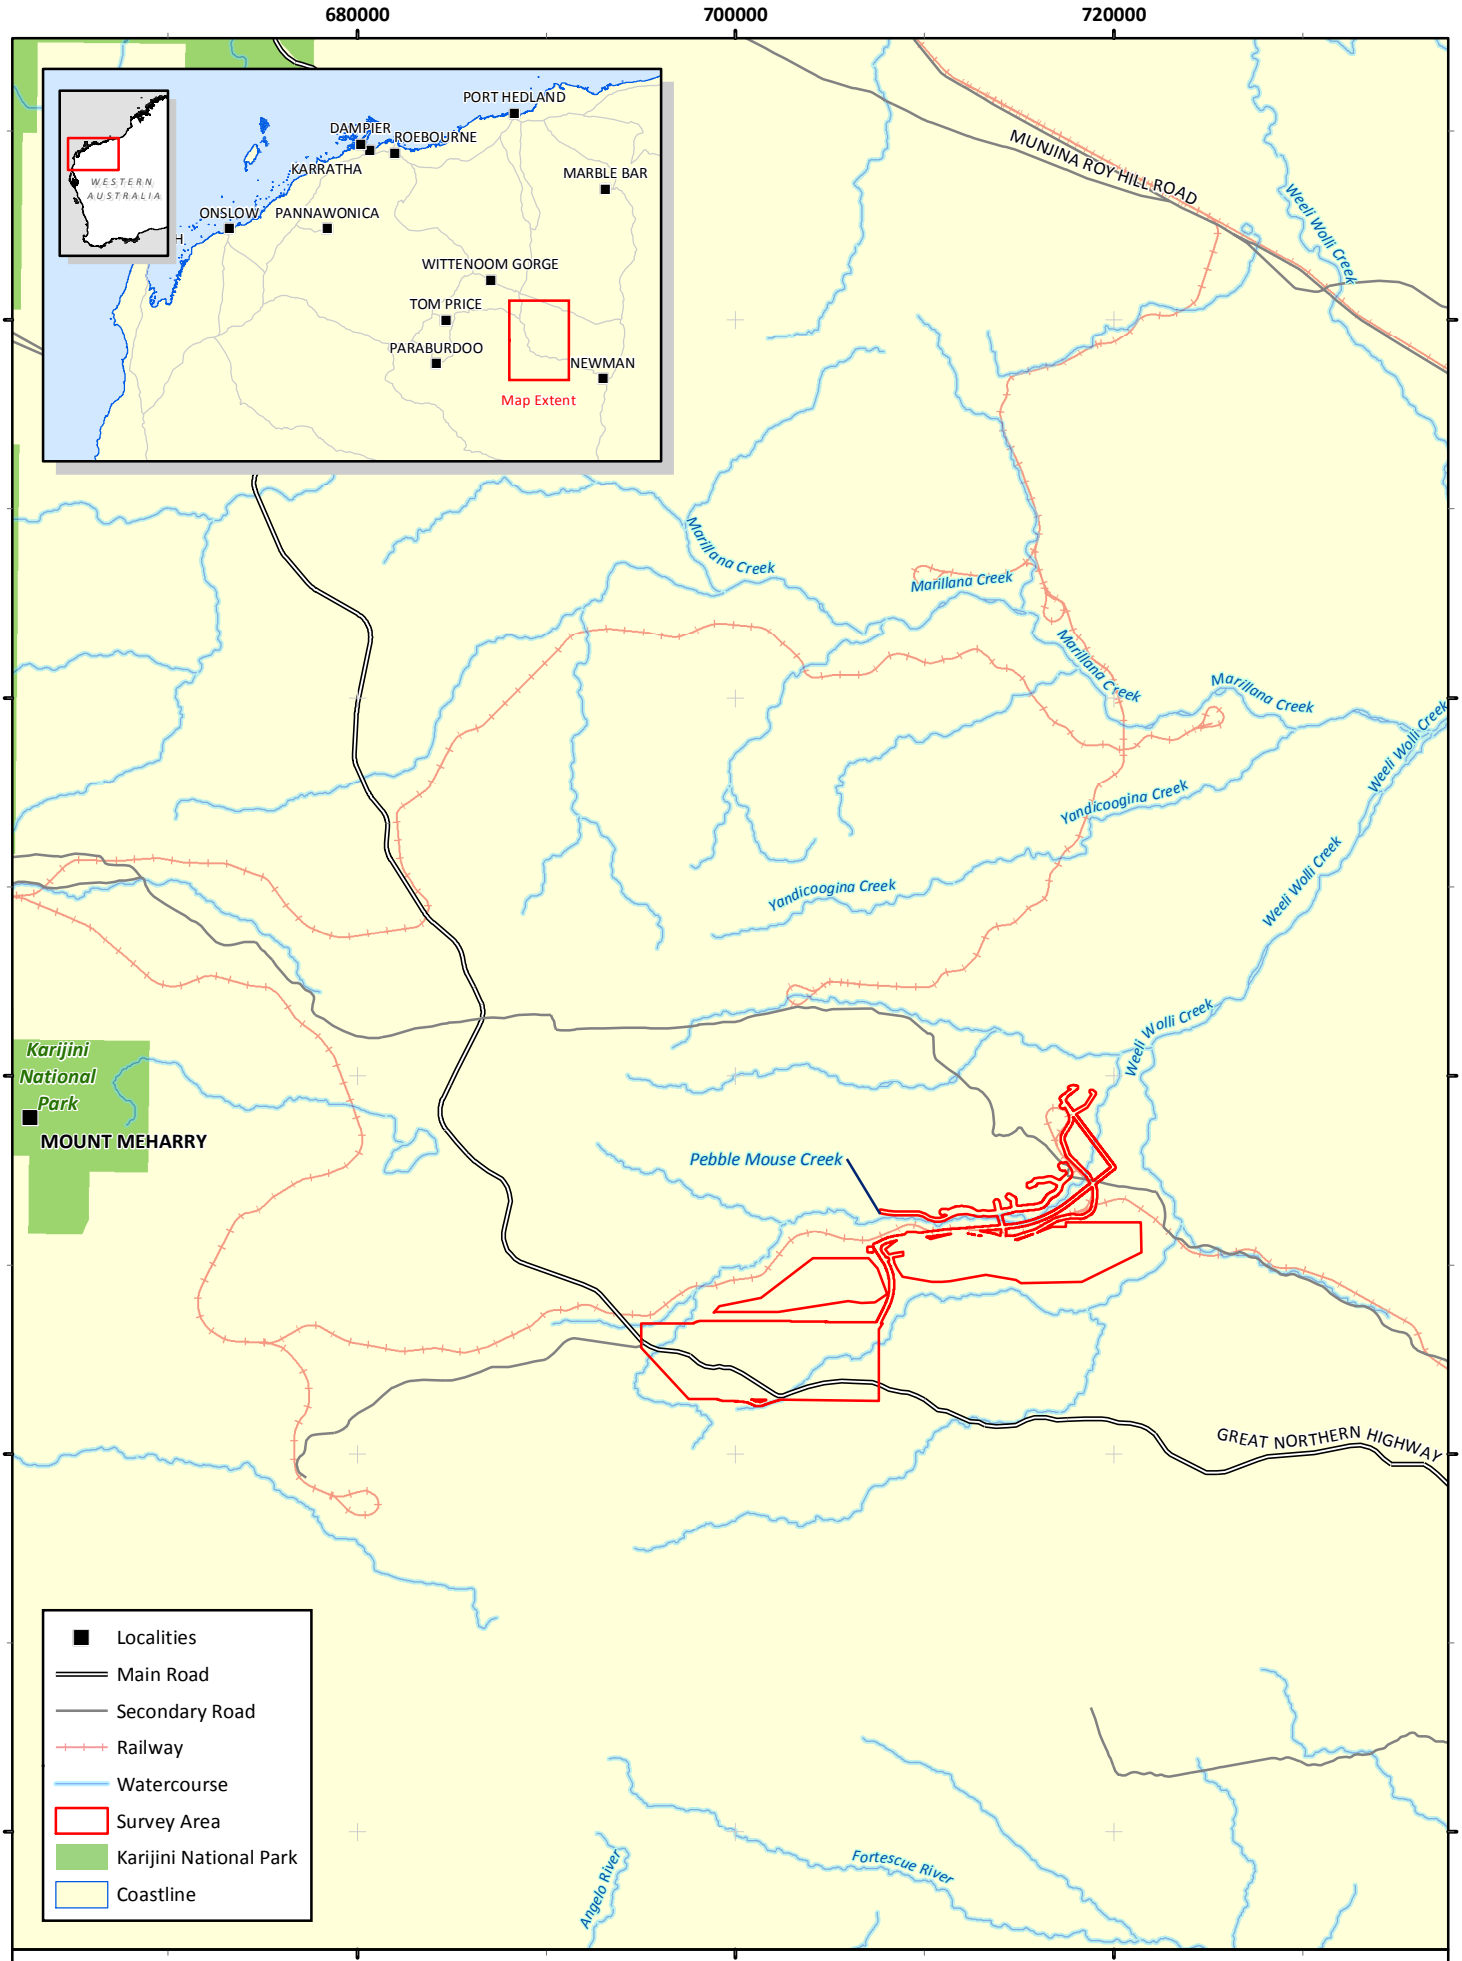
1 Introduction

1.1 Project Background

Rio Tinto is evaluating the potential development of additional iron ore deposits at Hope Downs 2 (HD2) in the Pilbara region of Western Australia, approximately 68 km north-west of Newman. Astron Environmental Services (Astron) was commissioned to undertake a multiple-phase Level 2 fauna survey of the 10,817.7 ha HD2 Development Envelope, which includes two deposits: HD2 and Bedded Hilltop, and herein is referred to as the survey area (Figure 1). This report presents the findings of the Level 2 surveys completed in November/December 2017, May 2018 and March 2019 as an overarching assessment.

1.2 Scope and Objectives

The objective was to undertake a terrestrial Level 2 vertebrate fauna and Short Range Endemic (SRE) invertebrate fauna assessment through a desktop assessment and field survey, and to incorporate data from previous biological surveys conducted in the vicinity of the survey area. The resultant data have been utilised to produce this report, which is intended to support and inform the environmental assessment process in accordance with the requirements of the Environmental Protection Authority. The scope of works was to undertake a:



- desktop assessment, including database searches and literature review of available resources
- terrestrial vertebrate fauna field survey, including:
  - systematic fauna sampling
  - targeted Matters of National Environmental Significance (MNES) species sampling and searches
  - fauna habitat mapping.
- targeted SRE field survey, including:
  - targeted survey and searches
  - dry pitfall trap sampling
  - SRE fauna habitat mapping.

Astron conducted the fauna survey in accordance with the regulatory guidance detailed in Table 1 and Rio Tinto Data Standards (Rio Tinto 2019).

The scope and key limitations of the survey are outlined in Table 1. Section 3.7 of this report provides more detail on the limitations of the survey.

Table 1: Summary of Astron's vertebrate fauna and SRE invertebrate fauna assessment.

Level of survey	Survey area size	Survey timing	Relevant regulatory guidance documents	Key survey limitations
Level 2 terrestrial vertebrate and SRE fauna survey	10,817.7 ha	21 November to 2 December 2017 (Phase 1) 18 to 27 May 2018 (Phase 2) 8 to 18 March 2019 (Phase 3)	• Position Statement No. 3 (Environmental Protection Authority 2002) • Technical Guidance - Sampling Methods for Terrestrial Fauna (Environmental Protection Authority 2016a) • Technical Guidance – Sampling of Short Range Endemic Invertebrate Fauna (Environmental Protection Authority 2016b) • Technical Guidance - Terrestrial Fauna Surveys (Environmental Protection Authority 2016c) • *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) referral guideline for the Endangered Northern Quoll *Dasyurus hallucatus* (Department of the Environment and Energy 2016) • Survey Guidelines for Australia's Threatened Reptiles, Birds, Mammals and Bats (Department of Sustainability Environment Water Population and Communities 2011b; Department of the Environment 2010b; Department of Sustainability Environment Water Population and Communities 2011a; Department of the Environment 2010a) • Interim Guidelines for Preliminary Surveys of the Night Parrot (*Pezoporus occidentalis*) in Western Australia (Department of Parks and Wildlife 2017)	• Rainfall in the three months preceding Phase 2 and Phase 3 was below average, this led to potentially dry unfavorable conditions for SRE and vertebrate fauna sampling. However the rainfall received during the Phase 3 survey itself enabled a good sampling opportunity for vertebrate fauna and SRE species. • Only one SRE taxa could be assigned a species name and 17 of the 49 SRE invertebrate taxa could not be identified. • These are classified as minor limitations for vertebrate and SRE fauna as they are not expected to have a major impact on survey outcomes.

2 Environmental Context

2.1 Physical Environment

2.1.1 Climate

The climate of the Pilbara region of Western Australia is classified as arid tropical with two distinct seasons: a hot, wet summer (October – April) and a mild, dry winter (May – September) (Bureau of Meteorology 2019).

Based on long-term climatic data from the nearest Bureau of Meteorology weather station at Newman Aero (Station 007176) (approximately 90 km south-east of the survey area) the mean annual rainfall since 1971 is 329.5 mm. The mean maximum daily temperatures since 1996 range between 23.0°C and 39.2°C, and range above 30°C for much of the year (Bureau of Meteorology 2019) (Figure 2).

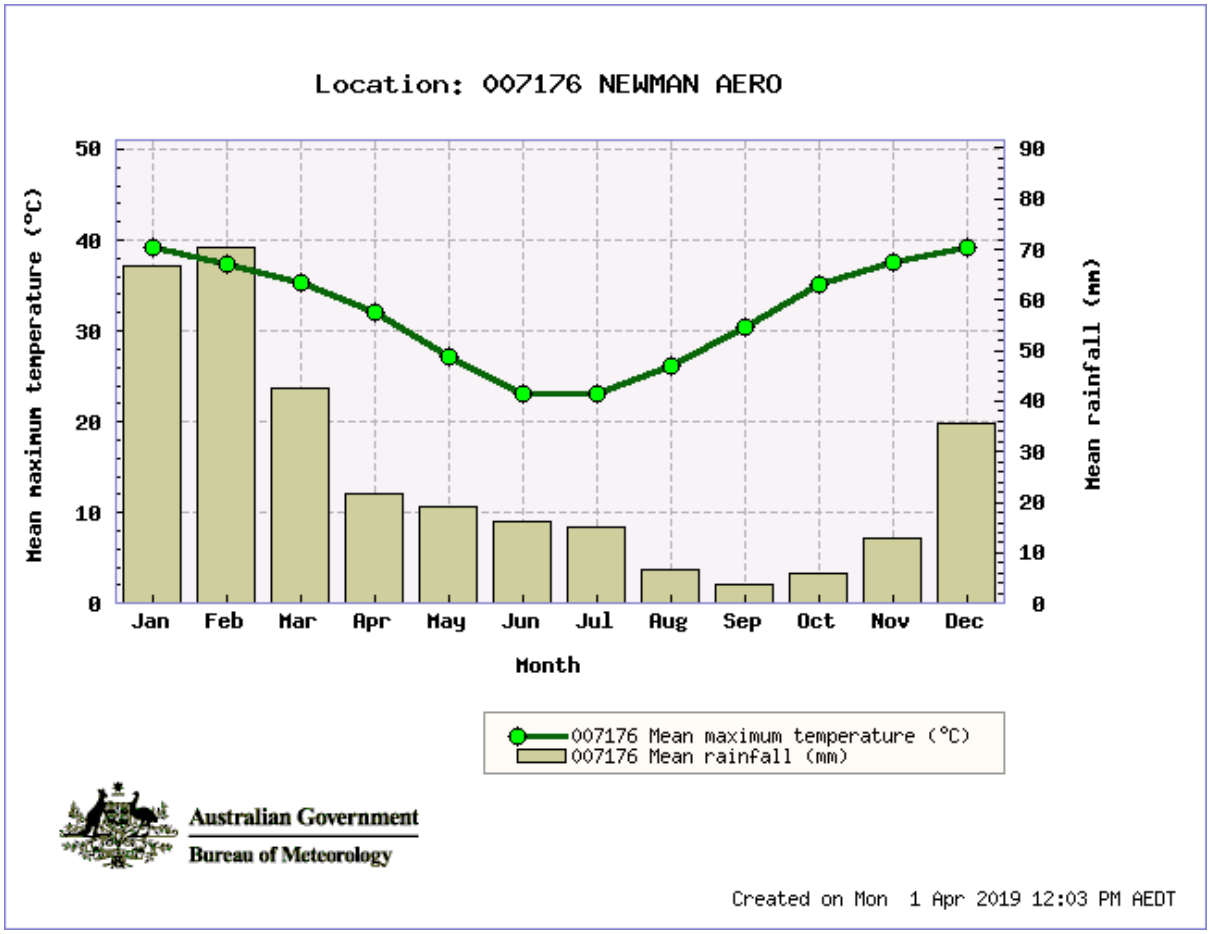

Figure 2: Climate data for Newman Aero Station (Station 007176). Mean annual rainfall data has been calculated from 1971 – 2019 and mean maximum temperature has been calculated from 1996 – 2019 (Bureau of Meteorology 2019).

2.1.2 Geology and Soils

The surface geology of the survey area is comprised of 10 units (Stewart et al. 2008), with Colluvium 3841 being the most dominant (Table 2). Geological mapping of the survey area and surrounds is presented in Figure A.1 (Appendix A).

Table 2: Geological units of the survey area (Stewart et al. 2008).

Geological name	Label	Area (ha)
Alluvium 38485: Channel and flood plain alluvium; gravel, sand, silt, clay, locally calcreted.	Qa	431.4
Brockman Iron Formation: banded iron-formation, chert, mudstone and siltstone.	Lchk	681.7
calcrete 38497 - Pisolitic, nodular or massive calcrete; ferruginous inclusions; calcareous cementing of bedrock and transported materials; locally with intercalated chalcedony; as low mounds, in playa lakes, or as valley calcrete; locally dissected and karstified	Czk	18.1
Colluvium 38491: Colluvium, sheetwash, talus; gravel piedmonts and aprons over and around bedrock; clay-silt-sand with sheet and nodular kankar; alluvial and aeolian sand-silt-gravel in depressions and broad valleys in Canning Basin; local calcrete, reworked laterite.	Qrc	2,587.8
Fortescue Group: Metadolerite, dolerite, gabbro; medium to coarse grained, massive grey-green rock, usually foliated.	Adf	763.6
Jeerinah Formation: Shale, sandstone, siltstone, mudstone, dolomite, local microbanded chert, jaspilite, conglomerate; fine-grained massive rhyolite; mafic tuff with local accretionary lapilli and agglomerate; thin basalt/dolerite and andesitic basalt flows.	Awfj	1,443.9
Marra Mamba Iron Formation: Chert, ferruginous chert, jaspilite, banded iron-formation, minor shale, siltstone, mudstone.	Achm	2,328.3
Mount McRae Shale and Mount Sylvia Formation: Interbedded shale, chert, banded iron-formation.	Ashm	1,212.5
Weeli Wolli Formation: Banded iron-formation (commonly jaspilitic), mudstone, siltstone; common interlayered metadoleritic sills.	Lchw	1,036.1
Wittenoom Formation: Calcitic dolomite, interbedded chert and shale in upper and lower parts, volcaniclastic sandstone.	Alhw	314.3

2.1.3 Surface Water and Hydrology

No Wetlands of International Importance (i.e. Ramsar wetlands) or Nationally Important Wetlands occur within the survey area (Department of the Environment and Energy 2017a, 2017b). The nearest Nationally Important Wetland is Fortescue Marshes, located 40 km north of the survey area, which has been nominated as a proposed Ramsar site. Pebble Mouse Creek passes through a large proportion of the survey area. One of the upper tributaries of Weeli Wolli Creek passes through the HD2 area.

2.2 Biological Environment

2.2.1 Interim Biogeographic Regionalisation of Australia

The Interim Biogeographic Regionalisation for Australia (IBRA version 7) divides the Australian continent into 89 bioregions and 419 subregions (Department of the Environment and Energy 2017c). The IBRA regions represent a landscape-based approach to classifying the land surface, including attributes of climate, geomorphology, landform, lithology, and characteristic flora and fauna. The survey area occurs in the Pilbara bioregion, of which 8.4% is represented in the national reserve system (Department of the Environment and Energy 2016b).

The biodiversity of the 53 subregions recognised in Western Australia was documented as part of a national audit to provide priorities for conservation action (Department of Conservation and Land Management 2002). The survey area occurs within the Hamersley subregion of the Pilbara region and is described in the audit as:

- Hamersley PIL3 – dissected bold plateaux and ranges of flat lying, moderately folded sandstone and quartzite with vegetation described as Mulga low woodland over tussock grasses occurring on fine textured soils in valley floors, with scattered Snappy gum (*Eucalyptus leucophloia*) over *Triodia brizoides* on skeletal soils of the ranges (Kendrick 2001).

2.2.2 Land Systems

Land systems of the Western Australian rangelands have been mapped and described by the Department of Primary Industries and Regional Development (formerly the Department of Agriculture and Food) outlining the distributions and providing comprehensive descriptions of biophysical resources, including soil and vegetation condition. A total of 102 land systems occur in the Pilbara bioregion covering 181,723 km^2. Nine land systems occur in the survey area (Table 3). The layout of these land systems within the survey area is shown in Figure A.2 (Appendix A).

Table 3: Distribution of land systems within the survey area.

Land system	Total area within bioregion (ha)	Total area (ha) (proportion of survey area (%))
Boolgeeda - stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands.	961,847	1,486.0 (13.7)
Calcrete - Low calcrete platforms and plains supporting shrubby hard spinifex grasslands.	134,834	4.9 (<0.1)
Egerton - Highly dissected plains and slopes with sparse mulga shrublands or shrubby hard spinifex grasslands.	66,849	1.4 (<0.1)
McKay - Hills, ridges, plateaux remnants and breakaways of meta sedimentary and sedimentary rocks supporting hard spinifex grasslands with acacias and occasional eucalypts.	426,124	326.7 (3.0)
Newman - rugged jaspilite plateaux, ridges and mountains with hard spinifex.	1,994,339	4,647.2 (43.0)
Pindering - Gravelly hardpan plains supporting groved mulga shrublands with hard and soft spinifex.	38,738	410.5 (3.8)
Platform - dissected slopes and raised plains supporting shrubby hard spinifex grasslands.	236,390	2,522.2 (23.3)
Rocklea - basalt hills, plateaux, lower slopes and minor stony plains supporting hard spinifex and occasionally soft spinifex grasslands with scattered shrubs.	2,880,288	1,314.1 (12.1)
Wannamunna - Hardpan plains and internal drainage tracts supporting mulga shrublands and woodlands and occasionally eucalypt woodlands.	63,004	104.5 (1.0)

2.2.3 Pre-European Vegetation

Beard (1975) completed broad-scale (1:1,000,000) pre-European vegetation mapping at an association level. The Beard mapping was later used by the Department of Agriculture and Food (Shepherd, Beeston, and Hopkins 2002) to compile vegetation units that assisted with identifying pre-European and current extents of vegetation throughout Western Australia.

Three pre-European vegetation units, 82, 18 and 29 (Shepherd, Beeston, and Hopkins 2002), are associated with the survey area (Figure A.3, Appendix A). Table 4 summarises the current and pre-European extent of these three vegetation units in the Pilbara bioregion and the survey area.

Table 4: Extent of pre-European vegetation within the survey area (Government of Western Australia 2018).

Vegetation association	Mapping unit (Beard 1975)	Description	Total area (ha) (proportion of survey area (%))	Pre-European extent (ha)	Current extent in bioregion (ha)	Proportion of pre-European extent remaining (%)	Pre-European extent with formal protection (%)
82	e16Lr t3Hi	Hummock grasslands, low tree steppe; snappy gum over *Triodia wiseana*	5,452.2 (50.4)	2,168,702	2,156,558	99.4	13.7
18	a1Li	Low woodland, open low woodland or sparse woodland; mulga (*Acacia aneura*)	5,339.0 (49.4)	580,512	576,389	99.3	29.6
29	a1Lp	Mulga (*Acacia aneura*) and associated species.	26.5 (0.2)	172,083	171,975	99.9	12.8

2.3 State and Commonwealth Conservation Categories and Management

Commonwealth and State regulatory authorities maintain databases of the locations and conservation status of significant flora, fauna and ecological communities in Western Australia.

The EPBC Act provides a legal framework to protect and manage MNES including listed flora, fauna and ecological communities. These listed flora, fauna and ecological communities are allocated a conservation category, which are outlined in Tables B.1 and B.6 (Appendix B).

Ecological communities may be subject to processes that threaten to destroy or significantly modify it across much of its range. These communities are identified as threatened ecological communities (TECs) and are listed at both Commonwealth level under the EPBC Act and State level under the *Biodiversity Conservation Act 2016* (BC Act)[1] (Tables B.1 and B.2, Appendix B). The Department of Biodiversity, Conservation and Attractions (DBCA) maintains a list of priority ecological communities (PECs), which may also be under threat and are assigned one of four Priority rankings according to the criteria outlined in Table B.3 (Appendix B).

Under Western Australian legislation, all native fauna is protected and it is an offence to 'take' protected fauna. The BC Act also provides for native fauna species that have been adequately searched for and are deemed to be, in the wild, threatened, extinct or in need of special protection to be gazetted as Threatened, Extinct or Specially Protected (Table B.4, Appendix B). In addition, due to the diversity of Western Australia's fauna, many species are known from only a few collections or locations, but have not been adequately surveyed. Such fauna may be rare or threatened, but cannot be considered for declaration as Threatened fauna until adequate surveys have been undertaken. These fauna species are included on a supplementary conservation list managed by DBCA called the *Priority Fauna List*. Priority fauna are categorised according to level of threat and other information and the conservation categories are described in Table B.5 (Appendix B).

2.4 Land Use and Tenure

The survey area is located within the Shire of East Pilbara. The local area is mainly used for mineral exploration and mining activity. Karijini National Park is the nearest conservation reserve, located approximately 35 km to the west of the survey area (Figure 1).

[1] From 1 January 2019, the *Wildlife Conservation Act 1950* has been replaced by the *Biodiversity Conservation Act 2016* (BC Act) and its regulations. Phase 1 and 2 of this study was completed in 2017-18, prior to the BC Act being enacted.

3 Methods

3.1 Desktop Assessment

A desktop assessment was undertaken to assess whether any conservation listed vertebrate and invertebrate species, SRE invertebrate species or communities, or PECs/TECs were likely to occur within the survey area. For vertebrate species, the review focused on key habitats for conservation listed fauna and species of MNES. For SRE invertebrates, the review focused on invertebrate groups with a known high proportion of SRE species (the SRE groups): centipedes (Chilopoda), harvestmen (Opiliones), millipedes (Diplopoda), non-marine snails (Gastropoda), pseudoscorpions (Pseudoscorpiones), scorpions (Scorpiones), terrestrial slaters (Isopoda) and spiders (Araneae).

3.1.1 Database Searches

Environmentally Sensitive Areas (ESAs) are declared by the Minister for Environment under Section 51B of the *Environmental Protection Act 1986* to prevent incremental degradation of important environmental values such as declared rare flora, TECs or significant wetlands. A search for ESAs in the vicinity of the survey area was conducted using Western Australian government datasets (Department of Water and Environmental Regulation 2017) and the Register of the National Estate dataset (Department of the Environment and Energy 2008). In addition, database searches for fauna were conducted with search details summarised in Table 5.

Table 5: Database searches requested.

Database name	Date search results received	Search focus	Search area
NatureMap (Department of Biodiversity, Conservation, and Attractions 2017a)	25/10/2017	Terrestrial fauna and fauna of conservation significance	40 km radius from a central point defined by the coordinates: 23°04'04" S, 119°01'56" E
Threatened and Priority Ecological Communities Database (Department of Biodiversity, Conservation, and Attractions 2017b)	16/11/2017	Listed threatened and priority ecological communities	20 km radius from the survey area boundary
Threatened and Priority Fauna Database (Department of Biodiversity, Conservation, and Attractions 2017b)	03/11/2017	Threatened and Priority fauna species	40 km radius from the survey area boundary
Protected Matters Search Tool (Department of the Environment and Energy 2017d)	25/10/2017	Threatened and Priority fauna species	40 km radius from a central point defined by the coordinates: 23°04'04" S, 119°01'56" E
Western Australian Museum Invertebrate Database (Western Australian Museum 2018)	21/05/2018 - 28/05/2018	Arachnids, myriapods, crustaceans, and molluscs	100 km buffer from survey area bounded by the coordinates: Top left corner (north-west): -22.175902°, 118.070211°; Bottom right corner (south-east): -23.956909°, 120.008080°

3.1.2 Literature Review

Fauna surveys have been previously commissioned by Rio Tinto within the vicinity of the survey area and supplied to Astron for the desktop assessment. The previous survey areas in relation to the current survey area are shown in Figure 3. The reports reviewed as part of this assessment include:

- Biota Environmental Sciences (2006) Hope Downs Rail Corridor (Juna Downs Section) Fauna Survey
- Biota Environmental Sciences (2009) Hope Downs Section 45C Targeted Fauna Review
- Biota Environmental Sciences (2011) Hope Downs Project Life of Mine Targeted Fauna Survey
- Biota Environmental Sciences (2014) Hope Downs South West Marra Mamba Development Targeted Fauna Survey
- Ecologia Environment (2014) Greater West Angelas Terrestrial Fauna Assessment
- Ninox Wildlife Consulting (2009a) A Vertebrate Fauna Survey of the Proposed Hope Downs 4 Infrastructure Corridor Option 1 Near Newman Western Australia
- Ninox Wildlife Consulting (2009b) A Vertebrate Fauna Survey of the Proposed Hope Downs 4 Infrastructure Corridor Option 6 Near Newman Western Australia.

For further contextualisation of the survey records relevant to the local vicinity of the survey area, consideration was also made of recent publicly available Environmental Impact Assessments in proximity to Hope Downs, specifically the work conducted at Southern Flank as part of Mining Area C operations for BHP Billiton Iron Ore:

- Biologic Environmental Survey (2016) Mining Area C – Southern Flank Environmental Impact Assessment for Ghost Bat (*Macroderma gigas*)
- Biologic Environmental Survey (2017) Proposed Mining Area C Development Envelope Vertebrate Fauna Desktop Assessment.

3.1.3 Habitat Characterisation

Using orthophotos provided by Rio Tinto and the available literature, the survey area was split into distinct landform types that were evaluated further for their likelihood of conservation listed vertebrate or SRE species occurrence. The assessment followed several criteria, such as the availability of moisture, extent of shade and shelter, and soil and vegetation types. Emphasis was given to landforms that may contain 'relict' species (surviving in sheltered and moist conditions) and those that may support habitat specialists (i.e. species restricted to rocky outcrops).

3.1.4 Conservation Assessment

Conservation listed vertebrate fauna species returned from the database searches were categorised for likelihood of occurrence within the survey area prior to the field survey, according to the criteria listed in Table B.7 (Appendix B). Post survey, the likelihood table was re-assessed utilising the information obtained during the field survey (Table B.7, Appendix B) and updated accordingly.

SRE invertebrates are species with distributions of less than 10,000 km^2 and their occurrence within their distribution is usually fragmented and highly localised (Harvey 2002; Ponder and Colgan 2002). However, it is often difficult to determine whether or not a species in one of the target SRE groups actually has a range < 10,000 km^2. For the purpose of desktop review, SRE status was determined by

the staff of the Western Australian Museum (WAM) through providing the results of SRE searches of the WAM databases. This assessment was reviewed and supplemented with information contained in previous environmental reports, the published literature and online databases. For morphospecies collected during the survey, the criteria outlined in Table B.8 (Appendix B) were used to determine SRE status. The SRE categories of the WAM (confirmed SRE, potential SRE and widespread species) were used to assess the status of species, with sub-categories applied in accordance with the WAM Taxonomic Services guidelines (Table B.8, Appendix B).

3.2 Field Survey

3.2.1 Survey Timing and Personnel

The fauna assessment was conducted over three survey phases (Table 6). All technical survey personnel have over five years of experience conducting Level 2 vertebrate fauna surveys or invertebrate surveys.

Table 6: Details of the fauna surveys completed within the survey area.

Phase	Dates	Personnel	Fauna licence number
1	21 November – 2 December 2017	Matthew Love; Dr Kellie McMaster; Tim Sachse; Michael Brown; Ray Lloyd; Sam Mueller	08-002227-1
2	18 – 27 May 2018	Matthew Love; Dr Kellie McMaster; Tim Sachse; Michael Brown; Dr Palitha Jayasekara	08-002227-1
3	8 – 18 March 2019	Matthew Love, John Trainer, David Keirle, Dr Erich Volschenk	BA27000015

3.2.2 Weather

Daily observations for rainfall and temperature were recorded by Rio Tinto at the HD1 Weather Station; however there was a period between 13 and 31 January 2018 where data was not recorded. Data was substituted for this period from the nearby Hope Downs 4 Weather Station which is approximately 48 km south-east of the HD1 Weather Station. Long term rainfall and temperature observations were sourced from the Newman Aero Bureau of Meteorology station (number 007176), approximately 90 km south-east of the survey area and 87 km south-east of the HD1 Weather Station. Local rainfall and temperatures preceding the survey are presented in Figure 4.

The daily maximum temperatures during the Phase 1 survey averaged 37.2°C ± 2°C and daily minimum temperatures averaged 19.4°C ± 3°C. Mean maximum and minimum daily temperatures were similar during the Phase 1 survey and the long-term means for November (Bureau of Meteorology 2019). Rainfall in the 12 months preceding the Phase 1 survey in November 2017 was 175 mm (50%) above the long-term mean of 329.5 mm. Rainfall in the 12 weeks preceding the Phase 1 survey was 14 mm (14%) below the mean rainfall for the same period.

The daily maximum temperatures during the Phase 2 survey averaged 35.6°C ± 2°C and daily minimum temperatures averaged 18.6°C ± 2°C. Mean maximum daily temperatures were higher during the Phase 2 survey than the long-term mean and the mean minimum daily temperatures were comparable to the long-term mean for May (Bureau of Meteorology 2019). Rainfall in the 12 months preceding the Phase 2 survey in May 2018 was 121 mm (63%) below the long-term mean of 329.5 mm. In the 12 weeks preceding the Phase 2 survey 75 mm of rain was recorded, which equates to 56% below the mean average rainfall for the same time period (136 mm).

The daily maximum temperatures during the Phase 3 survey averaged 37.9°C ± 3°C and daily minimum temperatures averaged 25.5°C ± 4°C. Mean maximum and minimum daily temperatures were warmer during the Phase 3 survey compared to the long-term means for March (Bureau of Meteorology 2019). A total of 14.2 mm of rainfall fell over five days during the Phase 3 survey. Rainfall in the 12 months preceding the Phase 3 survey in March 2019 was 161 mm (51%) below the long-term mean of 329.5 mm. Rainfall in the 12 weeks preceding the Phase 3 survey was 110 mm (37%) below the mean rainfall for the same period.

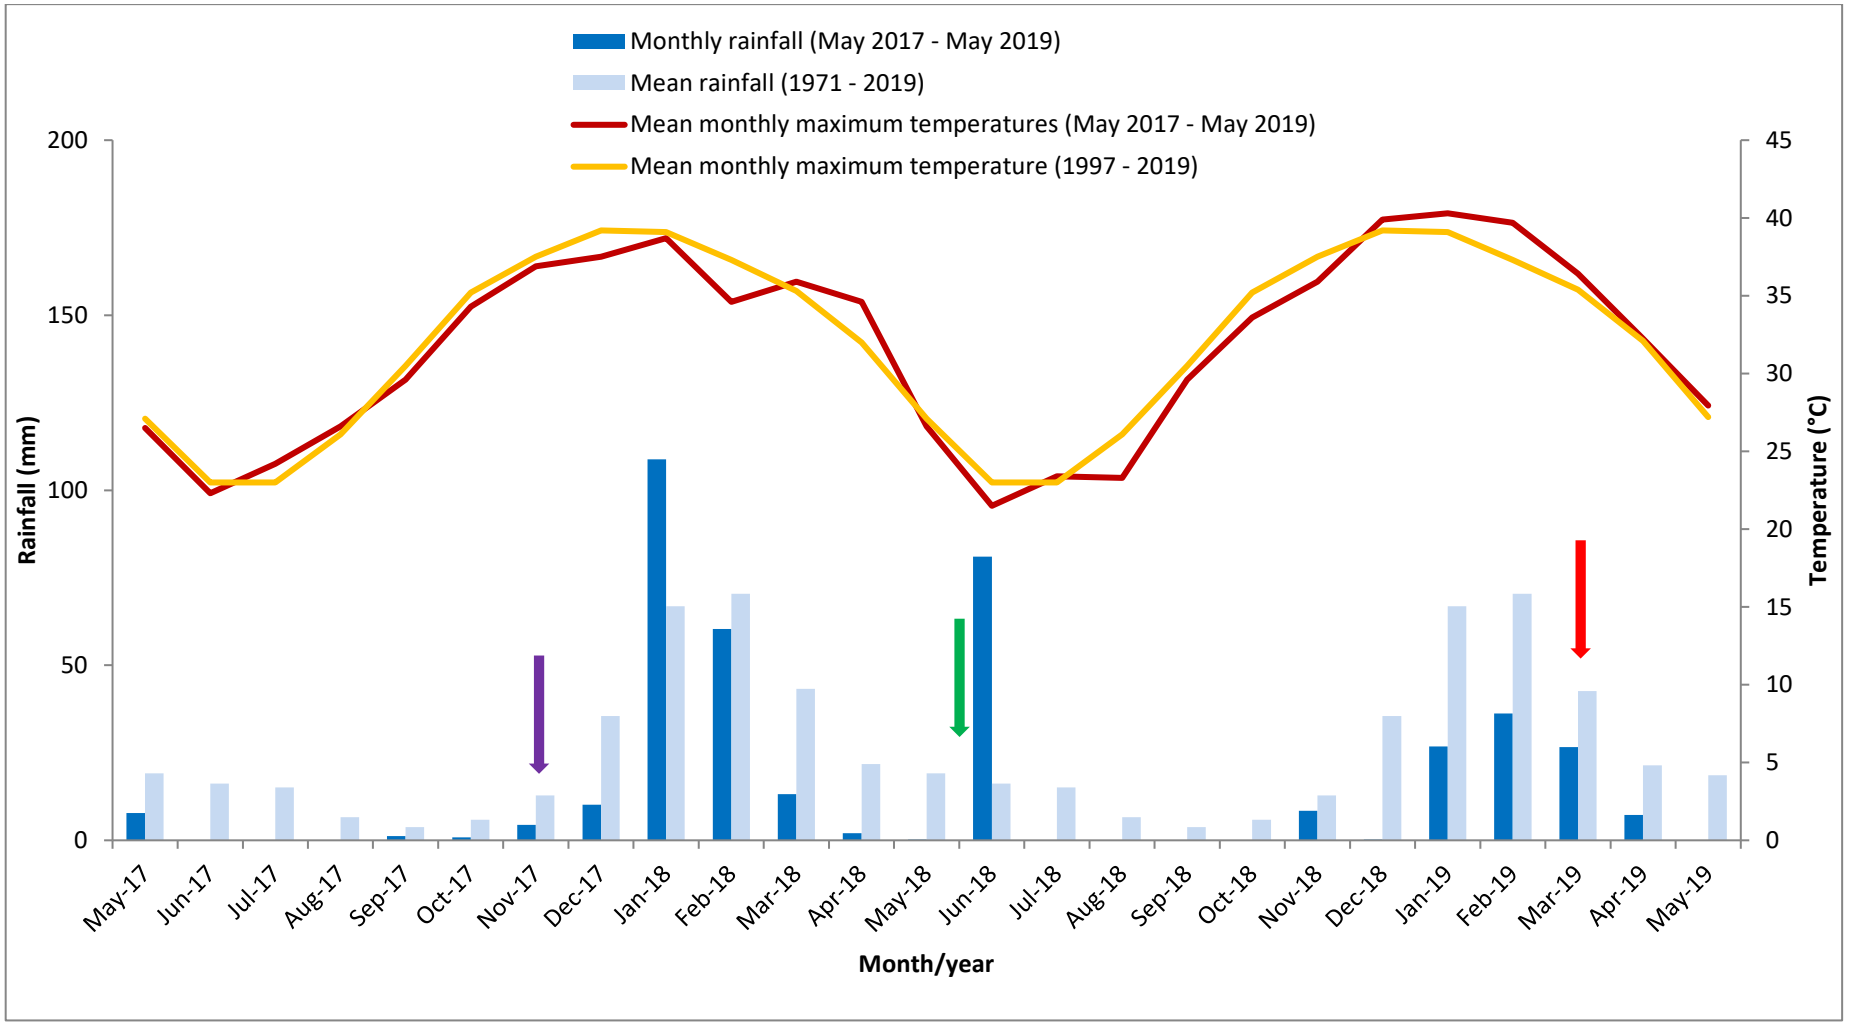

Figure 4: Mean monthly and recorded monthly rainfall (mm) and mean monthly and recorded monthly maximum temperatures (°C). Daily records supplied by Rio Tinto and long term records supplied by the Bureau of Meteorology from the Newman Aero station (number 007176) (Bureau of Meteorology 2019). The purple arrow displays the timing for the Phase 1 survey, the green arrow displays the timing for the Phase 2 survey and the red arrow displays the timing for the Phase 3 survey.

3.2.3 Vertebrate Fauna

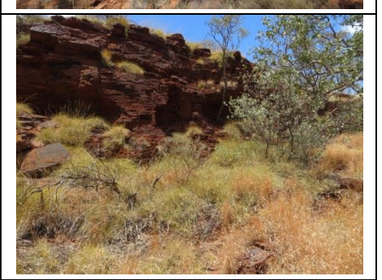
3.2.3.1 Habitat Assessment

Twelve fauna habitat assessments conducted within the eight fauna habitat types present in the survey area (Table C.1, Appendix C). The locations of the fauna habitat assessments are shown in Figure C.1 (Appendix C). The following information was collected at each site:

- location – coordinates measured using a handheld GPS (GDA94)
- recorder and date – personnel involved in undertaking the fauna habitat assessment and the survey date
- habitat/landform – position in the landscape - major fauna habitat types were described based on the landform and vegetation
- vegetation type – a broad description of vegetation type and structure
- soils – a brief description of soil type
- microhabitat – presence of specific microhabitat features, for example, leaf litter, logs, burrows, rocky outcrops, rock crevices, hollows, permanent or semi-permanent water
- condition – habitat condition was assessed based on the presence of anthropogenic (human-induced) disturbances, and using the condition ratings suggested by Thompson and Thompson (2010) (Table B.9, Appendix B)
- disturbance – any disturbance such as clearing, fire, weeds, flooding, vehicular, machinery, tracks or grazing
- photographs – a representative photograph was taken of each habitat assessment site.

The information derived from the fauna habitat assessments was used to delineate fauna habitats throughout the survey area, which were then mapped accordingly. The potential for the mapped habitats to provide suitable habitat for MNES species Northern Quoll (*Dasyurus hallucatus*) (EN, EN), Ghost Bat (*Macroderma gigas*) (VU, VU), Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) (VU, VU), Night Parrot (*Pezoporus occidentalis*) (EN, CR) and Pilbara Olive Python (*Liasis olivaceus barroni*) (VU, VU) were ranked according to the criteria listed in Table B.10 (Appendix B).

Any caves identified within the survey area were assessed based on definitions for Ghost Bat usage according to Bat Call WA (2019) (Appendix I) and categorised as:



- Category 1 – diurnal roost caves with permanent occupancy
- Category 2 – diurnal roost caves with regular occupancy
- Category 3 – roost caves with occasional occupancy.
- Category 4 – nocturnal roost caves (opportunistic usage).

3.2.3.2 Trapping Sites

A total of 19 trapping sites were sampled within the survey area (Figure C.1, Appendix C). Changes to survey boundaries between surveys resulted in three of the trapping sites being outside the survey area. Eleven trapping sites were sampled during the Phase 1 fauna assessment, and 13 trapping sites during the Phase 2 fauna assessment (Table 7). An additional six trapping sites were sampled during the Phase 3 fauna assessment (Table 7). Further detail on the trapping sites are provided in Table C.1 (Appendix C).

Table 7: Trapping site locations and survey effort.

Total trapping effort										**1,539**	

*Due to changes in survey boundaries between phases, these trapping grids were outside the survey area.

Astron used the following trap design for the fauna assessment:

- 11 trap sites were established with 10 pitfall traps (20 L buckets), six funnel traps, 20 Elliot traps and four cage traps (wire mesh cage trap)
- five trap sites were established as cage/Elliot sites, each with 10 Elliott traps and 10 cage traps arranged in a linear layout along suitable habitat features
- three trap sites were established as funnel sites, each with 10 funnels, 20 Elliott traps and four cage traps arranged in a linear layout.

Pitfall traps were not established within the Breakaway, Gorge/Gully and Rocky Hill trap sites due to the rocky terrain and hard bedrock not being conducive to this type of trap. The ground dwelling reptiles and mammals in this area were targeted through other sampling techniques such as active searching and opportunistic recordings.

Five cage traps were established within the survey area during Phase 2 for one night to target Northern Quolls (Figure C.1 and Table C.1, Appendix C). This trap site was designed as an opportunistic capture of a Northern Quoll from noticeable site occupancy due to the presence of recent scats and foraging evidence. These data are not part of the data analysis detailed in Section 3.6.

All but one nominal trap site contained pitfall and funnel traps that were used in conjunction with a 100 m drift fence running over the centre of the pit, directing animal movement into the pitfall trap. One site (TS16) was designed as two independent lines of 50 m drift fence directing animal movement into the pitfall trap. The trap sites remained open for a minimum of seven nights during the phases of fauna surveying. Traps were cleared each morning within three hours of sunrise to minimise the potential of trap death.

3.2.3.3 Avifauna Surveys

A total of 2,280 minutes (38 hours) of systematic avifauna (bird) censuses were conducted within the survey area.

During the Phase 1 and Phase 2 fauna assessment, bird censuses were undertaken at each trapping grid for 20 minutes each day on four occasions resulting in 80 minutes of survey effort at each site. This equates to a total of 1,920 minutes (32 hours) of avifauna censuses conducted for Phase 1 and Phase 2.

During the Phase 3 fauna assessment the bird census were undertaken at each trapping grid for 20 minutes each day on three occasions resulting in 60 minutes of survey effort at each site for this phase. This equates to a total of 360 minutes (6 hours) of avifauna censuses conducted for Phase 3.

All species were recorded from sightings and/or from species-specific bird calls. Opportunistic records of species across the survey area were also recorded and habitats that may support species of conservation significance were targeted.

3.2.3.4 Motion Sensitive Cameras

Motion sensitive cameras (Moultrie and Reconyx HC600 HyperFire) were set at 35 locations for between three and nine nights with a combined trapping effort of 202 camera trap nights (Figure C.1 and Table C.1, Appendix C). The cameras were baited and placed in prospective/suitable habitat such as cave entrances and water holes aimed at targeting MNES species.

3.2.3.5 Acoustic Bat Surveys

Acoustic ultrahigh frequency equipment was used to record the presence of bats, in particular the Pilbara Leaf-nosed Bat and Ghost Bat. Acoustic recording devices (Song Meter (SM) 2 SM2BAT+ and SM4) were positioned in a total of 23 locations to achieve a broad coverage of the survey area (Figure C.1 and Table C.1, Appendix C). The detectors were set for two to nine nights, resulting in a total of 108 recording nights. The bat echolocation data collected in the field was analysed by Robert Bullen (Bat Call WA 2019). One unit at BAT22 (SM2 7634) failed to operate (Bat Call WA 2019) and BAT11 was found to be outside the survey area due to survey boundary changes; the results have not been included in this report.

3.2.3.6 Night Parrot Survey

Due to the recent discovery of Night Parrot populations in Western Australia, the DBCA have published interim guidelines for Night Parrot surveys in Western Australia (Department of Parks and Wildlife 2017). The survey area is located in the area mapped as 'high priority for survey' for this species so passive acoustic surveys using Autonomous Recording Units (ARUs) were undertaken in the most prospective habitats (Stony Plain habitat containing *Triodia*).

ARUs were positioned at two sites during the Phase 2 and Phase 3 surveys. The ARUs were set at each location for between four and seven nights, resulting in a total of 23 recording nights (Figure C.1 and Table C.1, Appendix C). The ARUs were set for recording between from 1 hour pre-sunset to 1 hour post-dawn. The audio data was recorded at 44.1 kHz sampling rate and covered the frequency range 100 kHz to 21,000 kHz which brackets the Night Parrot call frequency range of 1,500 kHz to 3,500 kHz. The ARU data collected in the field was analysed by Robert Bullen (Bat Call WA 2019).

3.2.3.7 Active Foraging

Active searches were undertaken in microhabitats suitable for ground-dwelling reptiles and mammals. Active searches included the following:

- searching and recording scats, tracks and other traces
- turning over rock and logs and peeling off bark
- raking soil and leaf litter
- searching rocky habitats in cracks and caves, around water bodies and inside bore hole caps.

3.2.3.8 Targeted Searches

The aim of the targeted searches was to identify areas of potentially suitable habitat for conservation significant fauna, such as caves, and secondary signs including tracks, scats, diggings and burrows. Visual observation for conservation significant fauna habitat was ongoing whilst moving through the survey area. Track logs were recorded using a handheld GPS and are shown in Figure C.1 (Appendix C). Any opportunistic sightings of fauna species were recorded whilst traversing the survey area.

3.2.3.9 Nocturnal Spotlighting

Spotlighting at night was undertaken on foot and from vehicles to target fauna that are nocturnal or crepuscular, particularly conservation significant species. A total of 72 person hours of nocturnal spotlighting was undertaken in the survey area over all three phases of the fauna assessment.

Approximately two nights of spotlighting (3 hours per night) was conducted per phase of fauna surveying.

3.2.4 SRE Invertebrates

3.2.4.1 Habitat Assessment

Fauna habitats within the survey area were mapped for their suitability to support SRE invertebrates as part of an initial desktop assessment (Section 3.1) that was further refined following the field survey.

3.2.4.2 Active Foraging

Astron sampled a total of 37 systematic sites (including the 14 pitfall/funnel trapping sites) for SRE fauna across the survey area (Figure C.1, Appendix C). All sites were sampled by active foraging and litter-soil samples. The sites were selected so that they represented the landforms and vegetation associations inferred as prospective in the desktop assessment. Detailed site descriptions, including associated landforms and vegetation features are provided in Table C.1 (Appendix C). The descriptions provide qualitative information about factors influencing the macroclimate (e.g. landform, vegetation type, dominant substrate, and indicative plant species) and microclimate (e.g. amount of organic matter or existing damage).

Foraging was focused under boulders, crevices in rocky outcrops, at the base of tree logs, under loose tree bark, in moist and dry leaf litter accumulations and in *Triodia* clumps, but occurred in all habitats. The search for mygalomorph spider burrows was by visual inspections. Night-time searching for scorpions was undertaken in conjunction with the nocturnal spotlighting. Leaf litter was sifted *in situ* with a 16 mm soil sieve, and potential SRE invertebrates preserved directly in 98% ethanol. Approximately 46 person hours were spent searching the 23 SRE active foraging sites (excluding the pitfall/funnel trapping sites). Any potential SRE invertebrates observed in the dry pitfall or funnel traps at each of the 14 relevant trapping grids were also collected.

3.3 Specimen Identification

All vertebrate fauna were identified in the field. Field guides and accepted scientific peer review references were used for fauna identification. One reptile specimen was vouchered with the WAM to confirm its identification as it was thought to be *Lerista macropisthopus remota*, a P2 species.

The samples were separated and sorted to morphospecies level under a dissecting microscope by Dr Erich Volschenk. Morphological identifications to species level were attempted for all collected specimens. These identifications were based on the available taxonomic literature and keys, environmental reports and online databases. Compound microscopes were used to examine fine taxonomic characters not visible otherwise, for example, trichobothria patterns in pseudoscorpions.

Dr Simon Judd contributed information about isopod distributions, SRE assessment and specimen identification. The remaining identifications (spiders, pseudoscorpions, scorpions and snails) were carried out by Dr Erich Volschenk. Further details on SRE specimen identification are provided in Appendix D (Alacran Environmental Science 2019).

3.4 Taxonomy and Nomenclature

Nomenclature and sequence for vertebrate fauna within this report is as per WAM's *Checklist of the Vertebrates of Western Australia* (Western Australian Museum 2019).

For species identified in the desktop assessment, every effort was made to determine the current scientific name for each taxon, including wherever there was doubt as to their true taxonomy (through subsequent name changes). A comprehensive description of SRE taxonomy and nomenclature is provided in Appendix D (Alacran Environmental Science 2019).

The biology of many SRE species is not well known and the precise distribution and life history are poorly, if at all, documented (Harvey 2002; Harvey et al. 2011). Species identification is often very difficult because few specimens have been collected, reference collections are unavailable, the specimens are the wrong sex or life stage for identification, or they are morphologically cryptic and require DNA analyses. Taxonomic resolution can also be poor, either because there are no published taxonomic revisions for a group in question (terrestrial isopods in Western Australia), or because there is no expert actively working on one of the SRE groups.

3.5 DNA-Barcoding

A number of invertebrates collected could not be identified morphologically, so molecular barcoding techniques were used in an attempt to verify the identity of some of these specimens.

All of the target samples were sourced from field collected specimens detailed in Appendix D (Alacran Environmental Science 2019). Sequences and tissue samples were obtained from the following sources:

- WAM (tissues and comparative sequences): codes beginning with “T” and followed by a string of numbers
- Alacran Environmental Science (comparative sequences and tissues): samples predating 2019 begin with “ESV” and later samples beginning with “AES”
- Genbank (comparative sequences): codes beginning with two letters and followed by six numbers.
- Dr Erich Volschenk scorpion research (comparative sequences): codes beginning with “EVR”.

Sequences of the gene COI (cytochrome c oxidase subunit I) were amplified from muscle tissues obtained from specimens preserved in >95% (WAM tissue collection) or *ca.* 70% to >95% ethanol (wet collections of WAM and Dr Simon Judd). Sequence generation from tissues was undertaken by Xytogen Pty Ltd and AGRF Perth.

Sequence contigs were assembled from forward and reverse amplicons using Geneious R7 version 7.1.9 and were subsequently edited and pruned by eye, prior to consensus sequences being created.

Phylogenetic analyses and sequence alignments undertaken by Alacran were performed with Geneious R7. For each analysis, sequences were assembled and aligned using ClausalW or the Geneious alignment tool. Eight separate analyses were undertaken, with each analysis aiming to assess the identification of the target taxa for the respective group: Selenopidae, Barychelidae, Idopidae, Pseudoscorpiones, *Lychas* (Scorpiones, Buthidae), *Urodacus* (Scorpiones, Urodacidae), Geophilomorpha and Diplopoda. Further details on the barcoding techniques and analyses are provided in Appendix D (Alacran Environmental Science 2019).

Nineteen of the sequences from Barychelidae, Buthidae, Chthoniidae, Olpiidae, Selenopidae, Trigoniulidae and Urodacidae were also provided to WAM to use their sequences to determine the taxonomic identity of the specimens. Provided DNA sequences were each blasted against publicly accessible sequences in GenBank and with data sets derived from current research projects at WAM. The top 20 blast hits for each major taxon were gathered, duplicates removed and analysed with a

Maximum Likelihood phylogenetic analysis using a GTR+G model of evolution and 100 bootstraps (RAxML). Distances were calculated via tree-based estimates of identical bases in Geneious Prime 2019.2.1. Further details on the analyses are provided in Appendix D (Wilson, Huey, and Harvey 2019).

3.6 Statistical Analyses

3.6.1 Sampling Effort

Sampling effort was assessed using species accumulation curves and modelled estimates of the total species pool. Species accumulation curves were created by randomly sampling an incremental number of sites while plotting the total number of species sampled. Species estimators are particular statistical models of species accumulation which estimate the total species pool available. Four species estimators were compared: Chao 2, Jackknife 1, Jackknife 2 and Bootstrap (Colwell and Coddington 1994). Species accumulation curves were created for each faunal group (mammals, birds and herpetofauna) and for the different surveys (Astron Phase 1, 2 and 3 surveys separately and combined). Species estimations shown were based on all phases of survey combined. All analyses were performed in R 3.2.1 (R Development Core Team 2016) using the package "Vegan".

3.6.2 Site Classification

The similarity of species assemblages amongst sites (using all surveys) was assessed using two dimensional ordinations based on Sorensen's index of similarity amongst sites. Significant groupings of sites by habitat type were identified using the ANOSIM function (Clarke, Somerfield, and Gorley 2008) within the package "Vegan". Ordinations and ANOSIM tests were performed for each faunal group (mammals, birds and herpetofauna) separately.

3.7 Limitations

Following completion of the desktop assessment and field survey, a review of any limitations that may affect a complete assessment of the data collected was conducted. The limitations listed in Table 8 are based on those suggested as considerations in Technical Guidance - Terrestrial Fauna Surveys (Environmental Protection Authority 2016c).

Species accumulation curves did not reach an asymptote, particularly for herpetofauna, but when taking into account previous records as well as species recorded from methods other than trapping, then a large portion of the predicted assemblage was recorded. The low number of captures and reduced herpetofauna assemblage recorded during the Astron trapping program is likely due to a combination of dry seasonal conditions experienced during the surveys and the trap methods used. Due to the rocky terrain and hard bedrock within certain habitat types, eight out of the 19 trap sites did not utilise pitfall traps. In addition eight sites (TS12 – TS19) only had a single phase (post-wet season) of trapping. However, the ground dwelling reptiles usually captured through pitfall traps were sampled through other techniques such as active searching and opportunistic recordings. This is considered a very minor limitation, as the herpetofauna assemblage expected to occur in the survey area is common and widespread and is unlikely to include any conservation significant fauna that have not been previously recorded from other fauna assessments conducted in the vicinity (Appendix E). The ground dwelling reptiles and mammals usually captured through pitfall traps were sampled through other techniques such as active searching and opportunistic recordings. Also the single phase sites (TS12-TS19) were conducted during the 'wet season' of the Pilbara region of Western Australia which is seen as the most productive period for sampling vertebrate fauna species.

Due to the number of targeted fauna surveys conducted in the survey area the populations of conservation significant fauna were well documented, particularly for the conservation significant Pilbara Leaf-nosed Bat and Ghost Bat. However, the presence of other conservation significant fauna within the general vicinity of the survey area, such as the Northern Quoll and Night Parrot, were less well known prior to the current surveys. Seventeen of the 49 SRE taxa identified are currently undescribed. Only one SRE specimen could be identified to a valid species name. Many others belong to known but unnamed taxa and many remain to be clarified at the species level.

Table 8: Statement of limitations for the vertebrate and SRE invertebrate fauna survey.

Potential limitation	Degree of limitation	Statement regarding potential limitations
(i) Competency/experience	No limitation	The ecologists responsible for conducting the survey have extensive experience in conducting Level 2 vertebrate and SRE fauna surveys in the Pilbara.
(ii) Scope What faunal groups were sampled and were some sampling methods not able to be employed because of constraints such as weather conditions.	Very minor limitation (Vertebrates)	The survey scope was completed to an adequate level. Most sampling methods were satisfactorily employed, although the low number of captures and reduced (between 66% and 85% of expected) herpetofauna assemblage recorded is likely due to a combination of dry conditions preceding the surveys and the trap methods used, where eight out of the 19 trap sites did not utilise pitfall traps. However, the ground dwelling reptiles usually captured through pitfall traps were sampled through other techniques such as active searching and opportunistic recordings. The number of herpetofauna species recorded were similar or greater than other previous surveys in the vicinity. The fauna observed and identified are likely to represent a portion of the suite of species that utilise the survey area and were typical of the Hamersley subregion.
(iii) Proportion of fauna identified, recorded and/or collected	Minor Limitation	The fauna observed and identified are likely to represent a portion of the suite of species that utilise the survey area. Fauna habitats were able to be adequately described and a list of species likely to be present was prepared based on this assessment. Species accumulation curves did not reach an asymptote, particularly for herpetofauna, but when taking into account previous records as well as species recorded from methods other than trapping, then a large portion of the predicted assemblage was recorded. It is not possible to determine bat species abundance from echolocation records; bat activity levels provide a relative measure of the abundance of each species within the survey area. Seventeen of the 49 SRE taxa sampled represented ambiguously identified groups.
(iv) Sources of information Previously available information (whether historic or recent) as distinct from new data.	No limitation	Adequate information was available from database searches and previous studies in the survey area and region.
(v) Proportion of task achieved. Further work which might be needed?	No limitation	The survey scope was completed and most sampling methods adequately employed. Trap sites TS12 - TS19 were only sampled over one phase of trapping (post-wet season), however this is seen as the most opportune time to sample vertebrate species in the Pilbara region of Western Australia.

Potential limitation	Degree of limitation	Statement regarding potential limitations
(vi) Timing/weather/season/ cycle	Minor Limitation	Rainfall in the three months preceding all three phases of survey was below average; however rainfall experienced during the Phase 3 survey enabled good SRE and vertebrate sampling opportunities aside from Opiliones (harvestmen spiders). The SRE target group Opiliones often requires a substantial buildup of rainfall preceding surveys to be effective in enabling capture of these species (pers. com. E. Voslchenck 15 May 2019) and 'post wet' season is considered the most optimal time for sampling the majority of vertebrate species. The temperatures during the survey were above or close to the long term average. As such fauna abundance should not have been adversely affected.
(vii) Disturbances For example fire, flood, accidental human intervention which affected results of survey	Minor limitation	Large areas of BHT were affected by recent fires and therefore were not suitable for sampling. No other disturbances were recorded in the survey area that would have affected the survey results.
(viii) Intensity In retrospect, was the intensity adequate?	No limitation	The intensity of the surveys was considered adequate for a Level 2 assessment.
(ix) Completeness Was the relevant area fully surveyed?	No limitation	All main habitats in the survey area were surveyed; coverage of habitat assessments and targeted surveys completed as part of this assessment and previous survey efforts are considered adequate.
(x) Resources Degree of expertise available in animal identification to taxon level.	No limitation	Adequate resources were available to identify fauna species. All technical personnel involved in identification have extensive experience in conducting Level 2 vertebrate and SRE fauna surveys in the Pilbara. Taxonomic experts were consulted for all SRE fauna groups to help identify the selected taxa.
(xi) Remoteness and/or access problems	No limitation	No access constraints affected the survey outcomes.
(xii) Availability of contextual information For example biogeographic information on the region.	No limitation	Database searches and previous vertebrate fauna surveys in the vicinity of the survey area provided contextual information.

4 Results

4.1 Desktop Assessment

4.1.1 Environmentally Sensitive Areas

No ESAs intersected the survey area. The nearest ESA is Hamersley Range National Park (1977 boundary), now referred to as Karijini National Park, the nearest boundary of which occurs approximately 35 km west of the survey area (Department of the Environment and Energy 2008).

4.1.2 Vertebrate Fauna

The database searches and literature review results indicate that 312 vertebrate fauna have been previously recorded in the vicinity of the survey area, including eight amphibian species, 109 reptile species, 147 bird species and 48 mammal species (including nine introduced mammal species) (Table E.1-E.4, Appendix E). Of these, 26 species are of conservation significance, including four reptile species, 15 bird species and seven mammal species (Table F.1, Appendix F). Of these, 10 species were considered to have a 'high' likelihood (inclusive of those recorded within the survey area), four species were considered to have a 'moderate' likelihood and 12 were considered to have a 'low' likelihood of occurrence within the survey area (Table F.1, Appendix F). This is based on their respective ecology, habitats considered likely to be present and any previous records from historic survey and database records.

Previous surveys undertaken for Rio Tinto in the vicinity of the survey area recorded six conservation significant vertebrate fauna species: Pilbara Barking gecko (*Underwoodisaurus seorsus*) (P2), Fork-tailed Swift (*Apus pacificus*) (IA; IA), Northern Quoll, Pilbara Leaf-nosed Bat, Ghost Bat, and Western Pebble-mound Mouse (*Pseudomys chapmani*) (P4) (Table 9). The Rainbow Bee-eater (*Merops ornatus*), Cattle Egret (*Ardea ibis*) and the Eastern Great Egret (*Ardea modesta*) were previously listed as Migratory (IA) under the EPBC Act and Schedule 5 (IA) under the BC Act but have subsequently been delisted.

4.1.3 SRE Invertebrates

The database searches yielded a total of 12,376 records from within the search area (Appendix D; (Alacran Environmental Science 2019)). Of those, 4,335 records were attributed to SRE and potential SRE species. The SRE and potential SRE groups were represented by 282 taxa of which eight (3%) were named species, 182 (64%) were morphospecies and 92 (33%) were undetermined taxa, e.g. *Tyrannochthonius* sp. and Chthoniidae sp. (Table 10). The majority (260) of these taxa were classified as potential SRE 'Data Deficient' (DD) and 24 were confirmed SREs. The high proportion of potential SREs and undescribed morphospecies indicates a poor state of knowledge about these invertebrates in this region.

Table 10: Summary of Western Australian Museum database search results for SRE and potential SRE taxa.

Order	Named species	Morphospecies	Un-named taxa ("sp.")	Totals
Araneae: Araneomorphae (modern spiders)	2	5	3	**10**
Araneae: Mygalomorphae (trapdoor spiders)	2	78	21	**101**

4.2 Field Survey

4.2.1 Vertebrate Fauna Habitat

4.2.1.1 Fauna Habitats in the Survey Area

Eight broad fauna habitat types were recorded in the survey area: Minor Drainage, Gorge/Gully, Breakaway, Rocky Hill, Low Hill and Slopes, Alluvial Plain, Mulga Woodland and Stony Plain (Table 12 and Figure G.1, Appendix G).

Areas of cleared habitat were prevalent throughout the Bedded Hilltop (BHT) and HD2 sections of the survey area and associated with mineral drilling programs such as drill pads and drill access tracks. These areas totalled 832.3 ha (7.7%) and were considered in 'disturbed' condition. The fauna habitats surrounding these areas have been impacted by edge effects, lack of connectivity, grazing and the vegetation is often covered in dust. The majority of the habitats away from the mining operations were considered 'very good' to 'high quality' condition owing to the lack of disturbances from fire, weeds and grazing. The Minor Drainage habitats were heavily impacted by weed species such as **Cenchrus ciliaris* (Buffel Grass) and **Malvastrum americanum* (American Malvastrum), as well as impacts through extensive grazing and erosion from livestock. The Gorge and Breakaway habitats generally had the highest quality fauna habitat condition due to isolation from these threatening processes.

Minor Drainage habitat is a commonly recorded habitat for the Pilbara region and considered to be of moderate value to a wide spectrum of fauna species. The Minor Drainage habitat comprised a reduced diversity and density in vegetation species and communities, particularly when in the creek bed, and when present it was usually less dense and complex when compared to riparian habitats, such as Weeli Wolli Creek located to the east of the survey area. When present, vegetation typically exhibited a moderate diversity of microhabitats, with some tree hollows and woody debris such as

logs and leaf litter. The woody debris provides foraging and sheltering potential to ground dwelling reptiles and mammals. There were limited locations in this habitat that supported the potential for semi-permanent water bodies to form. Ground dwelling fauna are likely to utilise the linear nature of this habitat to traverse between habitats.

Gorge/Gully habitat is one of the more restricted habitats in the survey area. Gorges are a common feature of the Pilbara; however, as they tend to be narrow, linear features, gorges represent a small proportion of the total land area. In addition, they represent important shelter or roosting habitat for a number of MNES species, including the Pilbara Olive Python, Ghost Bat, Pilbara Leaf-nosed Bat and Northern Quoll. They may also support Priority listed species such as the blind snake *Anilios ganei* (P1). Occasional deep caves and semi-permanent rock pools are features within this habitat that can provide refuge for fauna during harsher drier seasonal conditions. There were no standing water bodies present during the survey; however, there are a number of locations where water could potentially pool after significant rain events, particularly within the BHT area. This habitat was considered of high value as it contains a complexity of microhabitats and potentially supports conservation significant fauna species.

Breakaway habitat is a common feature of the Pilbara but because they tend to be narrow, linear features, they represent a small proportion of the total land area. The breakaways of the survey area were often associated with the drop off areas of the Rocky Hill habitat and were specifically pertinent to BHT. Breakaway habitat contained microhabitats such as crevices, overhangs and shallow caves that provide shelter opportunities for MNES species. The caves have the potential to be used as diurnal roosts and nocturnal feeding roosts for the Ghost Bat, potential den sites for the Northern Quoll and Pilbara Olive Python. The Breakaway habitat provides important habitat values to a number of conservation listed species including MNES; therefore, it was considered of high importance for fauna.

Rocky Hill habitat is common and widespread throughout the Pilbara. This habitat generally has low vegetation complexity and low diversity of microhabitats; however, MNES species (such as the Northern Quoll) are likely to traverse and forage within these habitats. Other conservation significant species such as the Western Pebble-mound Mouse, *Anilios ganei* and the Pilbara Barking Gecko may also utilise this habitat. The soils are generally stony and compact, reducing the potential opportunities for burrowing species. Therefore this habitat was considered of moderate value for fauna.

Low Hill and Slopes habitat is widespread and common throughout the Pilbara region and although there are a few conservation listed species that may utilise this habitat, they are unlikely to be restricted to it, with the possible exception of the Western Pebble-mound Mouse. This habitat generally has low vegetation complexity and low diversity of microhabitats available for fauna species to exploit. The soils were generally stony and compact, reducing potential opportunities for burrowing species. This habitat was considered to be of low value to a broad spectrum of fauna species.

Alluvial Plain habitat is associated closely with drainage landforms of the Pilbara as it is often formed from the sediment overflow from drainage systems during flooding events. The Alluvial Plain habitat was considered to be of moderate value to a wide spectrum of fauna species as this habitat typically exhibited a moderate diversity of microhabitats, with some tree hollows and logs and some areas of sandy soils suitable for burrowing. At the time of the survey, the tree hollows of this habitat supported nesting potential for small passerines such as pardalotes, thornbills and multiple species of honeyeaters. Within the survey area the vegetation of this habitat was generally less complex when compared to Minor Drainage habitat, with an absence of large eucalypts. This habitat may provide some limited foraging opportunities for Ghost Bats and Pilbara Leaf-nosed Bats.

Mulga Woodland habitat is characterised by vegetation communities dominated by Mulga (*Acacia aneura*) on a stony mantle. The open to moderately dense woodlands consisted of an understorey composed of sparse tussock or hummock grasses. The woodlands provide nesting and shelter habitats for birds and reptiles and the tussocks and hummocks provide habitat for small birds, reptiles and mammals. Mulga Woodlands are also subject to sheet water flow after rainfall and vegetation is often densely clumped or banded due to the sheet flow, often forming large groves. However due to a low diversity of microhabitats present (generally the understorey and leaf litter were considered sparse), this habitat type was considered of low value to a wide spectrum of fauna species.

Stony Plain habitat is widespread and common throughout the Pilbara region and although there are a few species of conservation significance that may utilise it, they are not restricted to this habitat type. Conservation significant fauna likely to occur in this habitat type include the Western Pebble-mound Mouse. This habitat generally had low vegetation complexity and microhabitat diversity, and was considered to be of low value for fauna.

Table 12: Fauna habitat types recorded in the survey area.

Habitat type	Extent in survey area (proportion)	Broad habitat description	Vegetation description	Microhabitats	Sites	Habitat condition	Value (broad faunal assemblage and MNES species)	Representative photo
Minor Drainage	869.7 ha (8.1%)	Open drainage areas on stony soils. Water bodies only present during times of heavy inundation	*Eucalyptus victrix* (*Eucalyptus camaldulensis*) woodland over *Petalostylis labicheoides* and *Acacia* spp. tall open shrubland over tussock grassland	Hollow bearing trees and logs, thick ground cover/ vegetation, deep leaf litter	BAT9, BAT14, CAM15, CAM19, HA14, HA20, HA31, SRE3, SRE8, SRE14, TS6, TS7,	Good to High Quality	Moderate value to a wide spectrum of fauna species that are likely to reside in Minor Drainage habitats. Low value to target MNES species as they do not provide significant shelter.	
Gorge/ Gully	65.5 ha (0.6%)	Deep often rocky gorges, sometimes with ephemeral or semi-permanent pools	*Eucalyptus leucophloia* subsp. *leucophloia* and *Corymbia ferriticola* scattered low trees or *Eucalyptus repullulans* scattered low mallee over *Triodia pungens*, *Triodia vanleeuwenii* very open hummock grassland and scattered tussock grasses	Overhangs, crevices, caves, tree hollows, ephemeral, semi-permanent water	BAT1, BAT2, BAT7, BAT10, BAT17, BAT19, BAT22, BAT24, BAT25, CAM2, CAM3, CAM4, CAM5, CAM9, CAM18, CAM20, CAM22, CAM23, CAM24, CAM27, CAM28, CAM31, CAM32, CAM33, HA1, HA8, HA33, HA35, HA40, Q1, SRE1, SRE2, SRE4, SRE10, SRE13, SRE17, SRE18, SRE19, SRE20, TS10, TS11,	Very Good to High Quality	Primary high value habitat for target MNES species. Provides significant shelter sites and supports a diversity of fauna species.	
Breakaway	241.6 ha (2.2%)	Breakaway or ridge line, falling away to steep scree slope or drainage	*E. leucophloia* subsp. *leucophloia* scattered low trees over *Acacia* spp. tall shrubs over *T. pungens* very open hummock grassland, sometimes with scattered tussock grasses	Caves (roost/feed caves), cracks and crevices, sheltered leaf litter	BAT3, BAT4, BAT6, BAT8, BAT13, BAT16, BAT21, BAT23, BAT26, CAM1, CAM6, CAM7, CAM8, CAM11, CAM12, CAM13, CAM14, CAM17, CAM21, CAM30, CAM34, CAM35, HA4, HA5, HA9, HA24, HA38, SRE5, SRE9, TS8, TS9, TS19	Very Good to High Quality	High value to a low diversity of fauna species that are likely to reside in Breakaway habitats. High value to target MNES species as they are likely to roost and den within this habitat type.	
Rocky Hill	987.9 ha (9.1%)	Stony hills on high ranges with dissected valleys and gorges	*E. leucophloia* subsp. *leucophloia* and *Corymbia hamersleyana* scattered low trees to low open woodland over mixed open shrubland over open *Triodia wiseana, T. pungens, T. vanleeuwenii* hummock grassland	Shallow overhangs, boulders and crevices	BAT5, BAT15, CAM10, CAM16, CAM25, CAM26, CAM29, HA3, HA7, HA10, HA11, HA12, HA13, HA34, HA39, SRE11, SRE21, TS4, TS12, TS13, TS15	Good to High Quality	Moderate value for target MNES species as they are likely to traverse and forage within these habitats. Moderate value to a low diversity of fauna species that are rocky habitat specialists.	

Habitat type	Extent in survey area (proportion)	Broad habitat description	Vegetation description	Microhabitats	Sites	Habitat condition	Value (broad faunal assemblage and MNES species)	Representative photo
Low Hills and Slopes	5,460.0 ha (50.5%)	Low stony hills and slopes with dissected valleys and drainage on stony soils	*E. leucophloia* subsp. *leucophloia* and/or *C. hamersleyana* scattered low trees over mixed and *Acacia* spp. open shrubland over open *T. pungens, T. vanleeuwenii* hummock grassland	Termite mounds, *Triodia* hummocks, minimal leaf litter	AU2, HA2, HA17, HA19, HA22, HA25, HA36, HA37, HA41, HA42, TS5, TS16	Very Good to High Quality	Low value to a wide spectrum of fauna species that are likely to reside in within these habitats. Low value to target MNES species as this habitat type offers minimal ecological value to these species.	
Alluvial Plain	161.8 ha (1.5%)	Flood plain surrounding drainage areas	*Acacia pruinocarpa, Acacia aptaneura, Eremophila longifolia* tall open shrubland over tussock grassland	Dense leaf litter, termite mounds and spinifex clumps, cracking clays	TS2, TS14	Very Good	Low value to a wide spectrum of fauna species that are likely to reside in within these habitats. Low value to target MNES species as this habitat type offers minimal ecological value to these species.	
Mulga Woodland	1,031.4 ha (9.5%)	Stands of Mulga groves on clay based stony plains	*Acacia catenulata*, (*A. pruinocarpa*) tall shrubland over *Eremophila fraseri* scattered tall shrubs over *T. pungens* very open hummock grassland	Limited microhabitats, termite mounds, minimal leaf litter	AU1, BAT12, HA6, HA18, HA28, HA29, HA30, HA32, SRE6, SRE7, SRE12, SRE15, SRE16, SRE23, TS1, TS3, TS18	Disturbed to High Quality	Low value to a wide spectrum of fauna species that are likely to reside in within these habitats. Low value to target MNES species as this habitat type offers minimal ecological value to these species.	
Stony Plain	1,167.6 ha (10.8%)	Broad flat low lying plains to undulating plain on soft loamy soils	*A. aptaneura, A. pruinocarpa, A. catenulata* tall shrubland over *T. pungens* (and sometimes *T. vanleeuwenii)* hummock grassland or tussock grassland	Limited leaf litter, termite mounds and spinifex clumps	AU3, AU4, HA15, HA16, HA27, SRE11, SRE22, TS4, TS17	Very Good	Low value to a wide spectrum of fauna species that are likely to reside in within these habitats. Low value to target MNES species as this habitat type offers minimal ecological value to these species.	
Cleared	832.3 ha (7.7%)	Cleared areas from mining and pastoralism activities	Vegetation structure disturbed or absent.	None	None	Highly Degraded	Little value as fauna habitat.	

4.2.1.2 Significant Habitat Areas

None of the fauna habitats were considered to be synonymous with any TECs or PECs relating to terrestrial fauna listed in the Pilbara region (Department of Biodiversity, Conservation, and Attractions 2018).

Gorge/Gully habitats present in the survey area are considered important as refuge sites on a local scale due to the significant microhabitats they provide, such as caves and water pools. This habitat was considered highly suitable foraging and potential shelter for the MNES species Northern Quoll, Pilbara Leaf-nosed Bat, Ghost Bat and Pilbara Olive Python and would be considered habitat critical to the survival of the Northern Quoll and Ghost Bat under the EPBC Act definitions (Department of Environment 2013; Department of the Environment and Energy 2016; Threatened Species Scientific Committee 2016).

Twelve significant habitat features were recorded throughout the survey area: seven caves and five pebble mounds of the Western Pebble-mound Mouse (Figure G.1 and Table G.1, Appendix G). Of the seven caves, two caves (Caves 1 and 5) were categorised as Category 3 roost caves with occasional occupancy due to the presence of Ghost Bat feeding evidence (scats) and/or the physical properties of the caves were conducive to diurnal roosting. The remaining five caves (Cave 2, 4, 6, 7 and 8) were categorised as Category 4 nocturnal roost caves (opportunistic usage) given the physical properties of the caves. Ghost Bat feeding evidence was recorded in Caves 4 and 7; however, these sites were more overhangs rather than caves and not conducive to diurnal roosting for this species. An additional two Category 4 nocturnal roost caves (Caves 3 and 9) were recorded just outside the survey area (Figure G.1 and Table G.2, Appendix G). One additional pebble mound was also recorded just outside the survey area (Figure G.1 and Table G.1, Appendix G).

The survey area contained habitat with the potential to support semi-permanent surface water, specifically in the Gorge/Gully habitat within the BHT area. However no pools (standing water), semi-permanent wetlands or surface water were recorded in the survey area at the time of survey. All refuge areas in the gorges or gullies of the survey area were generally dry.

4.2.1.3 Habitat Suitability for MNES Species

Northern Quoll

Approximately 107 ha (1%) of the survey area, comprising Gorge/Gully and some Breakaway habitats mainly within the BHT area, was considered 'probable shelter and foraging habitat' (or core habitat as per the referral guidelines (Department of the Environment and Energy 2016)), based on proximity to known quoll records, microhabitat features and orientation aspect (Figure G.2, Appendix G). Approximately 200 ha (2%) of the survey area was considered 'potential shelter and foraging habitat', comprising mainly smaller Breakaway habitat within the HD2 area (Figure G.2, Appendix G). The Gorge/Gully and Breakaway habitats contain rocky environments of high relief that are particularly important for Northern Quolls in the Pilbara as they provide potential denning sites for breeding and shelter and diverse microhabitats for foraging.

Approximately 1,858 ha (17%) of the survey area was considered suitable foraging and dispersal habitat (Minor Drainage and Rocky Hill habitats), particularly where these habitats were in close association with the Gorge/Gully and Breakaway habitats as they provided microhabitats such as crevices and cracks for foraging (Figure G.2, Appendix G). The remaining 8,653 ha (80%) of the survey area was considered to provide limited foraging and dispersal habitat, consisting of Alluvial Plain, Low Hills and Slopes, Mulga Woodland, Stony Plain and Disturbed habitats (Figure G.2, Appendix G).

Pilbara Leaf-nosed Bat

Approximately 307 ha (3%) of the survey area, comprising the Gorge/Gully and Breakaway habitat, was considered potential shelter and foraging habitat for this species due to the presence of nocturnal refuge caves (Figure G.3, Appendix G). Approximately 9,678 ha (89%) of the survey area, which consisted of Alluvial Plain, Minor Drainage, Low Hills and Slopes, Mulga Woodland, Rocky Hill and Stony Plain habitats was considered suitable foraging and dispersal habitat (Figure G.3, Appendix G). The remaining 833 ha (8%) of the survey area, comprising Disturbed areas, was considered to provide limited foraging and dispersal habitat (Figure G.3, Appendix G).

Ghost Bat

Approximately 307 ha (3%) of the survey area, comprising the Gorge/Gully and Breakaway habitat, was considered potential shelter and foraging habitat (Figure G.4, Appendix G), due to the presence of caves that potentially support roost sites. Often Gorge/Gully and Breakaway habitats contain caves and deep shelters that are used as nocturnal feeding roosts by Ghost Bats. During the survey two caves (Caves 1 and 5) were categorised as Category 3 roost caves with occasional occupancy due to the presence of Ghost Bat feeding evidence (scats) and/or the physical properties of the caves were conducive to diurnal roosting. The remaining five caves (Cave 2, 4, 6, 7 and 8) were categorised as Category 4 nocturnal roost caves (opportunistic usage) given the physical properties of the caves. It is considered unlikely that additional significant caves exist within the survey area; however, the possibility cannot be discounted as the survey area was not searched in its entirety. If present, they are likely to be found within the Gorge/Gully and Breakaway habitats only. No previously known or confirmed diurnal roosts or maternal roosts have been recorded in the survey area. Both habitats also contain complex vegetation structures and microhabitats that support prey species and foraging sites for the Ghost Bat.

Approximately 1,858 ha (17%) of the survey area, which consisted of Minor Drainage and Rocky Hill habitats, was considered suitable foraging and dispersal habitat (Figure G.4, Appendix G). The taller trees found in the Minor Drainage habitats provide ideal foraging/hunting perches particularly in areas that have the potential for semi-permanent surface water and contain thicker vegetation. The Rocky Hill habitat contains microhabitats such as boulder piles, cracks and crevices that support a wide range of prey species for the Ghost Bat. The remaining 8,653 ha (80%) of the survey area, comprising the Alluvial Plain, Low Hills and Slopes, Mulga Woodland, Stony Plain and Disturbed habitats, was considered to provide limited foraging and dispersal habitat (Figure G.4, Appendix G).

Night Parrot

None of the habitats of the survey area supported old, large and unburnt *Triodia* clumps that are considered the primary habitat requirement for the Night Parrot (Department of Parks and Wildlife 2017). The Alluvial Plain, Minor Drainage, Mulga Woodland and Stony Plain habitats (3,230 ha, 30%) within the survey area were mapped as suitable foraging and dispersal habitat; however, the Night Parrot is unlikely to occur within the survey area (Figure G.5, Appendix G). However, most of these habitats (particularly within the BHT and HD2 areas) were impacted by recent fires (less than 10 years old), pastoral and mining impacts over a long duration, very sparse ground cover vegetation and a lack of chenopod communities or suitable size/age *Triodia* hummocks and are unlikely to support the Night Parrot. The remaining 7,587 ha (70%) was considered to provide limited foraging and dispersal habitat (Figure G.5, Appendix G).

Pilbara Olive Python

Approximately 307 ha (3%) of the survey area, comprising the Gorge/Gully and Breakaway habitats, was considered as potential shelter and foraging habitat for the Pilbara Olive Python (Figure G.6, Appendix G). The caves and overhangs of the Gorge and Breakaway habitats are likely to provide denning sites and ambush locations frequented by this species.

Approximately 870 ha (8%) of the survey area was considered suitable foraging and dispersal habitat, which consisted of Minor Drainage habitat (Figure G.6, Appendix G). The remaining 9,641 ha (89%) of the survey area was considered to provide limited foraging and dispersal habitat, consisting of Alluvial Plain, Low Hills and Slopes, Mulga Woodland, Rocky Hill, Stony Plain and Disturbed habitats (Figure G.6, Appendix G).

4.2.2 Vertebrate Fauna Species

There were 174 vertebrate fauna species recorded within the survey area over the three phases of fauna surveying (Table 13). A complete list of recorded species is provided in Tables E.5-E.9 (Appendix E). The following sections provide detailed results for each major taxonomic group sampled.

Table 13: Number of vertebrate fauna species recorded during the survey.

Fauna taxonomic group	No. of species recorded	No. of conservation significant species recorded	No. of introduced species recorded
Amphibians	2	0	0
Reptiles	55	1	0
Birds	84	2	0
Mammals	33	4	7
Total	**174**	**7**	**7**

4.2.2.1 Herpetofauna

Two amphibian species were recorded during the fauna assessment: *Litoria rubella* (19 records) and *Cyclorana maini* (four records) (Table E.5, Appendix E). Frogs were either sighted (trapped) or heard calling during targeted searches. No conservation significant species were recorded.

Fifty-five reptile species were recorded the three phases of fauna surveying (Table E.6, Appendix E). The most abundant groups encountered were the skinks (114 records, 43%), followed by the geckos (84 records, 31%). Both of these groups were also the most speciose with 17 species of skinks and 12 species of geckos. The most commonly recorded species were *Carlia munda* (30 records), *Ctenotus pantherinus* (20 records) and *Oedura fimbria* (17 records). The most speciose sites were TS04 (Stony Plain) with 15 species and TS16 (Low Hills and Slopes) with 12 species. Ten species were recorded by methods other than trapping. One conservation significant reptile species was recorded during the survey, *Lerista macropisthopus remota* (P2).

Species accumulation curves did not asymptote when all surveys were considered (Figure 5), and based on estimates of total species richness, between 66% and 85% of the total species pool was recorded (Table 14). Only one of the previous surveys within the vicinity of the survey area used species accumulation curves and determined that 92% of the total expected species was recorded for herpetofauna (Ecologia Environment 2014). The reduced herpetofauna captures are likely to be a combination of the dry seasonal conditions and the trap methods used, with only eight out of the 19

trap sites using pitfall traps (see Section 3.7 for more detail). Ten reptile species (18%) were recorded opportunistically during the fauna assessment.

There was a significant difference in species composition between habitat types (ANOSIM R = 0.458, P = 0.004). The two Mulga Woodland (TS1, TS3) and two Low Hills and slopes (TS5, TS16) sites showed the highest within habitat type similarity, while the Rocky Hills habitat was the most distinct herpetofauna assemblage (Figure 6). This is because three species were recorded only in this habitat type: *Delma butleri*, *Furina ornata* and *Pseudonaja nuchalis*. These species are habitat generalists (and not rock-dwelling specialists), so it is likely they were only recorded in this habitat type due to the higher number of funnel traps used, as they are considered a more effective trap to capture reptiles such as snakes that readily escape pit traps (Environmental Protection Authority 2016a).

Table 14: Total number of herpetofauna taxa systematically sampled in comparison to estimates of the total species pool based on several models.

	Observed	Estimated			
		Chao2	Jackknife 1	Jackknife 2	Bootstrap
Number of species	47	61	64	71	55
Estimated % sampled		77	73	66	85

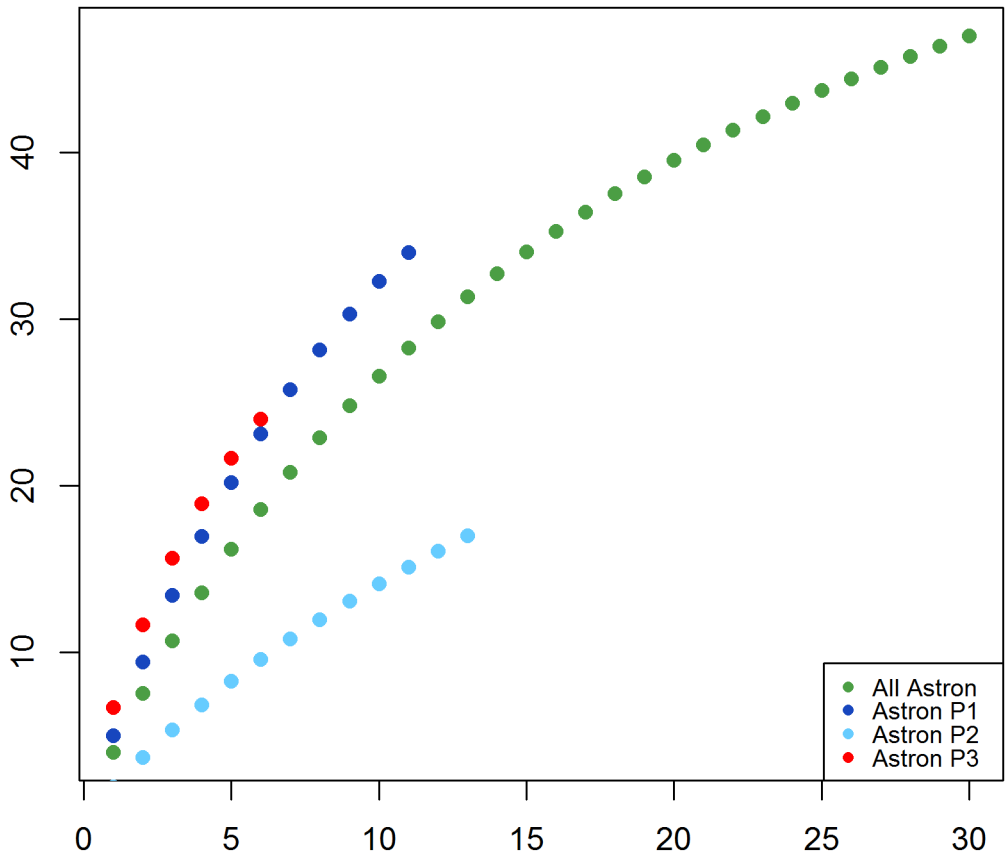

Figure 5: Species accumulation curves for herpetofauna surveys.

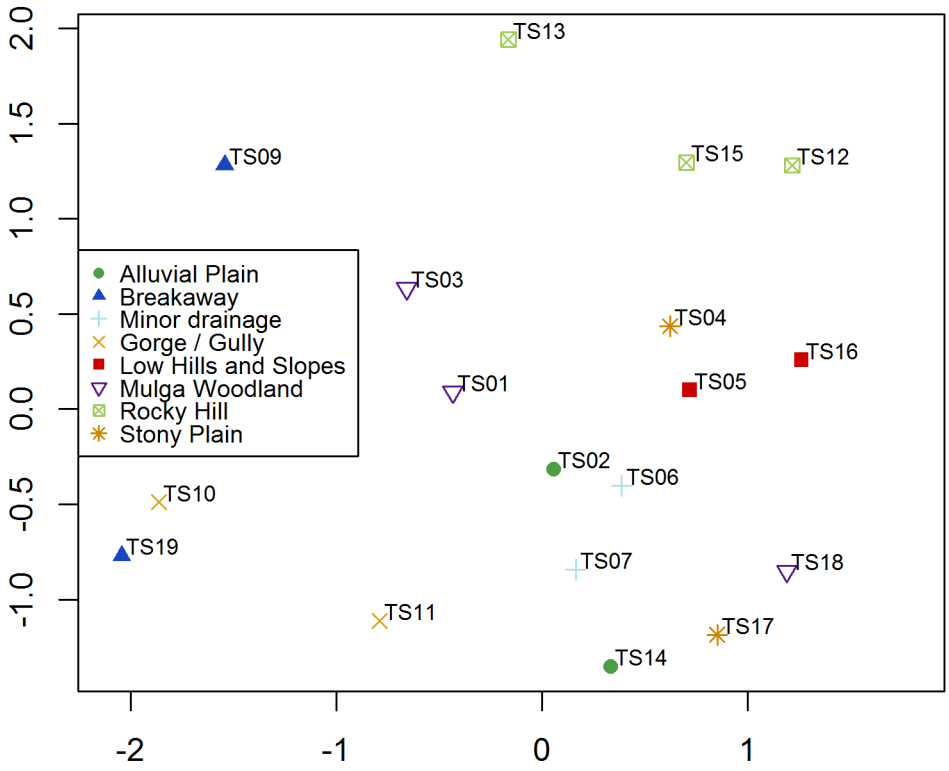

Figure 6: Two-dimensional ordination of herpetofauna species assemblages of each site.

4.2.2.2 Birds

Eighty-four bird species were recorded over the three phases of fauna surveying (Table E.7, Appendix E). The most commonly recorded species was the Weebill (*Smicrornis brevirostris*) with 50 records followed by the Zebra Finch (*Taeniopygia guttata*) with 44 records and the Singing Honeyeater (*Gavicalis virescens*) with 43 records. The most commonly recorded group of birds was the Meliphagidae (honeyeaters), with 120 records, followed by the Acanthizidae (Australasian warblers) with 70 records and Estrildidae (finches) with 63 records. The most speciose families observed were the Accipitridae (eagles, kites and hawks) and Meliphagidae (honeyeaters), which comprised eight and six species, respectively. The most speciose sites were TS6 (Minor Drainage) with 29 species and TS4 (Stony Plain) with 27 species. Of the 84 bird species recorded 19 species (22%) were not recorded at trapping grids, but from targeted and opportunistic searches.

Two bird species of conservation significance was recorded during the survey, Oriental Plover (*Charadrius veredus*) (IA; IA) and the Letter-winged Kite (*Elanus scriptus*) (P4).

The species accumulation curve for total survey effort is tending towards an asymptote (Figure 7), and based on estimates of total species richness, between 71% and 89% of the total species pool was recorded (Table 15). This compares with Ecologia Environment (2014) that recorded between 82% and 98% of the total expected species for birds.

There was a significant difference in species composition between habitat types (ANOSIM R = 0.353, P = 0.003; Figure 8) with the Rocky Hill sites showing the most distinct species composition compared to sites of other habitat types (Figure 8). This is most likely due to the low species richness recorded at the Rocky Hill sites, with only between three and six species recorded. Avifauna of hill tops and hill slopes is typically of low variety as it consists of open vegetation with limited dense vegetation cover from shrubs or trees (Ecologia Environment 2014).

Table 15: Total number of bird taxa systematically sampled in comparison to estimates of the total species pool based on several models.

	Observed	Estimated			
		Chao2	Jackknife 1	Jackknife 2	Bootstrap
Number of species	65	85	82	92	73
Estimated % sampled		76	79	71	89

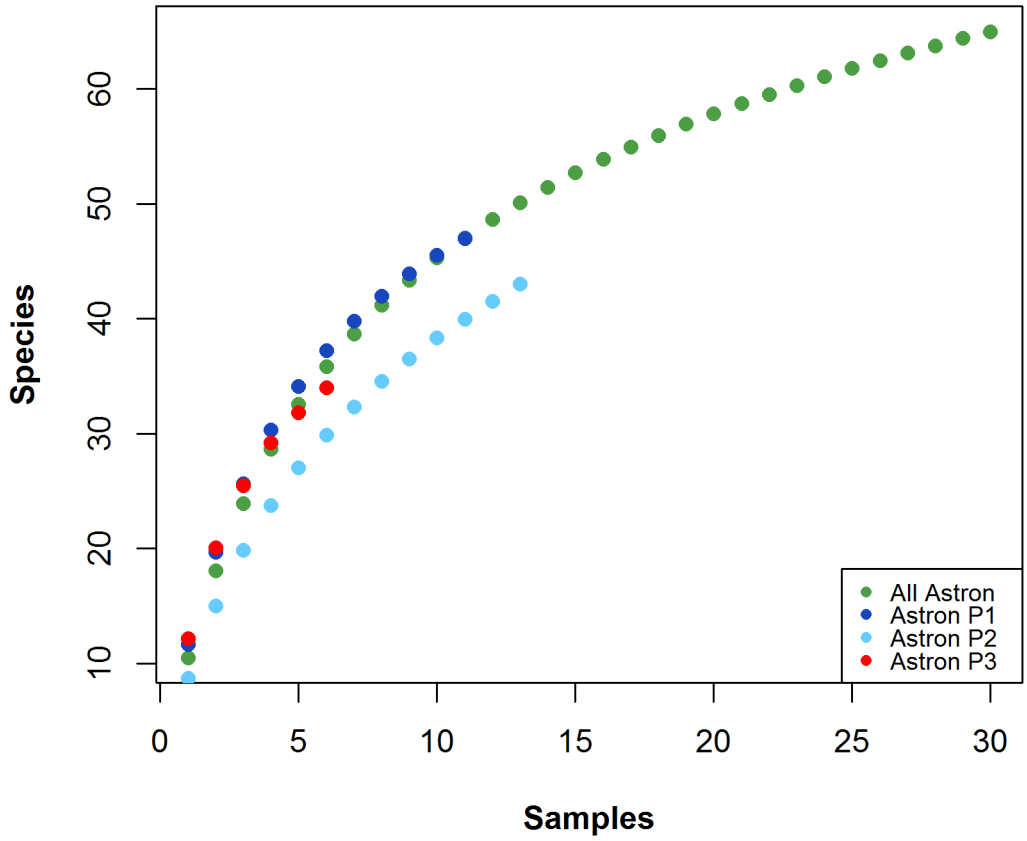

Figure 7: Species accumulation curves for bird surveys.

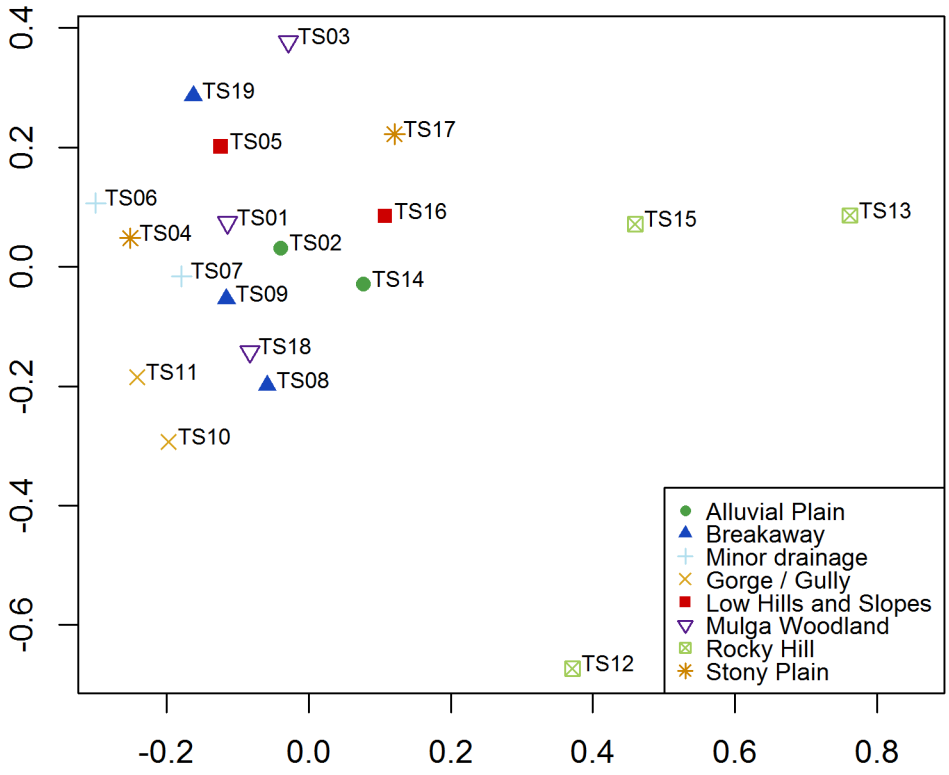

Figure 8: Two-dimensional ordination of bird species assemblages of each site.

4.2.2.3 Mammals

Thirty-three species of mammal were recorded during the three phases of fauna surveying, including seven introduced species: Cat (**Felis catus*), Dog/Dingo (**Canis familiaris*), European Cattle (**Bos taurus*), Camel (**Camelus dromedarius*), Donkey (**Equus asinus*), Rabbit (**Oryctolagus cuniculus*) and House Mouse (**Mus musculus*) (Table E.8, Appendix E). The most commonly recorded species was the Common Rock-rat (*Zyzomys argurus*) with 37 records followed by the Kaluta (*Dasykaluta rosamondae*) with 33 records. The most speciose trapping sites were TS4 (Stony Plain), TS5 (Low Hills and Slopes) and TS6 (Minor Drainage) with five species each. Twelve bat species were recorded from the echolocation recording sites (Table E.9, Appendix E).

Four species of conservation significance were recorded during the survey: Northern Quoll, Pilbara Leaf-nosed Bat, Ghost Bat and Western Pebble-mound Mouse.

Species accumulation curves were starting to reach an asymptote during the current survey (Figure 9), and based on estimates of total species richness, between 88% and 93% of the total species pool were recorded (Table 16). This compares with Ecologia Environment (2014) that recorded between 81% and 96% of the total expected species for birds. The data do not include bat species, which make up 36% (12 species) of the mammal species recorded. Also seven species were only recorded opportunistically and not using acoustic or trapping methods.

There was no significant difference in species composition between habitat types (ANOSIM R = 0.206, P=0.088, Figure 10), which was considered to be expected as most mammal species are habitat generalists, with the exception of only a few species that are rock-specialists. Rocky sites (i.e. Rocky Hill, Gorges/Gullies and Breakaway habitats) were generally grouped together and showed a slightly different species composition from sites in the other habitat types.

Table 16: Total number of mammal taxa systematically sampled in comparison to estimates of the total species pool based on several models.

	Observed	Estimated			
		Chao2	Jackknife 1	Jackknife 2	Bootstrap
Number of species	14	15	16	15	15
Estimated % sampled		93	88	93	93

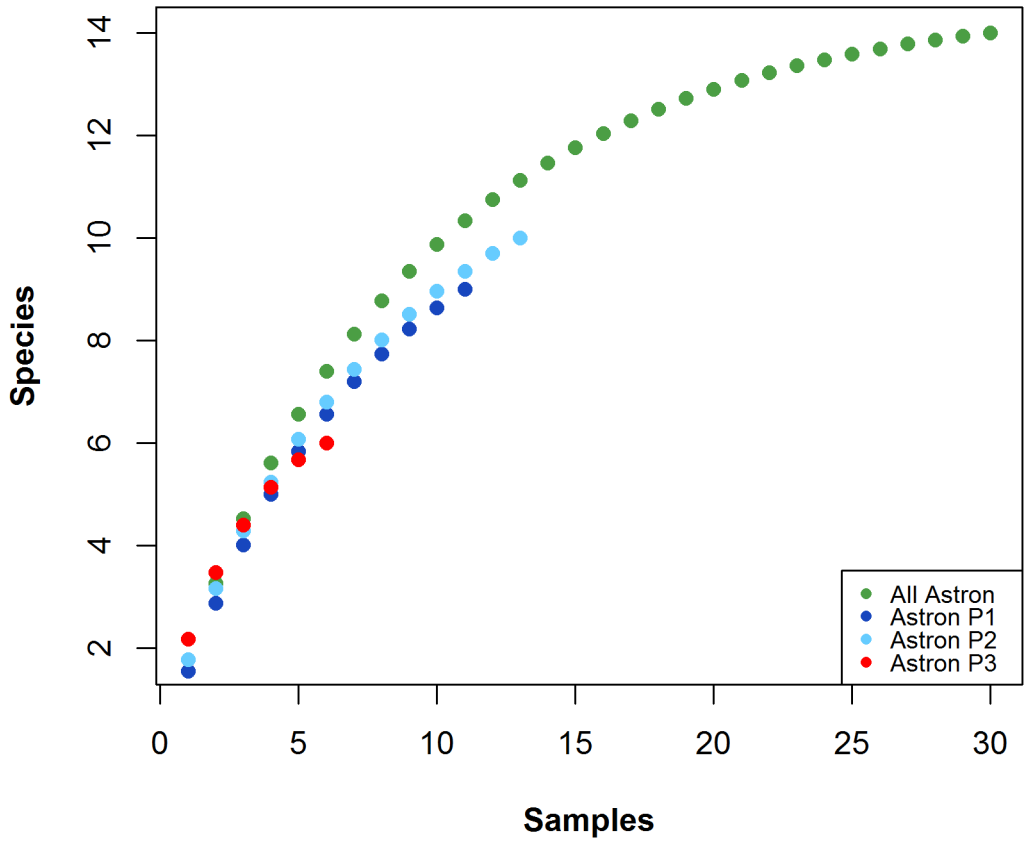

Figure 9: Species accumulation curves for mammal surveys.

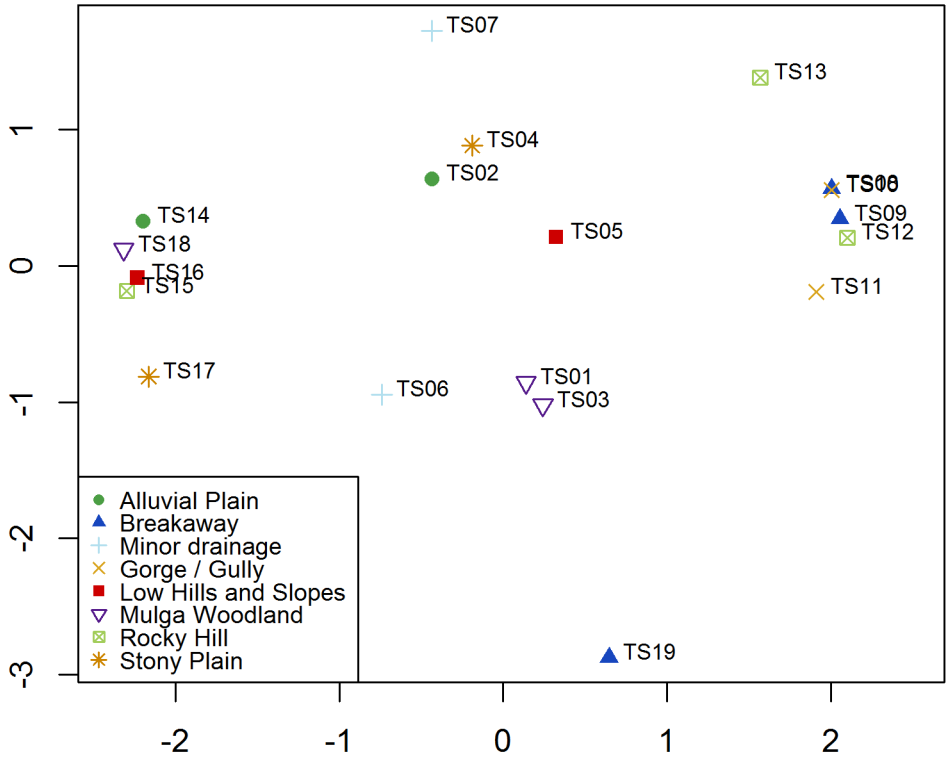

Figure 10: Two-dimensional ordination of mammal species assemblages of each site.

4.2.2.4 *Conservation Listed Species Recorded*

Seven vertebrate species of conservation significance were recorded within the survey area (Figure H.1 and Table H.1, Appendix H).

Northern Quoll (*Dasyurus hallucatus*) (EN; EN)

The Northern Quoll occurs in a variety of habitats (Oakwood 2008) but is commonly found in open lowland savannah forest and rocky escarpments. Rocky areas are a particularly important zone for Northern Quolls in the Pilbara as these areas retain water and provide a diversity of microhabitats. These areas also tend to have greater floristic diversity and productivity resulting in greater prey density compared to non-rocky areas. These rocky areas also provide refuge from feral cats, fire and livestock (Hill and Ward 2010) and provide breeding potential (Department of the Environment 2013).

The Northern Quoll was recorded 14 times during the fauna assessment: one record during Phase 1, 12 records during Phase 2 and one record during Phase 3 (Figure H.1 and Table H.1, Appendix H). The majority of the records were made via motion camera detection (10 records), followed by scat recordings (three records) and a solitary male individual was captured. Most of the records were made at BHT (10 recordings), followed by four records at the Wonmunna (WM) area. No records of the Northern Quoll were made within the HD2 area. The recordings were generally made within the Gorge/Gully or Breakaway fauna habitat types at BHT.

During Phase 2 a capture of an individual Northern Quoll was made at a Gorge/Gully habitat behind the HD1 village camp on the night of 25 May 2018 (potentially early in the evening, released on the morning of 26 May 2018). This individual was male and determined as a sub-adult potentially

looking to expand its individual home range in preparation for the breeding season. The scats recorded in this area are likely to be from the same individual.

The camera recordings were made at two separate locations also on 25 May 2018, suggesting that at least two individuals, possibly three, may be present in the survey area. Camera recordings were also made at two separate locations on the nights of the 22, 23 and 24 May 2018. These two locations are separated by approximately 5 km, suggesting that more than one individual is present in the area.

During Phase 3 a solitary recording of an individual was made at one location on motion camera at BHT. The individual was recorded on 14 March 2019 within a Breakaway habitat type.

The Northern Quoll records within the survey area are significant due to the paucity of previous local and regional records and that the survey area is at the edge of this species' regional distribution. The Northern Quoll has been previously recorded from fauna surveys highlighted in the desktop review, near HD1 mine site (Biota Environmental Sciences 2011). One male Northern Quoll was captured within a drainage line fauna habitat and subsequently recaptured over an additional two nights (Biota Environmental Sciences 2011).

Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) (VU; VU)

Pilbara Leaf-nosed Bats are known to require deep caves characterised by high levels of humidity and stable temperatures (Churchill 2008). This is a result of their limited ability to conserve heat and water (Armstrong 2001; Churchill 1991). Caves deep enough to create this environment are relatively uncommon in the Pilbara, with only 20 to 25 roost sites being known (R. Bullen 2014, pers. comm. 20 Oct 2014). Foraging habitat for the Pilbara Leaf-nosed Bat is diverse and includes riparian vegetation, hummock grassland, and sparse tree and shrub savannah (Duncan, Baker, and Montgomery 1999). Roost sites for the Pilbara Leaf-nosed Bat can be classified (Department of the Environment 2017) based on the following criteria:

- Permanent diurnal roosts—occupied year-round and likely the focus for some part of the nine-month breeding cycle; considered as critical habitat that is essential for daily survival.
- Non-permanent breeding (maternal) roosts—evidence of usage during some part of the nine-month breeding cycle (July to March), but not occupied year-round; considered as critical habitat that is essential for both daily and long-term survival.
- Transitory diurnal roosts—occupied for part of the year only, outside the breeding season (i.e. April to June), and which could facilitate long distance dispersal in the region; considered as critical habitat that is essential for both daily and long-term survival.
- Nocturnal refuge—occupied or entered at night for resting, feeding or other purposes, with perching not a requirement. Excludes overhangs. Not considered critical habitat, but are important for persistence in a local area.

Pilbara Leaf-nosed Bats have also been recorded flying over small watercourses amongst granite boulder terrain, over pools and low shrubs in ironstone gorges, and above low shrubs and around pools in gravelly watercourses with *Melaleuca leucadendron*, such as in Barlee Range Nature Reserve (Armstrong 2001). In the Pilbara, the species has been observed in *Triodia* hummock grasslands covering low rolling hills and shallow gullies, with scattered *Eucalyptus camaldulensis* along the creeks (Armstrong 2001; Churchill 1991).

The Pilbara Leaf-nosed Bat was recorded at three of the23 bat detector locations (BAT13, BAT17 and BAT21) at low activity levels (Appendix I; Bat Call WA (2019)). BAT13 and BAT17 were located within

the BHT area and BAT21 was located within the HD2 area (Figure H.1 and Table H.1, Appendix H). The Pilbara Leaf-nosed Bat records were from foraging individuals in Gorge/Gully and Breakaway fauna habitats, as the calls at all three sites were at least three hours after dusk and are not consistent with the presence of a permanent roost cave nearby (Appendix I; Bat Call WA (2019)). This species was not detected at any of the caves at which bat detectors were placed. This species is likely to forage only occasionally within the survey area taking advantage of benign conditions and dispersing temporarily in search of additional foraging and roosting opportunities (Bat Call WA 2019).

This species was previously recorded by Ecologia Environment (2014) at Greater West Angelas, approximately 15 km south-west of the survey area. Three locations were recorded, all at low levels, with call times not conducive to a roost nearby (Ecologia Environment 2014). A further nine records were recorded within the vicinity of the survey area (Department of Biodiversity, Conservation, and Attractions 2017b).

Ghost Bat (*Macroderma gigas*) (VU; VU)

The preferred habitat of Ghost Bats is considered to be rocky gorges and breakaways that support caves and crevices used as maternity roosts. The Ghost Bat uses different natural formations for various purposes and for groups to persist they generally require habitats that provide:

- a selection of roosting opportunities with night roosts or feeding sites, day roosts and at least one deep cave with characteristics of a maternity roost
- nearby gullies and gorges with vegetation of vertical complexity (diverse vegetation heights and density) and presence of water that would attract prey species
- a productive foraging area within a 5 km to 10 km radius, usually including a good quality riparian drainage line.

Transient roosts and feeding sites are used by small numbers of Ghost Bats, whereas maternity roosts are used by larger colonies (Armstrong and Anstee 2000). Ghost Bats require caves of varying shapes and sizes to fulfil each of its ecological requirements. Cave usage can be classified into three categories: feed caves, day roosts and maternal roosts.

- Feed caves are typically shallow caves or overhangs high in the strata that are poorly insulated from the elements (Armstrong and Anstee 2000). Ghost Bats hunt at night and use feed caves to consume prey they have captured in the surrounding area. Feed caves often contain Ghost Bat scats and/or feeding remnants (typically feathers and small animal bones).
- Day roosts are generally deep, complex caves or disused mines that contain domed ceilings, fissures or passages which create a stable microclimate. These caves are usually lower in the strata making them well insulated. The stable temperature and elevated humidity of these caves relative to the ambient conditions create physiologically benign conditions (McKenzie and Bullen 2009; Armstrong and Anstee 2000; Hall et al. 1997; Leitner and Nelson 1967).
- Maternal roosts like day roosts are generally deep, complex caves or disused mines that contain domed ceilings, fissures or passages which create a stable microclimate and often contain multiple entrances (McKenzie and Hall 2008). Maternal roosts have a stable temperature of 23°C to 28°C and moderate to high relative humidity of 50% to 100% (Armstrong and Anstee 2000; Churchill 1991; Churchill and Helman 1990; Pettigrew et al. 1986).

The Ghost Bat can have a relatively small nightly foraging range (up to 2 km from the roost where it has been studied in Queensland) (Tidemann et al. 1985; Pettigrew et al. 1986), but has the flight capability to range widely (Bullen and McKenzie 2002), perhaps tens of kilometres in a night. This is evident from genetic markers, which suggest that males are particularly likely to disperse long distances throughout the landscape (Worthington Wilmer et al. 1994; 1999).

The Ghost Bat was recorded on nine occasions over the three phases of survey within the survey area through acoustic recordings (calls), scats recorded in nocturnal feed caves and an individual sighted during spotlighting within the HD2 area (Figure H.1 and Table H.1, Appendix H). Four records were made within the HD2 area, four records within the BHT area and one record within the WM area (Figure H.1, Appendix H). One Ghost Bat record (scats recorded in Cave 9) was made outside the survey area boundary (Figure H.1 and Table H.1, Appendix H).

A total of seven caves were recorded within the survey area, two which (Caves 1 and 5) were deemed to be Category 3 roost caves with occasional occupancy. These caves are not considered significant to the long-term presence of the species (Bat Call WA 2019) (Appendix I). The other five previously recorded caves were deemed to be Category 4 nocturnal roost caves (opportunistic usage) and are not considered significant. An additional two caves (Caves 3 and 9), deemed to be Category 4 nocturnal roost caves (opportunistic usage) were recorded outside the survey area (Figure G.1 and Table G.2, Appendix G). It is considered unlikely that additional significant caves exist within the survey area; however, the possibility cannot be discounted as the survey area was not searched in its entirety. If present, they are likely to be found within the Gorge/Gully and Breakaway habitats only.

The individual recorded during Phase 2 nocturnal spotlighting is significant given the sighting was made approximately 1 to 1.5 hours post-civil twilight, so it is likely to have originated from a roost nearby, but possibly outside the survey area. The ridge line where it was recorded is important foraging habitat for this species as another record was made from an echolocation recording device on a separate evening.

An opportunistic recording of a solitary individual found hooked on a fence line was recorded by Biota (2006) in the Hope Downs area, approximately 10 km west of the survey area. Regionally this species has a strong presence in the vicinity of the survey area. In particular, numerous records were made at Southern Flank, approximately 10 km to the north-west of the survey area. Thirty-three caves (12 high value, 21 low value) were recorded at Southern Flank through an extensive search of gorges and gullies (Biologic Environmental Survey 2016). In addition a further 75 records in a 40 km radius around the survey area, mainly to the north and north-east, were detailed through DBCA's Threatened and Priority Fauna Database (Department of Biodiversity, Conservation, and Attractions 2017b).

Oriental Plover (*Charadrius veredus*) (IA, IA)

The Oriental Plover is a non-breeding visitor to Australia, where the species occurs in both coastal and inland areas, mostly in northern Australia. Most records are along the north-western coast, between Exmouth Gulf and Derby in Western Australia (Department of the Environment and Energy 2019). This species occupies sparsely vegetated plains, beaches and tidal flats, and saltworks and sometimes sewage ponds.

One individual was opportunistically sighted during the Phase 3 survey at the HD1 village camp, likely due to the presence of water at the camp. (Figure H.1, Appendix H). This species was not previously recorded from fauna surveys conducted within the vicinity of the survey area (Biota

Environmental Sciences 2006, 2009, 2011, 2014; Ecologia Environment 2014; Ninox Wildlife Consulting 2009a, 2009b).

***Lerista macropisthopus remota* (P2)**

This species favours sandy to sandy loam soils which support *Acacia* shrubland or woodland. It inhabits loose soil under leaf litter at the base of shrubs (Wilson and Swan 2010). Threats to this species are not well known, it is listed as conservation significant due to its very restricted distribution range. This subspecies was described in 1991 and was only known from one locality at the time in the arid central interior of Western Australia, 40 km north-east of Jiggalong (Storr 1991); there are currently no records on NatureMap (Department of Biodiversity, Conservation, and Attractions 2019a). Three records all within 2 km of each other were detailed through DBCA's Threatened and Priority Fauna Database (Department of Biodiversity, Conservation, and Attractions 2017b). The nearest record from the DBCA database is within 4 km of the survey area. From this limited information, it appears that this subspecies is rarely recorded due to a restricted distribution.

One individual was captured during the Phase 3 survey within a Mulga Woodland habitat within the WM area (Figure H.1, Appendix H). This individual was lodged and its identification confirmed at the WAM (#R179612). This species may also be found within the Alluvial Plain and Minor Drainage habitats of the survey area.

Letter-winged Kite (*Elanus scriptus*) (P4)

The Letter-winged Kite is classified as an infrequent non-breeding visitor to Western Australia (Johnstone and Storr 1998). This species inhabits open country and grasslands across arid and semi-arid Australia. When a dry spell follows a number of good seasons, single individuals or small groups of this species appear in north Western Australia, outside of their core range and generally do not stay long in these areas (Menkhorst et al. 2017).

One individual was opportunistically sighted during the Phase 2 survey from Minor Drainage habitat within the HD2 area (Figure H.1, Appendix H). It may also occur within the Stony Plain, Alluvial Plain and Mulga Woodland habitats of the survey area. This species was not previously recorded from fauna surveys conducted within the vicinity of the survey area (Biota Environmental Sciences 2006, 2009, 2011, 2014; Ecologia Environment 2014; Ninox Wildlife Consulting 2009a, 2009b), or identified via desktop review (Department of Biodiversity, Conservation, and Attractions 2017b, 2017a; Department of the Environment and Energy 2017d). The record during the current survey represents a new record for this species within the local area as the nearest record to the survey area is approximately 120 km to the north (Department of Biodiversity, Conservation, and Attractions 2017a). This reflects their habits of translocating across a landscape in response to increased foraging resources (Menkhorst et al. 2017).

Western Pebble-mound Mouse (*Pseudomys chapmani*) (P4)

Extant Western Pebble-mound Mouse populations are widespread in the extensive ranges of the central and southern Pilbara region (Start 2008). The persistence of abandoned mounds in the Gascoyne and Murchison regions and small, isolated, coastal ranges in the Pilbara indicates considerable recent decline (Start 2008). Colonies occur on the gentler slopes of rocky ranges where the ground is covered by stony mulch and vegetated by hard spinifex, often with a sparse overstorey of eucalypts and scattered shrubs, typically *Senna, Acacia* and *Ptilotus* (Start 2008). Mounds are also sited close to narrow ribbons of *Acacia* dominated scrub along incised drainage lines (Start 2008).

The Western Pebble-mound Mouse was recorded nine times during the Astron surveys, comprising of six pebble mounds (three active) and three individual captures. Five pebble mounds were recorded within the Stony Plain, Rocky Hill and Mulga Woodland habitats of the survey area (Figure H.1 and Table H.1, Appendix H). This species is also likely to be found within the Low Hills and Slopes habitat and possibly stony areas within the Alluvial Plain habitat of the survey area. The three individuals and one recently inactive mound (PMM 3) were recorded outside the survey area (Figure H.1 and Table H.1, Appendix H).

Numerous records of this species exist from the vicinity of the survey area, given the commonality of their preferred habitat (stony plains, hills and rises) across the bioregion. The DBCA Threatened and Priority Fauna Database search identified 237 records (Department of Biodiversity, Conservation, and Attractions 2017b). This species was previously recorded from all systematic fauna assessments conducted within the vicinity of the survey area (Biota Environmental Sciences 2006; Ecologia Environment 2014; Ninox Wildlife Consulting 2009a, 2009b).

4.2.2.5 Conservation Listed Species Potentially Occurring in the Survey Area

Three species that were not recorded during the current survey were considered highly likely to occur, given that suitable habitat occurs and a number of records are known from within the vicinity of the survey area.

Pilbara Olive Python (*Liasis olivaceus barroni*) (VU; VU)

The Pilbara Olive Python prefers escarpments, deep gorges, water holes and rock piles associated with permanent pools in rocky areas in the ranges of the Pilbara region (Pearson 1993; Wilson and Swan 2010). Microhabitat preferences of the Pilbara Olive Python are under rock piles, on top of rocks or under spinifex (Tutt et al. 2004). Individuals spend the cooler winter months within caves and rock crevices away from water sources. In the warmer summer months, the pythons are found to move around widely, usually in close proximity to water and rock outcrops (Wilson and Swan 2010).

This species is likely to be found within the Gorge/Gully, Breakaway and Minor Drainage habitats, particularly at sites that have the potential to support semi-permanent water. There are 14 previous records of this species in the vicinity of the survey area (Department of Biodiversity, Conservation, and Attractions 2017b), 10 of which are associated with river systems including Weeli Wolli Creek, Marillana Creek and Tunnel Creek.

***Anilios ganei* (P1)**

The blind snake, *Anilios ganei*, is often poorly collected in vertebrate fauna surveys, but is known from the Hope Downs area. This species has been associated with moist gorges and gullies (Wilson and Swan 2010), but potentially occurs over a wide range of other stony habitats. Given its cryptic

fossorial habit this species is rarely encountered. Little is known of this species' ecology but like most other blind snakes, it is insectivorous, feeding on termites and their eggs, and larvae and pupae of ants (Wilson and Swan 2010).

This species was not previously recorded from fauna surveys conducted within the vicinity of the survey area for Rio Tinto (Biota Environmental Sciences 2006, 2009, 2011, 2014; Ecologia Environment 2014; Ninox Wildlife Consulting 2009a, 2009b), however it has been recorded (four records) within the vicinity of the survey area (Department of Biodiversity, Conservation, and Attractions 2017b). This species is likely to be present within suitable habitats, including the Gorge/Gully, Breakaway and Rocky Hill habitat types of the survey area.

Pilbara Barking Gecko (*Underwoodisaurus seorsus*) (P2)

The Pilbara Barking Gecko is a rock-inhabiting, restricted-range species encountered at mid elevations in the Hamersley Ranges, widely separated from the closest populations of the related Barking Gecko *Underwoodisaurus milii* in the northern Goldfields and Shark Bay in Western Australia (Doughty and Oliver 2011).

This species was recorded at Greater West Angelas (Ecologia Environment 2014) and an additional eight records are detailed within DBCA's Threatened and Priority Fauna Database (Department of Biodiversity, Conservation, and Attractions 2017b) within a 30 km range, with the nearest record to the survey area less than 500 m. This species is likely to be found in elevated fauna habitat such as the Rocky Hill recorded within the BHT area of the survey area.

Four species were not found in the survey area but were all considered to have a moderate likelihood of occurrence: Fork-tailed Swift (*Apus pacificus*) (IA; IA), Grey Falcon (*Falco hypoleucos*) (VU), Peregrine Falcon (*Falco peregrinus*) (OS), and Short-tailed Mouse (*Leggadina lakedownensis*) (P4) (Table F.1, Appendix F). Although suitable habitat is present within the survey area, these species are seasonal migrants that are only present at certain times of the year, species that are not readily trapped during fauna surveys, and/or species with large home ranges.

An additional 12 species not found in the survey area were considered to have a low likelihood of occurrence due to lack of suitable habitats, including the Night Parrot (Table F.1, Appendix F). No calls attributed to the Night Parrot were recorded during two passive acoustic surveys or analysis of the data recorded from the ARUs (Appendix I; Bat Call WA (2019)). The Stony Plain habitat generally did not support old, large and unburnt *Triodia* clumps that are considered the primary habitat requirement for this species, particularly the plains at BHT and HD2, due to the effects of recent fires (less than 10 years old), pastoral and mining impacts over a long duration, very sparse ground cover vegetation and lack of chenopod communities or suitable size/age hummocks. As such, the Night Parrot was classified as having a low likelihood of occurrence in the survey area.

4.2.3 Invertebrate Fauna Habitats

Eight potential SRE habitat types were identified differing in their prospectivity for SRE fauna (Figure G.1, Appendix G). Whilst all of the habitats have the potential to support SREs, five habitats were considered more conducive to relictual SREs: Breakaway, Minor Drainage, Gorge/Gully, Rocky Hill and Mulga Woodland habitats (Table 17). The rocky habitats are associated with an isolated ridge running in an east-west direction, so most of the breakaways and rocky slopes are south-facing and therefore conducive to SREs (Harvey 2002). The Breakaway and Gorge/Gully habitats provide moist, shaded microhabitats that potentially support relictual endemism. These habitats supported Philosciidae sp, *Troglarmadillo* sp. and *Pseudodiploexochus* sp. which, while being ambiguously defined, represent likely SREs. The latter two taxa represent forms that are very rarely sampled from

epigean habitats in the Pilbara and are not arid adapted. The presence of arid sensitive taxa in these habitats indicates that SRE habitats are present. Additional SRE species are likely to occur in these habitats.

The Minor Drainage and Rocky Hill habitats provide a moderate level of habitat suitability for SRE species but lack the moist microhabitats preferred by SRE groups. The pseudoscorpion *Anatemnus* sp. is enigmatic in that it has all of the features of a troglobite (blind and pale) and the only other Pilbara record of this genus is troglobitic. One specimen was sampled from riparian leaf litter of a dry creek line (SRE10). There is a small chance that this species is troglobitic and in rare cases, troglobites have been observed at the entrance of caves during very humid conditions. In the Pilbara, troglobitic *Nocticola* have been sampled from creek gravels (Volschenk personal observations) indicating that Minor Drainage is potential habitat for troglobitic taxa. The Mulga Woodland contained deep leaf litter supporting SRE species and specifically the Mulga Woodland in HD2 was species rich where eight of the nine centipede taxa and four of the five millipede taxa were recorded.

Table 17: SRE fauna habitats present within the survey area, with prospective habitats shaded in grey.

Habitat type	Extent in survey area (ha)	Proportion in survey area (%)
Alluvial Plain	161.8	1.5
Breakaway	241.6	2.2
Minor Drainage	869.7	8.1
Gorge/Gully	65.5	0.6
Low Hills and Slopes	5,460.0	50.5
Mulga Woodland	1,031.4	9.5
Rocky Hill	987.9	9.1
Stony Plain	1,167.6	10.8
Cleared	832.3	7.7
Total	**10,817.7**	**100.0**

Minor Drainage habitats were generally comprised a reduced diversity and density in vegetation species and communities, particularly when in the creek bed, and when present it was usually less dense and complex when compared to major riparian habitats, such as Weeli Wolli Creek located to the east of the survey area. There were limited locations in this habitat that supported the potential for semi-permanent water bodies to form; however, there were some areas of deep, moist leaf litter. This habitat was sampled as sites SRE3, SRE8, SRE14, TS6 and TS7. The potential SRE scorpion *Lychas* 'multipunctatus complex' and potential SRE pseudoscorpions *Anatemnus* sp., *Tyrannochthonius* 'sp. indet. (AESHD2)' and *Beierolpium* 'sp. indet. (AESHD1)' were collected from this habitat.

Gorge/Gully habitat was associated with the Rocky Hill or Breakaway habitats, where deeply carved rock incisions and drainage lines provide shade and diverse microhabitats. Minor creek lines and water run-off lead to higher moisture availability compared to the surrounding areas. This was a relatively uncommon habitat type in the survey area but due to its prospectivity for SRE species it was well sampled; sites included SRE1, SRE2, SRE4, SRE10, SRE13, SRE17, SRE18, SRE19 and SRE20. As a result a substantial number of potential and confirmed SRE species were collected from this habitat type: spiders *Karaops banyjima*, *Karaops* sp. 'ARA001', *Aurecocrypta* 'sp. indet. (AESHD1)' and *Synothele* sp.; pseudoscorpions *Austrohorus* 'sp. indet. (AESHD5)', *Euryolpium* sp., *Indolpium* sp., Olpiidae sp. 'Genus 7/4 PSE118' and *Tyrannochthonius* 'sp. indet. (AESHD2)'; scorpion *Urodacus* 'HD1'; earth centipedes *Sepedonophilus* sp., *Sepedonophilus*'HD1' and *Mecistocephalus* 'HD1';

round-backed millipedes *Austrostrophus* 'Clade A' and *Austrostrophus* sp.; and isopods *Buddelundia* '77', *Troglarmadillo* sp., *Pseudodiploexochus* sp. and Philosciidae sp.

Breakaway habitat was often associated with the drop off areas of the Rocky Hill habitat, specifically within the BHT area. It contained exposed south-facing rock faces with accumulations of rock boulders and scree, conducive to SREs. It provides shelter for SRE fauna and diverse microhabitats for both habitat specialists and moisture-dependent SRE fauna. This habitat type was sampled at sites SRE5 and SRE9. This habitat is small in size, as well as being vertical and linear in the landscape, hence only two sites were sampled. Breakaway habitat was closely associated with Gorge/Gully habitat, so although only two sites were sampled, some of the Gorge/Gully sites sampled also had breakaway features. One potential SRE species was recorded from this habitat: the pseudoscorpion *Euryolpium* 'sp. indet. (AESHD7)'.

Rocky Hill habitat denoted the high-elevation rock features, mostly associated with the BHT deposit running in an east-west direction, meaning most rocky slopes were south-facing and therefore, conducive to SREs. This habitat type was sampled at site SRE21 and dry pitfall trapping (funnel traps only) sites TS12, TS13 and TS15. Based on its rocky microhabitats it is expected to provide habitat for specialist species that live under rocks and gravel, similar to those found in the Breakaway habitats. The potential and confirmed SRE species that were collected from this habitat include the spiders *Karaops banyjima* and *Aname* sp.; pseudoscorpion 'Genus 7/4 PSE118'; and earth centipede *Mecistocephalus* 'HD1'.

Low Hills and Slopes habitat generally had low vegetation complexity and low diversity of microhabitats available for SRE species. No targeted SRE sampling was undertaken in the Low Hills and Slopes habitat as it was not considered prospective SRE habitat; however, vertebrate trap sites TS5 and TS16 were located within this habitat type. Two potential SRE species was recorded from this habitat: the scorpion *Lychas* 'bituberculatus complex' and the isopod *Buddelundia* '10ma'.

Alluvial Plain habitat exhibited a good diversity of microhabitats, with some tree hollows and logs, and some areas of sandy soils suitable for burrowing, dense leaf litter and large *Triodia* hummocks. No targeted SRE sampling was undertaken in the Alluvial Plain habitat as it was not considered prospective SRE habitat; however, vertebrate trap sites TS2 and TS14 were located within this habitat type. In addition some targeted 'blacklighting' for scorpions occurred during the nocturnal surveying events for the fauna assessment, collecting *Urodacus* 'HD1'. A large number of potential SRE species was recorded from this habitat including: the trapdoor spider *Yilgarnia* 'MYG197'*;* pseudoscorpion *Beierolpium* 'sp. indet. (AESHD2)'; scorpions *Lychas* 'bituberculatus complex' and *Lychas* 'multipunctatus complex'; the millipede *Austrostrophus* 'Clade E'; and isopods Buddelundiinae sp. and Philosciidae sp.

Mulga Woodland habitat was characterised by vegetation communities dominated by Mulga with a stony mantle; however, the SRE sites sampled comprised softer soil, suitable for burrowing species. The deep leaf litter were considered important for SRE species within this habitat and often mygalomorph spider burrows are found here. This habitat type was sampled at sites SRE6, SRE7, SRE12, SRE15, SRE16, SRE23, and trap sites at TS1, TS3 and TS18. The Mulga Woodland in HD2 supported numerous centipede taxa: *Mecistocephalus* 'HD1', *Mecistocephalus* 'HD2', *Mecistocephalus* 'HD3', *Sepedonophilus* 'HD1', *Sepedonophilus* 'HD2', Geophilomorpha sp., *Orphnaeus* 'HD1' and *Cryptops* 'HD1'; and the millipede taxa *Antichiropus* sp., *Antichiropus* 'wonmunna', *Austrostrophus* sp. and *Austrostrophus* 'Clade E'. Other SRE species include isopods *Buddelundia* '77', *Buddelundia* sp. and Buddelundiinae sp.; pseudoscorpions '*PSEAAA* sp. indet. (AESHD4)' and *Sundochernes* sp.; and mygalomorphs: *Synothele* sp., *Synothele* 'MYG309' and *Synothele* 'MYG311'.

Stony Plain habitat was generally exposed and had low microhabitat diversity compared to other landforms. The Stony Plain habitat was sampled at sites SRE11 and SRE22 and trap sites TS4 and TS17. Ten potential SRE species were recorded from this habitat: the isopods *Buddelundia* '10ma' and *Buddelundia* '77'; the millipede *Austrostrophus* 'Clade E'; scorpions *Lychas* 'bituberculatus complex' *Lychas* 'hairy tail complex' and *Lychas* 'multipunctatus complex'; pseudoscorpion *Euryolpium* 'sp. indet. (AESHD6)' and mygalomorph spiders: Nemesiidae sp., *Synothele* sp. and *Aurecocrypta* 'MYG315'.

4.2.4 Invertebrate Fauna Species

The field surveys generated a total of 202 samples (comprising 358 individual specimens) from SRE target taxa. Morphological and DNA-barcoding identified 67 different taxa. One species was an SRE (*Karaops banyjima*), 48 were either likely or potential SREs and 18 were known to be widespread (Table 18 and Table E.10, Appendix E). The locations of these species records from the current survey are shown in Figure H.2 and Table H.2 (Appendix H). WAM lodgement details for representative vouchers to date are provided in Appendix J.

Table 18: Summary of the potential SRE species recorded within the survey area.

Order	Family	Species	Taxonomic resolution	SRE status
Araneae	Selenopidae	*Karaops banyjima*	Species confirmed using morphology (DNA sequencing suggested different species)	SRE
	Selenopidae	*Karaops* sp. 'ARA001' DNA	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
	Actinopodidae	*Missulena rutraspina*	Species confirmed (widespread distribution)	Widespread
	Barychelidae	*Aurecocrypta* 'MYG315' DNA	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
	Barychelidae	*Aurecocrypta* 'sp. indet. (AESHD1)' DNA	No DNA matches available	Potential SRE: DD
	Barychelidae	*Synothele* 'MYG309' DNA	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
	Barychelidae	*Synothele* 'MYG311' DNA	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
	Barychelidae	*Synothele* sp.	Not sequenced	Potential SRE: DD
	Barychelidae	*Synothele* 'xkarara'	Species confirmed (widespread distribution)	Widespread
	Idiopidae	*Gaius tealei*	Species confirmed (widespread distribution)	Widespread
	Nemesiidae	*Aname mellosa*	Species confirmed (widespread distribution)	Widespread
	Nemesiidae	*Aname* 'MYG004'	Species confirmed (widespread distribution)	Widespread
	Nemesiidae	*Aname* sp.	Species unknown (not sequenced)	Potential SRE: DD
	Nemesiidae	*Yilgarnia* 'MYG197'	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
	Nemesiidae	Nemesiidae sp.	DNA sequencing failed	Potential SRE: DD
Pseudoscorpiones	Atemnidae	*Anatemnus* sp.	Species unknown (not sequenced)	Potential SRE: DD
	Atemnidae	*Oratemnus* sp.	Species unknown (not sequenced)	Widespread
	Chernetidae	*Sundochernes* sp.	Species unknown (not sequenced)	Potential SRE: DD
	Chthoniidae	*Tyrannochthonius* 'sp. indet. (AESHD1)' DNA	No DNA matches available	Potential SRE: DD
	Chthoniidae	*Tyrannochthonius* 'sp. indet. (AESHD2)' DNA	No DNA matches available	Potential SRE: DD
	Olpiidae	*Austrohorus* 'sp. indet. (AESHD5)' DNA	No DNA matches available	Potential SRE: DD
	Olpiidae	*Beierolpium* '8/4 small'	Species confirmed (widespread distribution)	Widespread

Order	Family	Species	Taxonomic resolution	SRE status
Pseudoscorpiones	Olpiidae	*Beierolpium* 'sp. indet. (AESHD1)' DNA	No DNA matches available	Potential SRE: DD
	Olpiidae	*Beierolpium* 'sp. indet. (AESHD2)' DNA	No DNA matches available	Potential SRE: DD
	Olpiidae	*Beierolpium* '8/4'DNA	Species confirmed (widespread distribution)	Widespread
	Olpiidae	*Euryolpium* 'sp. indet. (AESHD6)' DNA	No DNA matches available	Potential SRE: DD
	Olpiidae	*Euryolpium* 'sp. indet. (AESHD7)' DNA	No DNA matches available	Potential SRE: DD
	Olpiidae	*Euryolpium* sp.	Species unknown (not sequenced)	Potential SRE: DD
	Olpiidae	'Genus 7/4 PSE118' DNA	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
	Olpiidae	'*PSEAAA* sp. indet. (AESHD4)' DNA	No DNA matches available	Potential SRE: DD
	Olpiidae	*Indolpium* sp.	Species unknown (not sequenced)	Potential SRE: DD
	Olpiidae	Olpiidae sp.	DNA sequencing failed	Potential SRE: DD
Scorpiones	Buthidae	*Isometroides* 'pilbara 1'	Species confirmed (widespread distribution)	Widespread
	Buthidae	*Lychas* 'bituberculatus complex'	Unresolved taxonomic clade (restricted/unknown distribution)	Potential SRE: DD
	Buthidae	*Lychas* 'hairy tail complex'	Unresolved taxonomic clade (restricted/unknown distribution)	Potential SRE: DD
	Buthidae	*Lychas* 'harveyi complex'	Unresolved taxonomic clade (widespread distribution)	Widespread
	Buthidae	*Lychas* 'multipunctatus complex'	Unresolved taxonomic clade (restricted/unknown distribution)	Potential SRE: DD
	Buthidae	*Lychas* 'pilbara 1'	Species confirmed (widespread distribution)	Widespread
	Urodacidae	*Urodacus* 'pilbara 12'	Species confirmed (widespread distribution)	Widespread
	Urodacidae	*Urodacus* 'HD1' DNA	No DNA matches available	Potential SRE: DD
Geophilomorpha	Chilenophilidae	*Sepedonophilus* 'HD1' DNA	No DNA matches available	Potential SRE: DD
	Chilenophilidae	*Sepedonophilus* 'HD2' DNA	No DNA matches available	Potential SRE: DD
	Chilenophilidae	*Sepedonophilus* sp.	DNA sequencing failed	Potential SRE: DD

Order	Family	Species	Taxonomic resolution	SRE status
Geophilomorpha	Geophilomorpha^	Geophilomorpha sp.	DNA sequencing failed	Potential SRE: DD
	Mecistocephalidae	*Mecistocephalus* 'HD1' DNA	No DNA matches available	Potential SRE: DD
	Mecistocephalidae	*Mecistocephalus* 'HD2' DNA	No DNA matches available	Potential SRE: DD
	Mecistocephalidae	*Mecistocephalus* 'HD3' DNA	No DNA matches available	Potential SRE: DD
	Oryidae	*Orphnaeus* 'HD1' DNA	No DNA matches available	Potential SRE: DD
Scolopendromorpha	Cryptopidae	*Cryptops* 'HD1' DNA	No DNA matches available	Potential SRE: DD
Polydesmida	Paradoxosomatidae	*Antichiropus* sp.	Species unknown (not sequenced)	Potential SRE: DD
	Paradoxosomatidae	*Antichiropus* 'wonmunna' DNA	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
Spirobolida	Trigoniulidae	*Austrostrophus* 'Clade A' DNA	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
	Trigoniulidae	*Austrostrophus* 'Clade E' DNA	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
	Trigoniulidae	*Austrostrophus* sp.	Species unknown (not sequenced)	Potential SRE: DD
Eupulmonata	Pupillidae	*Gastrocopta* sp.	Species unknown	Widespread
	Pupillidae	*Pupoides* sp.	Species unknown	Widespread
	Subulinidae	*Eremopeas interioris*	Species confirmed (widespread distribution)	Widespread
	Subulinidae	Subulinidae sp.	Species unknown	Widespread
Isopoda	Armadillidae	*Buddelundia* '10ma'	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
	Armadillidae	*Buddelundia* '15'	Species confirmed (widespread distribution)	Widespread
	Armadillidae	*Buddelundia* '16'	Species confirmed (widespread distribution)	Widespread
	Armadillidae	*Buddelundia* '77'	Species confirmed (restricted/unknown distribution)	Potential SRE: DD
	Armadillidae	*Buddelundia* sp.	Species unknown (not sequenced)	Potential SRE: DD
	Armadillidae	Buddelundiinae sp.	Species unknown (not sequenced)	Potential SRE: DD
	Armadillidae	*Pseudodiploexochus* sp.	Species unknown (not sequenced)	Potential SRE: DD
	Armadillidae	*Troglarmadillo* sp.	Species unknown (not sequenced)	Likely SRE
	Philosciidae	Philosciidae sp.	Species unknown (not sequenced)	Potential SRE: DD

DNA putative species recognised with DNA barcoding

Of these SRE category taxa, 32 were identified to the level of species or morphospecies:

- seven spiders: *Karaops banyjima*, *Karaops* sp. 'ARA001', *Aurecocrypta* 'MYG315', *Aurecocrypta* 'sp. indet. (AESHD1)', *Synothele* 'MYG309', *Synothele* 'MYG311' and *Yilgarnia* 'MYG197'
- nine pseudoscorpions: *Tyrannochthonius* 'sp. indet. (AESHD1)', *Tyrannochthonius* 'sp. indet. (AESHD2)', *Austrohorus* 'sp. indet. (AESHD5)', *Beierolpium* 'sp. indet. (AESHD1)', *Beierolpium* 'sp. indet. (AESHD2)', *Euryolpium* 'sp. indet. (AESHD6)', *Euryolpium* 'sp. indet. (AESHD7)', 'Genus 7/4 PSE118' and '*PSEAAA* sp. indet. (AESHD4)'.
- four scorpions; *Lychas* 'bituberculatus complex', *Lychas* 'hairy tail complex', *Lychas* 'multipunctatus complex' and *Urodacus* 'HD1'
- seven centipedes: *Sepedonophilus* 'HD1', *Sepedonophilus* 'HD2', *Mecistocephalus* 'HD1', *Mecistocephalus* 'HD2', *Mecistocephalus* 'HD3', *Cryptops* 'HD1' and *Orphnaeus* 'HD1'
- three millipedes: *Antichiropus* 'wonmunna', *Austrostrophus* 'Clade A' and *Austrostrophus* 'Clade E'
- two isopods: *Buddelundia* '10ma' and *Buddelundia* '77'.

Seventeen SRE taxa sampled represented ambiguously identified groups:

- three spiders: *Synothele* sp., *Aname* sp. and Nemesiidae sp.
- five pseudoscorpions: *Anatemnus* sp., *Sundochernes* sp., *Euryolpium* sp., *Indolpium* sp. and Olpiidae sp.
- two centipedes: *Sepedonophilus* sp. and Geophilomorpha sp.
- two millipedes: *Antichiropus* sp. and *Austrostrophus* sp.
- five isopods: *Buddelundia* sp., Buddelundiinae sp., *Pseudodiploexochus* sp., *Troglarmadillo* sp. and Philosciidae sp.

5 Discussion

5.1 Vertebrate Fauna

5.1.1 Habitats

Habitats within the survey area were not restricted at the local or sub-regional scale and no uncommon geological units or land systems occurred within the survey area. In a regional context, the Gorge and Breakaway habitats in the Pilbara are restricted to the Chichester and Hamersley Ranges, but they are well represented in these areas. The Gorge/Gully habitat, and Breakaway habitat to a lesser extent, were considered important habitat for fauna, including several MNES species. Deeply incised gorges, characteristic of the Hamersley subregion, generally have high levels of species endemism and diversity, and are considered important refuge sites in a local context (Kendrick 2001). This is due to the microhabitats they provide such as caves and semi-permanent water pools that can exist in these refuge type areas and are important for species foraging and sheltering requirements. Gorge/Gully and Breakaway habitats were considered suitable for MNES species including the Northern Quoll, Ghost Bat and Pilbara Leaf-nosed Bat that have all been recorded within the survey area and the Pilbara Olive Python that is considered highly likely to occur.

The Rocky Hill habitat is widespread and common throughout the Pilbara bioregion and is not restricted to the Chichester and Hamersley Ranges. This habitat generally had low vegetation complexity and low diversity of microhabitats as evidenced by a depauperate bird assemblage; however, MNES species such as the Northern Quoll and Pilbara Leaf-nosed Bat are likely to traverse and forage within these habitats.

The Minor Drainage habitats within the survey area were generally comprised of a reduced diversity and density in vegetation species and communities, particularly when compared to riparian habitats, such as Weeli Wolli Creek and are unlikely to provide significant refuge for species, although they may act as foraging or dispersal habitat for some fauna species. Minor drainage line habitats, although not necessarily large in terms of area, are also common and well-represented habitats within the immediate vicinity of the survey area and the wider Pilbara region.

The Low Hills and Slopes, Alluvial Plain, Mulga Woodland and Stony Plain habitat in the survey area provide fewer microhabitat opportunities for terrestrial fauna and are also more widespread in the immediate vicinity as well as the Hamersley subregion and wider bioregion.

5.1.2 Species

5.1.2.1 General Assemblage

The fauna species assemblage recorded during the survey is considered typical of the Hamersley subregion as well as a subset of typical fauna assemblages across the Pilbara bioregion. There were 174 vertebrate fauna species, comprising two amphibians, 55 reptiles, 84 birds and 33 mammals (including seven introduced species) recorded within the survey area. This equates to 56% of the vertebrate fauna species previously recorded for the local vicinity identified from the desktop assessment (312 vertebrate fauna species). However, not all species detailed through the desktop assessment are expected to be recorded during the survey given some species have specific habitat requirements, are seasonal migrants, are cryptic in behaviour and may not be readily trapped. Additionally, at the time of survey the survey area did not contain any permanent or semi-permanent water bodies that would support a number of wetland bird species and other species closely associated with water.

Species accumulation curves did not reach an asymptote for reptiles but were approaching, if not achieved, asymptote for birds and mammals. When taking into account previous records as well as species recorded from methods other than trapping, a large portion of the predicted assemblage was recorded. The lower number of captures and reduced herpetofauna assemblage recorded during the current survey is likely due to the dry seasonal conditions and moderated trap methods used. However, this is considered a very minor limitation that does not negatively impact on the outcome of the survey, as the herpetofauna assemblage expected to occur in the survey area is common and widespread and is unlikely to include any conservation significant fauna that have not been previously recorded from other fauna assessments conducted in the vicinity.

5.1.2.2 *Contextual Analysis*

The total recorded species from the current survey (174 species) is comparable or exceeds other systematic trapping surveys, where 97, 169, 74 and 124 vertebrate fauna species were recorded, respectively (Biota Environmental Sciences 2006; Ecologia Environment 2014; Ninox Wildlife Consulting 2009a, 2009b). However, the species composition is likely to be different due to the additional habitats surveyed, such as cracking clay and major drainage habitats (Ecologia Environment 2014) and a permanent pool on Weeli Wolli Creek (Ninox Wildlife Consulting 2009b), as well as the large area (17,565 ha) covered in the Greater West Angelas fauna assessment (Ecologia Environment 2014).

Although the species accumulation curve indicated that not all herpetofauna were recorded during the current survey (likely due to a combination of seasonal conditions and lack of pitfall traps used at some of the trap sites), the herpetofauna assemblage recorded was similar to other areas within the vicinity. The number of reptile and amphibian species recorded (55 species) is higher than most other Level 2 surveys conducted in the vicinity of the survey area, with the exception of 64 species recorded at Greater West Angelas (Ecologia Environment 2014). This is probably due to the larger size of the Greater West Angelas survey area, greater trapping effort and presence of additional fauna habitats (Ecologia Environment 2014).

The number of bird species recorded during the survey (84 species) is higher than other dual season surveys conducted in the area (37 to 80 species), which is unexpected given the lack of riparian habitats within the survey area compared to previous surveys such as the Greater West Angelas fauna assessment (Ecologia Environment 2014). The lower number of bird species recorded by Biota (2006) and Ninox (2009a) can be attributed to a single season survey only, and that a recent fire had affected 80% of the survey area in the Ninox (2009a) survey.

The current survey recorded a comparatively high number of mammal species (33 species) compared to other Level 2 surveys in the vicinity (13 to 25 species) (Biota Environmental Sciences 2006; Ecologia Environment 2014; Ninox Wildlife Consulting 2009a, 2009b). This was mainly due to the high number of bat species recorded; 12 species were recorded in the current survey compared to a maximum of nine species recorded in previous surveys (Ecologia Environment 2014; Ninox Wildlife Consulting 2009b), as well as a high number of introduced species recorded; six species recorded in the current survey compared to a maximum of three species in previous surveys (Biota Environmental Sciences 2006; Ninox Wildlife Consulting 2009a). The higher number of bat and introduced species recorded during the current survey is likely due to the increased use of sampling methods, such as acoustic bat recorders and motion sensitive cameras compared to the earlier surveys (Ninox Wildlife Consulting 2009b, 2009a; Biota Environmental Sciences 2006).

5.1.2.3 Conservation Significant Species

Of the 26 conservation significant species identified in the desktop assessment, seven species were recorded during the current survey and an additional three species were considered to have a 'high' likelihood of occurrence. Four species were deemed to have a 'moderate' likelihood and 12 species to have a 'low' likelihood.

Three of the five recorded conservation listed species are classified under the EPBC Act as MNES species: Northern Quoll, Pilbara Leaf-nosed Bat and Ghost Bat.

Recorded MNES Species

The Gorge and Breakaway habitats within the survey area were considered highly suitable for the recorded MNES species: Northern Quoll, Pilbara Leaf-nosed Bat and Ghost Bat and would be considered habitat critical to the survival of the Northern Quoll and Ghost Bat under the EPBC Act definitions (Department of Environment 2013, Department of the Environment and Energy 2016, Threatened Species Scientific Committee 2016). The breakaways, gorges and gullies contained microhabitats such as caves and semi-permanent water pools; approximately 307 ha (3%) of potential shelter and foraging habitat was recorded in the survey area. With respect to the Northern Quoll, these habitats were divided into 'probable shelter and foraging habitat' (or critical habitat), which comprised 107 ha (1%) of the Gorge/Gully habitat and some Breakaway habitats, particularly within the BHT area; and 'potential shelter and foraging habitat', comprising 200 ha (2%) of the smaller Breakaway habitats, particularly with the HD2 area.

The remaining habitats of the survey area were classified as 'lower' habitat suitability for these species as these habitats contained no significant refuge sites, shelter, or semi-permanent water and were considered less vital for these species' persistence. Differing foraging strategies exist for the conservation significant bat species recorded for the survey area. The Pilbara Leaf-nosed Bat have greater foraging capabilities and are known to traverse more of the landscape and across wide open plains as opposed to Ghost Bats who are known to follow drainage lines and/or ridgelines searching for prey.

The Northern Quoll was recorded 14 times during the current survey, mainly within the Gorge/Gully or Breakaway habitats. The relatively high number of records for this species within the survey area is significant given only one other record was made from previous fauna assessments in the vicinity of the survey area (Biota Environmental Sciences 2011). Also the survey area is at the fringe of this species' distribution, so generally a lower number of records are made within the Hamersley Ranges when compared to more coastal zones. A sub-adult male was captured during the Phase 2 survey, close to the HD1 village. Males, particularly this sub-adult male, may have been expanding their home range in preparation for the oncoming breeding season at the time of survey. However, a large number of motion camera recordings suggest that a resident population may exist in the survey area, particularly within the BHT area. The BHT deposit is a large isolated ridge in the landscape that contains numerous breakaways, gorges and gullies that support micro-niches important for the Northern Quoll.

The three Pilbara Leaf-nosed Bat recordings made in the survey area were from foraging individuals in Gorge/Gully and Breakaway fauna habitats. The recorded calls at low activity levels were made at least three hours after dusk and are not consistent with the presence of a permanent roost cave nearby (Bat Call WA 2019). This corresponds with the records by Ecologia Environment (2014) at Greater West Angelas, approximately 15 km south-west of the survey area, where call times were also not conducive to a nearby roost (Ecologia Environment 2014). This species is likely to forage occasionally within the survey area taking advantage of benign conditions and dispersing

temporarily in search of additional foraging and roosting opportunities (Bat Call WA 2019). Foraging habitat for this species is much broader than for the Ghost Bat and includes water courses, riparian vegetation, hummock grassland and sparse tree and shrub savannah habitats. Therefore the Pilbara Leaf-nosed Bat is likely to be found across the majority of the survey area, with the exception of cleared habitats.

The Ghost Bat was recorded on nine occasions within the survey area through acoustic recordings (calls), scats recorded in nocturnal feed caves and an individual sighted during spotlighting within the HD2 area. Regionally this species has a strong presence in the vicinity of the survey area, identified from previous fauna assessments in the Hope Downs area by Biota Environmental Sciences (2006), and Southern Flank area (Biologic Environmental Survey 2016), as well as 75 records from DBCA's Threatened and Priority Fauna Database (Department of Biodiversity, Conservation, and Attractions 2017b). Two of the seven caves recorded within the survey area (Caves 1 and 5) were deemed to be Category 3 roost caves with occasional occupancy based on their size and depth; however, no ultrasonic detections were recorded. The other five recorded caves were deemed to be Category 4 nocturnal roost caves (opportunistic usage). These Category 4 caves are common in the landscape as numerous observations suggest that the majority of caves and adits in the Pilbara are used in at least an opportunistic manner by itinerant Ghost Bats (Bat Call WA 2019). The caves recorded within the survey area are not considered significant to the long-term presence of the species (Bat Call WA 2019). The records are consistent with the Ghost Bat foraging in low numbers on the HD2 and BHT ridges (Bat Call WA 2019). It is also consistent with the known regional presence of the Ghost Bat across the central Pilbara region as well as locally on the major ridges immediately to the north of the survey area and west of the HD1 mining area (Bat Call WA 2019). It is highly unlikely that additional significant caves (Category 1 or 2) exist within the survey area.

Other Conservation Significant Species

Other conservation significant species recorded from, or likely to occur, within the survey area included the recorded Oriental Plover, *L. macropisthopus remota*, Letter-winged Kite and Western Pebble-mound Mouse; and the likely to occur Pilbara Barking Gecko, *Anilios ganei* and Pilbara Olive Python.

The Oriental Plover was recorded opportunistically during the Phase 3 survey at the HD1 village camp within the WM area. This species is a seasonal migrant and is only present during certain times of the year and is unlikely to be reliant upon the habitats present within the survey area given more suitable habitat is found outside the survey area.

The fossorial skink, *L. macropisthopus remota* was captured within the Mulga Woodland fauna habitat in the survey area. This ground-dwelling skink often favours sandy to loamy sand based substrates which support *Acacia* shrublands (such as Mulga) and woodlands where it inhabits loose soil under leaf litter usually at the base of shrubs. Threats to this species are not well known, it is listed as contribution significant due to its very restricted distribution range and its basic ecology is seen as poorly known.

One individual Letter-winged Kite was recorded during Phase 2 within Minor Drainage habitat of the survey area. This species is sparsely distributed and rarely encountered across its range and is unlikely to be reliant upon the habitats present within the survey area.

The Western Pebble-mound Mouse was recorded by five pebble mounds within the Stony Plain and Rocky Hill habitat of the survey area. An additional one pebble mound, as well as three individual captures, were also recorded just outside the survey area, indicating they are common within the local area. The Low Hill and Slopes, Stony Plain and Rocky Hill habitats of the survey area are likely to

support this species. These habitats are widespread and common within the vicinity of the survey area and the wider Pilbara region.

The small ground dwelling reptiles, *A. ganei* and Pilbara Barking Gecko, are difficult to detect due to their cryptic behaviours. The trap sites (particularly sites TS12, TS13 and TS15 within Rocky Hill habitat) did not capture these species during the current survey. Suitable Rocky Hill fauna habitat was found mainly within the BHT and WM areas and these areas generally had been heavily impacted from clearing due to exploration drilling operations and recent fire, possibly reducing their potential occurrence.

The Pilbara Olive Python has been previously recorded in the vicinity of the survey area and suitable foraging and denning habitats occur within the Gorge/Gully, Breakaway and Minor Drainage habitats, particularly in the locations that have the potential to support semi-permanent and permanent water, although no surface water was recorded during the survey.

5.2 SRE Invertebrates

5.2.1 Habitats

In general, the survey area appears to have great potential to support SRE species owing to the abundance of ideal habitats. These include the 'typical' SRE target habitats: south facing gorges, rocky slopes and breakaways. Prospective SRE habitats were mapped as Gorge/Gully, Breakaway, Rocky Hills and Minor Drainage habitats in the survey area. These habitats, particularly those associated with the BHT area, were considered as having a high likelihood of supporting SREs. BHT occupies a large portion of an isolated, east-west running ridge and appears to support numerous south facing rocky slopes and breakaways, as well as gullies and gorges. It therefore seems to have all the requirements for supporting relictual SREs species. These habitats supported Philosciidae sp, *Troglarmadillo* sp. and *Pseudodiploexochus* sp. which, while being ambiguously defined, represent likely SREs. The latter two taxa represent forms that are very rarely sampled from epigean habitats in the Pilbara and are not arid adapted. The presence of arid sensitive taxa in these habitats indicates that SRE habitats are present. Additional SRE species are likely to occur in these habitats.

The pseudoscorpion *Anatemnus* sp. has all of the features of a troglobite (blind and pale) and the only other Pilbara record of this genus is troglobitic. One specimen was sampled from a Minor Drainage Line habitat. There is a small chance that this species is troglobitic and in the Pilbara, troglobitic *Nocticola* have been sampled from creek gravels (Dr. E. Volschenk pers. obs.) indicating that this is potential habitat for troglobitic taxa.

In addition the Mulga Woodland contained deep leaf litter supporting SRE species and specifically the Mulga Woodland in HD2 was species rich, where eight of the nine centipede taxa and four of the five millipede taxa were recorded.

Several Short Range Endemic category invertebrates were found in multiple habitat types, suggesting that they may be less specialised with respect to their habitat preferences:

- *Lychas* 'bituberculatus complex', from Stony Plain, Alluvial Plain and Low Hills
- *Sepedenophilus* 'HD1', from Gorge/Gully and Mulga Woodland
- *Mecistocephalus* 'HD1', from Rocky Hills, Gorge/Gully and Mulga Woodland
- *Austrostrophus* 'Clade E', from Stony Plain, Alluvial Plain and Mulga Woodland

- *Antichiropus* 'wonmunna', from Mulga Woodland in the survey area, but from gully slopes and riparian vegetation outside of the survey area.

These species are likely to be found outside of the survey area.

5.2.2 Invertebrate Fauna Species

The database search results revealed a very species rich SRE category invertebrate taxa and most of these taxa were present within the Hamersley Range - the SRE and potential SRE groups were represented by 282 taxa of which eight (3%) were named species, 182 (64%) were morphospecies and 92 (33%) were undetermined taxa. The high degree of morphospecies most likely reflects the poor level of taxonomic knowledge about SREs in this part of the Pilbara. This position is reflected by the high degree of DD potential SRE taxa. Fifteen SRE taxa detailed from the database search were previously recorded within the survey area. Six of these taxa have been assigned to a species or morphospecies.

The field surveys generated a total of 202 samples from SRE target groups comprising 358 individuals. Following morphological identification and DNA-barcoding, the samples were found to comprise 67 different taxa; 18 of which were known to be widespread, one species was a known SRE (*Karaops banyjima*) and 48 were either likely or potential SREs. Of the 32 SREs or potential SREs recorded within the survey area that were identified to the level of species or morphospecies, 11 of these have previously been recorded within the 10,000 km^2 search area but outside the survey area.

Spiders

The search area contained 111 SRE category spider taxa, of which four were named species, 83 were morphospecies and 24 were unidentified taxa. Four of these taxa are SREs and the remainder are potential SRE (DD). Four potential SRE (DD) spider taxa were previously recorded from within the survey area:

- *Synothele* sp.: T116849, T116852
- *Idiosoma* sp.: T116854, T116851
- *Aname* sp.: T116850
- *Kwonkan* 'MYG339': T116853.

Additional species were also revealed to the north and south of the search area, suggesting that a greater diversity of trapdoor spiders might be expected than the survey yielded. It is likely that survey conditions or methods were not optimal for sampling the broader diversity of trapdoor spiders in the area. No harvestmen were recorded during the field survey and no previous records were within the survey area. The absence of Opiliones was difficult to interpret as conditions leading up to both surveys was quite dry and if they are present, the rain experienced during the Phase 3 survey may not have been sufficient to bring them out. If present, they are likely to be in the Gorge/Gully habitat of the BHT and WM areas.

Fifteen spider taxa were collected during these surveys, representing the families Selenopidae, Actinopodidae, Barychelidae, Idiopidae and Nemesiidae. Five of these represented widespread taxa, nine species were potential SRE owing to data deficiency (*Aname* sp., *Synothele* sp., *Yilgarnia* 'MYG197', *Karaops* sp. 'ARA001', Nemesiidae sp., *Aurecocrypta* 'sp. indet. (AESHD1)', *Aurecocrypta* 'MYG315', *Synothele* 'MYG309' and *Synothele* 'MYG311') and one species was a known SRE (*Karaops banyjima*). The assessment identity of *Karaops banyjima, Karaops* sp. 'ARA001', *Aurecocrypta*

'MYG315', *Synothele* 'MYG309' and *Synothele* 'MYG311' were verified using DNA-barcoding methods.

The SRE species *Karaops banyjima* was recorded from three unique localities within the survey area. Two of these localities were represented by Gorge/Gully habitat, and one by the Rocky Hill habitat. The WAM identified the *Karaops banyjima* (AES190099) specimen as *Karaops nyangumarta* as it was highly supported as conspecific with WAMT134063 (and others), sharing 98.88% genetic pairwise similarity (Wilson, Huey, and Harvey 2019). However, this species possesses very different morphological features to *Karaops banyjima*. Further consultation with Dr Sarah Crews, who described both species (Crews 2013), found that the morphological data strongly indicate that the specimen should be *Karaops banyjima*. Hence, the specimen remains as *Karaops banyjima*. This species is an SRE and the type locality is approximately 20 km north of the survey area.

Aurecocrypta 'MYG315' was identified from a single juvenile specimen. *Aurecocrypta* 'MYG315' was recorded from the search area and is a potential SRE owing to data deficiency regarding its distribution limits. The species appears to have a relatively wide distribution, within the constraints of an SRE, with records occurring approximately 5 km to the south of the survey area.

Synothele 'MYG309' and *Synothele* 'MYG311' were confirmed with DNA barcoding and are considered potential SRE: DD. These species were well represented within the search area but outside the survey area. The distribution of these species suggest they are restricted to the Eastern Hamersley range, but that their distributions extend outside of the survey area.

Pseudoscorpions

The search area contained 52 SRE category pseudoscorpion taxa, of which three are named species, 31 were morphospecies and 18 were unidentified taxa. Two species are SREs and the remaining taxa are potential SRE (DD). The field survey sampled 16 pseudoscorpion taxa from four families: Atemidae, Chernetidae, Chthoniidae and Olpiidae. Fourteen of the 16 pseudoscorpion taxa were classified as potential SRE including *Anatemnus* sp., *Austrohorus* 'sp. indet. (AESHD5)', *Beierolpium* 'sp. indet. (AESHD1)', *Beierolpium* 'sp. indet. (AESHD2)', *Euryolpium* 'sp. indet. (AESHD6)', *Euryolpium* 'sp. indet. (AESHD7)', *Euryolpium* sp., 'Genus 7/4 PSE118', '*PSEAAA* sp. indet. (AESHD4)', *Indolpium* sp., Olpiidae sp., *Sundochernes* sp., *Tyrannochthonius* 'sp. indet. (AESHD1)' and *Tyrannochthonius* 'sp. indet. (AESHD2)'.

In the Pilbara, epigean Olpiidae constitute species of *Austrohorus*, *Beierolpium*, *Euryolpium*, *Indolpium*, *Xenolpium,* Genus *PSEAAA* and 'Genus 7/4'. The constituent species of these genera have been problematic to assess using morphology alone. In the current survey, representatives of unresolved (using morphology) putative olpiid taxa from each sample sites were assessed using DNA-barcoding:

- *Austrohorus* 'sp. indet. (AESHD5)' was a distinct species, but its generic placement was ambiguous with an unresolved polytomy of *Austrohorus*, 'Genus 7/4' and *Nanolpium*
- two putative species of *Beierolpium* were recognised using DNA-barcoding: *Beierolpium* 'sp. indet. (AESHD1)' and *Beierolpium* 'sp. indet. (AESHD2)'
- two putative species of *Euryolpium* were recognised using DNA-barcoding: *Euryolpium* 'sp. indet. (AESHD6)' and *Euryolpium* 'sp. indet. (AESHD7)'
- all four specimens of 'Genus 7/4 PSE118' were confirmed with DNA barcoding
- '*PSEAAA* sp. indet. (AESHD4)' was identified by WAM using DNA barcoding.

Two samples were identified to *Euryolpium* sp., but the relationship of these with the two genetic species is not known. With the discovery *Euryolpium* 'sp. indet. (AESHD6)' and *Euryolpium* 'sp. indet. (AESHD7)', both potential SREs, unresolved *Euryolpium* sp. can no longer be regarded as widespread and are here considered to be potential SRE owing to taxonomic data deficiency. Attempts to obtain DNA sequences from this specimen of Olipiidae sp. were unsuccessful.

Four specimens belonging to 'Genus 7/4 PSE118' were confirmed with DNA barcoding. This species is currently regarded as a potential SRE owing to limited knowledge about its distribution. Area search records included a single representative of this species approximately 20 km north of the survey area.

The current survey obtained two samples of *Tyrannochthonius* which were identified as belonging to two different species using DNA barcoding: *Tyrannochthonius* 'sp. indet. (AESHD1)' and *Tyrannochthonius* 'sp. indet. (AESHD2)'. Both species represent potential SREs owing to data deficiency regarding their distribution limits. They either represent new discovered taxa or not-yet-sequenced taxa (Wilson, Huey, and Harvey 2019).

Of note, one specimen from the Atemidae family included a single adult female *Anatemnus* sp. This species was obtained from site SRE10, within a Gorge/Gully fauna habitat type. This species is very unusual by being eyeless and having relatively pale body colour colouration. These features closely resemble those seen in the troglobitic *Anatemnus subvastus*, the only described species in this genus from the Pilbara (Alexander, Burger, and Harvey 2014). The placement of this species into *Anatemnus* is also tentative owing to the uncertain relationship between this genus and several other genera in Atemnidae (Alexander, Burger, and Harvey 2014). This sample represents the first epigean representative of *Anatemnus* from the Pilbara. This species is a potential SRE owing to data deficiency regarding its taxonomy or distribution.

Scorpions

The search contained 25 scorpion taxa, of which none were named, 21 were morphospecies and four were unidentified taxa. One species is an SRE and the remaining 24 taxa are potential SRE (DD).

The field survey yielded eight species of scorpions from the families Buthidae and Urodacidae. Four potential SRE scorpions were collected from the survey area: *Lychas* 'bituberculatus complex', *Lychas* 'hairy tail complex', *Lychas* 'multipunctatus complex' and *Urodacus* 'HD1'. Representatives of *Lychas* are frequently collected in surveys and current investigations on the genus *Lychas* indicate the presence of several species' complexes, some of which appear to contain SREs. *Lychas* 'hairy tail complex' and *Lychas* 'bituberculatus complex' specimens have previously been recorded within approximately 1 km and 3 km of the survey area, respectively. The *Urodacus* specimen collected was a juvenile from site SRE13 and adult males are usually required for morphological identification. Preliminary barcoding analyses could not match this species to any within Alacran's sequence database (Alacran Environmental Science 2019). WAM sequencing found the specimen was supported as a conspecific with WAMT91922 (and others), sharing 93.49% genetic pairwise similarity, which did not allow a conclusion about whether they are conspecific or not (Wilson, Huey, and Harvey 2019). The closely related specimens are also unidentified at present (Wilson, Huey, and Harvey 2019).

Centipedes and Millipedes

The search area contained 13 centipede taxa, of which none were named species, two were morphospecies and 11 were unidentified taxa. All were considered potential SRE (DD). None of the search area records fell within the survey area; however, a large cluster of records of

Mecistocephalidae sp. and *Sepedenophilus* sp. records were recorded from the area immediately south of the survey area.

The field surveys yielded nine centipede taxa representing five families Cryptopidae, Chilenophilidae, Mecistocephalidae, Geophilomorpha and Oryidae. All taxon within the Geophilomorpha and Cryptopidae families are very poorly known in Western Australia. While keys to genera and families are available, there is no working morphological taxonomy for Australian species and all species assessments are currently based on comparisons using DNA sequences. DNA sequencing identified seven of these species, whilst sequencing failed for the other two taxa: *Sepedenophilus* sp. and Geophilomorpha sp. Two of the centipede taxa *Sepedenophilus* 'HD1' and *Mecistocephalus* 'HD1' were sampled from four and three separate locations each. These were represented by Rocky Hills, Gorge/Gully and Mulga Woodland, suggesting that these species may not be restricted to one habitat type.

The search area contained 30 millipede taxa, of which one was a named species, 20 were morphospecies and nine were unidentified taxa. Seventeen of these species were SREs and 13 species were potential SRE (DD). The field survey yielded numerous millipede samples belonging to the families Trigoniulidae and Paradoxosomatidae. The five species of millipede collected during the survey were classified as potential SRE (DD). *Antichiropus* 'wonmunna' was recorded from three separate localities in Mulga Woodland within the HD2 area. This species is also known from five records all within 10 km of the SRE sites SRE15 and SRE23 (Alacran Environmental Science 2019). *Antichiropus* sp. collected from two sites are likely to represent *Antichiropus* 'wonmunna'; however, there is also a chance that one or more may represent different species since multiple species of Paradoxosomatidae have been collected from the same locality (Alacran Environmental Science 2019).

Species delimitation using DNA barcoding indicated the presence of two putative species: *Austrostrophus '*Clade A' and *Austrostrophus* 'Clade E', as the specimens provided were highly supported as conspecific with WAMT122166 (and others) and WAMT100768 (and others), respectively (Wilson, Huey, and Harvey 2019). *Austrostrophus* sp. represents specimens that were not sequenced and were found at sites SRE13, SRE15, SRE16, SRE17, SRE18 and SRE19. In the absence of clear unambiguous identification, this taxon is regarded as a potential SRE owing to data limitation regarding species identity.

Isopods

The search area contained 34 isopod taxa, of which none were named species, 25 were morphospecies and nine were unidentified taxa; all are considered to be potential SRE (DD). The field survey collected seven potential SRE isopod species: *Buddelundia* '10ma', *Buddelundia* '77', *Buddelundia* sp., Buddelundiinae sp., *Pseudodiploexochus* sp., *Troglarmadillo* sp. and *Philosciidae* sp. Buddelundiinae sp. belongs to an undescribed genus closely related to *Buddelundia*. This genus is mostly found in the Pilbara region and lacks the morphological characters used to determine *Buddelundia*. Morphospecies are difficult to define in this group and there is a general lack of sequences with which to make comparisons. The *Buddelundia* '10' species group contains several species, including *Buddelundia* '10ma' recorded in this survey. This taxon has been previously collected from the Marillana and West Angelas areas and is regarded as a potential SRE (DD).

The *Pseudodiploexochus* sp. is only the second record of this genus from the Pilbara. The only other record of this genus in the Pilbara is from the West Angelas area, approximately 25 km south-west of this current record. This previous specimen is part of Simon Judd's isopod collections and is therefore not present in the WAM data records. Members of this genus do not have the well-developed lungs present in most terrestrial Armadillidae. For this reason, they are far more

susceptible to desiccation and are nearly always considered to be SRE in arid or semi-arid environments. *Pseudodiploexochus* sp. is therefore likely to represent an SRE but in the absence of additional taxonomic or distributional data, it is a potential SRE.

The *Troglarmadillo* sp. specimen could not be unambiguously identified; however, it showed closest affinity to *Troglarmadillo*, a genus almost entirely represented by troglobites in the Pilbara. Despite the genus name, the species sampled possesses well developed eyes and has faint body patterning, suggesting that it is not a troglobite. Subterranean *Troglarmadillo* species are nearly always SRE and it is likely that this species will be as well. In the absence of more resolved taxonomic and distributional data, this species is a potential SRE. While there are a number of sources for sequences for Pilbara *Troglarmadillo* species, all of them are from troglobites; therefore, sequencing this specimen is unlikely to provide useful results until more specimens are obtained.

Appendix B: Conservation Fauna Categories, Habitat Condition Scales and Likelihood Criteria

This page has been left blank intentionally.

Table B.1: Categories of Threatened Ecological Communities (Department of Environment and Conservation 2013).

PD: Presumed Destroyed
An ecological community that has been adequately searched for but for which no representative occurrences have been located. The community has been found to be totally destroyed or so extensively modified throughout its range that no occurrence of it is likely to recover its species composition and/or structure in the foreseeable future. An ecological community will be listed as presumed totally destroyed if there are no recent records of the community being extant **and either** of the following applies (A or B): A) Records within the last 50 years have not been confirmed despite thorough searches of known or likely habitats **or** B) All occurrences recorded within the last 50 years have since been destroyed.
CR : Critically Endangered
An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or that was originally of limited distribution and is facing severe modification or destruction throughout its range in the immediate future, or is already severely degraded throughout its range but capable of being substantially restored or rehabilitated. An ecological community will be listed as **Critically Endangered** when it has been adequately surveyed and is found to be facing an extremely high risk of total destruction in the immediate future. This will be determined on the basis of the best available information, by it meeting **any one or more of** the following criteria (A, B or C): A) The estimated geographic range, and/or total area occupied, and/or number of discrete occurrences since European settlement have been reduced by at least 90% **and either or both** of the following apply (i or ii): i) geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is imminent (within approximately 10 years); ii) modification throughout its range is continuing such that in the immediate future (within approximately 10 years) the community is unlikely to be capable of being substantially rehabilitated. B) Current distribution is limited, **and one or more** of the following apply (i, ii or iii): i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the immediate future (within approximately 10 years); ii) there are very few occurrences, each of which is small and/or isolated and extremely vulnerable to known threatening processes; iii) there may be many occurrences but total area is very small and each occurrence is small and/or isolated and extremely vulnerable to known threatening processes. C) The ecological community exists only as highly modified occurrences that may be capable of being rehabilitated if such work begins in the immediate future (within approximately 10 years).

En: Endangered
An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or was originally of limited distribution and is in danger of significant modification throughout its range or severe modification or destruction over most of its range in the near future. An ecological community will be listed as **Endangered** when it has been adequately surveyed and is not Critically Endangered but is facing a very high risk of total destruction in the near future. This will be determined on the basis of the best available information by it meeting **any one or more** of the following criteria (A, B, or C): A) The geographic range, and/or total area occupied, and/or number of discrete occurrences have been reduced by at least 70% since European settlement **and either or both** of the following apply (i or ii): i) the estimated geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is likely in the short term future (within approximately 20 years); ii) modification throughout its range is continuing such that in the short term future (within approximately 20 years) the community is unlikely to be capable of being substantially restored or rehabilitated. B) Current distribution is limited, **and one or more** of the following apply (i, ii or iii): i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the short term future (within approximately 20 years); ii) there are few occurrences, each of which is small and/or isolated and all or most occurrences are very vulnerable to known threatening processes; iii) there may be many occurrences but total area is small and all or most occurrences are small and/or isolated and very vulnerable to known threatening processes. C) The ecological community exists only as very modified occurrences that may be capable of being substantially restored or rehabilitated if such work begins in the short-term future (within approximately 20 years).
VU: Vulnerable
An ecological community that has been adequately surveyed and is found to be declining and/or has declined in distribution and/or condition and whose ultimate security has not yet been assured and/or a community that is still widespread but is believed likely to move into a category of higher threat in the near future if threatening processes continue or begin operating throughout its range. An ecological community will be listed as **Vulnerable** when it has been adequately surveyed and is not Critically Endangered or Endangered but is facing a high risk of total destruction or significant modification in the medium to long-term future. This will be determined on the basis of the best available information by it meeting **any one or more of** the following criteria (A, B or C): A) The ecological community exists largely as modified occurrences that are likely to be capable of being substantially restored or rehabilitated. B) The ecological community may already be modified and would be vulnerable to threatening processes, is restricted in area and/or range and/or is only found at a few locations. C) The ecological community may be still widespread but is believed likely to move into a category of higher threat in the medium to long term future because of existing or impending threatening processes.

Reference: Department of Environment and Conservation 2013, Definitions, Categories and Criteria for Threatened and Priority Ecological Communities DEC (Parks and Wildlife), <https://www.dpaw.wa.gov.au/images/plants-animals/threatened-species/definitions_categories_and_criteria_for_threatened_and_priority_ecological_communities.pdf.>

Table B.2: Definitions and criteria for Threatened Ecological Communities (Department of Environment and Conservation 2013).

Three categories exist for listing Threatened Ecological Communities under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act). An ecological community may be categorised as:

Categories of ecological communities	
Critically endangered	If, at that time, it is facing an extremely high risk of extinction in the wild in the immediate future.
Endangered	If, at that time, it is not critically endangered and is facing a very high risk of extinction in the wild in the near future.
Vulnerable	If, at that time, it is not critically endangered or endangered, and is facing a high risk of extinction in the wild in the medium-term future.

Reference: Department of Environment and Conservation 2013, Definitions, Categories and Criteria for Threatened and Priority Ecological Communities DEC (Parks and Wildlife), <https://www.dpaw.wa.gov.au/images/plants-animals/threatened-species/definitions_categories_and_criteria_for_threatened_and_priority_ecological_communities.pdf.>

Table B.3: Definitions and criteria for Priority Ecological Communities (Department of Environment and Conservation 2013).

Possible Threatened Ecological Communities that do not meet survey criteria or that are not adequately defined are added to the Priority Ecological Community Lists under Priorities 1, 2 and 3. Ecological communities that are adequately known, and are rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list, are placed in Priority 4. These ecological communities require regular monitoring. Conservation Dependent ecological communities are placed in Priority 5.

P1: Priority One – Poorly-known ecological communities
Ecological communities that are known from very few occurrences with a very restricted distribution (generally ≤5 occurrences or a total area of ≤ 100ha). Occurrences are believed to be under threat either due to limited extent, or being on lands under immediate threat (e.g. within agricultural or pastoral lands, urban areas, active mineral leases) or for which current threats exist. May include communities with occurrences on protected lands. Communities may be included if they are comparatively well-known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under immediate threat from known threatening processes across their range.
P2: Priority Two – Poorly-known ecological communities
Communities that are known from few occurrences with a restricted distribution (generally ≤10 occurrences or a total area of ≤200ha). At least some occurrences are not believed to be under immediate threat of destruction or degradation. Communities may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under threat from known threatening processes.
P3: Priority Three – Poorly-known ecological communities
(i) Communities that are known from several to many occurrences, a significant number or area of which are not under threat of habitat destruction or degradation or: (ii) communities known from a few widespread occurrences, which are either large or with significant remaining areas of habitat in which other occurrences may occur, much of it not under imminent threat, or; (iii) communities made up of large, and/or widespread occurrences, that may or may not be represented in the reserve system, but are under threat of modification across much of their range from processes such as grazing by domestic and/or feral stock, and inappropriate fire regimes. Communities may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and/or are not well defined, and known threatening processes exist that could affect them.
P4: Priority Four
Ecological communities that are adequately known, rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list. These communities require regular monitoring. (i) Rare. Ecological communities known from few occurrences that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These communities are usually represented on conservation lands. (ii) Near Threatened. Ecological communities that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable. (iii) Ecological communities that have been removed from the list of threatened communities during the past five years.
P5: Priority Five – Conservation dependent ecological communities
Ecological communities that are not threatened but are subject to a specific conservation program, the cessation of which would result in the community becoming threatened within five years.

Table B.4: Conservation codes for Western Australian fauna (Department of Parks and Wildlife 2019).

Code	Conservation category	Definition
CR	Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice under the *Biodiversity Conservation Act 2016*.	Fauna that is rare or likely to become extinct, as critically endangered fauna.
EN	Schedule 2 of the Wildlife Conservation (Specially Protected Fauna) Notice under the *Biodiversity Conservation Act 2016*.	Fauna that is rare or likely to become extinct, as endangered fauna.
VU	Schedule 3 of the Wildlife Conservation (Specially Protected Fauna) Notice under the *Biodiversity Conservation Act 2016*.	Fauna that is rare or likely to become extinct, as vulnerable fauna.
EX	Schedule 4 of the Wildlife Conservation (Specially Protected Fauna) Notice under the *Biodiversity Conservation Act 2016*.	Fauna that is presumed to be extinct.
IA	Schedule 5 of the Wildlife Conservation (Specially Protected Fauna) Notice under the *Biodiversity Conservation Act 2016*.	Birds that are subject to international agreements relating to the protection of migratory birds.
CD	Schedule 6 of the Wildlife Conservation (Specially Protected Fauna) Notice under the *Biodiversity Conservation Act 2016*.	Fauna that are of special conservation need being species dependent on ongoing conservation intervention.
OS	Schedule 7 of the Wildlife Conservation (Specially Protected Fauna) Notice under the *Biodiversity Conservation Act 2016*.	Declared to be fauna that is in need of special protection, otherwise than for the reasons mentioned.

Reference: Department of Parks and Wildlife 2019, *Conservation Codes For Western Australian flora and fauna*, The Government of Western Australia.

Table B.5: Priority species under Western Australian *Biodiversity Conservation Act 2016* (Department of Parks and Wildlife 2019).

Taxa that have not yet been adequately surveyed to be listed under Schedule 1 or 2 are added to the Priority Flora and Priority Fauna Lists under Priorities 1, 2 or 3. These three categories are ranked in order of priority for survey and evaluation of conservation status so that consideration can be given to their declaration as threatened flora or fauna. Taxa that are adequately known, are rare but not threatened, or meet criteria for Near Threatened, or that have been recently removed from the threatened list for other than taxonomic reasons, are placed in Priority 4. These taxa require regular monitoring. Conservation Dependent species are placed in Priority 5.

P1: Priority One – Poorly known taxa
Taxa that are known from one or a few collections or sight records (generally less than five), all on lands not managed for conservation, e.g. agricultural or pastoral lands, urban areas, Shire, Westrail and Main Roads WA road, gravel and soil reserves, and active mineral leases and under threat of habitat destruction or degradation. Taxa may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under immediate threat from known threatening processes.
P2: Priority Two – Poorly known taxa
Taxa that are known from one or a few collections or sight records, some of which are on lands not under imminent threat of habitat destruction or degradation, e.g. national parks, conservation parks, nature reserves, State forest, vacant Crown land, water reserves, etc. Taxa may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under threat from known threatening processes.
P3: Priority Three – Poorly known taxa
Taxa that are known from collections or sight records from several localities not under imminent threat, or from few but widespread localities with either large population size or significant remaining areas of apparently suitable habitat, much of it not under imminent threat. Taxa may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and known threatening processes exist that could affect them.
P4: Priority Four: Rare, near threatened and other taxa in need of monitoring
(a) Rare. Taxa that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These taxa are usually represented on conservation lands. (b) Near Threatened. Taxa that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable. (c) Taxa that have been removed from the list of threatened species during the past five years for reasons other than taxonomy.
P5: Priority Five: Conservation dependent taxa
Taxa that are not threatened but are subject to a specific conservation program, the cessation of which would result in the taxa becoming threatened within five years.

Reference: Department of Parks and Wildlife 2019, *Conservation Codes For Western Australian flora and fauna*, The Government of Western Australia.

Table B.6: Categories and definitions for EPBC Act listed fauna species.

Conservation category	Definition
Extinct	Taxa with no reasonable doubt that the last member of the species has died.
Extinct in the wild	Taxa known to survive only in cultivation, in captivity or as a naturalized population well outside its past range; or it has not been recorded in its known and/or expected habitat, at appropriated seasons, anywhere in its past range, despite exhaustive surveys over a time frame appropriate to its life cycle and form.
Critically endangered (CR)	Taxa facing an extremely high risk of extinction in the wild in the immediate future, as determined in accordance with the prescribed criteria.
Endangered (EN)	Taxa are not critically endangered; and are facing a very high risk of extinction in the wild in the near future, as determined in accordance with the prescribed criteria.
Vulnerable (VU)	Taxa are not critically endangered or endangered; and are facing a high risk of extinction in the wild in the medium-term future, as determined in accordance with the prescribed criteria.
Conservation dependent (CD)	Taxa are the focus of a specific conservation program the cessation of which would result in the species becoming vulnerable, endangered or critically endangered; or the following subparagraphs are satisfied: i) the taxa is a species of fish; ii) the taxa is the focus of a management plan that provides management actions necessary to stop the decline of, and support the recovery of, the taxa so that its chances of long term survival in nature are maximized; iii) the management plan is in force under a law of the Commonwealth or of a State or Territory; iv) Cessation of the management plan would adversely affect the conservation status of the taxa Fish includes all taxa of bony fish, sharks, rays, crustaceans, molluscs and other marine organisms, but does not include marine mammals/reptiles.
Migratory (IA)	Taxa are considered migratory species on International Agreements; i) if they are native to Australia and are included in the appendices to the Bonn Convention (Convention on the Conservation of Migratory Species of Wild Animals Appendices I and II); ii) all migratory species included in annexes established under the Japan-Australia Migratory Bird Agreement (JAMBA) and the China-Australia Migratory Bird Agreement (CAMBA); and iii) Are native, migratory species identified in a list established under, or an instrument made under, an international agreement approved by the Minister, such as the Republic of Korea-Australia Migratory Bird Agreement (ROKAMBA).

Note: CD and IA are only related to conservation significant fauna

Table B.7: Criteria used to define likelihood occurrence of conservation significant fauna species.

Likelihood of occurrence	Pre-survey	Post-survey
Recorded	N/A	Species or evidence of species recorded during survey.
High	Species has been recorded within the survey area or within 20 km of the survey area and preferred habitat appears to be present.	Core or preferred habitats present in the survey area which are abundant and/or high quality condition. OR Species is known to be cryptic and may not have been detected despite adequate survey effort and suitable habitat present within the survey area. OR Species or evidence of species recorded within the survey area however doubt remains over the taxonomic identification, validity of record.
Moderate	Species has not been recorded from within the survey area, however species has been recorded within the prescribed database search area and suitable habitat appears to be present.	Core or highly suitable habitats present in the survey area, however non-cryptic species that was not detected despite adequate survey effort. OR Core or preferred habitats present in the survey area are mainly in poor or modified condition.
Low	Species recorded from within the prescribed database search area but suitable habitat does not appear to be present.	Species has not been recorded in the survey area despite adequate survey effort. OR Species dependent on specific habitats that do not occur in the survey area. OR Species considered locally extinct.

Table B.8: Criteria used to determine SRE status of invertebrates.

Status	Criteria
Confirmed	This species has a high probability of being an SRE based on expert opinion, reference databases or the scientific literature. Usually, this species belongs to a group that is well known taxonomically and contains a high proportion of SRE species. Example: Millipedes belonging to the genus *Boreohesperus* (Car and Harvey 2013).
Potential	This species has a moderate probability of being an SRE because it belongs to a group with a high proportion of SRE species, has specific biological and/or ecological attributes that may indicate range restriction, or has been collected from a single microhabitat type. Usually, this species will belong to a group with a poorly or moderately resolved taxonomy. Example: Many trapdoor spiders in the infraorder Mygalomorphae (Castalanelli *et al.* 2014). The WAM recognises the uncertainty involved with this category and lists five sub-categories that may help elucidating this status: i) data deficient because there is insufficient information; ii) habitat indicators that are associated with potential SRE status; iii) morphological indicators; iv) molecular evidence; and v) research and expert knowledge held within the WAM (WAMTS staff 2013). These sub-categories are implicitly addressed as part of the species assessments.

Castalanelli, MA, Teale, RJ, Rix, MG, Kennington, WJ & Harvey, MS 2013, 'Barcoding of mygalomorph spiders (Araneae: Mygalomorphae) in the Pilbara bioregion of Western Australia reveals a highly diverse biota', *Invertebrate Systematics*, vol. 28, pp. 375-85.

Table B.9: Fauna habitat condition scale (Thompson and Thompson 2010).

Habitat condition	Condition description
High Quality Fauna Habitat (1.0)	These areas closely approximate the vegetation mix and quality that would have been in the area prior to any human induced disturbance. The habitat has connectivity with other habitats and is likely to support the most natural vertebrate fauna assemblage.
Very Good Fauna Habitat (0.8)	These areas show minimal signs of human induced disturbance (e.g. grazing, clearing, fragmentation, weeds) and retain almost all of the characteristics of the habitat had it not been disturbed. The habitat has connectivity with other habitats, and fauna assemblages in these areas are likely to be minimally effected by disturbance.
Good Fauna Habitat (0.6)	These areas show signs of human induced disturbance (e.g. grazing, clearing, fragmentation, weeds) but generally retain many of the characteristics of the habitat had it not been disturbed. The habitat still retains some connectivity with other habitats but fauna assemblages in these areas are likely to be affected by disturbance. Fauna assemblages in these areas are likely to be similar to what might be expected in this habitat.
Disturbed Fauna Habitat (0.4)	These areas show signs of human induced significant disturbance (e.g. mining, clearing, tracks and roads). Many of the trees, shrubs and undergrowth have died or have been cleared. These areas may be in the early succession and regeneration stages. Areas may show signs of significant grazing, contain an abundance of weeds or have been damaged by vehicles or machinery. Habitats are fragmented or have limited connectivity with other fauna habitats. Fauna assemblages in these areas are likely to differ significantly from what might be expected in the area had the disturbance not occurred.
Highly Degraded Fauna Habitat (<0.2)	These areas often have a significant human induced loss of vegetation, and / or a large number of vehicle tracks and / or have been completely cleared, and / or areas have been heavily grazed or farmed. There is limited or no fauna habitat connectivity. Fauna assemblages in these areas are likely to differ significantly from what existed prior to the disturbance, and are often depleted compared to what existed prior to the disturbance.

Table B.10: Suitability/significance of habitat ranking criteria for the target Matters of National Environmental Significance (MNES) species.

Species	Probable shelter and foraging habitat	Potential shelter and foraging habitat	Suitable foraging and dispersal habitat	Limited foraging and dispersal habitat
Pilbara Olive Python (*Liasis olivaceus barroni*)	N/A	Rocky habitat such as gorges, escarpments and breakaways along with drainage lines including or in close proximity to permanent or semi-permanent water holes.	Drainage lines with dense vegetation enabling transitory behaviours and/or providing foraging potential. Rocky habitats that are not in close proximity to water.	Habitat that has limited sheltering and foraging capacity with no permanent or semi-permanent water.
Northern Quoll *(Dasyurus hallucatus)*	Habitat as described in potential shelter and foraging habitat but is considered core habitat critical to the Northern Quoll. This was determined by proximity to known records and microhabitat features, such as south-facing, extent of habitat and whether it was in close association with a gorge or gully.	Rocky habitats such as ranges, escarpments, mesas, ranges, gorges, breakaways and boulder fields. Also major drainage lines or tree-lined drainage systems that are structurally diverse and contain large diameter trees, termite mounds or hollow logs.	Habitat important for foraging, dispersal and buffering of the species including moderate to small sized drainage lines and native vegetation in close proximity (within 2 km) denning or shelter habitat.	Habitat that has limited sheltering and foraging capacity and not connected to potential denning/shelter and foraging habitat.
Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) and Ghost Bat (*Macroderma gigas*)	N/A	Rocky habitat that contains caves suitable as diurnal or maternity roosts sites, or potentially contains these caves and has not adequately surveyed OR Areas highly suitable for foraging that are likely to be used on a regular basis.	Habitat important for foraging including diverse rocky terrain, moderately sized drainage lines and dense complex vegetation stands.	Habitat that has limited ecological value but may provide capacity for transitory movement across the landscape and/or limited foraging potential.

Species	Probable shelter and foraging habitat	Potential shelter and foraging habitat	Suitable foraging and dispersal habitat	Limited foraging and dispersal habitat
Night Parrot (*Pezoporus occidentalis*)	N/A	Isolated habitat not subjected to predation pressure, fire pressure, and altered habitat from pastoralism and mining activities. Generally roosting habitat that contains old and large spinifex clumps (>50 years unburnt), particularly ring-forming hummocks. OR Areas highly suitable for foraging in close association (<10 km) to potential roosting habitat, including *Triodia* (particularly at times of mass flowering and seeding) and chenopod communities dominated by *Sclerolaena*.	Very little is known on the foraging requirements of the Night Parrot. Habitat within 40 km of potential roosting and nesting sites, potentially important for foraging, including chenopod communities (particularly those dominated by *Sclerolaena*), *Triodia* and areas rich in herbs, including forbs, grasses and grass-like plants.	Habitat that has limited roosting and foraging potential for the Night Parrot.

Limitation: The purpose of this report is to inform Astron about the identity and distribution of conservation significant invertebrates (short-range endemics) within the proposed Short-range Endemic Assessment of Invertebrates from the Hope Downs 2 Level 2 Survey Area. Alacran Environmental Science accepts no liability or responsibility for any use or reliance on this report for any other purpose. The accuracy and completeness of the information supplied by Astron or other data sources including (but not limited to) The Western Australian Museum, The Australian Bureau of Meteorology or the Western Australian Department of Minerals and Petroleum, have not been reviewed or verified.

EXECUTIVE SUMMARY

This report presents the findings of a desktop study, and the identification and SRE (short-range endemic) assessment of invertebrates sampled during two field surveys undertaken by Astron. The information in this report is intended to be used by Astron in their preparation of an overarching fauna report for Rio Tinto. The aim of that report is to provide information to Rio Tinto to enhance the level of knowledge about fauna within the Hope Downs 2 Level 2 Survey Area (the Study Area). This information is also intended to inform any future environmental impact assessment within the region.

The study area occupies 10,817.7 ha and is located approximately 75 km west north-west of Newman.

The desktop assessment of SRE invertebrates was undertaken within approximately 40,000 km^2 square area (the Search Area) centred on the Study Area. Database searches were undertaken for SRE invertebrate records from the W. A. Museum's Arachnids and Myriapods, Crustaceans and Molluscs databases. These data were subsequently edited to enforce consistency in naming and then filtered for SREs and potential SREs.

The database search yielded 12,376 records from within the Search Area. Of those, 4,335 records were attributed to SRE groups, SREs and Potential SREs. The SRE groups represented 282 taxa, of which eight (2.8%) represented named species, 182 (64.5%) represented named morphospecies and 92 (32.6%) represented unidentified species belonging to taxa known to contain SRE representatives. Twenty-four (24) species and morphospecies represented SREs with the remaining 258 taxa being Potential SRE owing largely to data deficiency (DD).

The field surveys generated a total of 202 samples from SRE target taxa comprising 67 different taxa. Eighteen (18) of these species were known to be widespread, 48 were either likely or potential SREs and one confirmed SRE, *Karaops banyjima*. Of these SRE category taxa, 32 were identified to the level of species or morphospecies:

- seven spiders: *Karaops banyjima*, *Karaops* 'ARA001', *Aurecocrypta* 'MYG315', *Aurecocrypta* 'HD1', *Synothele* 'MYG309', *Synothele* 'MYG311' and *Yilgarnia* 'MYG197';
- nine pseudoscorpions: *Tyrannochthonius* 'HD1', *Tyrannochthonius* 'HD2', *Austrohorus* 'HD5', *Beierolpium* 'HD1', *Beierolpium* 'HD2', *Euryolpium* 'HD6', *Euryolpium* 'HD7', 'Genus 7/4 PSE118', 'PSEAAA HD4';
- four scorpions; *Lychas* 'bituberculatus complex', *Lychas* 'hairy tail complex', *Lychas* 'multipunctatus complex', *Urodacus* 'HD1';
- seven centipedes: *Sepedonophilus* 'HD1', *Sepedonophilus* 'HD2', *Mecistocephalus* 'HD1', *Mecistocephalus* 'HD2', *Mecistocephalus* 'HD3', *Orphnaeus* 'HD1', *Cryptops* 'HD1',
- three millipedes: *Antichiropus* 'wonmunna', *Austrostrophus* 'Clade A', *Austrostrophus* 'Clade E', and
- two isopods: *Buddelundia* '10ma', *Buddelundia* '77'.

Seventeen (17) SRE taxa sampled represent ambiguously identified groups:

- three spiders: *Synothele* sp., *Aname* sp., Nemesiidae sp.;
- five pseudoscorpions: *Anatemnus* sp., *Sundochernes* sp., *Indolpium* sp., *Euryolpium* sp., Olpiidae sp.;
- two centipedes: *Sepedonophilus* sp., Geophilomorpha sp.;

- two millipedes: *Antichiropus* sp. and *Austrostrophus* sp., and
- five isopods: *Buddelundia* sp., Buddelundiinae sp., *Pseudodiploexochus* sp., *Troglarmadillo* sp., Philosciidae sp.

Habitat mapping was undertaken by Astron and five habitats stand out as being conducive to relictual SREs: Breakaways, Mulga Woodland, Minor Drainage lines, Gorges and Gullies, and Rocky Hills. Most of these latter habitats are associated with an isolated ridge running in an east-west direction, so most of the breakaways and rocky slopes are south-facing and therefore conducive to SREs.

Several SRE category invertebrates were found in multiple habitat types, suggesting that they may be less specialised with respect to their habitat preferences:

- *Lychas* 'bituberculatus complex', from stony hills and eucalypt woodland;
- *Sepedenophilus* 'HD1', from rocky slopes and gullies, and mulga woodland;
- *Mecistocephalus* 'HD1', from rocky slopes and gullies, and mulga woodland;
- *Austrostrophus* 'Clade E', from mulga woodland and open eucalypt woodland;
- *Antichiropus* 'wonmunna', from mulga woodland in this study area, but from gully slopes and riparian vegetation outside of this study area.

These species are likely to be found outside of the limits of the study area.

1 INTRODUCTION

1.1 SCOPE

In March 2019, Rio Tinto (Rio) commissioned Astron and Alacran Environmental Science (Alacran) to undertake a second (wet-season) short-range endemic invertebrate (SRE) survey within the Hope Downs 2 Level 2 Survey Area (10,817.7 ha) located approximately 75 km WNW of Newman (the Study Area), Figure 2.1. These areas form part of the larger Hope Downs 1 Development Envelope.

This survey followed from an initial Level 2 survey undertaken in May 2018 (Here after referred to as "T1") which yielded a modest collection (110 specimens) comprising 11 SREs and potential SREs:

- two trapdoor spiders: *Gaius* sp. and *Nemesiidae* sp.;
- four pseudoscorpion taxa: *Austrohorus* sp., *Indolpium* sp., Olpiide sp. and *Tyrannochthonius aridus*.
- three scorpion taxa*: Lychas* 'bituberculatus complex', *Lychas* 'multipunctatus complex' and *Lychas* 'hope downs';
- one earth centipede (Geophilomorpha): *Sepedenophilus* sp.; and
- one isopod: *Buddelundia* sp.

In the time since that survey, two species can be removed from the list:

- the genus *Gaius* (Rix et al. 2018c) was revised subsequent to the report and *Gaius* sp. is now known to represent the species *Gaius tealei* which is widespread in the Pilbara;
- *Lychas* 'hope downs' is the same as *Lychas* 'harveyi complex' following examination of additional specimens of *Lychas* 'harveyi complex' obtained from the T2 survey. *Lychas* 'harveyi complex' is a widespread species in the Pilbara.

One of the primary limiting factors for that survey was the dry conditions during and preceding the survey, reflecting the suboptimal season for undertaking SRE surveys.

The present survey aimed to bolster the survey effort for SREs in the study area by surveying in March, in the latter half of the Pilbara wet season (EPA 2016). The present report combined the results from both surveys and therefore supersedes report No. 1807 (Alacran 2018).

The overall purpose of the survey was to gather additional biological information through a desktop study and intensive field surveys to enhance and contextualise the level of knowledge at the locality scale.

Alacran provided specialist support for the short-range endemic component of the survey by way of:

- recommending likely field locations within the Study Area to undertake SRE sampling (T1 and T2),
- guided SRE field survey (T2),
- undertaking a desktop assessment including area searches of relevant W. A. Museum databases,
- identification and SRE assessment of field samples (T1 and T2),
- coordinating DNA sequencing and analyses of target samples.

OVERVIEW

1.1.1 Short-range endemism

Short-range endemics are organisms with small geographic distributions (Harvey 2002b; Ponder and Colgan 2002), nominally less than 10,000 km^2(Harvey 2002b). These organisms are typically characterised by one or more of the following characteristics:

- limited dispersal capabilities,
- seasonal activity (cooler or wetter periods),
- slow growth, and
- low levels of fecundity.

Their limited dispersal capabilities result in small populations being isolated from each other by inhospitable geographic features such as rivers, rocky ridges or plains. Prolonged isolation between populations eventually results in speciation, with each population becoming genetically and morphologically distinct. Two types of short-range endemism have been recognised: Relictual Endemism and Habitat Specialist Endemism (Harvey 2002b; Ponder and Colgan 2002).

Relictual SREs result when speciation occurs following the fragmentation of continuous habitat into two or more refugia. In Australia, the primary driver of this over the last 65 million years has been aridification, which acted to isolate formerly widespread species living in mesic forests to small patches of mesic refugia. Relictual SREs include scorpions in the genus *Aops* (Volschenk and Prendini 2008), pseudoscorpions in the genera *Tyrannochthonius* (Harvey 1991; Edward and Harvey 2008), *Indohya* (Harvey 1993b; Harvey and Volschenk 2007) and *Idioblothrus* (Muchmore 1982; Harvey 1993a; Harvey and Leng 2008b) and millipedes in the genus *Antichiropus* (Car et al. 2013; Car and Harvey 2014). Troglobites (obligate subterranean species) are thought to be extreme examples of relictual SREs; most troglobites from the Pilbara have surface dwelling relatives living in the more mesic forests of northern Australia (Harvey 2002b; Ponder and Colgan 2002).

Habitat specialist SREs are species that have adapted to very specific environment types, including those found in arid environments (e.g. rocky outcrops or isolated dune systems). These habitats are often relatively young (<10 million years) and therefore are not refugial. Examples of habitat specialist SREs include spiders in the family Selenopidae and pseudoscorpions in the genera *Synsphyronus* (Harvey 2011b, 2012) and *Feaella* (Harvey 1989; Harvey and Volschenk 2007), and scorpions in the genera *Lychas* and *Urodacus*.

2 METHODS

2.1 DEFINING SHORT-RANGE ENDEMISM

Assessment of short-range endemism can be challenging when data for evaluation are absent or limited. Limitations may include any of the following:

- **Poor survey coverage,** e.g. the fauna of an area has not been sampled extensively enough to enable assessment of species distributions. The absence of a species from survey records may not mean that it is absent from the area.
- **Poor taxonomic resolution,** e.g. a species has not been subject to systematic investigation, and/or the identity is either difficult or impossible to determine. Good taxonomic resolution does not necessarily need to be in the form of published revisions, as it can be facilitated by any of the following:
  - a researcher actively working on the group who can authorise identifications,
  - a publicly accessible reference collection, and/or;
  - assessment of species boundaries using genomic methods such as DNA barcoding (Hebert et al. 2003a; Hebert et al. 2003b).
- **Identification issues**, e.g. surveys sampled life stages of SREs that are impossible to identify based on morphological characters. Examples of relevant taxa include juvenile or female millipedes, mygalomorph spiders and *Urodacus* scorpions. Genomic methods have great potential to overcome this type of limitation.

There are no published systems for assessing the SRE potential for a species. The W. A. Museum previously employed the following system to assess SRE-status of invertebrates:

- **Confirmed SRE:** This category applies when the identity of the taxon is unambiguous, and its distribution is less than 10 000km^2 based on publicly available vouchered records. Supporting data can be either genomic (from DNA sequences) or morphological, ideally both.
- **Potential SRE:** This category applies to situations where there are knowledge gaps for the taxon. The following sub-categories further elucidate this status:
  - **Data Deficiency (DD):** This category covers taxa for which there is insufficient data available to determine SRE status. Factors that fall under this category include:
    - insufficient geographic information,
    - insufficient taxonomic information, and/or
    - inappropriate life stages prevent identification to species level.
  - **Habitat Indicators (H):** This category employs habitat characteristics to evaluate SRE status when habitats are known to support SRE taxa. For example, many species sampled from subterranean habitats are known to be range restricted; a new species discovered from such habitat therefore has greater potential to be range restricted (i.e. an SRE) than widespread.
  - **Morphological Evidence (M):** This category uses one or more morphological characters that are characteristic of SRE taxa inhabiting restricted environments, e.g. the specialised morphological features of animals adapted to subterranean habitats, including body markings that are absent or significantly paler than surface dwelling relatives, eyes that are absent or significantly reduced, and/or longer appendages (legs and antennae) than surface relatives.
  - **Unpublished Research & Expertise (U):** This category relies on unpublished research or expertise to develop SRE status.

These categories of potential SRE may be helpful in developing conservation priorities; however, each taxon should be assessed on its merit and in accordance with the *Precautionary Principle* (EPA 2002):

> "*where there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason to postpone measures to prevent environmental degradation*".

— **Widespread (not an SRE)**: This category applies when vouchered evidence demonstrates a distribution greater than 10,000 km^2.

2.2 TAXONOMY

The taxonomic nomenclature of invertebrates follows the references detailed in Table 2.1. Morphospecies designations follow the parataxonomy of the scientist(s) working on the group; these informal names are written between single quotation marks rather than being italicised as they are not valid under the International Code of Zoological Nomenclature (1999).

Alacran follows the "Phylogenetic Species Concept" (Cracraft 1983) when delineating species or morphospecies:

> "A species is the smallest diagnosable cluster of individual organisms within which there is a parental pattern of ancestry and descent."

2.2.1 Identification

For this report, Dr Simon Judd contributed information about isopod distributions, SRE assessment and specimen identification. The remaining identifications (spiders, pseudoscorpions, scorpions, millipedes, centipedes, silverfish and snails) were carried out by the Dr Erich Volschenk. The references used for species determination are summarised in Table 2.1.

Where morphological identification was not possible, attempts were made to assess the identity of the specimen using DNA Barcoding of the gene COI (Cytochrome C oxidase subunit I). The DNA barcoding study for this survey is detailed in Appendix 3.

Table 2.1. The following 'general' references and collections were used to assist with morphospecies designations

Order	Taxonomic reference	Morphospecies and reference collection
Araneae	(Raven et al. 2002; Crews and Harvey 2011; Harvey et al. 2012; Crews 2013; World Spider Catalog 2014; Castalanelli et al. 2017; Rix et al. 2017a; Rix et al. 2017b; Harrison et al. 2018; Harvey et al. 2018; Rix et al. 2018a; Rix et al. 2018b; Rix et al. 2018c)	Reference collection at the W. A. Museum
Pseudoscorpiones	(Harvey 1992; Harvey and Volschenk 2007; Edward and Harvey 2008; Harvey and Leng 2008a; Murienne et al. 2008; Harvey 2011a, 2012, 2013b; Alexander et al. 2014; Harrison et al. 2014; Harvey et al. 2016)	Reference collection at the W. A. Museum
Scorpiones	(Glauert 1925b, a; Acosta 1990; Kovařík 1997; Fet et al. 2000; Volschenk et al. 2000; Volschenk and Prendini 2008; Volschenk et al. 2010)	Morphospecies designation by Dr Erich S Volschenk. Reference collection at the W. A. Museum and with Dr Erich S. Volschenk.
Chilopoda	(Colloff et al. 2005)	Reference collection at the W. A. Museum
Diplopoda	(Car and Harvey 2013; Car et al. 2013; Car and Harvey 2014)	Reference collection at the W. A. Museum
Isopoda	(Judd and Horwitz 2003; Schmalfuss 2003; Judd 2004; Schmidt and Leistikow 2004; Schotte et al. 2008; Judd and Perina 2013)	Morphospecies designation by Dr Simon Judd. Reference collection at the W. A. Museum and with Dr Simon Judd.
Gastropoda	(Solem 1985, 1997; Johnson et al. 2004; Johnson et al. 2012; Whisson and Köhler 2012; Johnson et al. 2013; Whisson and Kirkendale 2014; Stanasic et al. 2017)	Reference collection at the W. A. Museum

2.2.2 Specimen Lodgement and Data Access

In accordance with *EPA Guidance Statement 20* (2009), specimens submitted to Alacran for taxonomic identification will be offered to the W. A. Museum for inclusion in their biological collections.

Supporting data are attached as appendices:

Appendix 1. Short-range endemic records from an area search by the W. A. Museum.
Appendix 2. Short-range endemic and target group records from the field survey.
Appendix 3. Targeted DNA barcoding of Invertebrates from the Hope Downs 2 Project Area.

2.3 DESKTOP ASSESSMENT

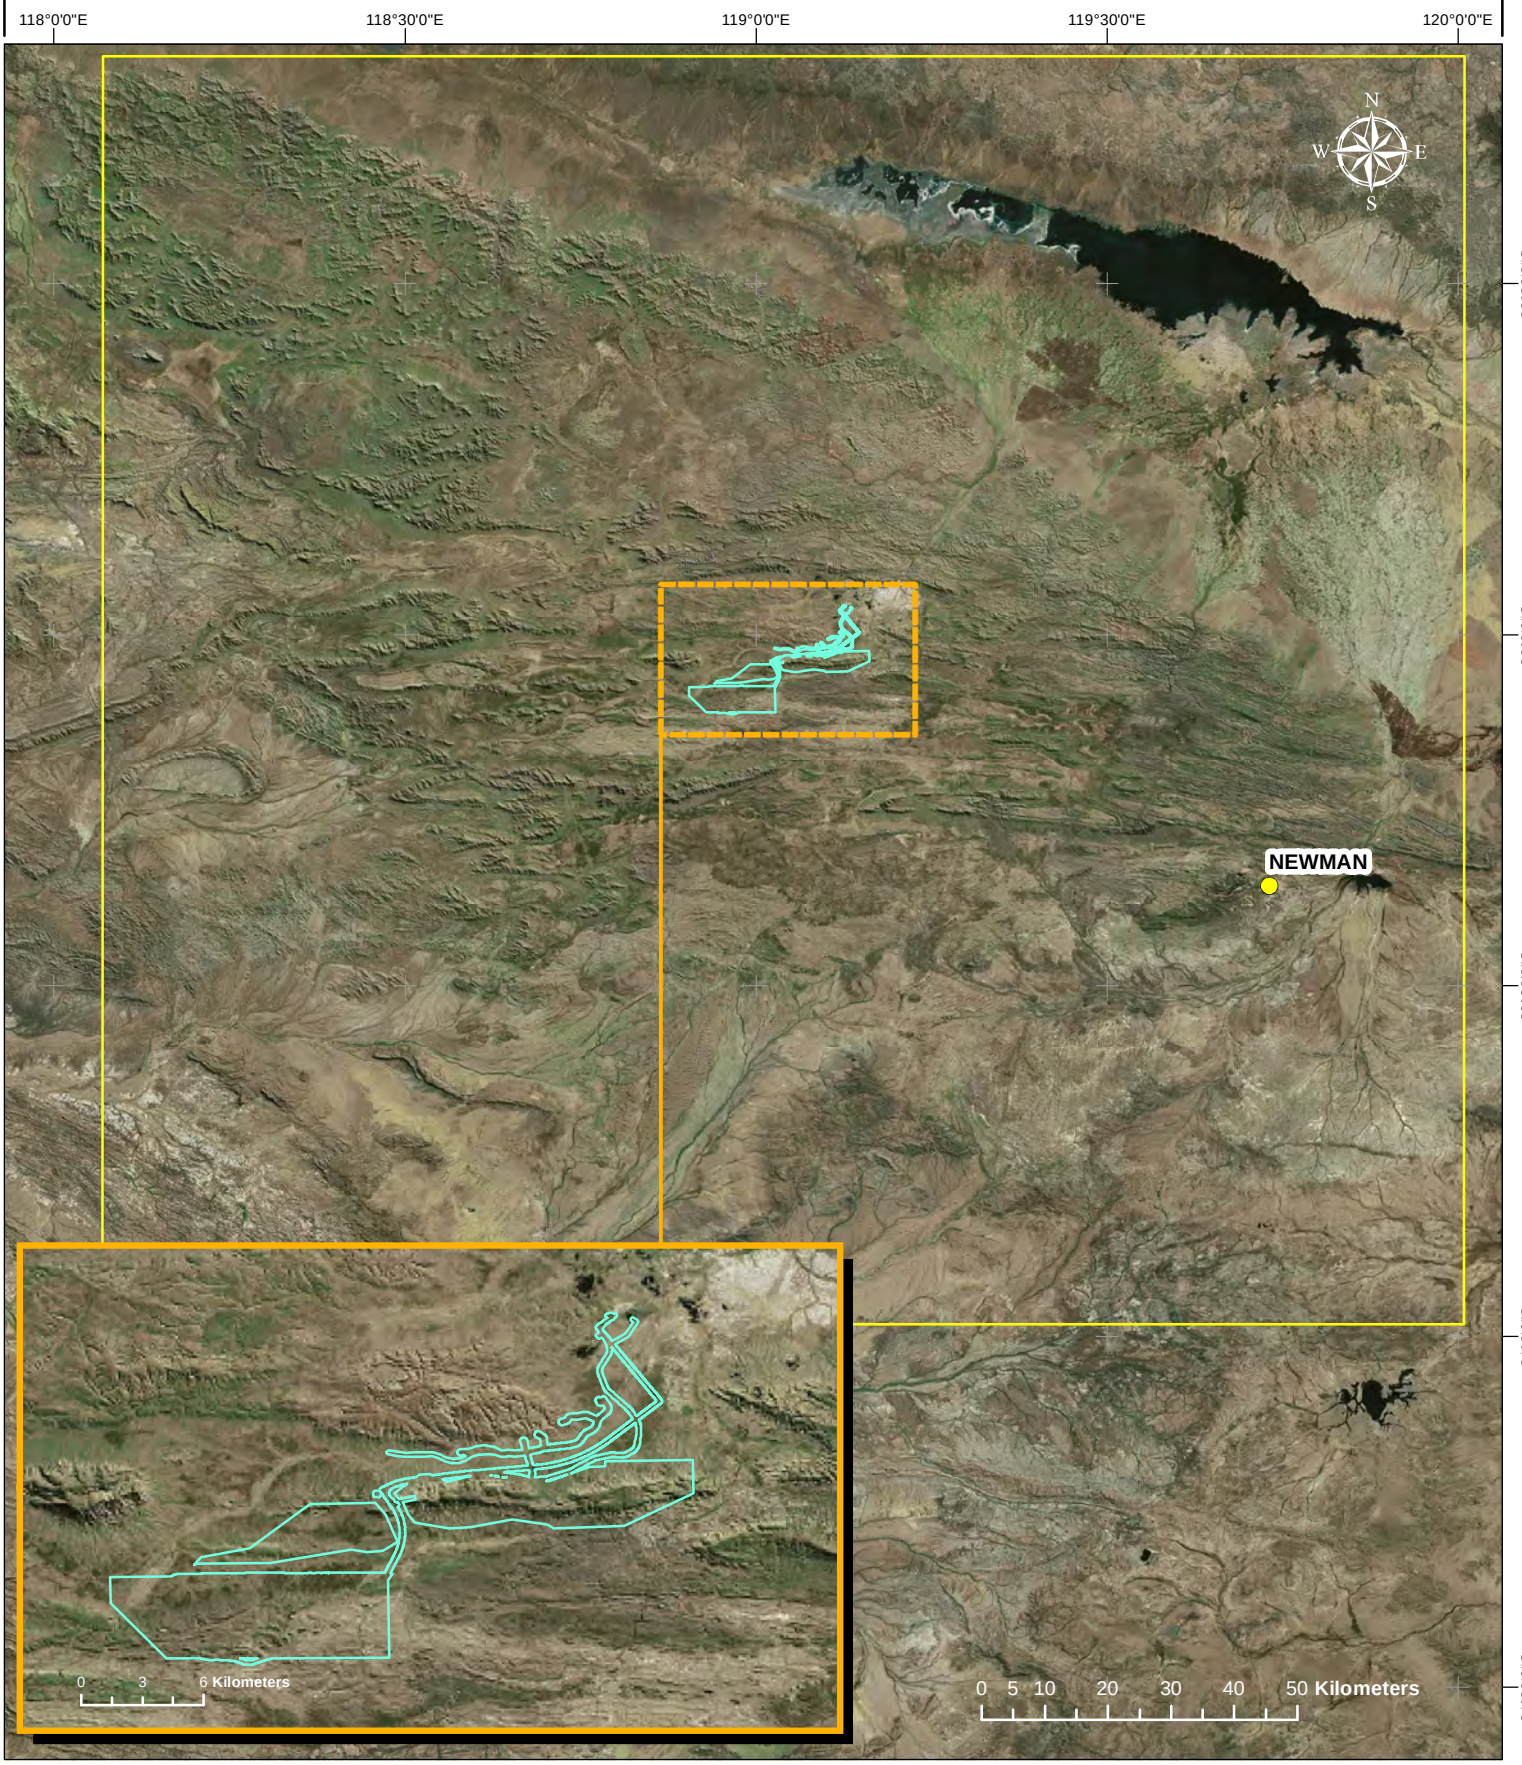
2.3.1 Database search

2.3.1.1 Search area

For this report, the Search Area is defined as the area investigated for SREs surrounding the Study Area. Based on the nominal area threshold for SRE distributions, <10,000 km^2 (Harvey 2002b), a square area was generated using "Google™ Earth Pro", centring on the Study Area and extended approximately 100 km north, south east and west from it. The following corner coordinates of the Search Area was used when undertaking searches from within the W. A. Museum's databases: Top left corner (North West): -22.175902°, 118.070211°; Bottom right corner (South East): -23.956909°, 120.008080°. The total area searched was approximately 40,000 km^2 (a square with 200 km sides) (Figure 2.1).

2.3.1.2 Search area data edits and filtering

At the time when the area searches were requested from the W. A. Museum, limited taxonomic support was provided for database searches with **limited** screening for SREs or subterranean fauna from the department of Arachnids and Myriapods. Database search results constituted data 'dumps' of ALL records from within the Search Area requested. Database search results were edited prior to screening for SREs to enforce consistency between the different departmental databases. The following edits and filtering were applied to the combined data:



1. A new field "Binomial" was created, into which the Genus and Species field values were concatenated, *e.g.* Genus [Lychas] + Species [`gracilimanus`] → Binomial [Lychas 'gracilimanus']
    a. Where the genus field was empty or contained the values "Unknown" or "gen. nov.", the family rank name was used instead of genus.
    b. Where both family and genus fields were empty, unknown, the order rank was used in place of the genus.
    c. all unidentified 'species' in the 'Binomial' field (*e.g.* "sp. indet.", "sp. indet. (juvenile)", "sp?", "unknown") were renamed to "sp."
    d. All Binomial morphospecies names ending in "sp. n." were renamed without that suffix, *e.g.* "*Rhagada* 'pannawonica' sp. n." was renamed to *Rhagada* 'pannawonica'.

2. Another field was created called "Ecotype", into which the ecotype of the species was manually recorded, based on taxon and/or sampling methods:
    a. **Epigean**: all species obtained through terrestrial survey methods or belonging to taxa only known to be epigean in W. A., *e.g.* trapdoor spiders.
    b. **Subterranean, Troglobite** or **stygobite**: 'named' species or morphospecies obtained using subterranean sampling methods or from taxa known predominantly from subterranean habitats, *e.g.* schizomids.
    c. **?Epigean**: unidentified species from subterranean survey methods of groups known to contain epigean SREs in the Pilbara, *e.g.* Centipedes from the order Geophilomorpha or family Cryptopidae.

d. **?troglobite**: Unidentified species obtained from subterranean fauna survey methods of orders or families rarely sampled in SRE surveys in the Pilbara, *e.g.* Millipede families Haplodesmidae and Dalodesmidae.
e. **Marine** and **Aquatic**: marine and freshwater species respectively.

3 The data were filtered for records with ecotypes of either “epigean” or “?epigean”.
4 The SRE status of each species present in the filtered data was assessed according to the SRE categories previously used by the W. A. Museum Taxonomic Service and described in **2.1**.

3 RESULTS

3.1 LITERATURE REVIEW

This review focusses on the data obtained from the W. A. Museum invertebrate departments as these are based on vouchered reference specimens. Numerous invertebrate surveys have been undertaken in (or partly in) the Search Area and many of these are not publicly available. The specimen records from all these surveys are however accessible from the W. A. Museum. Species referred to in reports that were not lodged in the W. A. Museum are of questionable value since their relevance to any subsequently collected specimens cannot be assessed. References to informative literature are made in the "Justification" column of the taxon summary tables.

3.2 W. A. MUSEUM DATABASE SEARCH

The Area Searches yielded a total of 12,376 records. After applying the SRE data edits and filters (**2.3.1.2 search area data edits and filtering**), that number was reduced to 4,335 records of SRE and Potential SRE species. These were represented by 282 taxa of which eight (2.8%) were named species, 182 (64.5%) were morphospecies and 92 (32.6%) were undetermined taxa, e.g. *Tyrannochthonius* sp. and Chthoniidae sp. The majority (260) of these taxa were potential SRE and 24 were confirmed SRE.

These results are summarised by Order in Table 3.1. The corresponding data file is embedded within this file as Appendix 1.

Table 3.1. Summary of W. A. Museum database search results for SRE and potential SRE taxa.

Order	Named species	Morphospecies	Un-named taxa ("sp.")	Totals
Araneae: Araneomorphae (modern spiders)	2	5	3	**10**
Araneae: Mygalomorphae (trapdoor spiders)	2	78	21	**101**
Opiliones (harvestmen)	0	0	2	**2**
Pseudoscorpiones (pseudoscorpions)	3	31	18	**52**
Schizomida (short-tailed whip scorpions)	0	1	0	**1**
Scorpiones (scorpions)	0	19	6	**25**
Geophilomorpha (earth centipedes)	0	1	9	**10**
Scolopendromorpha (centipedes)	0	0	3	**3**
Polydesmida (flat-back millipedes	0	18	4	**22**
Polyzoniida (sucking millipedes)	0	0	1	**1**
Spirobolida (millipedes)	1	2	5	**8**
Symphyla	0	0	1	**1**
Isopoda (Slaters)	0	25	9	**34**
Eupulmonata (land snails)	0	2	10	**12**
Totals	**8**	**182**	**92**	**282**

3.3 FIELD SURVEY

The field survey yielded a total of 202 samples, representing 66 taxa belonged to SRE groups. Of those 67 taxa, one was an SRE, 48 were either likely SRE or potential SRE and 18 were widespread; Table 3.2, Figure 3.1, Figure 3.2 and Figure 3.3. The summary of SRE species records per site is given in Table 3.3.

Table 3.2. Taxonomy and SRE status of field survey records with SRE category taxa shaded green.

Class	Order	Family	Species	SRE status
Arachnida	Araneae	Selenopidae	*Karaops banyjima* DNA	SRE

4 DISCUSSION

4.1 ARACHNIDA

Among the classes containing SREs, the arachnids stand out with the number of orders and families that contain SREs. With the exception of most modern spiders, and some pseudoscorpions and mites, most arachnids have relatively poor dispersal capabilities and are therefore significant candidates for exhibiting short-range endemism (Harvey 2002a; Harvey et al. 2011).

4.1.1 Araneae (spiders)

Spiders are instantly recognisable arachnids. In Australia, there are thought to be between 15,000 and 20,000 species, although only approximately 4,000 are currently named (White and Anderson 2017). Australia's spiders are broadly divided into two groups, the Araneomorphae (modern spiders) and the Mygalomorphae (trapdoor spiders). Most modern spiders are widely distributed and achieve this through 'ballooning'; a process where a spiderling creates and releases a long strand of silk into the wind. The silk strand eventually becomes long enough to 'catch the wind' like a kite and lift the spiderling into the wind to be deposited elsewhere, potentially many kilometres from its 'take-off' site. In the Pilbara, the modern spiders currently considered to contain SREs are members of the family *Selenopidae* (wall crab spiders) (Crews and Harvey 2011; Crews 2013).

Most of W.A's SRE spiders are trapdoor spiders. In W. A., nine trapdoor spider species are currently listed in the *Wildlife Conservation* (Specially Protected Fauna) *Notice* 2016 (Western Australian Government 2017); however, none of these are known from the Pilbara region. In the Pilbara, trapdoor spiders are represented by seven families: Actinopodidae, Barychelidae, Halonoproctidae, Dipluridae, Idiopidae, Nemesiidae and Theraphosidae, of which all except Theraphosidae are known to contain representatives with confirmed or potential short-range distributions (Harvey et al. 2012; Castalanelli et al. 2014; Rix et al. 2017b; Rix et al. 2018c).

The Search Area contained 111 SRE category spider taxa, of which four were named species, 83 were morphospecies and 24 were unidentified taxa (Table 4.1 and Figure 4.2-Figure 4.5). Four of these taxa are SREs and the remainder are potential SRE (DD) (Table 4.1).

The Search Area included several potential SRE (DD) spider taxa from within the Study Area:

- *Synothele* sp. (Figure 4.2): T116849, T116852; Mudlark, 87 km WNW. of Newman
- *Idiosoma* sp. (Figure 4.4): T116854, T116851; Mudlark, 87 km WNW. of Newman;
- *Aname* sp. (Figure 4.5): T116850; Mudlark, 87 km WNW. of Newman;
- *Kwonkan* 'MYG339' (Figure 4.5): T116853; Mudlark, 87 km WNW. of Newman.

Additional species were also revealed to the north and south of the Study Area, suggesting that a greater diversity of trapdoor spiders might be expected than the survey yielded. It is likely that survey conditions or methods were not optimal for sampling the broader diversity of trapdoor spiders in the area. Morphological identification of trapdoor spiders relies on characteristics of the adult male morphology and male trapdoor spiders are generally most active shortly after good summer or winter rains, when they leave their burrows and search for mates. Pitfall trapping (wet or dry) appears to be the most efficient way to sample these

spiders; however, since the males are wandering from their burrows, the specific microhabitat supporting these spiders may be difficult to determine. Wet pitfall traps are generally active for longer periods and have the greatest chance of being active during rainfall events.

Fourteen spider taxa were collected during these surveys, representing the families Selenopidae, Actinopodidae, Barychelidae, Idiopidae and Nemesiidae. Five of these represented widespread taxa, eight species were potential SRE owing to data deficiency (*Aurecocrypta* 'HD1', *Aurecocrypta* 'MYG315', *Synothele* 'MYG309', *Synothele* 'MYG311', *Synothele* sp., *Aname* sp., *Yilgarnia* 'MYG197', Nemesiidae sp.) and one species was a known SRE (*Karaops banyjima*). The identity of *Karaops banyjima, Aurecocrypta* 'HD1', *Aurecocrypta* 'MYG315', *Synothele* 'MYG309' and *Synothele* 'MYG311' were verified with DNA barcoding (Appendix 3).

4.1.1.1 Selenopidae (wall crab spiders or flatties)

Karaops banyjima. Four samples of *Karaops* were obtained, of which three were identified as *Karaops banyjima* using Crews (2013). This species is an SRE and the type locality is 19.2 km north of the centre of the study area (Figure 4.2). *Karaops banyjima* was sampled from sites SRE18, SRE19 and SRE21 (Figure 3.1).

A COI sequence from this species (AES190099) was obtained to confirm its relationship with this species. The barcoding study undertaken by Alacran (Appendix 3) found this sample to be most similar to the Genbank sequence of *Karaops banyjima*. Assessment by the W.A. Museum (Appendix 4); however, assigned *Karaops nyangumarta* to this sequence, not *Karaops banyjima*. In order to resolve the issue of species identity, a third opinion was requested from Dr Sarah Crews, who is an authority on the global systematics of Selenopidae and the author of both *Karaops banyjima* and *Karaops nyangumarta* (Crews 2013). On the basis of the photographs provided (Figure 4.1) Dr Crews identified this species as *Karaops banyjima* and this identification is followed here.

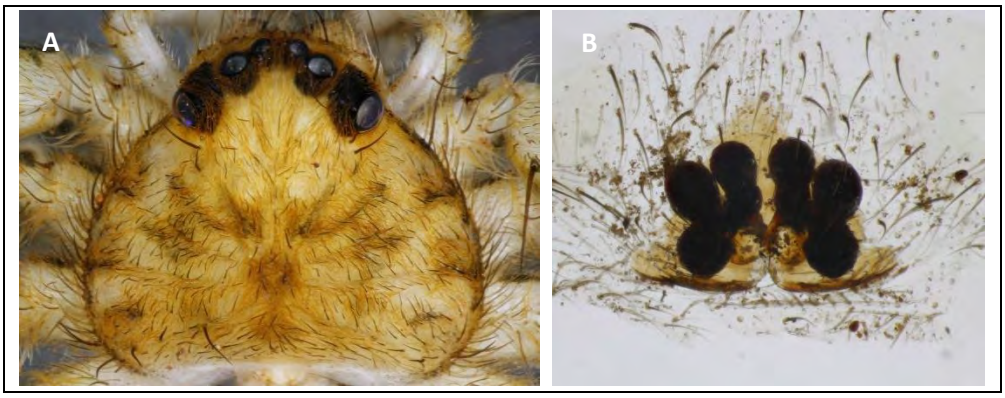

Figure 4.1 Photographs used to confirm the identity of *Karaops banyjima* (AES190099): A, carapace; B, epigynum morphology.

***Karaops* 'ARA001'.** This species was represented by a juvenile specimen and identified using DNA barcoding of COI. The W. A. Museum identified this sample as *Karaops* 'ARA001', a potential SRE species owing to data deficiency concerning its taxonomy and distribution limits.

4.1.1.2 Actinopodidae (mouse spiders)

***Missulena rutraspina*.** Two samples of *Missulena rutraspina* were obtained from site TS18. This species is widespread in the Pilbara (DBCA 2019).

4.1.1.3 Barychelidae (brush footed trapdoor spiders)

***Aurecocrypta* 'MYG315'**. This species was identified from a single juvenile specimen from site SRE22. This specimen was identified with DNA barcoding (Appendix 3). *Aurecocrypta* 'MYG315' was also recorded from the Search Area (Figure 4.2) and is a potential SRE owing to data deficiency regarding its distribution limits. The species appears to have a relatively wide distribution, within the constraints of an SRE, with records occurring from the north west of the Search Area to just north of Newman (Figure 4.2). This project is therefore unlikely to present a significant threat to this species.

***Aurecocrypta* 'HD1'**. This species was represented by a single female specimen from site SRE17. While DNA sequences were obtained from this specimen, no matches could be found by either Alacran or W. A. Museum barcoding studies (Appendix 3 and Appendix 4). *Aurecocrypta* 'HD1' is a potential SRE owing to data deficiency regarding its distribution limits.

***Synothele* 'xkarara'**. Four samples of this species were tentatively identified to *Synothele* 'xkarara', from sites TS07 and TS18. This morpho-species is extremely similar to *Synothele karara* and both have widespread distributions.

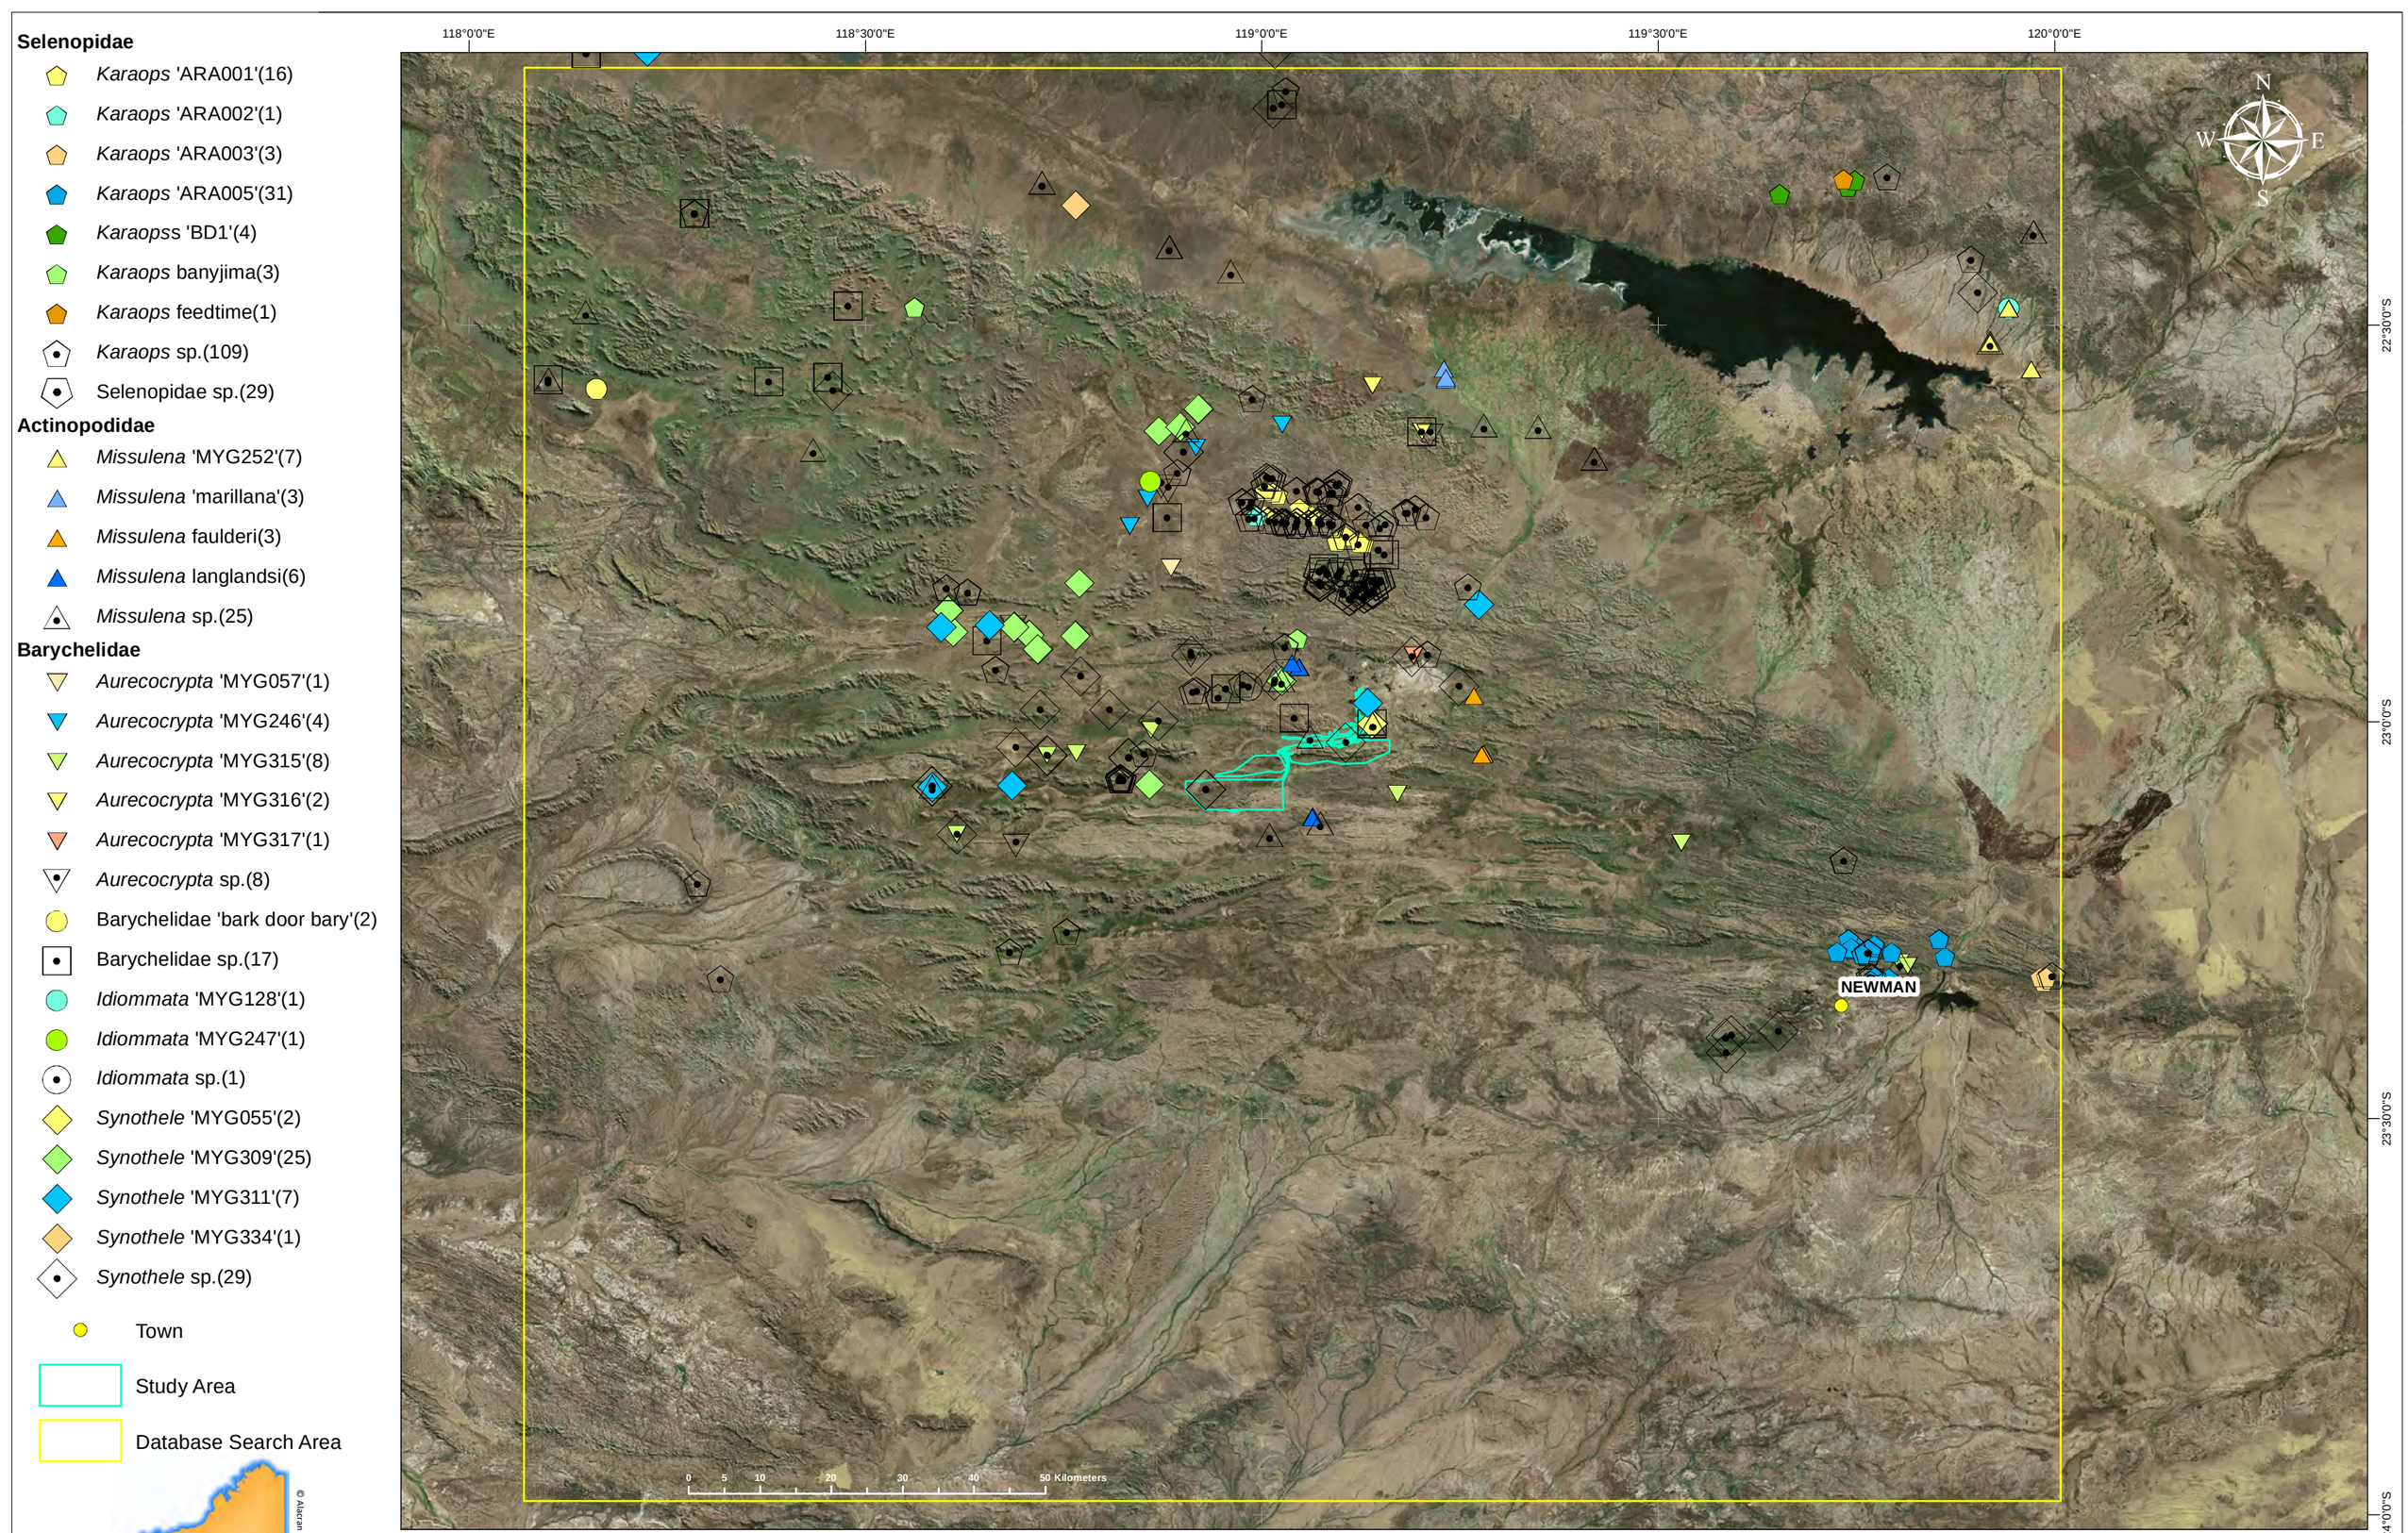
***Synothele* 'MYG309'.** A single sample of this species was represented by a juvenile specimen from site TS18 (Table 3.3 and Figure 3.1). The identity of the species was confirmed with DNA barcoding, Appendix 3. This species was represented by 25 samples at 10 different localities within the Search Area. The distribution of this species suggests that it is restricted to the Eastern Hammersley range, but that its distribution extends outside of the project area, Table 4.1 and Figure 4.2. This project is therefore unlikely to significantly threaten this species.

***Synothele* 'MYG311'**. A single sample of this species was represented by a female from site TS18 (Table 3.3 and Figure 3.1). The identity of the species was confirmed with DNA barcoding, Appendix 3. This species was represented by seven samples at six different localities within the Search Area. This species also appears to be restricted to the Eastern Hamersley range, but its distribution extends outside of the Study Area, Table 4.1 and Figure 4.2. This project is therefore unlikely to significantly threaten this species.

***Synothele* sp.** This taxon was represented by three samples, obtained from sites SRE12, SRE17 and SRE22 (Table 3.3 and Figure 3.1). These samples were either female or juvenile, so species level identification was not possible using morphology. Attempts to amplify COI sequences from these samples were unsuccessful. These samples are potential SREs owing to data deficiency concerning their species identity. The genus *Synothele* contains many SRE morphospecies and four are known from the search area (Table 4.1).

4.1.1.4 Idiopidae (spiny trapdoor spiders)

Gaius tealei. This species was represented by females and juveniles, from five sites SRE03, SRE16, SRE23, TS14 and TS18. During the T1 survey, this species was identified as *Gaius* sp.; however, since that survey, the genus was revised and *Gaius tealei* described (Rix et al. 2018c). *Gaius tealei* is the only known representative of this genus in the Pilbara where it is widespread (Rix et al. 2018c).

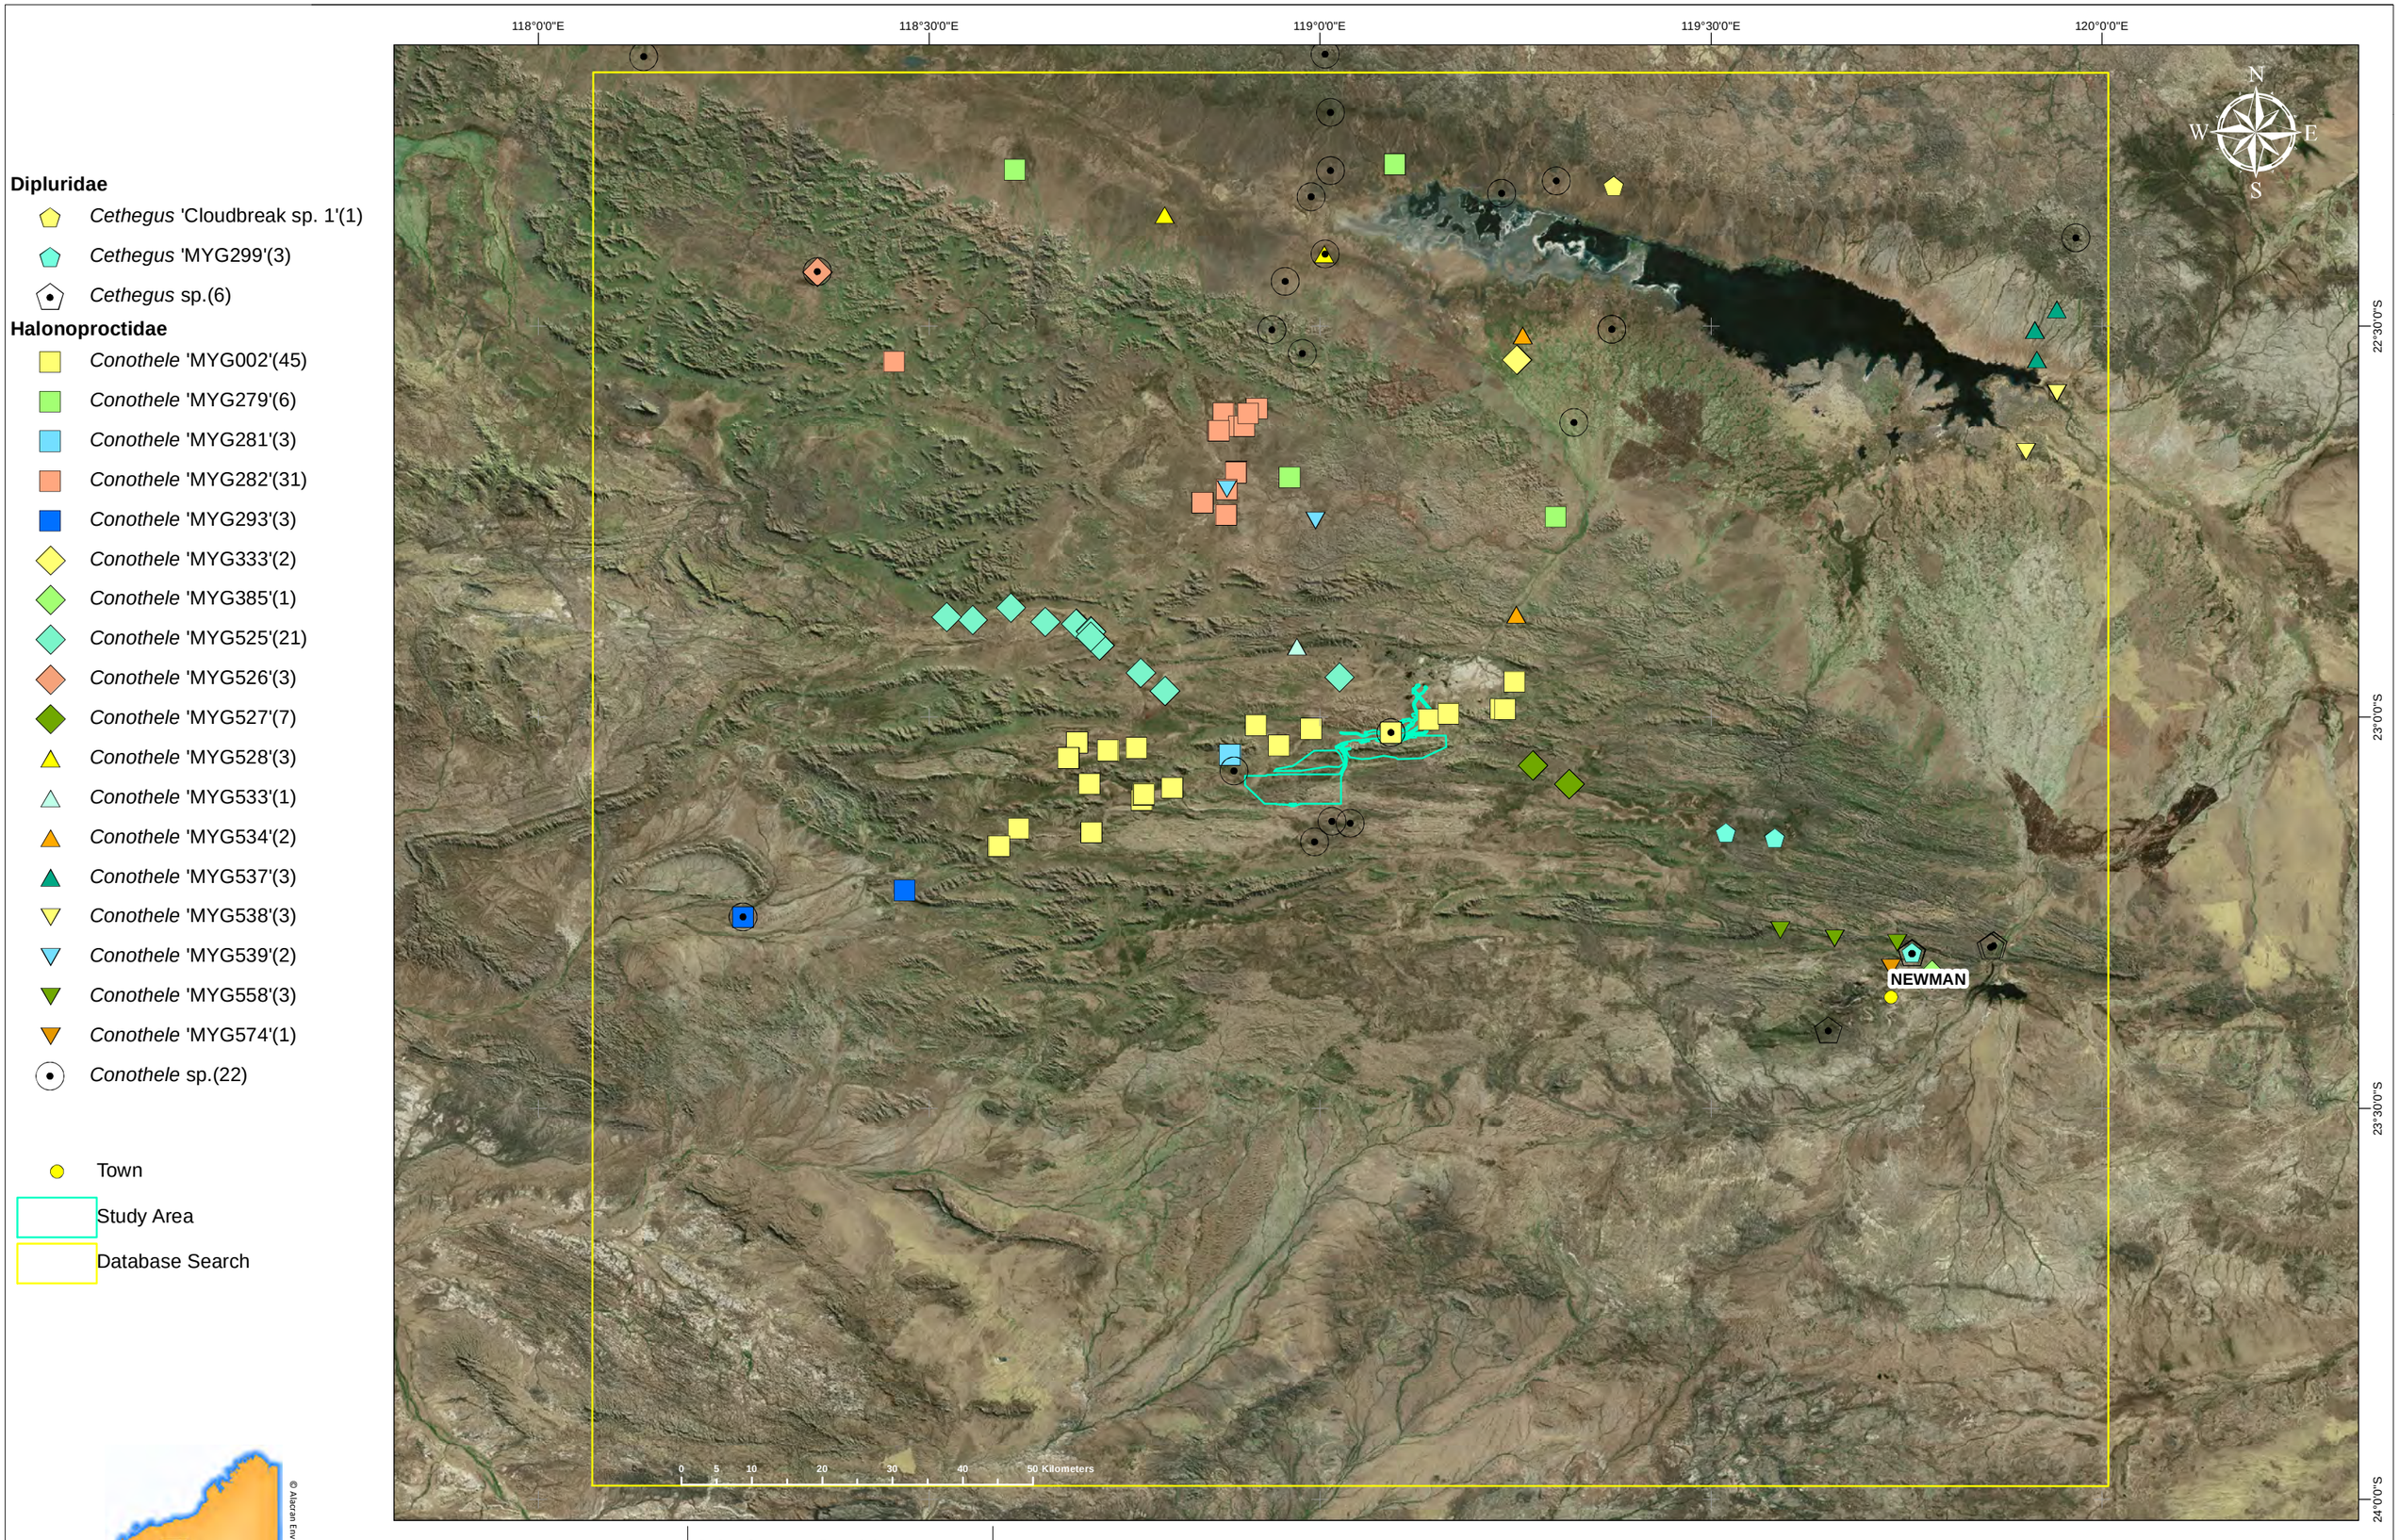


4.1.1.5 Nemesiidae (open-holed trapdoor spiders)

***Aname mellosa*.** *Aname mellosa* was represented by 27 samples from sites TS14, TS16-18, SRE16, SRE18, Bl01 and Hope Downs Village (camp). This species is widespread in the Pilbara (DBCA 2019).

***Aname* 'MYG004'.** A single sample of this morphospecies was collected from site TS17. This species is widespread in the Pilbara (Table 4.1).

***Yilgarnia* 'MYG197'.** Despite being an adult male, this specimen could not be clearly matched with any of the W. A. Museum voucher morphospecies. The identity if this species was confirmed using DNA sequences (Appendix 3). This species is a potential SRE since *Yilgarnia* contains potential SRE species (Table 4.1 and Figure 4.2).



Nemesiidae sp. This taxon was represented by a single female sample from site SRE11. This specimen could not be identified to genus or species as adult males are needed to do this (Harvey et al. 2018). Attempts to amplify COI sequences from this specimen were unsuccessful. The family Nemesiidae contains numerous potential SRE morphospecies and while the identity of this specimen is ambiguous it is a potential SRE owing to taxonomic data deficiency.

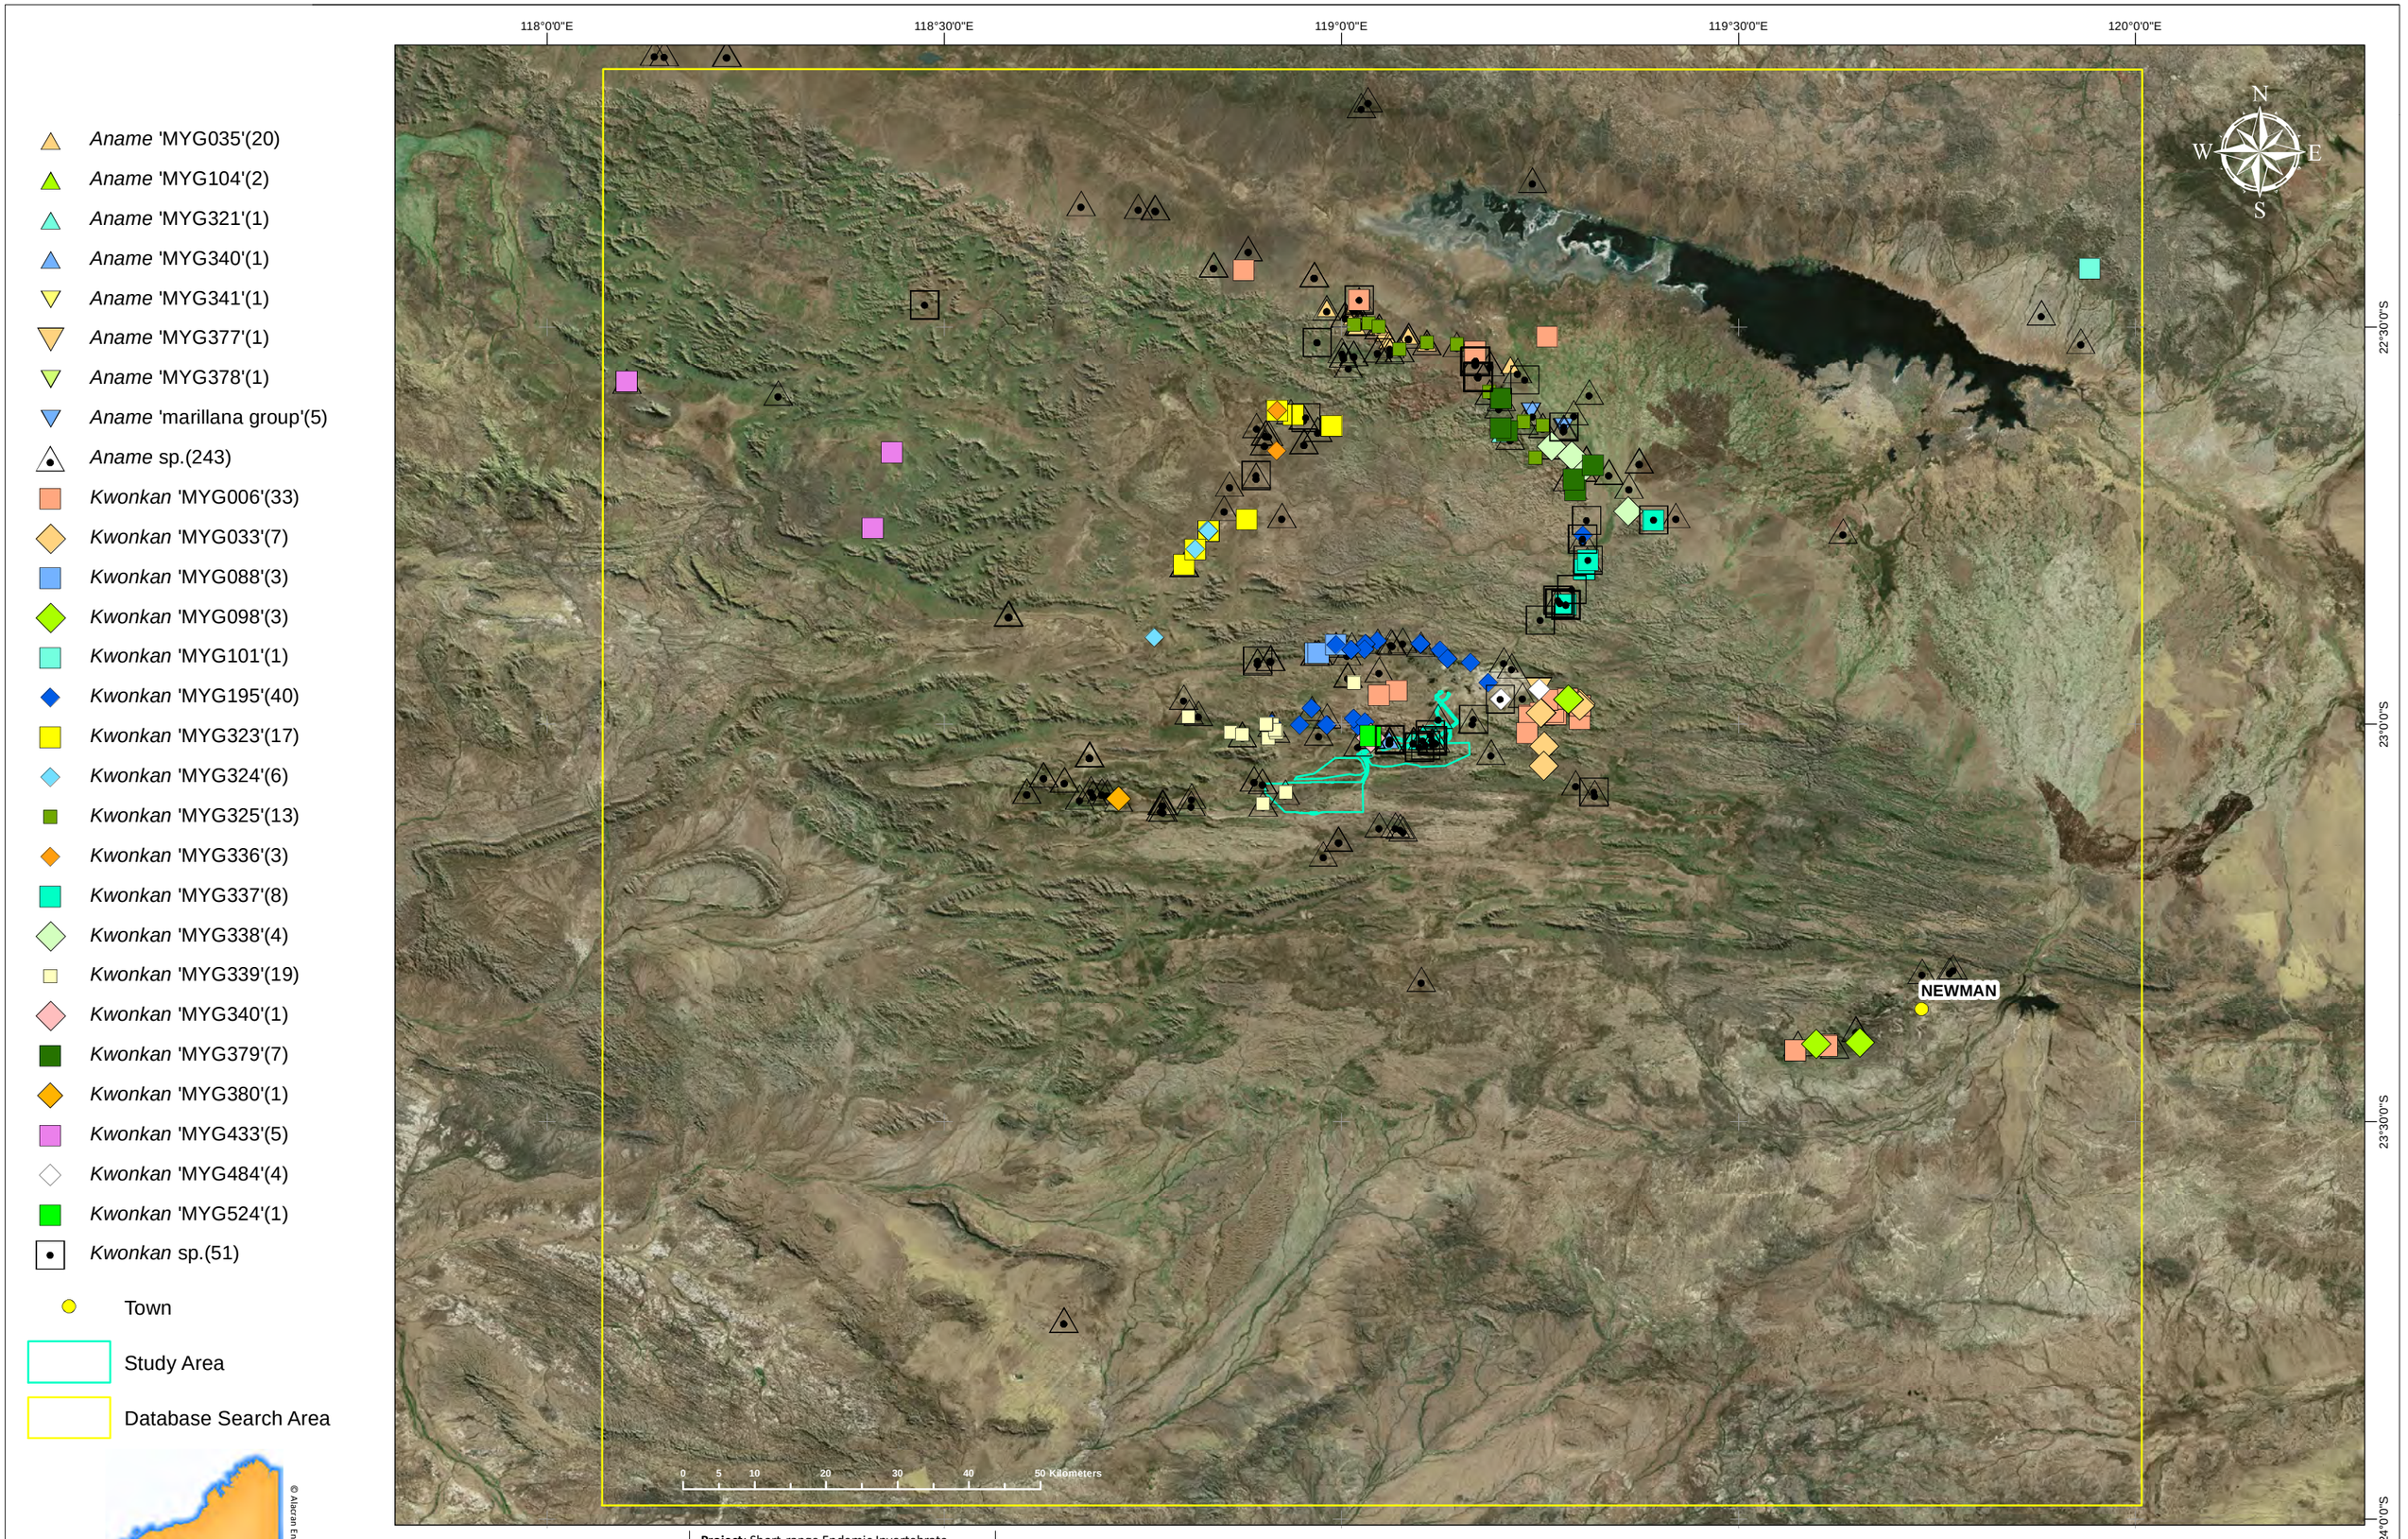

Figure 4.p0 Central and eastern Pilbara showing the distribution of SRE category spider records from the database Search Area: family Nemesiidae (part 2). Number of records in Parentheses.

4.1.2 Opiliones (harvestmen)

Opiliones appear superficially similar to small spiders, but differ from them by lacking a clearly defined division (constriction) between the cephalothorax and abdomen, as well as in numerous other aspects (Pinto-da-Rocha et al. 2007). In Australia, 11 families are recorded (ALA 2017). Some members of this order are SREs while others have wider distribution patterns (Harvey 2002b). The Pilbara diversity of Opiliones is poorly known but appears to be dominated by the genus *Dampetrus* (Assamiidae) (DPaW 2017), a diverse but poorly resolved genus confined to northern Australia (Shear 2001).

The Search Area contained two Opiliones taxa: Opiliones sp. and Assamiidae sp. (Figure 4.6). Both were considered Potential SRE: DD owing to their need for more mesic microhabitats. The field survey yielded no Opiliones and none of the Search Area records were within the Study Area. The absence of Opiliones was difficult to interpret as conditions leading up to both surveys was quite dry and if they are present, the rain experienced during the T2 survey may not have been sufficient to bring them out from their retreats. If present, they are likely to be in the rocky gorges and gullies in Bedded Hilltop and Wonmunna areas.

4.1.3 Pseudoscorpions (pseudoscorpions)

Pseudoscorpions superficially resemble scorpions, but they are not closely related to them. They are generally much smaller than most scorpions and lack the distinctive tail-like abdomen and stinging telson for which scorpions are infamous. In W. A. pseudoscorpions are represented by 19 families (Harvey 2013a). They occur on most undisturbed terrestrial habitats but are seldom noticed owing to their small size and cryptic behaviour (Harvey 1992). The Pilbara pseudoscorpion fauna is generally poorly known with only a few groups receiving taxonomic attention over the last decade and these are primarily focussed on troglobites (Harvey and Edwards 2007; Harvey and Volschenk 2007; Edward and Harvey 2008; Harvey and Leng 2008c). The epigean taxa flagged as SREs or Potential SREs are largely undescribed.

The Search Area contained 52 SRE category pseudoscorpion taxa, of which three are named species, 31 were morphospecies and 18 were unidentified taxa (Table 4.2, Figure 4.6 and Figure 4.7). Two species are SREs and the remaining taxa are Potential SRE (DD) (Table 4.2).

Table 4.2. Table of SRE category Pseudoscorpiones identified from the area search of the W. A. Museum's Terrestrial Invertebrates Database

Family	Binomial	SRE-Category	Justification
	Panctenata sp.	Potential SRE: DD	Infraorder contains SREs and potential SREs
	Pseudoscorpiones sp.	Potential SRE: DD	Order contains SREs and potential SREs
Atemnidae	*Paratemnoides* sp.	Potential SRE: DD	Genus likely to contain SREs and potential SREs
Chernetidae	Chernetidae sp.	Potential SRE: DD	Family contains SREs and potential SREs
Chernetidae	*Cordylochernes* 'cf. dingo'	Potential SRE: DD	W. A. Museum data
Chernetidae	*Haplochernes* '1'	Potential SRE: DD	Genus contains SREs and potential SREs

Family	Binomial	SRE-Category	Justification
Chernetidae	*Haplochernes* '2'	Potential SRE: DD	Genus contains SREs and potential SREs
Chernetidae	*Haplochernes* sp.	Potential SRE: DD	Genus contains SREs and potential SREs
Chernetidae	*Nesidiochernes* sp.	Potential SRE: DD	Genus likely to contain SREs and potential SREs
Chernetidae	*Sundochernes* 'PSE090'	Potential SRE: DD	W. A. Museum data
Chernetidae	*Troglochernes* 'PSE072'	Potential SRE: DD	
Chernetidae	*Troglochernes* sp.	Potential SRE: DD	Presence of SRE or potential SRE species in this genus
Chthoniidae	*Austrochthonius* sp.	Potential SRE: DD	Genus likely to contain SREs and potential SREs
Chthoniidae	Chthoniidae sp.	Potential SRE: DD	Family contains SREs and potential SREs
Chthoniidae	*Tyrannochthonius aridus*	Potential SRE: DD	See discussion
Chthoniidae	*Tyrannochthonius* 'aridus?'	Potential SRE: DD	See discussion
Chthoniidae	*Tyrannochthonius* sp.	Potential SRE: DD	Presence of SRE species in this genus (Edward and Harvey 2008)
Feaellidae	*Feaella callani*	SRE	(Harvey et al. 2016)
Garypidae	*Synsphyronus gracilis*	SRE	W. A. Museum data
Garypidae	*Synsphyronus* 'PSE006'	Potential SRE: DD	W. A. Museum data
Garypidae	*Synsphyronus* 'PSE014'	Potential SRE: DD	W. A. Museum data
Garypidae	*Synsphyronus* 'PSE085'	Potential SRE: DD	W. A. Museum data
Garypidae	*Synsphyronus* 'PSE086'	Potential SRE: DD	W. A. Museum data
Garypidae	*Synsphyronus* sp.	Potential SRE: DD	Genus contains SREs or potential SREs
Garypinidae	*Solinus* sp.	Potential SRE: DD	Genus contains SREs and potential SREs
Hyidae	*Indohya* 'Mt Meharry'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Austrohorus* '1 (big)'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Austrohorus* 'M1'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Austrohorus* 'M2'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Austrohorus* 'PSE119'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Austrohorus* 'PSE120'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Austrohorus* 'PSE121'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Austrohorus* 'PSE122'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Austrohorus* sp.	Potential SRE: DD	Genus likely to contain SREs and potential SREs
	Beierolpium 'PSE126'	Potential SRE: DD	W. A. Museum data
	Genus 7/4 *'PSE118'*	Potential SRE: DD	W. A. Museum data
Olpiidae	*Indolpium* '1'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Indolpium* '2'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Indolpium* 'PSE123'	Potential SRE: DD	W. A. Museum data

Family	Binomial	SRE-Category	Justification
Olpiidae	*Indolpium* 'PSE124'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Indolpium* 'PSE125'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Indolpium* 'long chelal hand'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Indolpium* sp.	Potential SRE: DD	Genus contains SREs and potential SREs
Olpiidae	*Linnaeolpium* sp.	Potential SRE: DD	Genus contains SREs and Potential SREs
Olpiidae	Olpiidae sp.	Potential SRE: DD	Family contains SREs and potential SREs
Olpiidae	'PSEAAA' sp.	Potential SRE: DD	W. A. Museum data
Olpiidae	*Xenolpium* '1'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Xenolpium* '2'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Xenolpium* 'PSE033'	Potential SRE: DD	W. A. Museum data
Olpiidae	*Xenolpium* sp.	Potential SRE: DD	Genus contains SREs and potential SREs

The field survey sampled eight pseudoscorpion taxa from four families: Atemidae, Chernetidae, Chthoniidae and Olpiidae (Table 3.2).

4.1.3.1 Atemidae

***Anatemnus* sp.** A single adult female specimen of *Anatemnus* sp. was obtained from site SRE10. This species is very unusual by being eyeless and having relatively pale body colour colouration. These features closely resemble those seen in the troglobitic *Anatemnus subvastus*, the only described species in this genus from the Pilbara (Alexander et al. 2014). The placement of this species into *Anatemnus* is also tentative owing to the uncertain relationship between this genus and several other genera in Atemnidae (Alexander et al. 2014). This sample represents the first epigean representative of *Anatemnus* from the Pilbara. This species is a potential SRE owing to data deficiency regarding its taxonomy and distribution limits.

***Oratemnus* sp.** Specimens of *Oratemnus* sp. were sampled from three sites: SRE03 SRE11, SRE13 and SRE23. This taxon has been collected widely throughout the Pilbara and is not an SRE.

4.1.3.2 Chernetidae

***Sundochernes* sp.** A single sample of this species was collected from site SRE23. Species in this genus are occasionally sampled in Pilbara surveys; however, they are seldom collected in large numbers or from more than two or three sites. They are potential SREs owing to data deficiency regarding their distribution and taxonomy.

4.1.3.3 Chthoniidae

Tyrannochthonius aridus is the only named epigean species in this genus from the Pilbara where it has been recorded across a wide distribution. The distribution of *Tyrannochthonius aridus* is inconsistent with that of the subterranean species, which are all SREs. The type locality for *Tyrannochthonius aridus* is Barrow Island

(Edward and Harvey 2008). Preliminary investigation into this species indicates the presence of more than one species in the Pilbara. The only two COI sequences for *Tyrannochthonius aridus* in GenBank (Benson et al. 2012) are KJ659959 from Wodgina Mine, 21.1790°S 118.6463°E and KJ659960 from Boodarie Stockyard, 20.4752°S 118.5071°E. The genetic divergence between these samples is 11.1%, suggesting that they represent different species. For this reason, the identity of all epigean *Tyrannochthonius* should be verified using molecular data.

This survey obtained two samples of *Tyrannochthonius*. The barcoding study undertaken by Alacran (Appendix 3) regarded these as different species owing to them being 13.13% divergent from one another. While confirming a similar genetic divergence (13%) the study undertaken by W. A. Museum did not consider these as clearly different species, but rather took the position that based on this genetic divergence "does not allow a conclusion about whether the two are conspecific or not" (Appendix 4). In this instance the more definitive and defensible approach of Alacran's report (Appendix 3) is adopted and the two species recognised are: ***Tyrannochthonius* 'HD1'** from site SRE14 and ***Tyrannochthonius* 'HD2'** from site SRE02 (Appendix 3). Both species represent potential SRE's owing to data deficiency regarding their distribution limits.

4.1.3.4 Olpiidae

In the Pilbara, epigean Olpiidae constitute species of *Austrohorus*, *Beierolpium*, *Euryolpium*, *Indolpium*, *Xenolpium* and 'Genus 7/4'. The constituent species of these genera have been problematic to assess using morphology alone. *Austrohorus* and *Indolpium* are suspected to contain numerous species; however, there is no morphological framework for identifying Pilbara species. *Beierolpium* has a basic taxonomic framework; however, it has not been tested with either robust morphological assessment or with DNA based species delimitation. A recent molecular investigation (Alacran, unpublished data) into the diversity of a small group of Pilbara Olpiidae revealed the presence of nine putative species from four genera. Independent assessment of those sequences by the W. A. Museum confirmed these identifications and all are potential SREs. That study was not exhaustive, either by way of sample intensity or survey area, and it seems likely that many more species of Olpiidae are present in the in the Pilbara.

In this study, representatives of unresolved (using morphology) putative olpiid taxa from each sample sites were assessed using DNA barcoding.

***Austrohorus* 'HD5'.** A single record of this species was sampled from site SRE01. While this species was distinct, its generic placement was ambiguous with an unresolved polytomy of *Austrohorus*, 'Genus 7/4' and *Nanolpium* (Appendix 3). The study undertaken by the W. A. Museum placed this species in *Austrohorus* but did not recognise this as a novel species, despite being 14.46% divergent from the most similar species in that analysis. The species delimitation presented by Alacran (Appendix 3) is followed here owing to the clear and testable framework for species delimitation.

***Beierolpium* '8/4 small'.** This survey recorded one sample of *Beierolpium* '8/4 small' from site SRE19. Attempts to sequence this sample were unsuccessful. *Beierolpium* '8/4 small' is thought to be widespread in the Pilbara.

Three putative species of *Beierolpium* were recognised by Alacran (Appendix 3) using DNA barcoding. The W. A. Museum indicated the presence of two species (Appendix 4). Where Alacran recognised two different species, based on 11% sequence divergence between samples AES190331 and AES190341, the W. A. Museum, based on similar sequence divergence, recognised one species and neither analyses could apply a name to these samples. For the purpose of this report, Alacran's analysis is followed as it offers a clear and published rationale for delimitation between species using sequences of COI: >8% COI sequence divergence based (Hebert et al. 2003b). The study undertaken by the W. A. Museum offered no rationale for species delimitation.

The three species of *Beierolpium* identified here are ***Beierolpium* 'HD1'** from site SRE14, potential SRE owing to data deficiency; ***Beierolpium* 'HD2'** from site TS14, a potential SRE owing to data deficiency, and ***Beierolpium* '8/4'** from site SRE13, a widespread species in the Pilbara.

Both barcoding studies (Appendix 3 and Appendix 4) recognised two putative species of *Euryolpium*: ***Euryolpium* 'HD6'** was identified from site SRE6 and ***Euryolpium* 'HD7'** from site SRE09. Representatives of both species are juveniles and were initially thought to be species of *Beierolpium*; however, the phylogenetic analyses used to assess relationships between these sequences placed both samples in monophyletic *Euryolpium* clade.

Prior to this study, the genus *Euryolpium* was thought to be represented by a single widespread species (undescribed) in the Pilbara and was not identified to a morphospecies. *Euryolpium* can be difficult to diagnose with morphology since the distinguishing characteristics are only distinctive in adult females.

Two samples were identified to ***Euryolpium* sp.** for sites SRE10 and SRE20. The relationship of these with the two genetic species is not known. With the discovery *Euryolpium* 'HD6' and *Euryolpium* 'HD7', both potential SREs, unresolved *Euryolpium* sp. can no longer be regarded as widespread and are here considered to be potential SRE owing to taxonomic data deficiency.

'Genus 7/4 PSE118'. Four specimens belonging to this species were identified from sites SRE02, SRE04 and SRE10. The identity of all four specimens was confirmed with DNA barcoding (Appendix 3). This species is currently regarded as a potential SRE owing to limited knowledge about its distribution. Area Search records included a single representative of this species in the northern portion of the Search Area (Figure 4.7).

'PSEAAA HD4'. This species was sampled from site SRE16 and was identified using DNA barcoding (Appendix 3 and Appendix 4). The study undertaken by the W. A. Museum assigned this sample to an undescribed species and genus of Olpiidae: 'PSEAAA' sp.; however, that relationship was based on a 13.61% sequence divergence with a voucher sequence of 'PSEAAA' sp.. Alacran (Appendix 3) identified this species as belonging to *Indolpium*; however, that study did not include representative sequences of the genus 'PSEAAA'. The species identity of 'PSEAAA HD4' follows the findings of the W. A. Museum and uses the species delimiting threshold >8% sequence divergence to recognise this as a novel species.

***Indolpium* sp.** was recorded from site SRE01 and represents an ambiguous identification. Recent DNA barcoding studies (Alacran, unpublished) identified three undescribed species (*Indolpium* 'PSE123',

Indolpium 'PSE124' and *Indolpium* 'PSE125') from this region of the Pilbara (Figure 4.7). All three are potential SREs and because of this, unresolved *Indolpium* species identifications are potential SRE.

Olpiidae sp. was represented by a single sample from site SRE01. Attempts to obtain DNA sequences from this specimen were unsuccessful. In the absence of a species level identification, Olpiidae sp is a potential SRE because the family contains numerous potential SRE species.

Figure 4.T. Central and eastern Pilbara showing the distribution of SRE category Pseudoscorpiones (part 2) records from the database Search Area: families Atemnidae, Chthoniidae, Chernetidae, Feaellidae, Garypidae, Garypinidae and Hyidae. Number of records in Parentheses

4.1.4 Schizomida (short-tailed whip scorpions)

Schizomida is an order of Arachnida that vaguely resemble small spiders, but are not related to them. They are more closely related to Uropygi (Wheeler and Hayashi 1998) which are not known from Australia. Australian schizomids are relatively well studied taxonomically (Harvey 2002b; Harvey et al. 2008; Abrams and Harvey 2015); however, numerous undescribed species are known. All Pilbara schizomids show very high levels of endemism and are all considered SREs.

The only known epigean schizomid from the Pilbara is an undescribed species: *Draculoides* 'SCH053' and is only known from deep shaded gorges of Karijini National Park (Figure 4.8). None of the survey samples contained schizomids. It is also unlikely for epigean schizomids to occur within the Study Area because the study area lacks very deep shaded gorges such as those that support this species in Karijini National Park.

4.1.5 Scorpiones (scorpions)

Scorpions are instantly recognisable arachnids and are represented by four families in W. A. Short-range endemic species are known from the families Buthidae, Urodacidae and Hormuridae. The Australian scorpion fauna is very poorly described with as much as 85% suspected of being undescribed (Volschenk et al. 2000; Volschenk 2008; Volschenk et al. 2010; Volschenk et al. 2012; Harvey 2014).

Species delineation in scorpions varies in complexity: species from the family Buthidae can be identified from all but 1st and 2nd instars; however, species identification of Bothriuridae, Urodacidae and Hormuridae is usually heavily dependent on characteristics only present in adult males. The families Buthidae and Urodacidae also contain several species complexes containing cryptic species, which can only be currently identified using DNA barcoding methods.

In W. A., the family Buthidae is represented by three genera, *Lychas*, *Isometroides* and *Isometrus*. Representatives of *Lychas* are frequently collected in surveys of W. A. and current investigations on the genus *Lychas* (W. A. Museum) indicates the presence of several species complexes, some of which appear to contain SREs.

The family Urodacidae is represented by two genera, *Urodacus* and *Aops*, the latter *Aops oncodactylus* is only known from a single specimen from Barrow Island (Volschenk and Prendini 2008). Most species of *Urodacus* appear to be relatively widespread but are often patchily distributed (Volschenk et al. 2010), meaning that their "distribution does not equate to their area of occupation". Several *Urodacus* species are also known to be SREs including the described species *Urodacus planimanus* and *Urodacus koolanensis* as well as several undescribed species from the Pilbara.

The Search Area contained 25 scorpion taxa, of which none were named, 21 were morphospecies and four were unidentified taxa (Table 4.3 and Figure 4.6). One species is an SRE and the remaining 24 taxa are Potential SRE (DD) (Table 4.3).

Table 4.3. Table of SRE category Scorpiones identified from the area search of the W. A. Museum's Terrestrial Invertebrates Database

Family	Binomial	SRE-Category	Justification
	Scorpiones sp.	Potential SRE: DD	Order contains SREs and potential SREs
Buthidae	Buthidae sp.	Potential SRE: DD	Family contains SREs and potential SREs
Buthidae	*Isometroides* sp.	Potential SRE: DD	Genus contains SREs and potential SREs
Buthidae	*Lychas* 'aitkeni complex'	Potential SRE: DD	rare scorpions, unresolved species complex likely to contain SREs
Buthidae	*Lychas* 'annulatus complex'	Potential SRE: DD	molecular evidence indicates several cryptic species involved, some of which appear to be SRE
Buthidae	*Lychas* 'bituberculatus complex'	Potential SRE: DD	molecular evidence indicates several cryptic species involved, some of which appear to be SRE
Buthidae	*Lychas* 'gracilimanus'	Potential SRE: DD	rare species with very disjunct distribution pattern, may contain cryptic species
Buthidae	*Lychas* 'hairy tail complex'	Potential SRE: DD	molecular evidence indicates several cryptic species involved, some of which appear to be SRE
Buthidae	*Lychas* 'Iron Valley'	Potential SRE: DD	W. A. Museum data
Buthidae	*Lychas* 'marandoo 1'	Potential SRE: DD	W. A. Museum data
Buthidae	*Lychas* 'mjobergi?'	Potential SRE: DD	W. A. Museum data
Buthidae	*Lychas* 'paraburdoo'	Potential SRE: DD	W. A. Museum data
Buthidae	*Lychas* 'Pilbara sp. 2'	Potential SRE: DD	W. A. Museum data
Buthidae	*Lychas* 'racing stripe'	Potential SRE: DD	W. A. Museum data
Buthidae	*Lychas* sp.	Potential SRE: DD	Genus contains SREs and potential SREs
Urodacidae	*Urodacus* 'cloudbreak'	Potential SRE: DD	W. A. Museum data
Urodacidae	*Urodacus* 'fat hands'	Potential SRE: DD	W. A. Museum data
Urodacidae	*Urodacus* 'firetail'	Potential SRE: DD	W. A. Museum data
Urodacidae	*Urodacus* 'megamastigus complex'	Potential SRE: DD	W. A. Museum data
Urodacidae	*Urodacus* 'micros'	SRE	W. A. Museum data
Urodacidae	*Urodacus* 'pale complex'	Potential	W. A. Museum data

Family	Binomial	SRE-Category	Justification
		SRE: DD	
Urodacidae	*Urodacus* 'Pilbara 5'	Potential SRE: DD	W. A. Museum data
Urodacidae	*Urodacus* 'SCO022'	Potential SRE: DD	W. A. Museum data
Urodacidae	*Urodacus* sp.	Potential SRE: DD	Genus contains SREs and potential SREs

The field survey yielded eight species of scorpions from the families Buthidae and Urodacidae, of which four are potential SREs.

4.1.5.1 Buthidae (narrow handed scorpions)

***Isometroides* 'pilbara 1'.** This species was recorded from sites TS14, TS16, TS17 and TS18. This species is rarely sampled during invertebrate fauna surveys but is occasionally sampled in the dry pitfall traps of vertebrate fauna surveys. This species is widespread in the Pilbara.

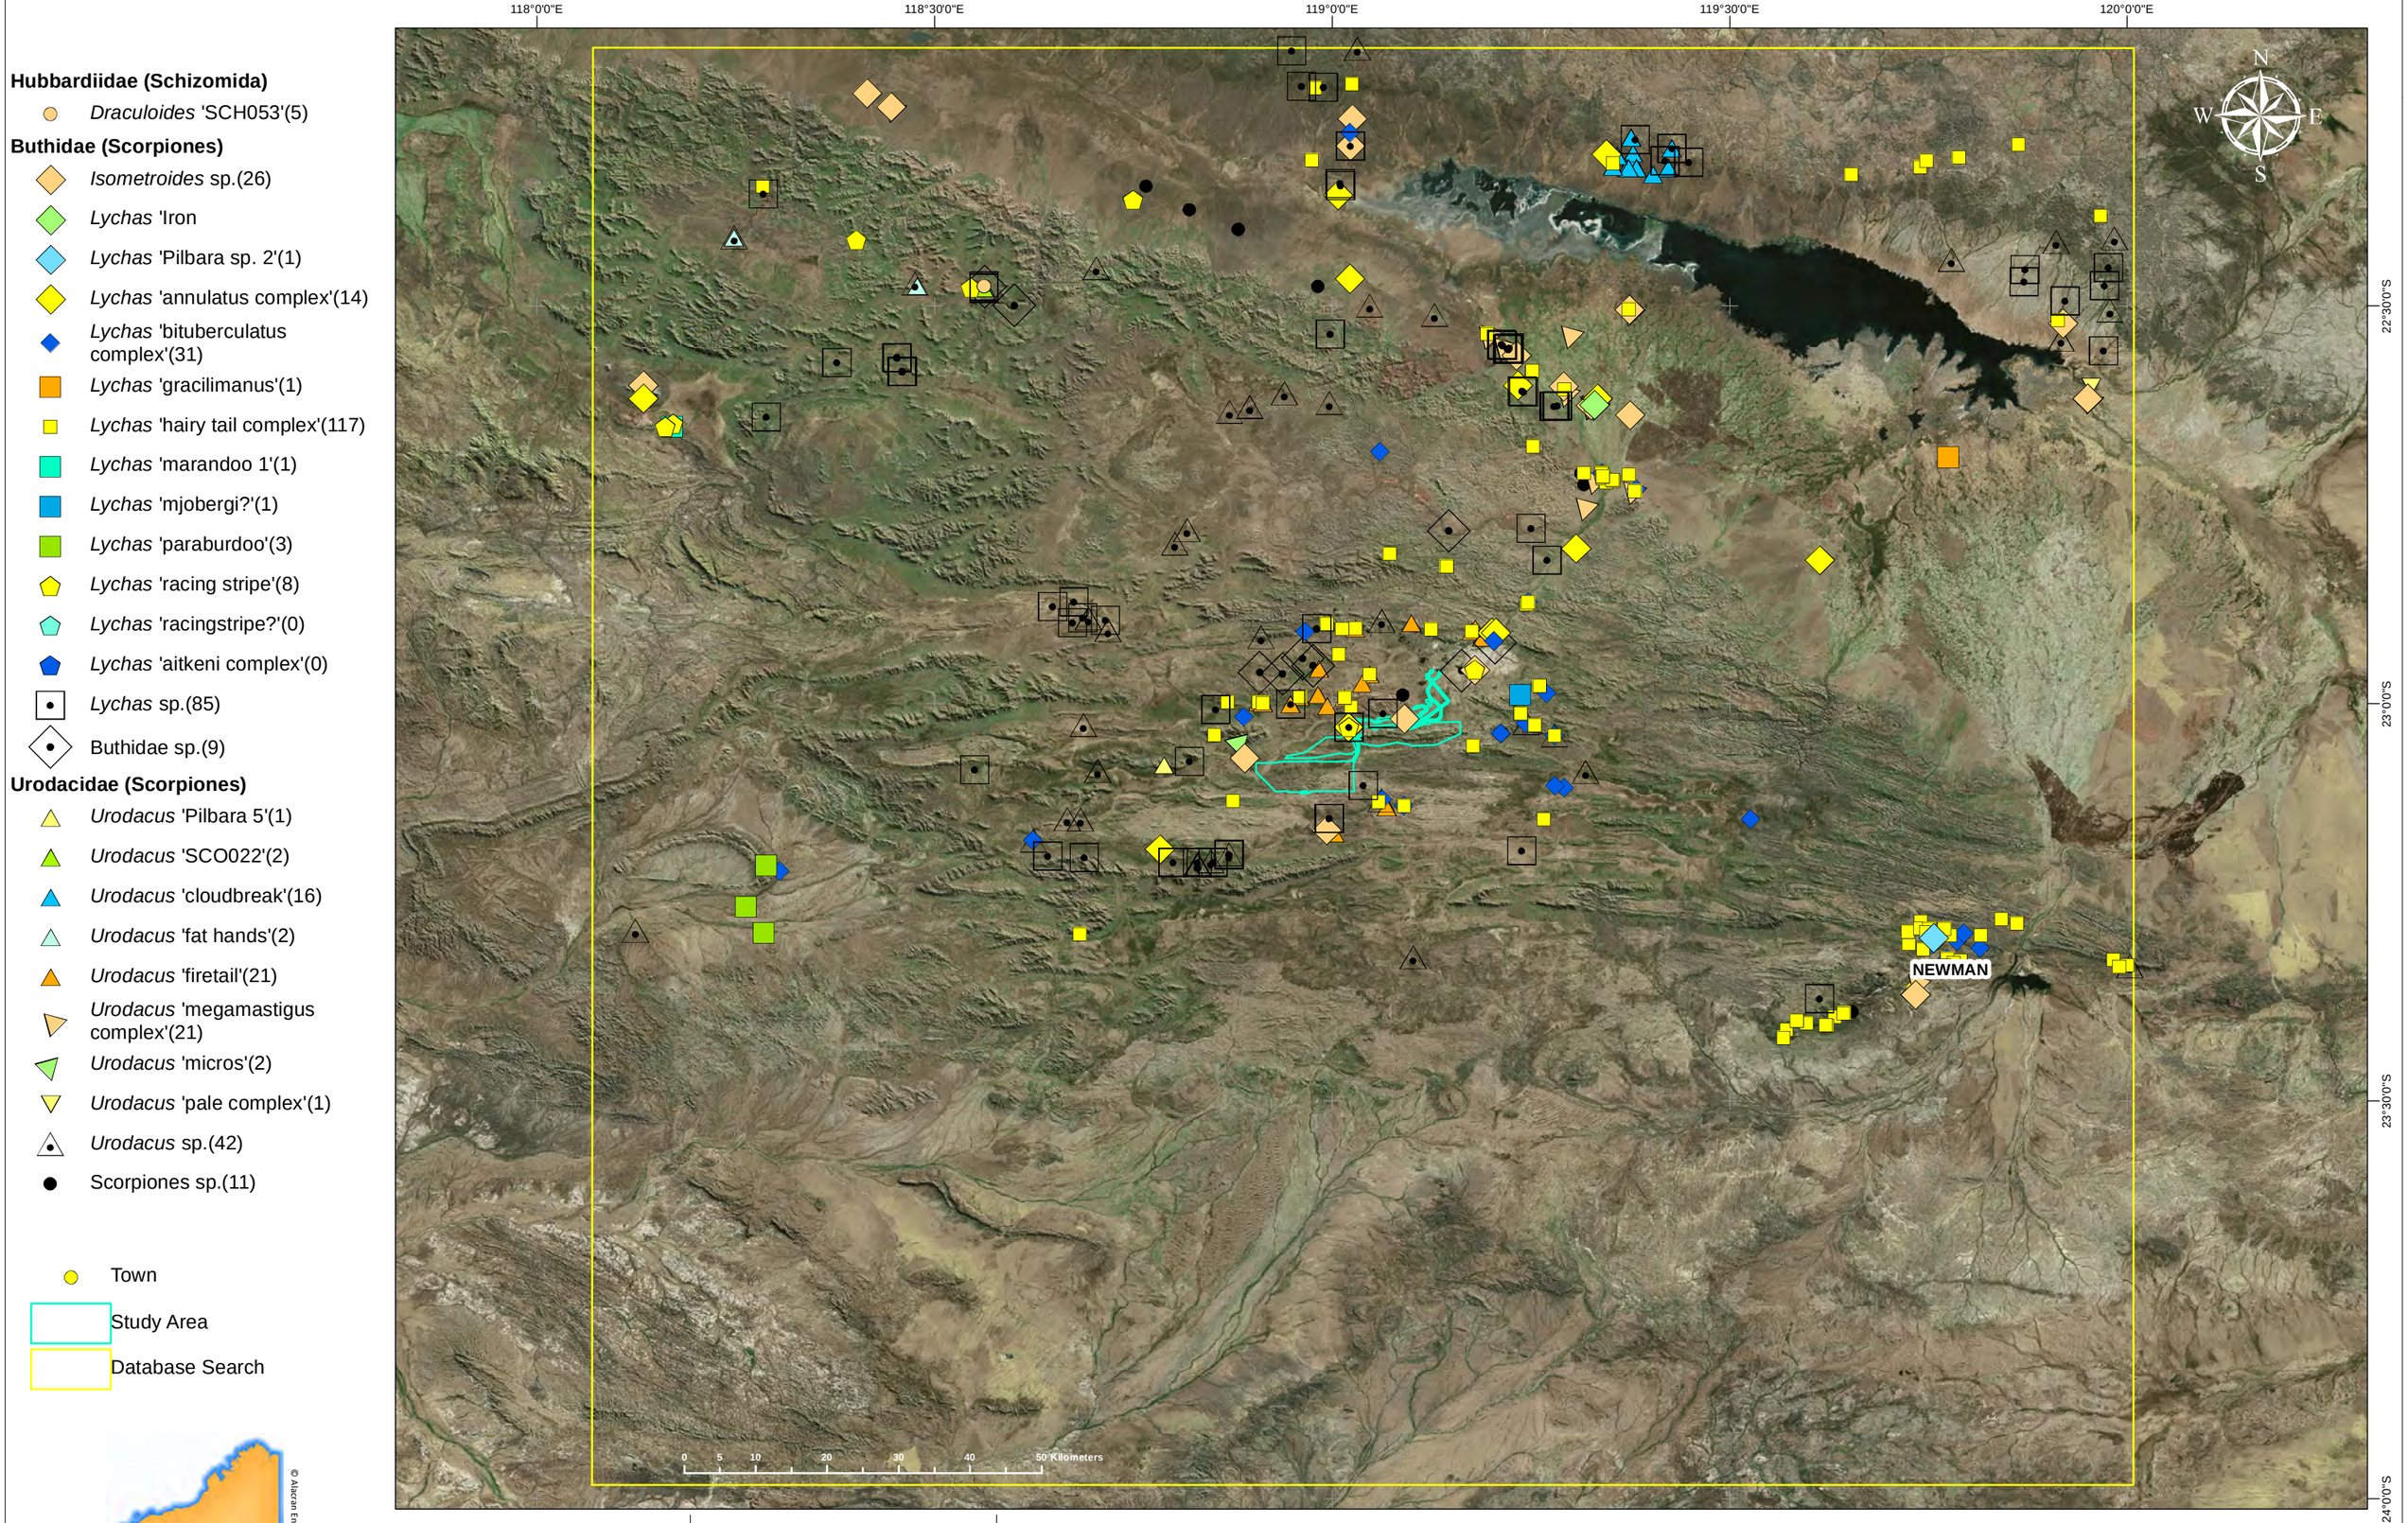
***Lychas* 'pilbara 1'.** This widespread species was recorded from site TS04. It is not an SRE.

***Lychas* 'bituberculatus complex'.** This scorpion was sampled from sites TS04, TS14, TS16, TS17 and Bl01. This taxon represents an unresolved species complex involving several cryptic species, some of which are suspected to be SREs. Until this group is resolved this taxon is a potential SRE owing to taxonomic data deficiency.

***Lychas* 'hairy tail complex'.** This species was sampled from site TS17. This taxon is similar in many ways to *Lychas* 'bituberculatus complex' in that it represents an unresolved species complex, suspected of containing SRE species. Until this group is resolved this taxon is a potential SRE owing to taxonomic data deficiency. Further resolution to the identity of this species may be possible using DNA barcoding methods.

***Lychas* 'harveyi complex'.** This species was sampled from sites TS14 and TS18. This taxon represents an unresolved species complex involving several cryptic species, however in this case they appear to be widespread.

Lychas 'Hope Downs' was identified by Alacran (2018); however, following examination of additional samples obtained during the second survey, that identification appears to have been erroneous and that specimen is here regarded as *Lychas* 'harveyi complex'.



***Lychas* 'multipunctatus complex'.** *Lychas* 'multipunctatus complex' was sampled from sites SRE08, TS14, TS17 and BL01. Like *Lychas* 'bituberculatus complex', this taxon represents an unresolved species complex and appears to contain SRE species. Until this group is resolved this taxon is a potential SRE owing to taxonomic data deficiency.

Assessment of *Lychas* 'bituberculatus complex' and *Lychas* 'multipunctatus complex' was undertaken by both Alacran and W. A. Museum; however, no additional information could be obtained from these studies to assist placing these samples within their respective species complexes.

4.1.5.2 Urodacidae (burrowing scorpions)

***Urodacus* 'pilbara 12'.** This scorpion was sampled from site SRE12. This is a widespread species in the Pilbara.

***Urodacus* 'HD1'.** This scorpion was represented by a juvenile from site SRE13. Since adult males are usually required for morphological identification, DNA barcoding was used to try and place this sample. Patterning on the body of this specimen, suggests that it may represent a different species to *Urodacus* 'Pilbara 12', with the latter species being generally devoid of darker patterns. Barcoding analyses by both Alacran and W. A. Museum could not match this species to any sequenced species (Appendix 3 and Appendix 4).

Figure 4.y. Central and eastern Pilbara showing the distribution of SRE category Schizomida and Scorpiones records from the database Search Area. Number of records in Parentheses.

4.2 CHILOPODA (CENTIPEDES)

Two orders of centipedes from the Pilbara are known to contain SREs: Geophilomorpha (Soil Centipedes) and members of the order Scolopendromorpha, mostly from the family Cryptopidae. Both geophilomorphs and cryptopids are blind and strongly associated with rocky environments, surface soil and deep leaf litter microhabitats. They are usually encountered when turning over rocks or larger pieces of fallen wood/logs and from leaf litter sifting samples. Members of both groups are also frequently collected in subterranean fauna surveys where their presence as troglofauna or soil fauna is often debated. Regardless of their specific ecophysiological requirements, preliminary genetic studies indicate high incidence of local endemism (Phoenix 2014a, b).

The Search Area contained 13 centipede taxa, of which none were named species, two were morphospecies and 11 were unidentified taxa (Table 4.4 and Figure 4.9). All were considered Potential SRE (DD) (Table 4.4). None of the Search Area records fell within the Study Area; however, a large cluster of records of Mecistocephalidae sp. and *Sepedenophilus* sp. records were recorded from the area immediately south east of the Study Area (Figure 4.9).

Table 4.4. Table of SRE category Chilopoda identified from the area search of the W. A. Museum's Terrestrial Invertebrates Database

Order	Family	Binomial	Justification
Geophilomorpha		Geophilomorpha sp.	Order contains SREs and potential SREs

Scolopendromorpha	Cryptopidae	*Cryptops* sp.	Genus contains SREs and potential SREs
Scolopendromorpha	Scolopendridae	*Cormocephalus* 'long anal legs'	W. A. Museum data

The field surveys yielded 21 Centipede samples representing the orders Scolopendromorpha (Family Cryptopidae) and Geophilomorpha (families Chilenophilidae, Mecistocephalidae and Oryidae). All Geophilomorpha and Cryptopidae are very poorly known in W. A. While keys to genera and families of Geopholomorpha are available (Colloff et al. 2005), there is no workable morphological framework for

species level identifications. For this reason, all identifications used in this report are based on DNA barcoding.

4.2.1 Geophilomorpha

Members of this order of centipedes are commonly referred to as Soil Centipedes. Unlike most centipedes, they have short legs and cannot move fast. They are adapted for burrowing through soil and leaf litter rather than rapid movement over the soil surface. Geophilomorpha is the most speciose of centipede orders with an estimated 8000 species (Adis and Harvey 2000). The combination of high species diversity and low vagility suggests that this order may support SREs. There are no specialists working on W. A. Soil Centipedes and none have been described from the Pilbara. For this reason, the entire taxonomic framework for W. A. Geophilomorpha used by Alacran relies on DNA barcoding of COI sequences.

Geophilomorpha sp. A single tiny specimen could not be identified using morphology and attempts to obtain COI sequences from this specimen were unsuccessful. Owing to the presence of numerous potential SREs within the Order Geophilomorpha, this taxon is a potential SRE owing to uncertainty about its identity.

4.2.1.1 Chilenophilidae

Two species were identified belonging to the family Chilenophilidae: ***Sepedonophilus* 'HD1'** from sites Op01, SRE01, SRE17 and SRE19, and ***Sepedonophilus* 'HD2'** from site SRE23. Both of these species are new and are potential SREs owing to uncertainty about their distribution limits.

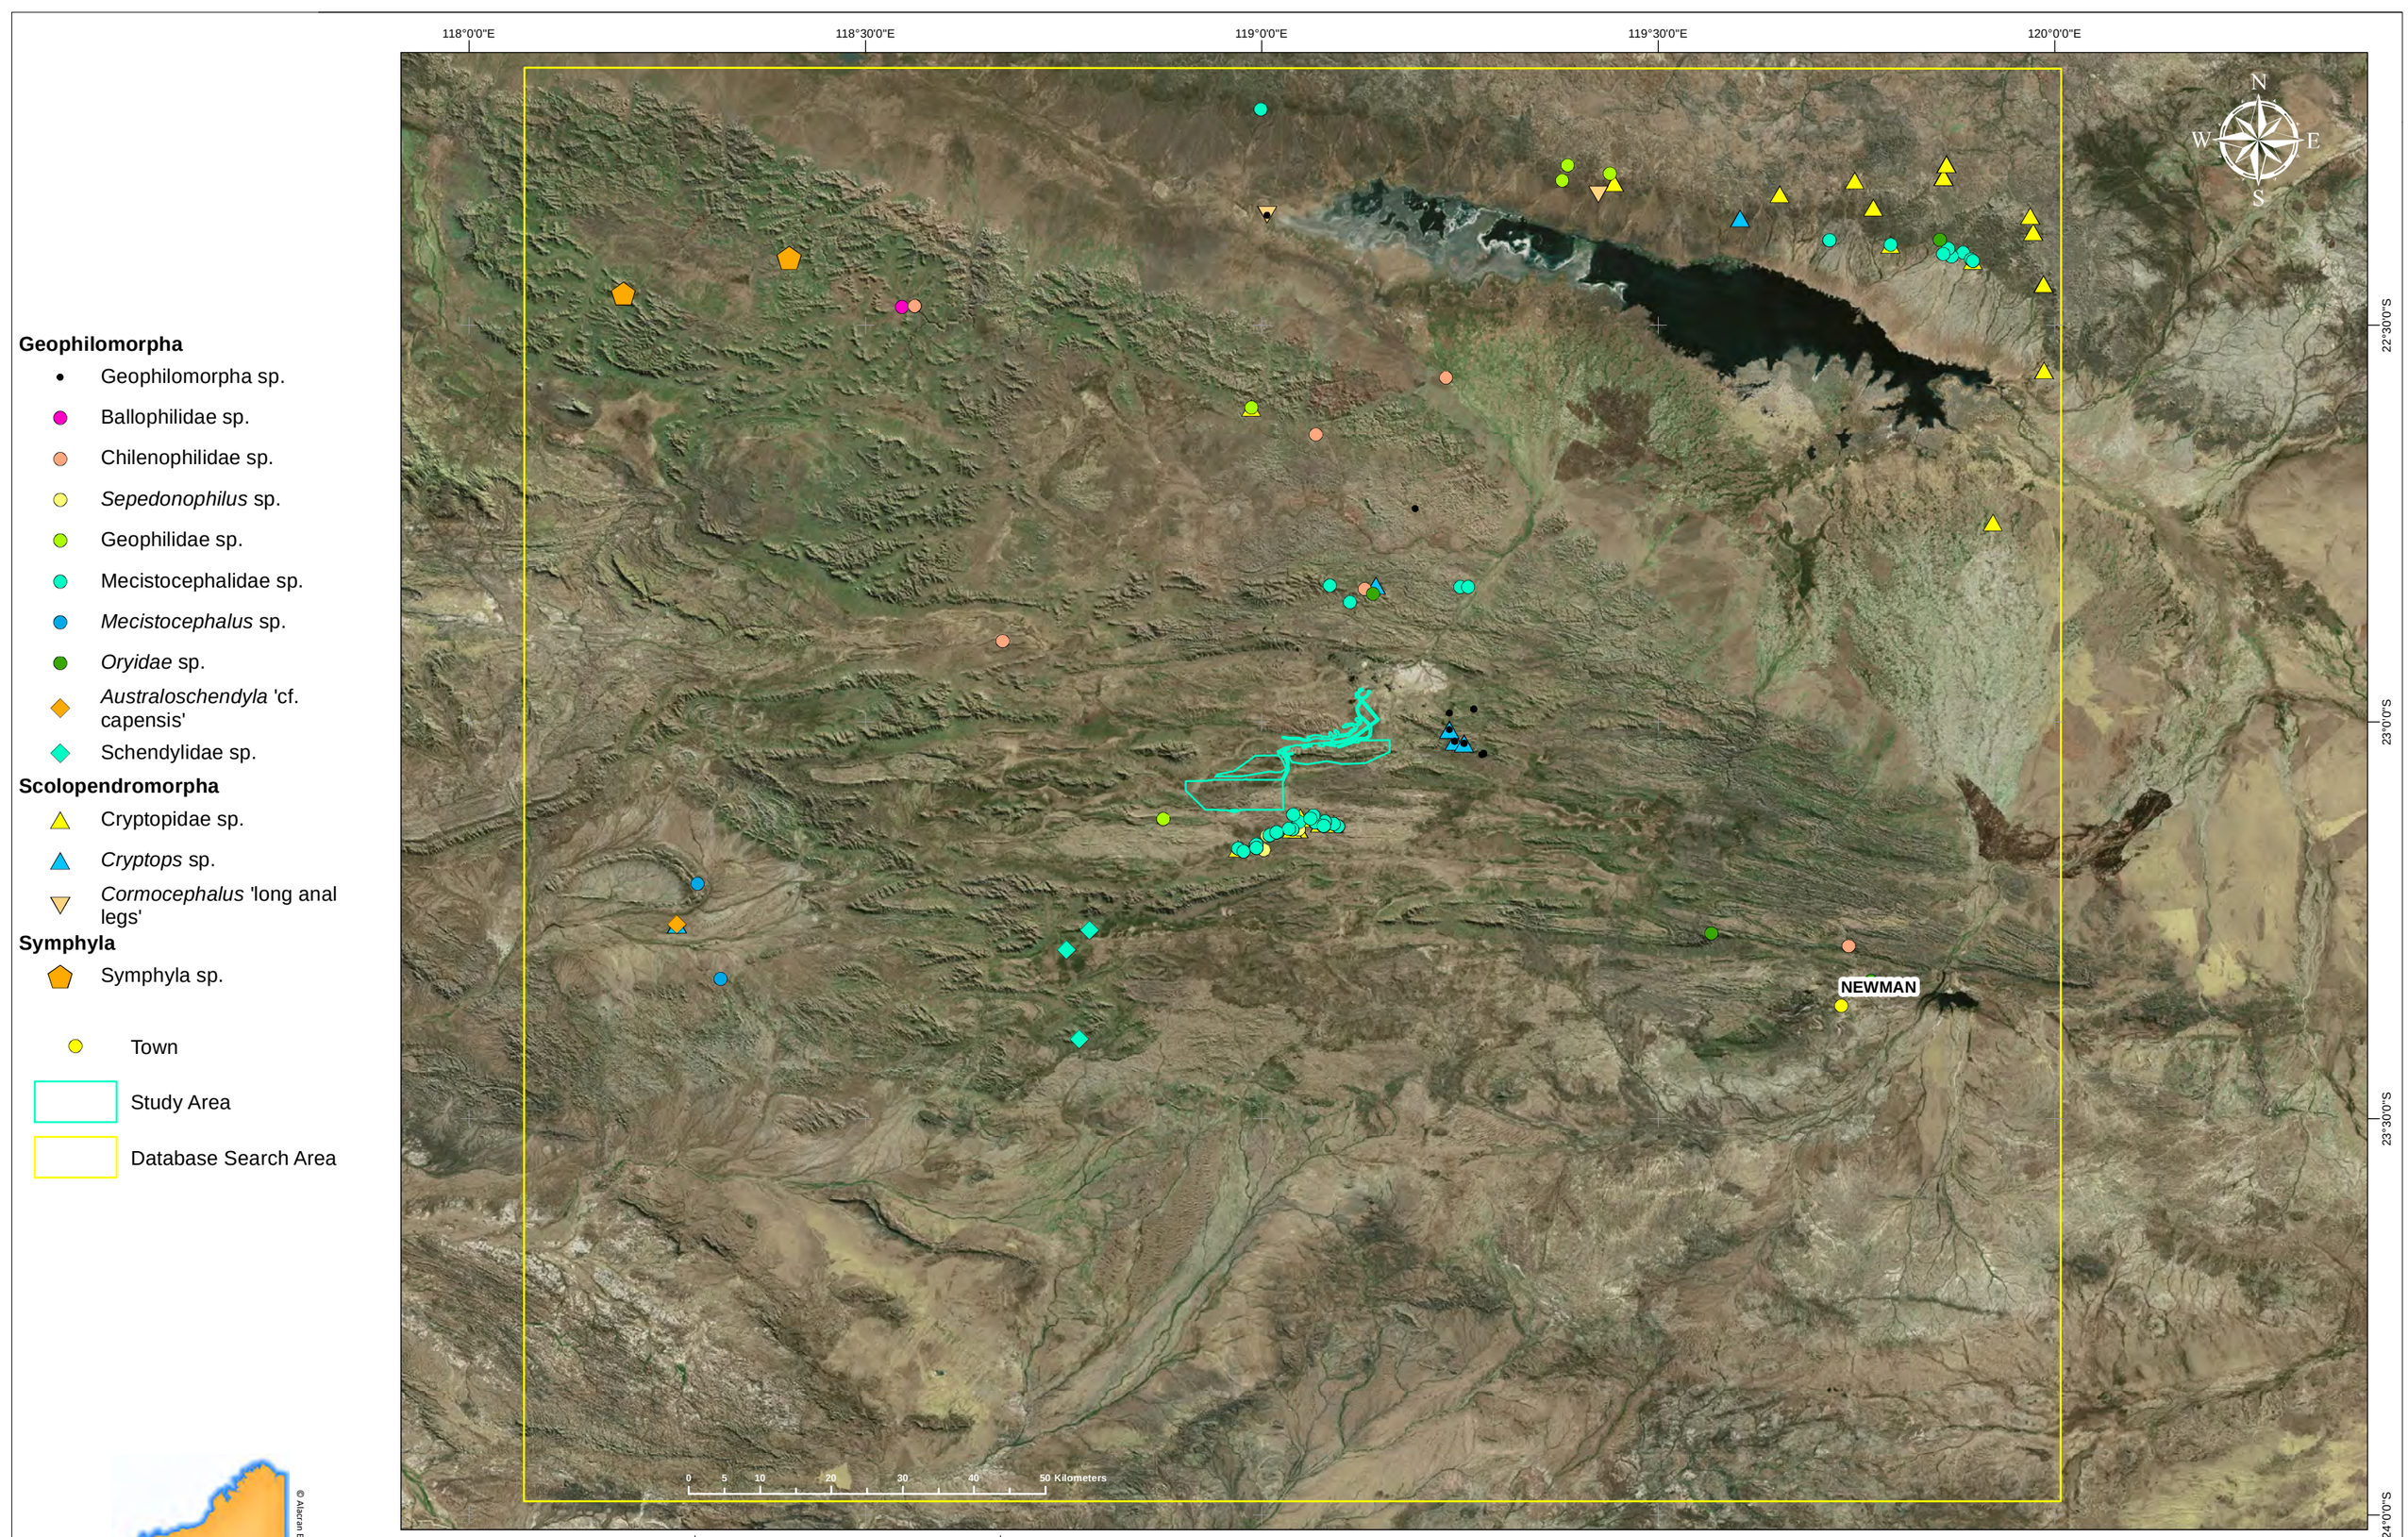
***Sepedenophilus* sp.** represents a specimen for which COI sequences were unsuccessful. This sample was from site SRE19. This specimen may be conspecific with *Sepedenophilus* 'HD1', which was also found at this site. As an ambiguous identification, *Sepedenophilus* sp. is a potential SRE since the genus contains numerous suspected SREs.

Mecistocephalidae

Three species were identified from the family Mecistocephalidae: ***Mecistocephalus* 'HD1'** from sites SRE13, SRE21 and SRE23, ***Mecistocephalus* 'HD2'** from site SRE23 and ***Mecistocephalus* 'HD3'** from site SRE15. All three species are new and are potential SREs owing to uncertainty about their distribution limits.

4.2.1.2 Oryidae

One species was identified from the family Oryidae: ***Orphnaeus* 'HD1'** from site SRE23.This is a new species and is a potential SRE owing to limited data about its distribution limits.



4.2.2 Scolopendromorpha

This order of centipedes contains the families Scolopendridae and Cryptopidae. Species in the family Scolopendridae have been relatively well studied taxonomically in Australia (Koch 1982b; Koch 1982a; Koch 1982c; Koch 1983c, b, a); however, the taxonomy of the family Cryptopidae is largely unstudied.

4.2.2.1 Cryptopidae

This family of centipedes is very poorly known in Australia and in the Pilbara, most species appear to be SREs. Most Pilbara Cryptopidae are represented by troglobites, and epigean records are uncommon. Species delimitation studies of epigean (surface dwelling) cryptopids suggests a significant diversity is present and most appear to be SREs. There is no taxonomic framework for Pilbara cryptopids, and all species assessments are currently based on comparisons using DNA sequences.

***Cryptops* 'HD1'.** This taxon was sampled from site SRE11 and was represented by three specimens. Alacran undertook DNA Barcoding of these samples (Appendix 3); however, this species could not be placed among those within Alacran's database of DNA sequences. This taxon is a potential SRE owing to uncertainty about its identity.

Figure 4.ϕ. Central and eastern Pilbara showing the distribution of SRE category Chilopoda and Symphyla records from the database Search Area. Number of records in parentheses.

4.3 DIPLOPODA (MILLIPEDES)

Diplopoda is a diverse class and in the Pilbara, it is represented by five orders: Polydesmida, Polyxenida, Polyzoniida, Spirobolida and Spirostreptida. Of these, only the order Polyxenida (pincushion millipedes) has mostly widespread epigean species (Short and Huynh 2011, 2013); however, molecular data (unpublished) indicates several troglobitic species are SREs. The orders Polyzoniida (sucking millipedes) and Spirostreptida are very poorly known from the Pilbara; however, based on investigations of the fauna of SW Australia (Harvey 2002b; Moir et al. 2009; Edward and Harvey 2010; Harvey et al. 2011), it seems likely that most Pilbara representatives will be SREs.

The Search Area contained 30 millipede taxa, of which one was a named species, 20 were morphospecies and nine were unidentified taxa (Table 4.5 and Figure 4.11). Seventeen of these species were SREs and the remainder were potential SRE (DD) (Table 4.5).

Spirobolida	Trigoniulidae	Trigoniulidae sp.	Potential SRE: DD	Presence of SRE or potential SRE species in this family

The field survey yielded numerous millipede samples belonging to the orders Spirobolida (family Trigoniulidae) and Polydesmida (family Paradoxosomatidae).

4.3.1 Polydesmida

The order Polydesmida (flatback millipedes) has received significant attention over recent years, particularly the family Paradoxosomatidae (Car and Harvey 2013; Car et al. 2013; Car and Harvey 2014). In the Pilbara, Paradoxosomatidae are represented by two described genera *Antichiropus* and *Boreohesperus*, both of which contain SRE representatives.

4.3.1.1 Paradoxosomatidae

A single species was identified from the family Paradoxosomatidae: *Antichiropus* 'wonmunna' from sites SRE15 (three samples) and SRE23 (one sample). These samples were matched with tissue obtained from a sample of *Antichiropus* 'wonmunna' (T118101) from the W. A. Museum. *Antichiropus* 'wonmunna' was represented by five samples (three different locations) in the Search Area and all are within 10 km of sites SRE15 and SRE23 (Figure 4.10). This species is a potential SRE owing to limited information about its distribution.

***Antichiropus* sp.** was also recorded from sites SRE11 and SRE23. These samples are likely to represent *Antichiropus* 'wonmunna'; however, there is also a chance that one or more may represent different species since multiple species of Paradoxosomatidae have been collected from the same locality (Car and Harvey 2013).

4.3.2 Spirobolida

4.3.2.1 Trigoniulidae

In the Pilbara, Spirobolida is represented by the family Trigoniulidae and the genera *Austrostrophus* and *Speleostrophus*. All epigean species belong to *Austrostrophus* which is represented by a single described species, *Austrostrophus stictopygus*. Molecular studies of this species at the W. A. Museum indicate significant variation between some Pilbara populations that are consistent with species level differences (W. A. Museum, unpublished data). *Austrostrophus stictopygus* therefore appears to represent a complex of species, some of which may be SREs.

Species delimitation by Alacran and the W. A. Museum indicated the presence of two putative species (Appendix 3 and Appendix 4) and the designations applied by the W. A. Museum are adopted here: ***Austrostrophus* 'Clade A'** from site SRE20 and ***Austrostrophus* 'Clade E'** from sites SRE15, SRE22, TS14 and TS18. Both are regarded as potential SREs owing to uncertainty about their distribution limits.

***Austrostrophus* sp.** represents specimens that were not sequenced and were found at sites SRE13, SRE15, SRE16, SRE17, SRE18 and SRE19. In the absence of clear unambiguous identification, this taxon is regarded as a potential SRE owing to data limitation regarding species identity.

4.4 SYMPHYLA (GARDEN CENTIPEDES)

Symphylans are tiny, less than 1 cm, centipede-like arthropods. Like centipedes, they have a multi-segmented body with one pair of legs per segment. They differ from centipedes in several ways, but most notably by the absence of the modified first pair of legs into poison claws, which is characteristic of all true centipedes. This group is poorly known and literature on the Australian species is very limited.

In the Pilbara, nearly all symphylans are recorded from subterranean habitats, where they are frequently SREs. In the absence of a workable taxonomy for Pilbara symphylans, species identification is heavily dependent on DNA sequencing methods. While epigean records of symphylans from the Pilbara are very scarce, it is plausible for them to be present in deep gorges that retain moist soil and leaf litter throughout most of the year.

The database search identified one Symphyla record which was not identified beyond the rank of Class: Symphyla sp. Insufficient data were available to assess whether these were sampled from subterranean habitats or not, therefore they are tentatively considered to be epigean and potential SRE: DD (Figure 4.11).

No symphylans were sampled during this survey; however, they may be present in south-facing gullies and scree slopes in the north west of the Study Area.

4.5 ISOPODA (SLATERS OR WOOD LICE)

Isopoda represent the only order of epigean crustaceans known to contain SREs. The suborder Oniscidae represents terrestrial and secondarily aquatic isopods with approximately 190 species described in Australia (Martin et al. 2011). The W. A. terrestrial isopod fauna is largely undescribed and is diverse (Judd and Horwitz 2003; Judd and Perina 2013). Isopods have poor dispersal capabilities and often have specific habitat preferences, making them target SRE taxa in W. A.

The Search Area contained 34 isopod taxa, of which none were named species, 25 were morphospecies and nine were unidentified taxa (Table 4.6 and Figure 4.9). These taxa were potential SRE (DD) (Table 4.6).

Philosciidae	*Laevophiloscia* 'Wonmunna B'	Potential SRE: DD	assessment by Dr Simon Judd
Philosciidae	Philosciidae sp.	Potential SRE: DD	All Philosciidae in the Pilbara are considered potential SREs.

4.5.1.1 Armadillidae

***Buddelundia* '10ma'.** This species was sampled from sites SRE11, TS4 and TS5. This species was only sampled during the T1 survey. The *Buddelundia* '10' species group contains several species, including this one. This taxon has been previously collected from the Marillana and West Angelas areas and is regarded as an SRE. The records of the W. A. Museum have not been updated to distinguish *Buddelundia* '10' from Buddelundia '10ma'; therefore, the latter species is not specifically represented in Figure 4.11. The distribution of *Buddelundia* '10' is mapped and some of these will be representatives of *Buddelundia* '10ma'.

***Buddelundia* '15'.** This isopod was sampled from sites SRE14, SRE15, SRE19 and SRE23. This is a relatively widespread Pilbara species.

***Buddelundia* '16'.** This species was sampled from sites SRE17 and SRE19. This is a relatively widespread Pilbara species complex.

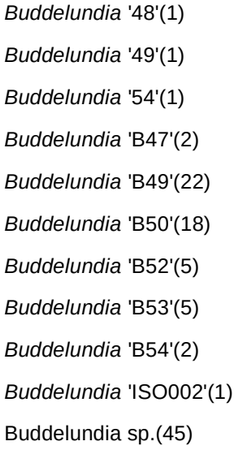
***Buddelundia* '77'.** This species was sampled from five sites: SRE15, SRE17, SRE19, SRE22 and SRE23. This species has a distinct disjunct distribution. It's is a small, likely cryptic species of *Buddelundia* and the isolated populations may be different species. This species is a potential SRE owing to taxonomic uncertainty and highly disjunct populations.

Buddelundiinae sp. This taxon was sampled from sites SRE23 and TS14. It belongs to an undescribed genus closely related to *Buddelundia*. This genus is mostly found in the Pilbara region and lacks the morphological characters used to determine *Buddelundia*. Morphospecies are difficult to define in this group and there is a general lack of sequences with which to make comparisons. They are all potential SRE species.

***Pseudodiploexochus* sp.** This unusual isopod was sampled from SRE17. This is the second record of this genus from the Pilbara. The only other record of this genus in the Pilbara is from the West Angelas area (23°07'26.83"S 118°53'09.08"E), approximately 25 km SW of the locality where it was sampled in this survey. That sample is part of the S. Judd Isopod collections and is therefore not present in the W. A. Museum data records. Further comparisons between these samples should be undertaken using DNA barcoding methods since the taxonomy of this group is also very poor in W. A.

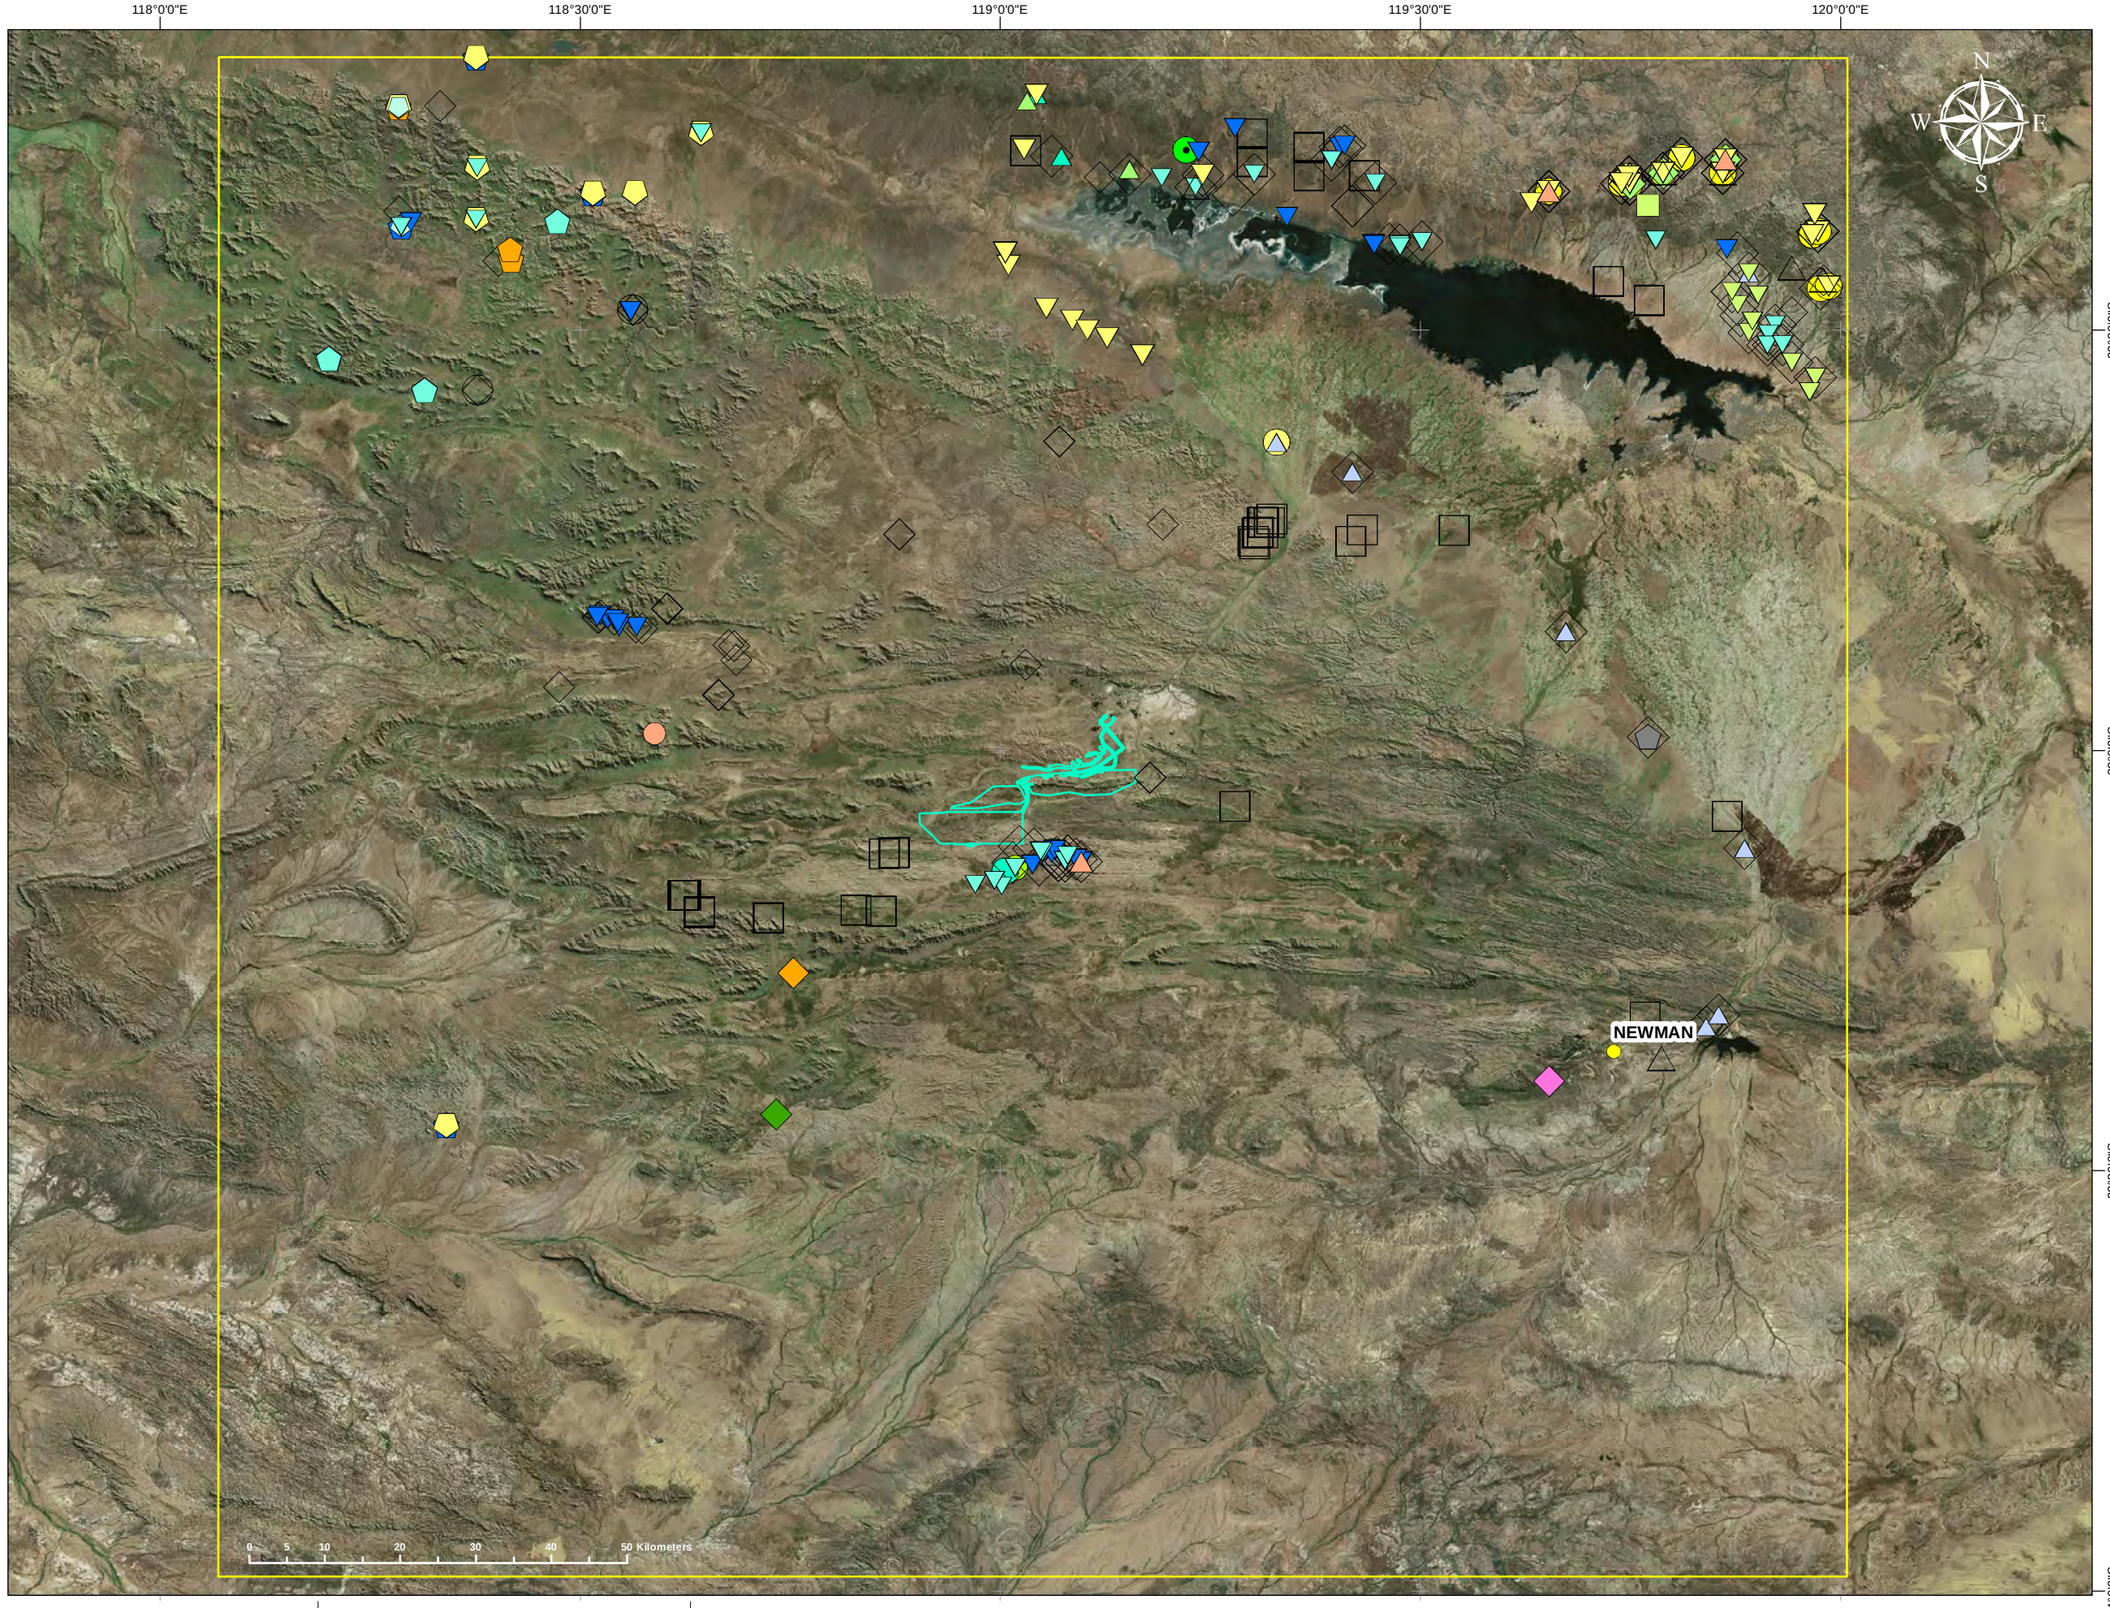
Members of this genus do not have the well-developed lungs present in most terrestrial Armadillidae. For this reason, they are far more susceptible to desiccation and are nearly always considered to be SRE in arid or semi-arid environments. *Pseudodiploexochus* is therefore likely to represent an SRE but in the absence of additional taxonomic or distributional data, it is a potential SRE.

***Troglarmadillo* sp.** This unusual isopod was sampled from site SRE13. This tiny specimen could not be unambiguously identified; however, it showed closest affinity to *Troglarmadillo*, a genus almost entirely represented by troglobites in the Pilbara. Despite the genus name, the species sampled possesses well developed eyes and has faint body patterning, suggesting that it is not a troglobite. Subterranean *Troglarmadillo* species are nearly always SRE and it is likely that this species will be as well. In the absence of more resolved taxonomic and distributional data, this species is a Potential SRE. While there are a number of sources for sequences for Pilbara *Troglarmadillo* species, all of them are from troglobites; therefore, sequencing this specimen is unlikely to be of much use until more specimens are obtained.



4.5.1.2 Family Philosciidae

The taxonomy of the Philosciidae is unknown in W. A. They are rarely collected in the Pilbara and are generally considered to be potential SREs.



Philosciidae sp. This taxon was collected at SRE19 and TS14. Several attempts were made to amplify COI sequences from these samples; however, all samples failed to yield useful sequences. In the absence of unambiguous species identification, this taxon is a potential SRE owing to data deficiency about its identity.

Project: Short-range Endemic Invertebrate assessment for the Hope Downs 2 Level 2 Survey Area
Client: Astron (Rio Tinto)
Coordinate System: GCS WGS 1984
Projection: Transverse Mercator
Author: E.S. Volschenk
Date: 2 Oct 2019

Figure 4.1M. Central and eastern Pilbara showing the distribution of SRE category Isopoda records from the database Search Area. Number of records in Parentheses.

4.6 EUPULMONATA, MOLLUSCA (LAND SNAILS)

Land snails are a diverse group of invertebrates and most of Australia's snail fauna is endemic (Beesley et al. 1998). Their limited dispersal capabilities, often combined with specific habitat requirements, makes them one of the SRE target groups in W. A. (Harvey 2002b; EPA 2009). In the Pilbara region of W. A., the families Camaenidae, Bothriembryonitidae and Succineidae are significant in containing SREs and potential SREs; however, much of the diversity is cryptic and dependent on molecular investigations to verify species boundaries (Johnson et al. 2012; Johnson et al. 2013; Whisson and Kirkendale 2014).

The Search Area contained 12 SRE category snail taxa, of which one was a named species, four were morphospecies and seven were unidentified taxa (Table 4.7 and Figure 4.12). All were considered potential SRE (DD) (Table 4.7).

Table 4.7. Table of SRE category Eupulmonata from the area search of the W. A. Museum's Mollusca Database

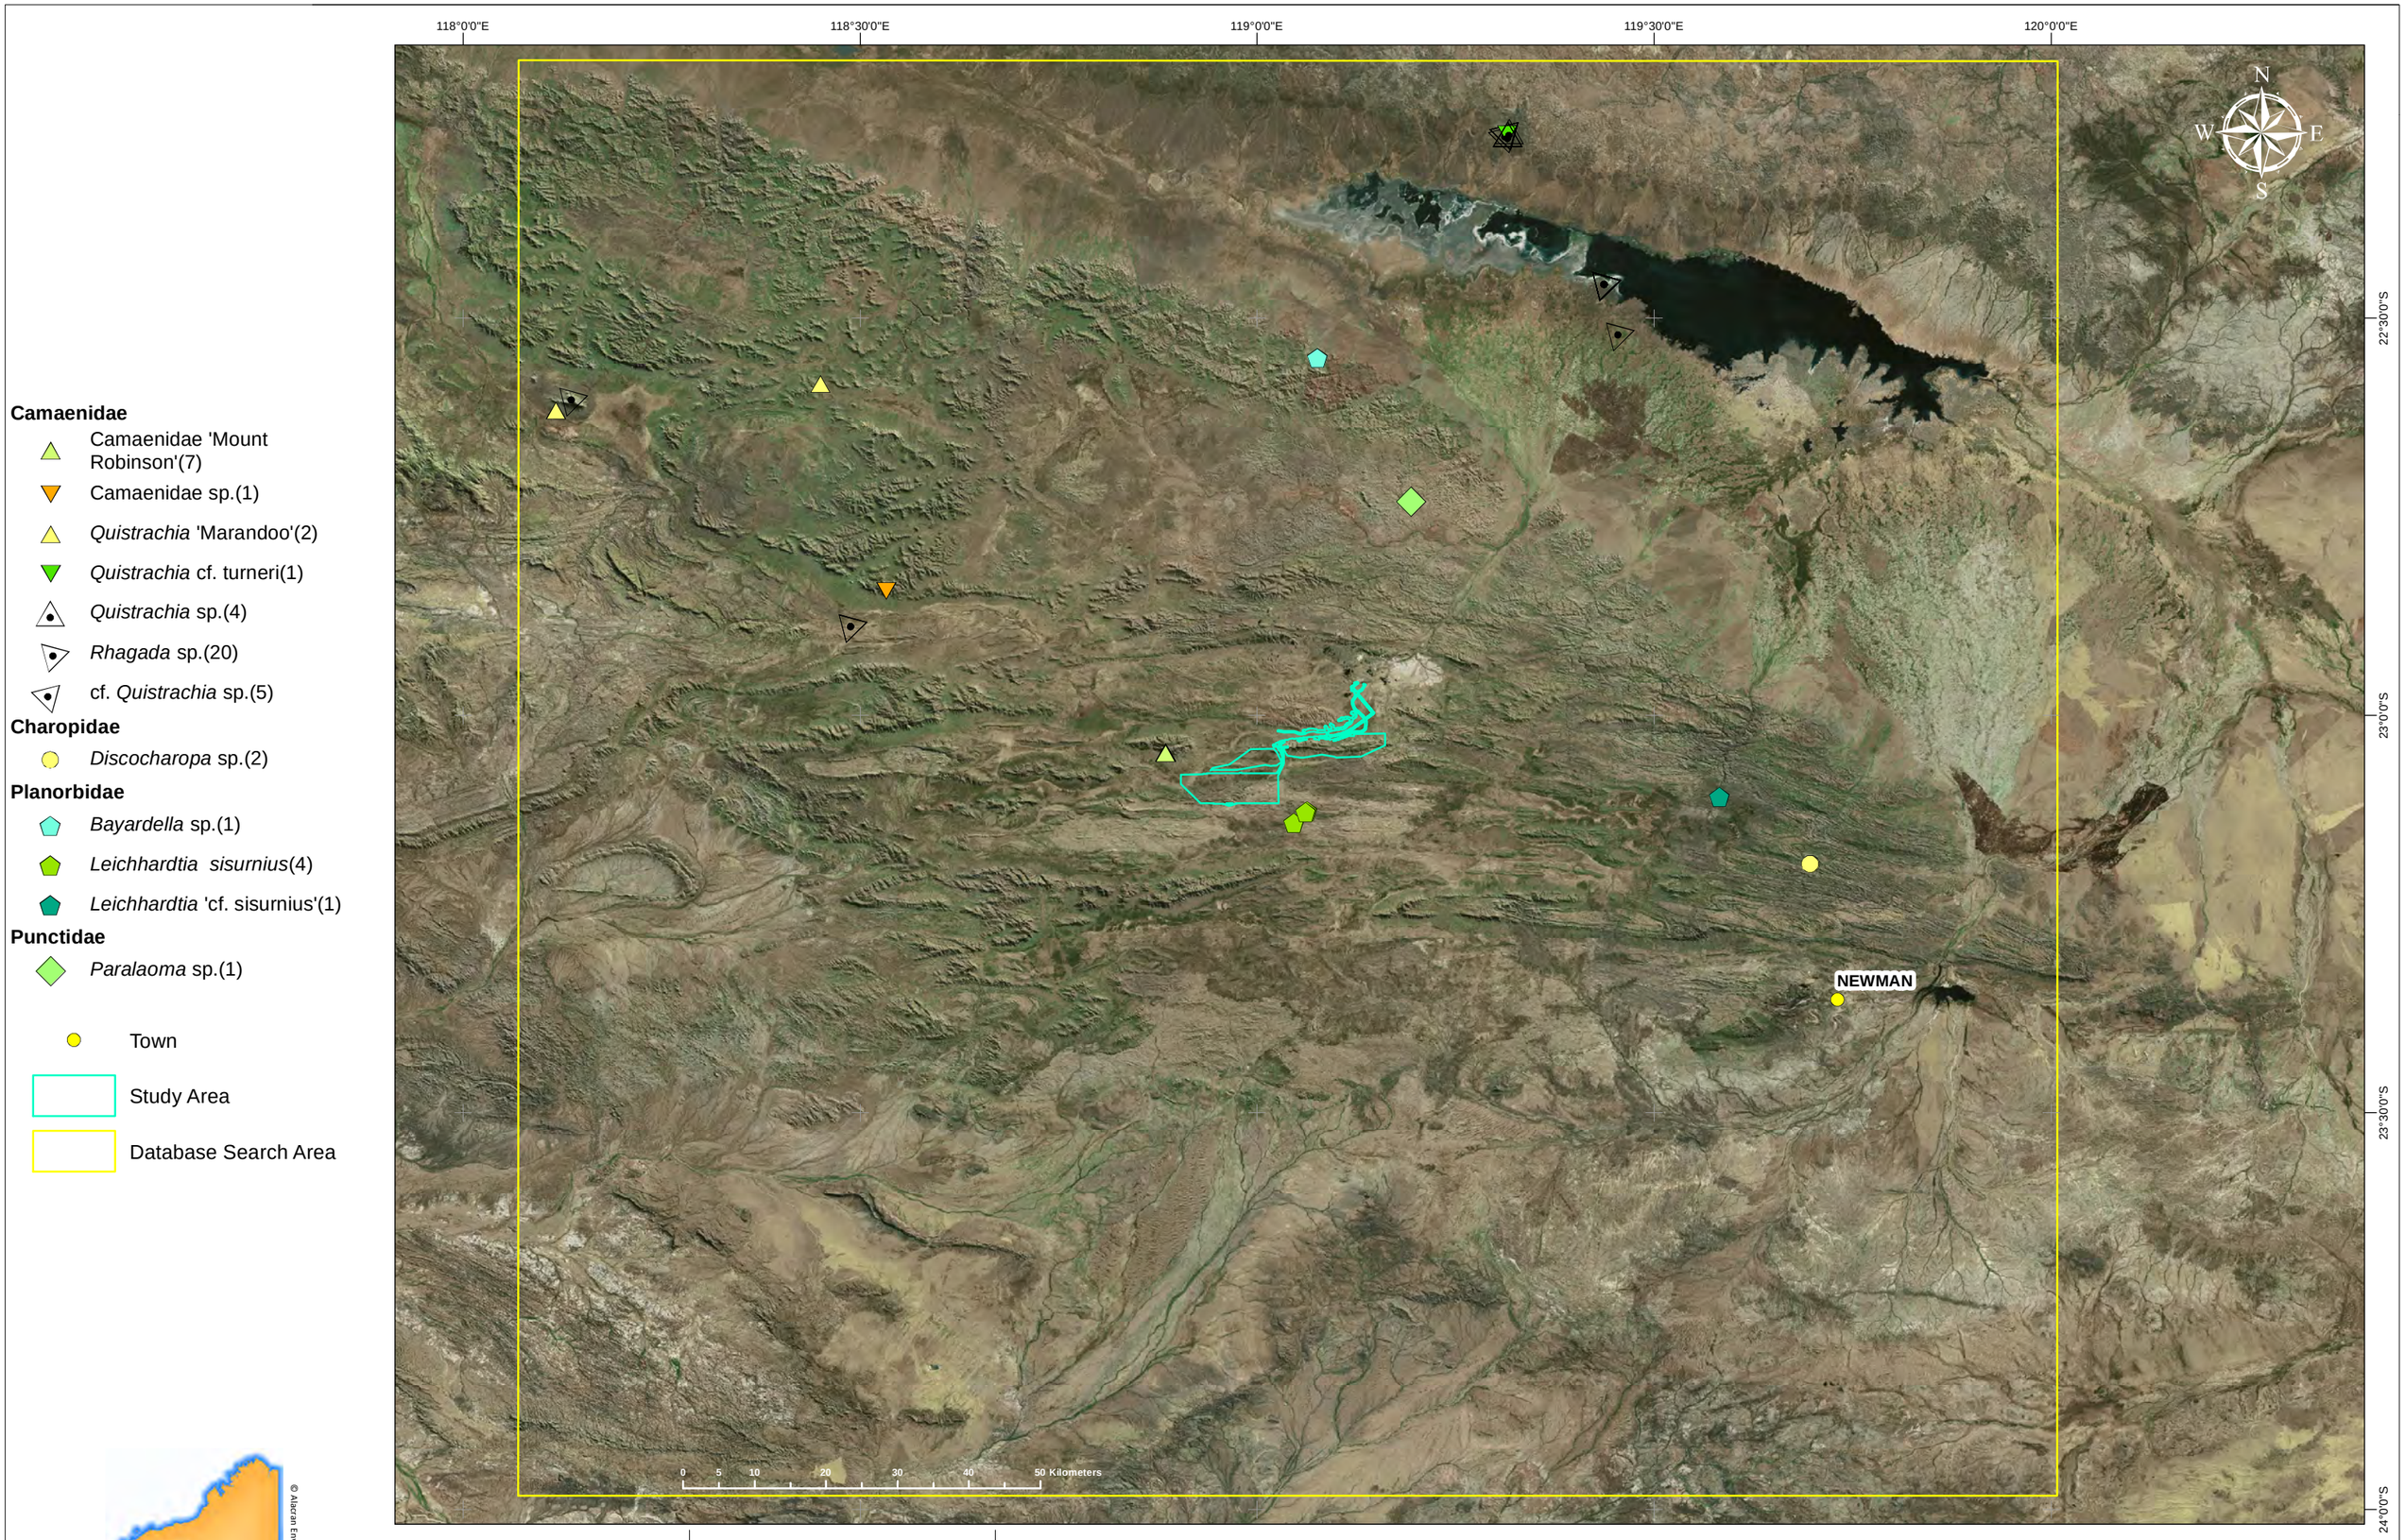
Family	Binomial	SRE-Category	Justification
Camaenidae	Camaenidae 'Mount Robinson'	Potential SRE: DD	W. A. Museum data
Camaenidae	Camaenidae sp.	Potential SRE: DD	(Whisson and Kirkendale 2014)
Camaenidae	cf. *Quistrachia* sp.	Potential SRE: DD	Genus contains SREs and potential SREs
Camaenidae	*Quistrachia* cf. turneri	Potential SRE: DD	W. A. Museum data
Camaenidae	*Quistrachia* 'Marandoo'	Potential SRE: DD	W. A. Museum data
Camaenidae	Quistrachia sp.	Potential SRE: DD	Genus contains SREs and potential SREs (Whisson and Kirkendale 2014)
Camaenidae	*Rhagada* sp.	Potential SRE: DD	Genus contains SREs and potential SREs (Whisson and Kirkendale 2014)
Charopidae	*Discocharopa* sp.	Potential SRE: DD	W. A. Museum data
Planorbidae	*Bayardella* sp.	Potential SRE: DD	W. A. Museum data
Planorbidae	*Leichhardtia sisurnius*	Potential SRE: DD	W. A. Museum data
Planorbidae	*Leichhardtia* cf. sisurnius	Potential SRE: DD	W. A. Museum data
Punctidae	*Paralaoma* sp.	Potential SRE: DD	W. A. Museum data

The field survey yielded three species of land snails: *Gastrocopta* sp., *Pupoides* sp. and *Eremopeas interioris*, all of which are widespread in the Pilbara (Table 3.2). The absence of SRE snails from the Study Area is difficult to assess. Among SRE groups, snails can be extremely difficult to find, making their absence in surveys difficult to interpret. Optimal conditions for surveying SRE snails (rainy nights) are often logistically

challenging for surveys in the Pilbara. When inactive, most species burrow into the ground or seal themselves against rocks deep in rock piles and remain inactive until rains return.

4.7 HABITAT ASSESSMENT

The Mulga Woodlands in the study area supported eight of the nine centipede taxa and both millipede taxa. Of note in these groups is the presence of the millipede genus *Antichiropus* and the centipede genus *Cryptops*. All Pilbara morphospecies and species of *Antichiropus* are SREs and all epigean *Cryptops* are potential SRE.



Hill slope gullies supported Philosciidae sp, *Troglarmadillo* sp. and *Pseudodiploexochus* sp. which, while being ambiguously defined, represent likely SREs. The latter two taxa represent forms that are very rarely sampled from epigean habitats in the Pilbara and are not arid adapted. The presence of arid sensitive taxa in these habitats indicates that SRE habitats are present. Additional SRE species are likely to occur in these habitats.

The pseudoscorpion *Anatemnus* sp. is enigmatic in that it has all of the features of a troglobite (blind and pale) and the only other Pilbara record of this genus is troglobitic. One specimen was sampled from riparian leaf litter of a dry creek line (SRE10). There is a small chance that this species is troglobitic and in rare cases, troglobites have been observed at the entrance of caves during very humid conditions. In the Pilbara, troglobitic *Nocticola* have been sampled from creak gravels (Volschenk personal observations) indicating that this is potential habitat for troglobitic taxa. The presence of this species from the subterranean fauna surveys of this area may offer evidence that this is a troglobite.

Several SRE category invertebrates sampled during this study were found in multiple habitat types, suggesting that they may be less specialised with respect to their habitat preferences:

- *Lychas* 'bituberculatus complex', from stony hills and eucalypt woodland;
- *Sepedenophilous* 'HD1', from rocky slopes and gullies, and mulga woodland;
- *Mecistocephalus* 'HD1', from rocky slopes and gullies, and mulga woodland;
- *Austrostrophus* 'HD2', from mulga woodland and open eucalypt woodland;
- *Antichiropus* 'wonmunna', from mulga woodland in this study area, but from gully slopes and riparian vegetation outside of this study area.

Habitat mapping was undertaken by Astron and while all of the habitats have the potential to support SREs, five habitats stand out as being conducive to relictual SREs: Breakaways, Mulga Woodland, Minor Drainage lines, Gorges and Gullies, and Rocky Hills. Most of these latter habitats are associated with an isolated ridge running in an east-west direction, so most of the breakaways and rocky slopes are south-facing and therefore conducive to SREs (Harvey 2002b).

SUMMARY

This study aimed to verify the identity of 60 samples of invertebrates from an invertebrate survey undertaken at Hope Downs using molecular barcoding techniques. Standard sanger sequencing methods were employed to amplify a DNA fragment of the gene Cytochrome C oxidase subunit I (COI).

Of the 60 samples assessed, 53 yielded useable DNA sequences, which were analysed using Bayesian phylogenetic reconstruction methods. Thirty (30) species and morphospecies were identified from the study. Ten (10) of these taxa represent species or morphospecies previously known from the Pilbara:

- *Karaops banyjima*: (AES190099, AES190069), a potential SRE: DD;
- *Aurecocrypta* 'MYG315' (AES190347), a potential SRE: DD;
- *Synothele* 'MYG311' (AES190039), a potential SRE: DD;
- *Synothele* 'MYG309' (AES190063), a potential SRE: DD;
- *Gaius tealei* (AES190072, AES190101), a widespread species;
- *Yilgarnia* 'MYG197' (AES190050), potential SRE: DD;
- 'Genus 7/4 PSE118' (T146562, T146561, T146559, AES190079), potential SRE: DD;
- *Lychas* 'bituberculatus cmplx' (AES190065), potential SRE: DD;
- *Lychas* 'multipunctatus cmplx' (AES190080), potential SRE: DD, and
- *Antichiropus* 'wonmunna' (AES190321, AES190104, AES190067, AES190040), potential SRE: DD.

Twenty-two (20) taxa could not be matched with available sequences:

- *Aurecocrypta* 'HD1' (AES190082), a brush-footed trapdoor spider (Barychelidae);
- *Beierolpium* 'HD1' (AES190331), a pseudoscorpion (Olpiidae);
- *Beierolpium* 'HD2' (AES190341), a pseudoscorpion (Olpiidae);
- *Beierolpium* 'HD3' (AES190012), a pseudoscorpion (Olpiidae);
- *Indolpium* 'HD4'(AES190014), a pseudoscorpion (Olpiidae);
- *Austrohorus* 'HD5' (T146556), a pseudoscorpion (Olpiidae);
- *Euryolpium* 'HD6' (T146557), a pseudoscorpion (Olpiidae);
- *Euryolpium* 'HD7' (T146564), a pseudoscorpion (Olpiidae);
- *Tyrannochthonius* 'HD1' (T146555), a pseudoscorpion (Chthoniidae);
- *Tyrannochthonius* 'HD2' (AES190330), a pseudoscorpion (Chthoniidae);
- *Urodacus* 'HD1' (AES190076), a burrowing scorpion (Urodacidae);
- *Mecistocephalus* 'HD1' (AES190336, AES190335, AES190308, AES190338), an earth centipede (Mecistocephalidae);
- *Mecistocephalus* 'HD2' (AES190337), an earth centipede (Mecistocephalidae);
- *Mecistocephalus* 'HD3' (AES190313, AES190322), an earth centipede (Mecistocephalidae);
- *Sepedenophilous* 'HD1' (AES190305, AES190306, AES190077, AES190006, T146570, AES190007, AES190106), an earth centipede (Chilenophilidae);
- *Sepedenophilus* 'HD2' (AES190061), an earth centipede (Chilenophilidae);
- *Orphnaeus* 'HD1' (AES190103), an earth centipede (Oryidae);
- *Cryptops* 'HD1' (AES190315, AES190318, AES190319),
- *Austrostrophus* 'HD1' (AES190092), a millipede (Trigoniulidae), and

- *Austrostrophus* 'HD2' (AES190028, AES190344, AES190074, AES190083), a millipede (Trigoniulidae).

These 19 taxa all have distribution and taxonomic characteristics that make them potential SREs.

1 AIMS

The aim of this study was to assess the species boundaries of eight groups of invertebrates from the Hope Downs area and surrounds, in the Pilbara region of Western Australia:

- spiders from the genus *Karaops* (family Selenopidae)
- brush-footed trapdoor spiders (Barychelidae)
- spiny trapdoor spiders (Idiopidae)
- pseudoscorpions (Olpiidae and Chthoniidae);
- *Lychas* scorpions;
- *Urodacus* scorpions;
- Earth centipedes (Chilenophilidae, Mecistocephalidae and Oryidae);
- Cryptic centipedes (Cryptopidae)
- millipedes in the genus *Austrostrophus* (family Trigoniulidae).
- wood lice (isopods from the family Philosciidae);

These samples were obtained during invertebrate surveys by Astron and Alacran Environmental Science (Alacran) and reported on in Alacran (2019). This report is intended as a supplement to Alacran (2019).

2 METHODS

Sequences and tissue samples were obtained from the following sources:

- Western Australian Museum (tissues and comparative sequences): codes beginning with “T” and followed by a string of numbers
- Alacran Environmental Science (comparative sequences and tissues): samples predating 2019 begin with “ESV” and later samples beginning with “AES”
- Genbank (comparative sequences): codes beginning with two letters and followed by six numbers.
- Erich Volschenk scorpion research (comparative sequences): codes beginning with “EVR”.

All of the target samples were sourced from field collected specimens detailed in a report provided to Astron by Alacran Environmental Science (Alacran), (Alacran 2019).

Sequences of the gene COI were amplified from muscle tissues obtained from specimens preserved in >95% (WA Museum tissue collection) or *ca.* 70%->95% ethanol (wet collections of WA Museum and Simon Judd). Sequence generation from tissues was undertaken by Xytogen Pty Ltd (https://xytogen.com.au/) and AGRF Perth (http://www.agrf.org.au).

Sequence contigs were assembled from forward and reverse amplicons using Geneious R7 version 7.1.9 and were subsequently edited and pruned by eye, prior to consensus sequences being created. Primers were removed from the consensus sequences which were then assessed for contamination using the NCBI Nucleotide Blast tool (https://blast.ncbi.nlm.nih.gov).

For analyses and alignment, additional sequences of species were obtained from Genbank or from Alacran (unpublished sequences) to better guide alignments and assessment of species boundaries. Species pairs were

selected from taxa within the same genus or family of the taxa under investigation and more than 400 bases long.

Phylogenetic analyses and Sequence alignments were performed with Geneious R7. For each analysis sequences were assembled and aligned using ClausalW or the Geneious alignment tool, implementing the following variable settings: Global alignment with free ends; Cost matrix, 70% similarity (IUB); Open gap penalty, 70; Gap extension penalty, 10; refinement iterations, 4.

Phylogenetic analyses were implemented using Geneious R7 and MrBayes (Huelsenbeck and Ronquist 2001; Ronquist et al. 2012). Outgroups were selected from (in order of preference): sister genus-, sister family- or sister order- to the group under investigation. Species delimitation was based on an 8% sequence divergence threshold (Hebert et al. 2003a; Hebert et al. 2003b; Barrett and Hebert 2005; Robinson et al. 2009) unless otherwise stated. Most of the analyses undertaken here were comprised of representatives of the same family; however, sequences were grouped at the Class level for Diplopoda, and order for Geophilomorpha and Pseudoscorpiones.

2.1 ANALYSES

Eight separate analyses were undertaken here, with each analysis aiming to assess the identification of the target taxa for the respective group.

Composition of the analyses are listed for each analysis as follows:

- Selenopidae - Table 1,
- Barychelidae - Table 2,
- Idopidae - Table 3,
- Nemesiidae - Table 4
- Pseudoscorpiones - Table 5,
- *Lychas* (Scorpiones, Buthidae) - Table 6,
- *Urodacus* (Scorpiones, Urodacidae) - Table 7,
- Geophilomorpha - Table 8,
- Cryptopidae - Table 9,
- Diplopoda - Table 10.

Reference samples	*Aname aragog* (JQ772136), *Aname ellenae* (JQ772137), *Aname mainae* (KJ745198), *Aname mellosa* (JQ772125), *Aname* 'MYG001' (KJ744409), *Aname* 'MYG004 (KJ744436), *Aname* 'MYG034' (KJ745375), *Aname* 'MYG067' (KJ745435), *Aname* 'MYG079' (KJ744406), *Kwonkan* 'MYG006' (KJ744608), *Kwonkan* 'MYG006' (KJ744607), *Kwonkan* 'MYG088' (KJ745206), *Kwonkan* 'MYG172' (KJ744388), *Kwonkan* 'MYG175' (KJ744403), *Kwonkan* 'MYG195' (MG800177), *Kwonkan* 'MYG325' (KJ744834, KJ744665), *Kwonkan* 'MYG337' (KJ744962, KJ744959), *Kwonkan* 'MYG338' (KJ744840, KJ744666), *Kwonkan* 'MYG341' (KJ745190, KJ745188), *Kwonkan* 'MYG343' (KJ745210), *Kwonkan* 'MYG352' (KJ745255, KJ745238), *Kwonkan* 'MYG361' (KJ745281), *Kwonkan* 'MYG378' (KJ744782), *Kwonkan* 'MYG379' (KJ744832, KJ744831), *Kwonkan* 'MYG390' (MG800173), *Kwonkan* 'MYG392' (MG800175), *Kwonkan* 'MYG394' (MG800176), *Kwonkan* 'MYG599' (MH932614), *Pseudoteyl* 'MYG353' (KJ745272, KJ745278, KJ745277), *Teyl* 'MYG021' (KJ745381, KJ745380), *Teyl* 'MYG027' (KJ744759), *Teyl* 'MYG412' (MG800164), *Teyl* 'MYG455' (MG800147), *Yilgarnia* 'MYG164' (KJ745511), *Yilgarnia* 'MYG165' (KJ745513, KJ745512), *Yilgarnia* 'MYG197' (MG800166), *Yilgarnia* 'MYG324' (KJ744777, KJ744773), *Yilgarnia* 'MYG327' (KJ745015, KJ745013), *Yilgarnia* 'MYG374' (KJ744695), *Yilgarnia* 'MYG375' (KJ744709), *Yilgarnia* 'MYG376' (KJ744725), *Yilgarnia* 'MYG458' (MG800155)
Outgroup	*Liphistius laoticus* (KP229896)

Table 5. Sample composition for the Pseudoscorpiones analysis

Sample type	Samples
Target samples	**Olpiidae**: *Austrohorus* sp. (T146556), *Beierolpium* sp. (AES190012, AES190341, AES190331, T146557, AES190090), *Indolpium* sp. (T146562, T146561, T146559, T146563, AES190014, AES190079); **Unresolved samples**: Olpiidae sp. (1T146564, T146565); **Chthoniidae**: Tyrannochthonius sp. (T146555, AES190330).
Reference samples	**Olpiidae:** *Austrohorus* 'PSE119' (T139670, T139676, T139680, T139687, T139697, T139700, T139702, T139703); *Austrohorus* 'PSE121' (T139681); *Austrohorus* 'PSE122' (T139706, T139707); *Beierolpium* 'PSE126' (T139688); *Indolpium* 'PSE123' (T139678, T139683, T139705 , T139675, T139696, T139701); *Indolpium* 'PSE124' (T136334); 'Genus 7/4 PSE118' (T139690). **Additional Olpiid Genera:** *Xenolpium* 'JM (2008' (EU559539), *Apolpium parvum* (EU559541), *Pachyolpium* 'JM (2008' (EU559542), *Nanolpium* 'JM (2008' (EU559543), *Beierolpium bornemisszai*, (EU559545) and *Euryolpium* 'JM (2008' (EU559546); **Chthoniidae**: *Tyrannochthonius aridus* (KJ659960, KJ659959), sequence of *Tyrannochthonius garthhumphreysi* (KJ659948)
Outgroup	*Siro exilis* (AY639579), *Buthus occitanus* (GQ168524)

Table 6. Sample composition for the *Lychas* analysis

Sample type	Samples
Target samples	*Lychas* 'bituberculatus cmplx' (AES190065), *Lychas* 'multipunctatus cmplx' (AES190080).
Reference samples	*Lychas* 'adonis' (T101228, T85763), *Lychas* 'annulatus cmplx' (T114330, T124554, T99992), *Lychas* 'bituberculatus cmplx' (EVR7959, T101960, T91706, T97380), *Lychas* 'pilbara 1' (T126898, T126932), *Lychas* 'hairy tail cmplx' (T92146, T97507, T97518, T97522, T98280, T99692), *Lychas jonesae* (T101224, T118598, T94832, T99995), *Lychas* 'LC' (ESV18:0359), *Lychas* 'cf mjobergi' (T94832), *Lychas* 'multipunctatus cmplx' (EVR7974), *Lychas* 'nigrescens' (T83597), *Lychas* 'splendens' (T94760, T97774), *Lychas* sp. (T126899).
Outgroup	Siro exilis (AY639579), *Buthus occitanus* (GQ168524), *Cercophonius sulcatus* (KT447038), *Heterometrus laoticus* (JN018160), *Orthochirus innesi* (JQ514244) and *Parabuthus transvaalicus* (JQ514247).

Table 7. Sample composition for the *Urodacus* analysis

Sample type	Samples
Target samples	*Urodacus* sp., AES190076
Reference samples	*Urodacus* 'Biota 2' (EVR6974, EVR6985), *Urodacus* 'bullsbrook' (EVR8013), *Urodacus butleri* (T123092, T85115), *Urodacus* cf.hartmeyeri (EVR2122), *Urodacus* 'eddiei' (EVR2342), *Urodacus* 'gibson 2' (EVR7981), *Urodacus* 'gibson 4' (EVR7999), *Urodacus* 'gibson 5' (EVR8011), *Urodacus* 'glauerti' (T79950, *Urodacus* 'granifrons' (EVR9141), *Urodacus hoplurus* (T75099), *Urodacus* 'karara' (T77953), *Urodacus koolanensis* (T101952), *Urodacus* 'laverton 2' (EVR7979), *Urodacus* 'laverton 3' (EVR7976), *Urodacus* 'laverton 5' (EVR7994), *Urodacus* 'majerorum' (EVR2878), *Urodacus* 'maret' (EVR6988), *Urodacus mckenziei* (EVR2689), *Urodacus* 'megamastigus cmplx' (T100386, T100390), *Urodacus* 'mingenew' (T53929), *Urodacus novaehollandiae* (EVR1540, EVR7993), *Urodacus* 'pale cmplx' (EVR1553, EVR529, EVR6978, EVR1552, EVR527), *Urodacus planimanus* (EVR1661), *Urodacus similis* (T85018), *Urodacus* sp. (ESV18:0205, ESV18:0578, ESV18:0587), *Urodacus* 'telfer' (T114318, T114321), *Urodacus varians* (T37723), *Urodacus* 'woodwardii' (EVR1664), *Urodacus* 'yaschenkoi cmplx' (EVR6984, EVR8007), *Urodacus* 'yeelirrie' (T101241, T101243)
Outgroup	*Siro exilis* (AY639579) was used as the outgroup for this analysis, along with the following scorpions: *Buthus occitanus* (GQ168524), *Centruroides exilicauda* (AY649858), *Cercophonius michaelseni* (T41784) and *Cercophonius sulcatus* (T81521).

Table 8. Sample composition for the Geophilomorpha analysis

Sample type	Samples
Target samples	**Chilenophilidae:** *Sepedenophilus* sp. (AES190305, AES146570, AES190306, AES190006, AES190077, AES190007, AES190106, AES190061); **Mecistocephalidae**: Mecistocephalus sp. (AES190335, AES190336); **Oryidae**: *Orphnaeus sp.* (AES190103 and AES190322); **Unresolved Geophilomorpha**: Geophilomorpha sp. (AES190313, AES190308, AES190337)
Reference samples	**Chilenophilidae**: *Sepedenophilous*, representing eight species, were included in the analysis: *Sepedonophilus* '01' (T126608, T126604), *Sepedonophilus* '02' (T126607, T126772), *Sepedonophilus* '03' (T126781, T126778, T128035), *Sepedonophilus* '04' (T128075, T128080), *Sepedonophilus* '05' (T136340), *Sepedonophilus* 'G1' (ESV18:1010), *Sepedonophilus* 'G2' (ESV18:1050), *Sepedonophilus* 'G3' (ESV18:0519); **Mecistocephalidae**: *Mecistocephalus* '02' (T126693), *Mecistocephalus* '03' (T126697, T128034), *Mecistocephalus* '04' (T128174), *Mecistocephalus* '05' (T128180), *Mecistocephalus* '06' (T126739, T128041), *Mecistocephalus* '07' (T126733), *Mecistocephalus* '08' (T128073, T128076), *Mecistocephalus* '09' (T128060, T136342, T136341), *Mecistocephalus* '10' (T128063, T128077), *Mecistocephalus* '11' (T126845); **Oryidae**: *Orphnaeus* 'WM1' (ESV18:0997), *Orphnaeus brevilabiatus* (T128175, T128176, AB608780).
Outgroup	*Lamyctes africanus* (KC688312)

Table 9. Sample composition for the Cryptopidae analysis

Sample type	Samples
Target samples	*Cryptops* sp. (AES190315, AES190318, AES190319)
Reference samples	*Cryptops anomalans* (KU497151, JN266283), *Cryptops doriae* (KF676500), *Cryptops hortensis* (KU497145, KU497144), *Cryptops indicus* (KF676505), *Cryptops japonicus* (AB610777), *Cryptops lamprethus* (JX422663, JF273305), *Cryptops parisi* (KU497140, KF676502), *Cryptops japonicus* (AB610778), *Cryptops niuensis* (JF273296, JF273294), *Cryptops pictus* (JF273264, JF273262), *Cryptops punicus* (KF676503), *Cryptops sarasini* (JF273306), *Cryptops trisulcatus* (KF676504), *Cryptops* sp. (T128039, T126647), *Cryptops* '06' (T136352, T136353, T128042, T128032, T128069), *Cryptops* '07' (T126644, T126674), *Cryptops* '13' (T112190), *Cryptops* '15' (T124753, T124750), *Cryptops* '16' (T124748, T126657), *Cryptops* '17' (T118071, T126662), *Cryptops* '18' (T136354), *Cryptops* 'K1' (ESV181007), *Cryptops* 'G1' (T149105, T149106)
Outgroup	*Lithobius agilis* (JN306649)

Table 10. Sample composition for the Diplopoda analysis

Sample type	Samples
Target samples	**Trigoniulidae** (**Spirobolida**)**:** *Austrostrophus* sp. (AES190083, AES190344, AES190028, AES190074, AES190092); **Paradoxosomatidae** (**Polydesmida**)**:** *Antichiropus* sp. (AES190104, AES190040, AES190321, AES190067).
Reference samples	**Trigoniulidae** (**Spirobolida**)**:** *Austrostrophus* sp. (T101121, T101128); **Paradoxosomatidae** (**Polydesmida**)**:** *Antichiropus anguinus* (MK735847), *Antichiropus apricus* (MK735886, MK735892), *Antichiropus cirratus* (MK735904, MK735906, MK735861), *Antichiropus cunicularis* (MK735862, MK735889), *Antichiropus* DIP019 (T128169), *Antichiropus* DIP174 (MH932612), *Antichiropus forcipatus* (MK735872, MK735882), *Antichiropus* G1 (ESV18:0003), *Antichiropus* 'G2' (ESV18:0434), *Antichiropus nimbus* (MK735887), *Antichiropus pendiculus* (MK735849, MK735923), *Antichiropus simmonsi* (MK735891), *Antichiropus sloanae* (MK735877, MK735888), *Antichiropus* sp. (ESV18:0440, ESV18:0449), *Antichiropus uvulus* (MK735848, MK735893), *Antichiropus variabilis* (JN637337, JN637362), *Antichiropus verutus* (MK735851, MK735860), *Antichiropus* 'wonmunna' (T118101), *Antichiropus whistleri* (JN637364, JN637365).
Outgroup	*Polyzonium germanicum* (JQ350463), order Polyzoniida

3 RESULTS

3.1 SELENOPIDAE (ARANEOMORPHAE)

Karaops banyjima (Figure 1)**.** The two target samples of *Karaops* differed from each other by 4.6% sequence divergence, indicating that they are likely to be conspecific Figure 1. These samples grouped with other samples also likely to represent *Karaops banyjima* but not previously identified (T134092, T134104, T139710, T139711, T139718, T139720, T139722, T139723, T139724, T139730). These samples differed from each other by 2.3% - 7.59%. These sampled differed from all other samples in the analysis by 7.56% or more sequence divergence.

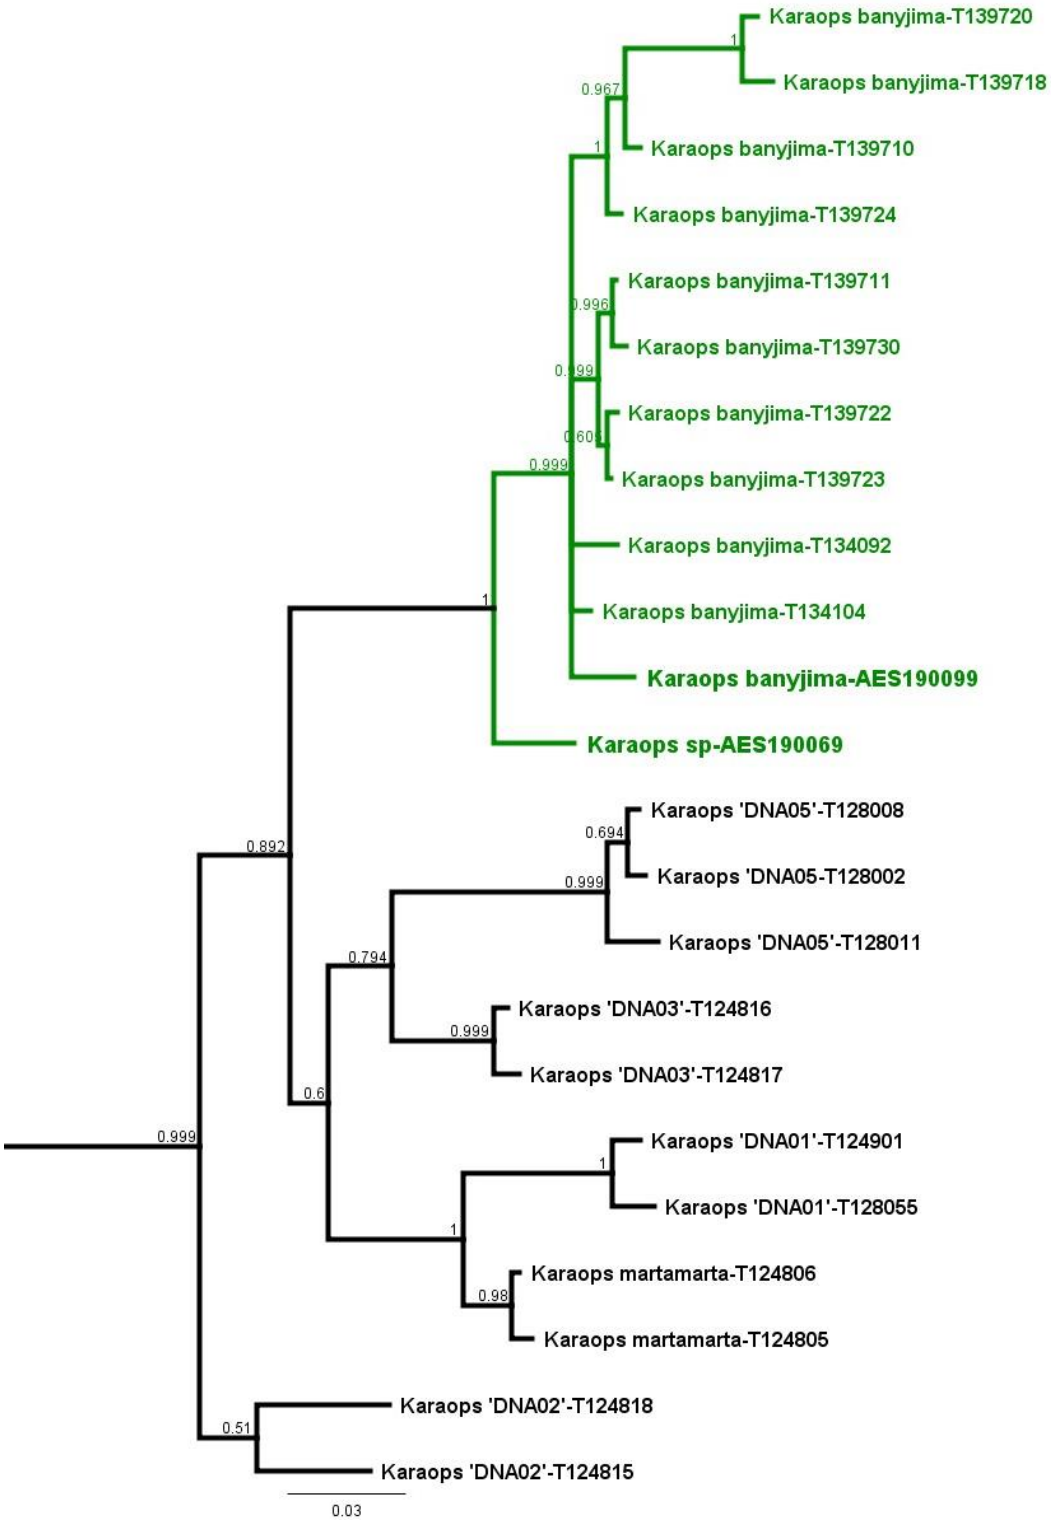

Figure 1 Phylogenetic relationships between *Karaops* samples analysed based on COI DNA sequences: *Karaops banyjima* clade in green, branch labels represent posterior probabilities; scale bar represents substitutions per site.

3.2 BARYCHELIDAE (MYGALOMORPHAE)

The analysis yielded a poorly resolved phylogeny with none of the ingroup genera being monophyletic (Figure 2)

Synothele **'MYG309'** (Figure 2)**.** Sample AES190063 was most similar to *Synothele* 'MYG309' (KJ744894, KJ744794) and differed from these samples by 2.66% and 9.19% sequence divergence respectively, indicating that they are likely to represent the same species. These three samples differed from all others included in this study by 9.57% or more sequence divergence.

Synothele **'MYG311'** (Figure 2)**.** Sample AES190039, grouped with four samples of *Synothele* 'MYG311' (KJ744654, KJ745445, KJ744869, KJ745034) and differed from these samples by 1.37% - 2.79% sequence divergence, indicating that they are conspecific. These five samples differed from all other samples in the analysis by 12.46% or more sequence divergence.

Aurecocrypta **'HD1'** (Figure 2)**.** Sample AES190082 differed from all other samples in the analysis by 9.75% or more sequence divergence indicating that it may not be conspecific with any of the species included in the analysis. The phylogenetic analysis placed this species as a sister to *Aurecocrypta* 'MYG317' (KJ744547) from which it differed by 11.03% sequence divergence. Sample AES190082 was placed in a clade comprising nine other samples of *Aurecocrypta* therefore it is cautiously regarded as a representative of this genus and is here referred to as *Aurecocrypta* 'HD1'.

Aurecocrypta **'MYG315'** (Figure 2)**.** Sample AES190347 grouped with two samples of *Aurecocrypta* 'MYG315' (KJ744636, KJ744575) and differed from these samples by 0.46% and 7.29% sequence divergence respectively. This sample therefore represents *Aurecocrypta* 'MYG315' and these three samples differed from all others in the analysis by 11.09% or more sequence divergence.

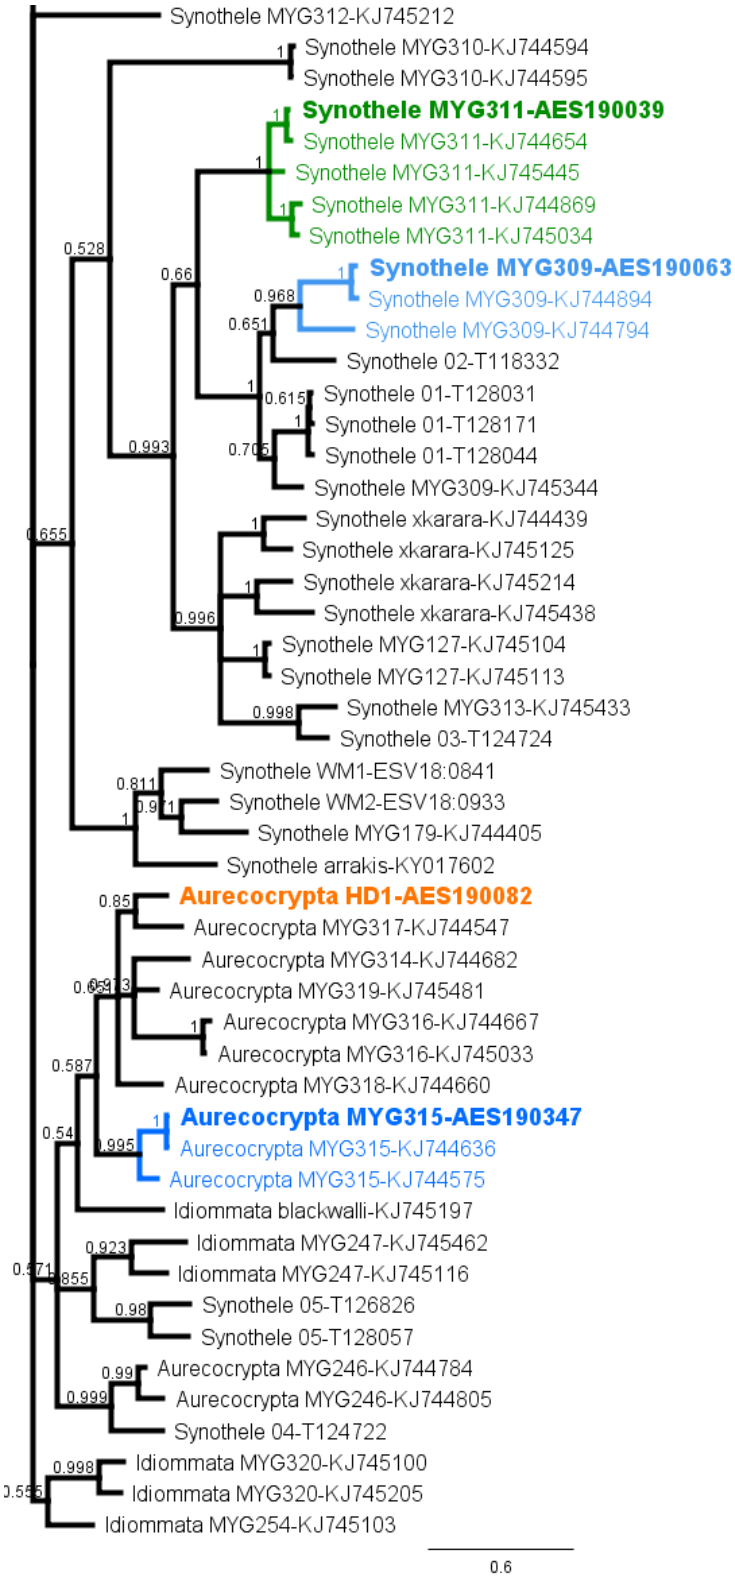

Figure 2 Phylogenetic relationships between samples of Barychelidae based on the analysis of COI DNA sequences: shaded clades represent target taxa and conspecific samples; taxa in bold text; branch labels represent posterior probabilities; scale bar represents substitutions per site.

3.3 IDIOPIDAE (MYGALOMORPHAE)

Gaius tealei (Figure 3)**.** The target samples AES190072 and AES190101 differed from one another by 0.15% sequence divergence, indicating that they are representatives of the same species. The phylogenetic analysis grouped them with *Gaius tealei* (KJ745055), from which they differed by 3.05% sequence divergence, indicating that they are likely to belong to this species (Figure 3). These samples differed from all others in the analysis by more than 15.42% sequence divergence or more.

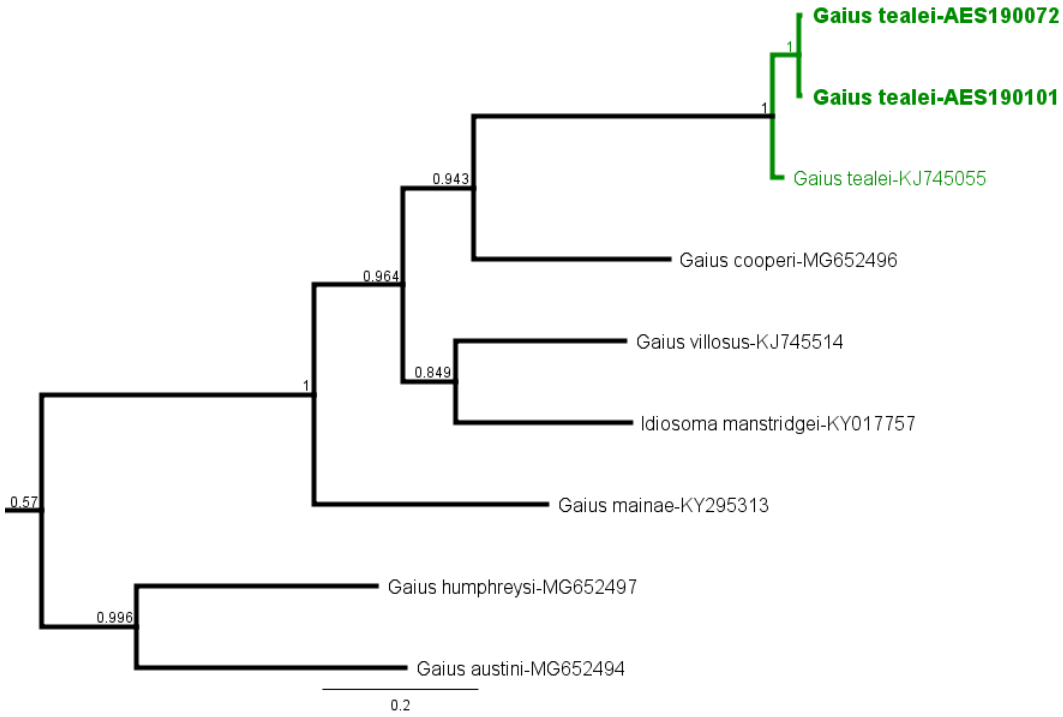

Figure 3 Subclade from the phylogeny of Idiopidae showing relationships between the targeted samples: target taxa in bold text; green clade, *Gaius tealei* branch labels represent posterior probabilities; scale bar represents substitutions per site.

3.4 NEMESIIDAE (MYGALOMORPHAE)

***Yilgarnia* 'MYG197'.** Sample AES190050 matched with a sample of *Yilgarnia* 'MYG197' and differed from it by 4.86% COI sequence divergence, indicating that they are conspecific. *Yilgarnia* 'MYG197' was placed in a clade dominated by other *Yilgarnia* sequences (Figure 4) indicating that the original placement of this sample into *Kwonkan* was incorrect and that *Yilgarnia* is the correct genus.

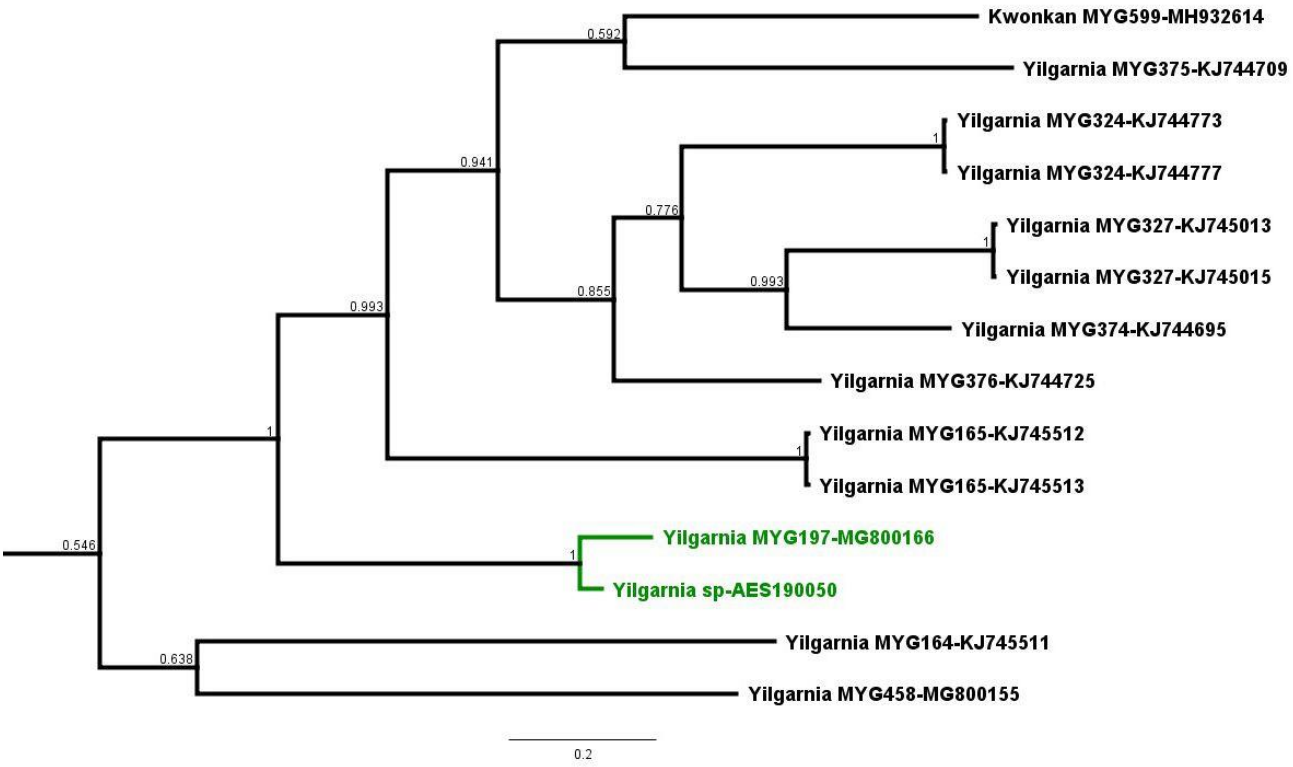

Figure 4. Clade of mostly *Yilgarnia* from the analysis of target Nemesiidae: branch labels represent posterior probabilities; scale bar represents substitutions per site.

3.5 OLPIIDAE AND CHTHONIIDAE (PSEUDOSCORPIONES)

***Beierolpium* 'HD1'** (Figure 5)**.** Sample AES190331 differed from all other samples in the analysis by 11% or more sequence divergence, indicating that is unlikely to be conspecific with any of the species included in this study. The most similar species was represented by sample AES190341.

***Beierolpium* 'HD2'** (Figure 5)**.** Sample AES190341 differed from all other samples in the analysis by 11% or more sequence divergence, indicating that is unlikely to be conspecific with any of the species included in this study.

***Beierolpium* 'HD3'** (Figure 5)**.** Sample AES190012 differed from all other samples in the analysis by 19.92% or more sequence divergence, indicating that is unlikely to be conspecific with any of the species included in this study.

In this analysis, *Beierolpium* was monophyletic, supporting the placement of these samples in this genus.

***Indolpium* 'HD4'** (Figure 5)**.** Sample AES190014 differed from all other samples in the analysis by 15.29% or more sequence divergence, indicating that it is unlikely to be conspecific with any of the species included in this study. This sample was placed basely on a monophyletic *Indolpium* clade confirming its placement within this genus.

***Austrohorus* 'HD5'** (Figure 5)**.** Sample T146556 differed from all other samples in the analysis by 15.29% or more sequence divergence, indicating that is unlikely to be conspecific with any of the species included in this

study. This sample was not monophyletic with the remaining *Austrohorus* samples in the analysis. This taxon is grouped in a polytomy with *Apolpium*, *Austrohorus* and (*Xenolpium* + 'Genus 7/4') making assignment to genus problematic. For the purpose of this study, the sample is regarded as a representative of *Austrohorus* and additional data will need to be included to resolve the placement of this taxon.

'Genus 7/4 PSE118' (Figure 5)**.** Four samples (T146559, T146561, AES190079 and T146562) differed from one another by 1.18% (6.63% sequence divergence indicating that they are likely to represent a single taxon. These samples differed from 'Genus 7/4 PSE118' (T139690) by 7.04% (7.44% sequence divergence, indicating that they are conspecific with this taxon. These samples of 'Genus 7/4 PSE118' differed from all other samples in the analysis by 15.65% or more sequence divergence. Samples AES146559, AES146561, AES190079 and AES146562 were previous incorrectly regarded as species of *Indolpium* (Alacran 2019).

***Euryolpium* 'HD6'** (Figure 5). Sample AES146557 differed from all other samples in the analysis by 15.04% or more sequence divergence, indicating that is unlikely to be conspecific with any of the species included in this study. This sample was previously not assigned to *Beierolpium* (Alacran 2019); however this study placed the sample in a clade containing a species of *Euryolpium*. This taxon is therefore regarded as a representative of the genus *Euryolpium*.

***Euryolpium* 'HD7'** (Figure 5). Sample AES146564 differed from all other samples in the analysis by 15.04% or more sequence divergence, indicating that is unlikely to be conspecific with any of the species included in this study. This sample was previously not assigned to any genus (Alacran 2019); however this study placed the sample in a clade containing a species of *Euryolpium*. This taxon is therefore regarded as a representative of the genus *Euryolpium*.

***Tyrannochthonius* 'HD1'**, AES146555) and ***Tyrannochthonius* 'HD2'**, AES190330 (Figure 5). The two target samples differed from one another by 13.13% sequence divergence, indicating that they are unlikely to be conspecific. These samples also differed from all other samples in the analysis by 17% or more sequence divergence, indicating that they are not conspecific with the two samples of *Tyrannochthonius aridus* from Genbank.

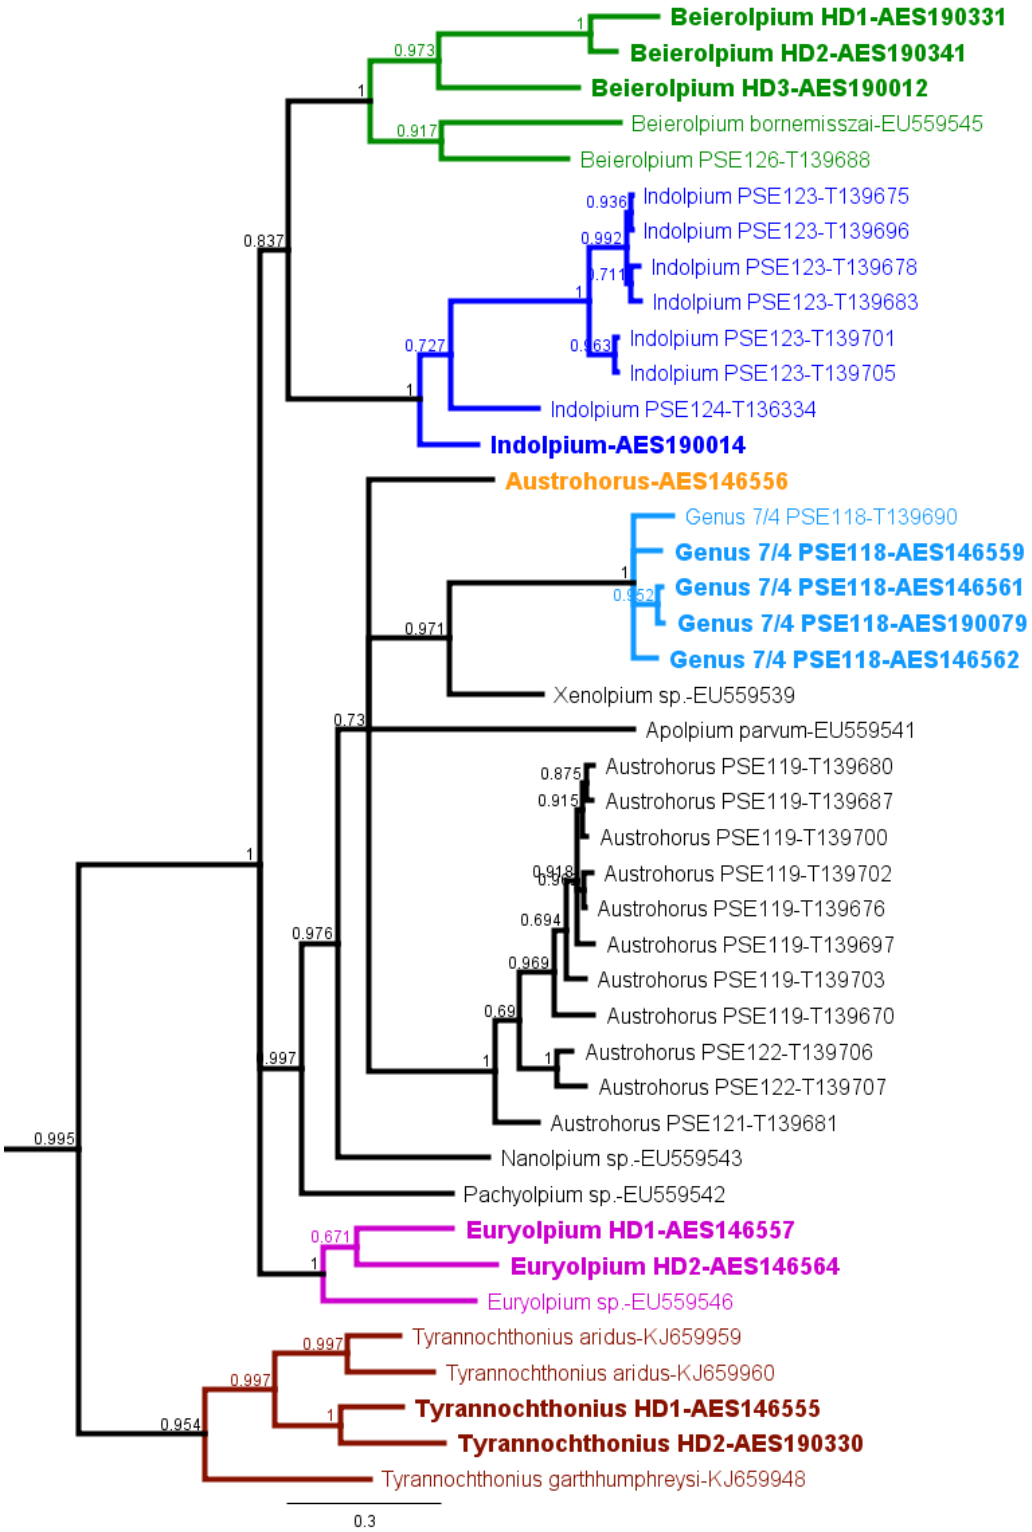

Figure 5. Phylogeny of pseudoscorpions included in this study with monophyletic clades shaded, target samples in bold; branch labels represent posterior probabilities; scale bar represents substitutions per site.

3.6 BUTHIDAE (SCORPIONES)

The phylogenetic analysis of these species produced a very poorly structured phylogeny (Figure 6).

***Lychas* 'bituberculatus cmplx'** (Figure 6)**.** Sample AES190065 was most similar to T91706 and differed from it by 0.94% sequence divergence, confirming that these belonging to the same species, thus supporting the placement of this species within this species complex. These two samples differed from other species in this complex (EVR7959, T97380, T91706) by between 10.03% and 10.53% sequence divergence. These five samples differed from all others in the analysis by 8.81% or more sequence divergence, further highlighting the confusing relationships between species in this genus.

***Lychas* 'multipunctatus cmplx'** (Figure 6)**.** Sample AES190080 was most similar to EVR7974 and differed from it by 1.82% sequence divergence, confirming that these belonging to the same species, thus supporting the placement of this species within this species complex. These two samples differed from all others in the analysis by 8.81% or more sequence divergence.

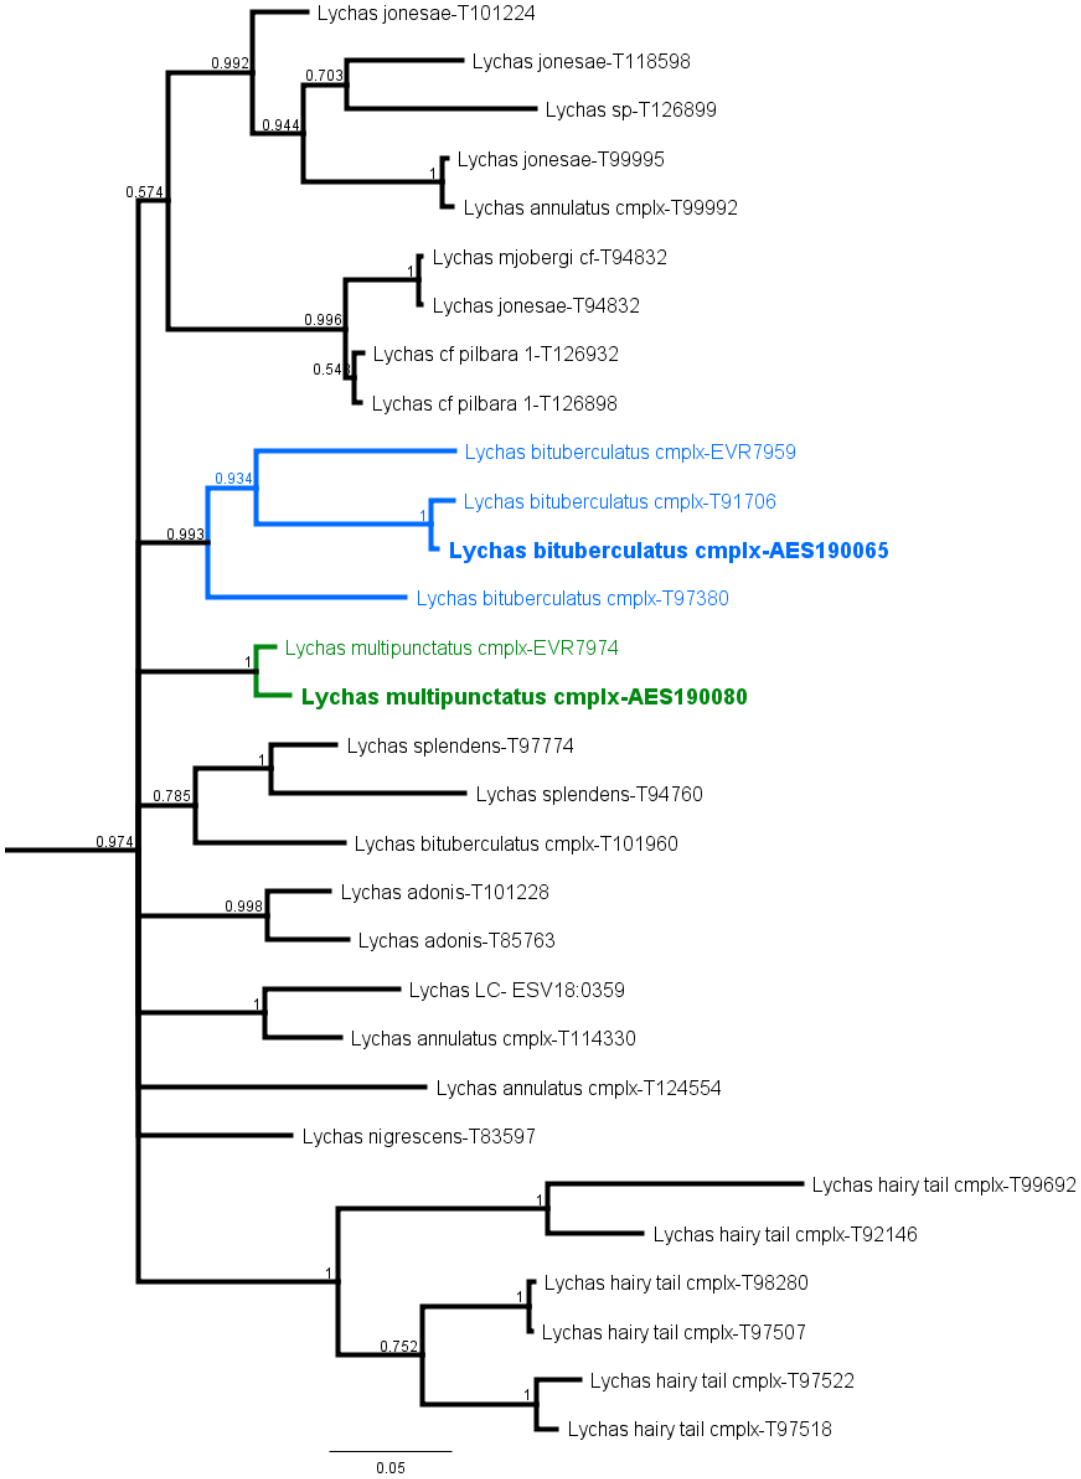

Figure 6. Phylogeny of *Lychas* species included in this study with monophyletic clades shaded, target samples in bold; branch labels represent posterior probabilities; scale bar represents substitutions per site.

3.7 URODACIDAE (SCORPIONES)

***Urodacus* 'HD1'** (Figure 7). Sample AES190076 showed no clear relationship with any of the samples included in the analysis Figure 7 and differed from all of them by 8.05% or more sequence divergence. The average divergence between this species and all other *Urodacus* samples in this study was 9.9% suggesting that the species delimiting threshold is likely to be less than 9% sequence divergence. Of the unambiguous species pairs analyses in this study, *Urodacus novaehollandiae* (EVR1540, EVR7993) showed the greatest divergence between specimens at 7.48% sequence divergence, suggesting that this may represent a more appropriate delimiting threshold for species of *Urodacus*. Sample AES190076 is here referred to as *Urodacus* 'HD1'.

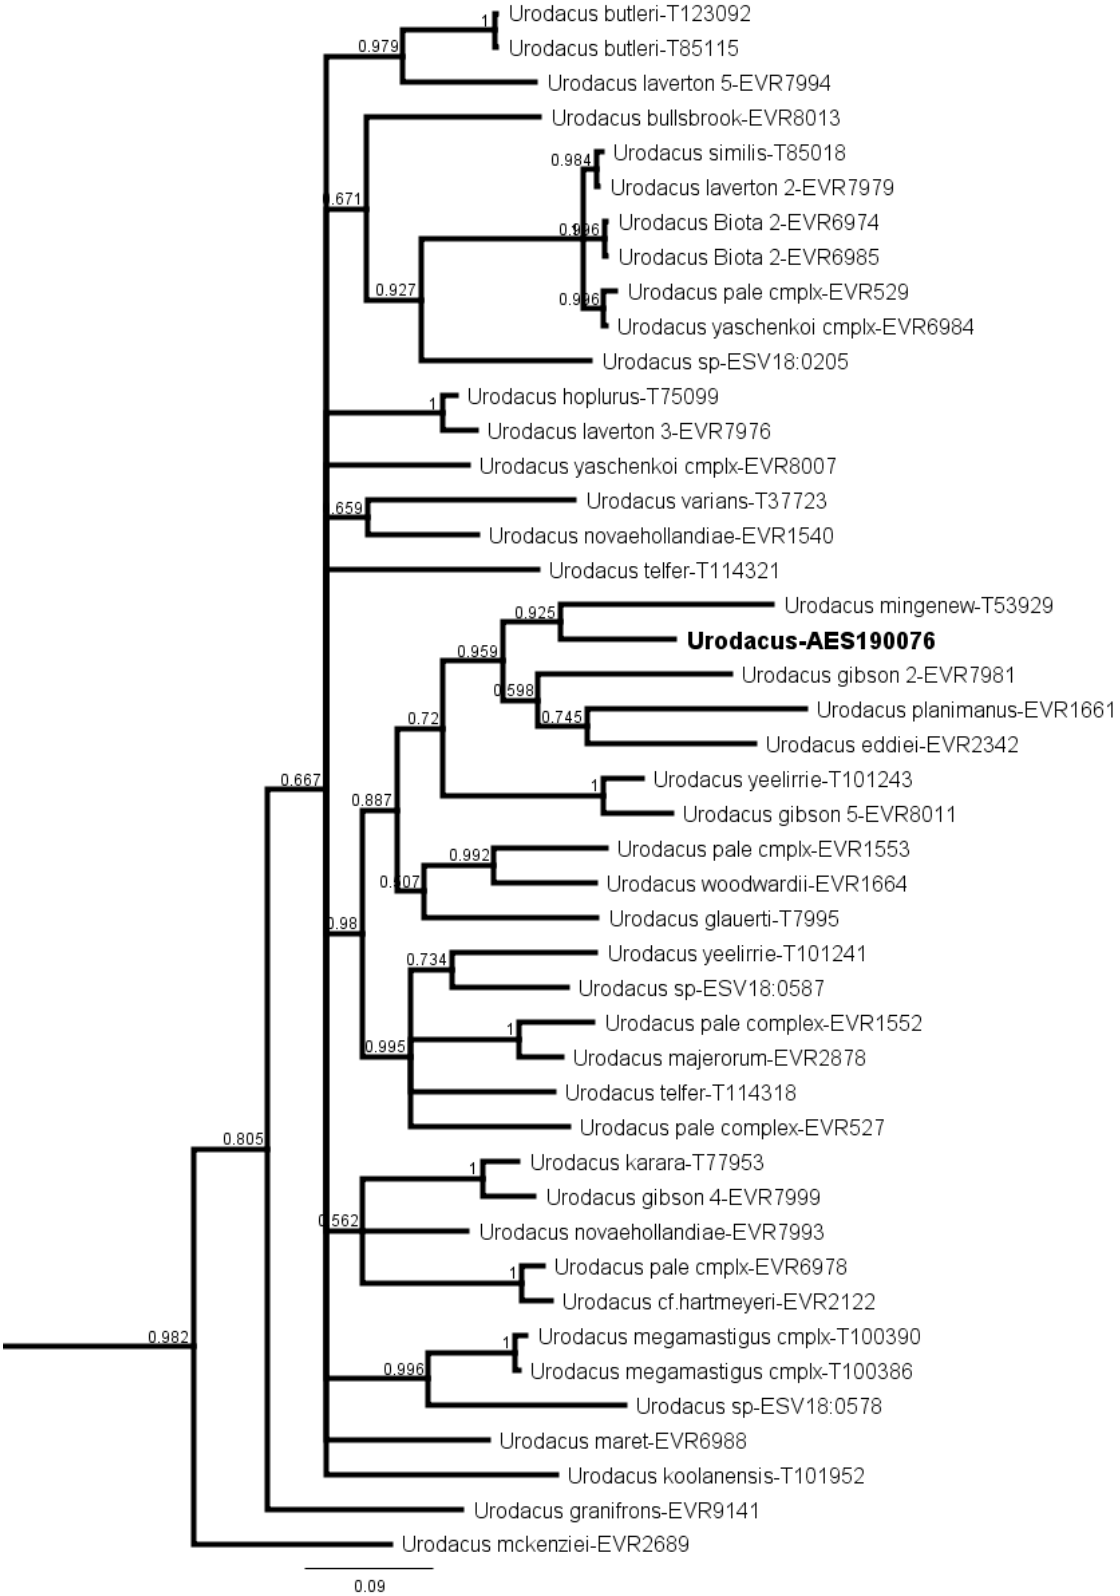

Figure 7. Phylogeny of *Urodacus* species and morphospecies included in this study: target sample in bold; branch labels represent posterior probabilities; scale bar represents substitutions per site.

3.8 CHILENOPHILIDAE, MECISTOCEPHALIDAE AND ORYIDAE (GEOPHILOMORPHA)

***Sepedenophilous* 'HD1'** (Figure 9)**.** Seven target taxa grouped together (AES190305, T146570, AES190306, AES190006, AES190077, AES190007, AES190106) with 0% - 7.34% sequence divergences. These samples differed from all others in the analysis by 12.23% or more sequence divergence.

***Sepedenophilus* 'HD2'** (Figure 9)**.** Sample AES190061 differed from all other samples in the analysis by 19.44% sequence divergence, therefore this species is not conspecific with any in the analysis. The sample was placed within a monophyletic clade of *Sepedenophilous* samples and is here referred to ad *Sepedenophilous* 'HD2'.

***Mecistocephalus* 'HD1'** (Figure 9)**.** Four samples (AES190338, AES190335, AES190336, AES190308) grouped together and differed from one another by 0.16% - 1.1% sequence divergence, indicating that they are conspecific. These samples differed from all other samples in the analysis by 10.97% or more sequence divergence. This species is here referred to as *Mecistocephalus* 'HD1'. Among the samples identified to this taxon, was one that was previously misidentified as a species of *Sepedenophilous* (AES190338) and one sample that could not be identified, Geophilomorpha sp. (AES190308) (Alacran 2019)

***Mecistocephalus* 'HD2'** (Figure 9). Sample (AES190337) differed from all others in the analysis by 10.97% or more sequence divergence. This sample could originally not be placed in a family or genus but was here placed in a monophyletic clade of *Mecistocephalus*. This species is here referred to as *Mecistocephalus* 'HD2'.

***Mecistocephalus* 'HD3'** (Figure 9)**.** Sample AES190322 grouped closely with AES190313 0.31% sequence divergence indicating that they are conspecific. These samples differed from all other sin the analysis by 18.03% or more sequence divergence. These samples were placed in a monophyletic clade of *Mecistocephalus*. These two samples are here referred to as *Mecistocephalus* 'HD3'. Sample AES190322 was originally misidentified as a species of *Orphnaeus* and sample AES190313 could not be identified to family or genus (Alacran 2019).

***Orphnaeus* 'HD1'** (Figure 9)**.** Sample AES190103 differed from all samples in the analysis by 15.09% or more sequence divergence, indicating that it is not conspecific with any of those species. This species was placed in a clade containing was placed in monophyletic clade of *Orphnaeus*, thus supporting its placement in this genus. This species is here referred to as *Orphnaeus* 'HD1'.

3.9 CRYPTOPIDAE (SCOLOPENDROMORPHA)

***Cryptops* 'HD1'** (**Figure 8**)**.** The three target taxa grouped together (AES190315, AES190318, AES190319) with 2.81% - 3.5% sequence divergences between them. These samples differed from all others in the analysis by 19.04% or more sequence divergence, indicating that they represent a unique taxon relative to those included in this study. This species is here referred to as *Cryptops* 'HD1'.

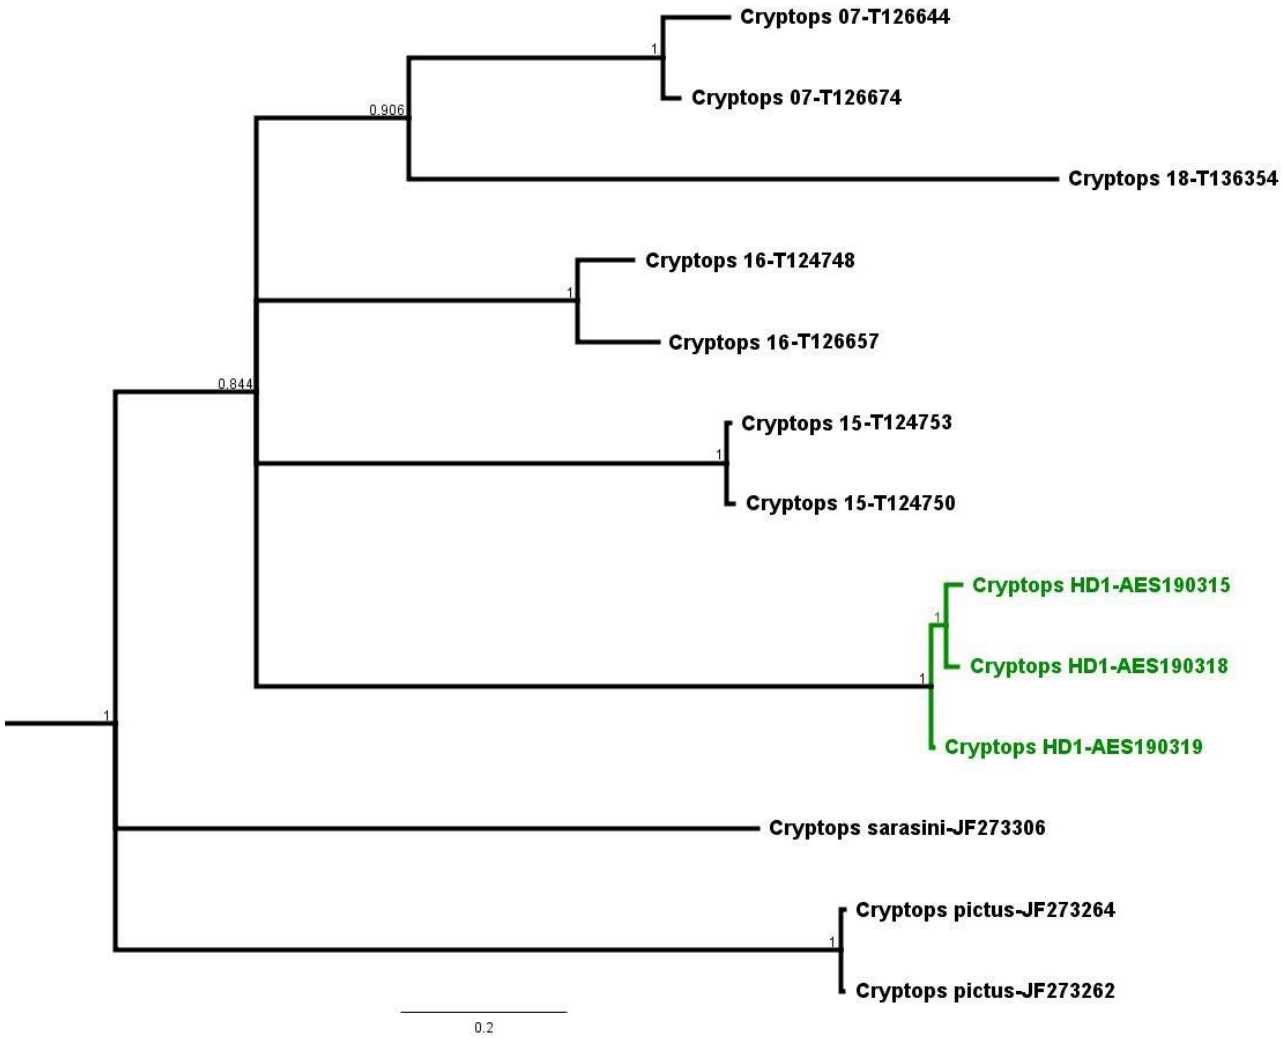

Figure 8. Sub-clade of the Cryptopidae phylogeny: target sample in green; branch labels represent posterior probabilities; scale bar represents substitutions per site.

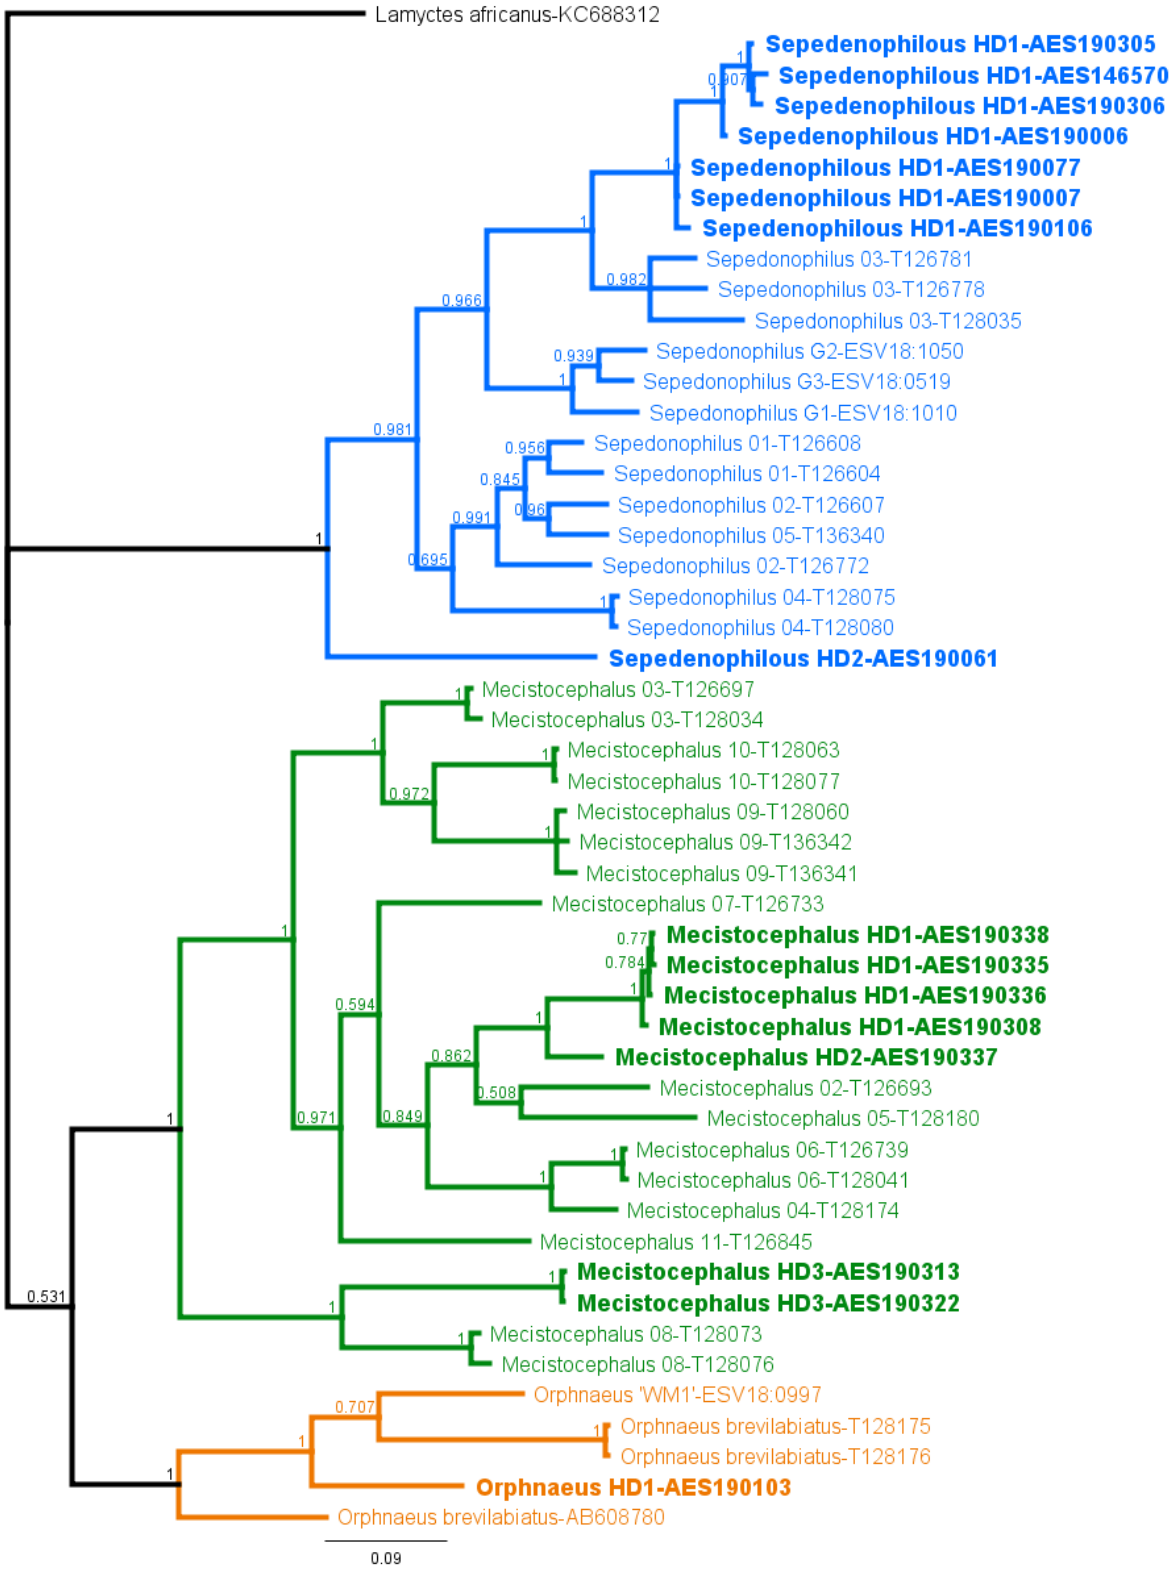

Figure 9. Phylogeny of Geophilomorpha: blue, *Sepedenophilus* clade; green, *Mecistocephalus* clade; orange, *Orphnaeus* clade; target samples in bold; branch labels represent posterior probabilities; scale bar represents substitutions per site.

3.10 TRIGONIULIDAE (SPIROBOLLIDA)

***Austrostrophus* 'HD1'** (Figure 10), was represented by three samples (T101128, T101121, AES190092) which differed from each other by 0.76% - 3.81% sequence divergence.

***Austrostrophus* 'HD2'** (Figure 10), was represented by four samples (AES190083, AES190028, AES190344, AES190074) which differed from each other by 0% - 0.46% sequence divergence.

Austrostrophus 'HD1' and *Austrostrophus* 'HD2' differed from each other by 7.7% - 8.38% sequence divergence with an average of 8.04% sequence divergence. The level of sequence divergence within the two groups was substantially less than the variation between these groups, indicating the likely hood that two lineages are present.

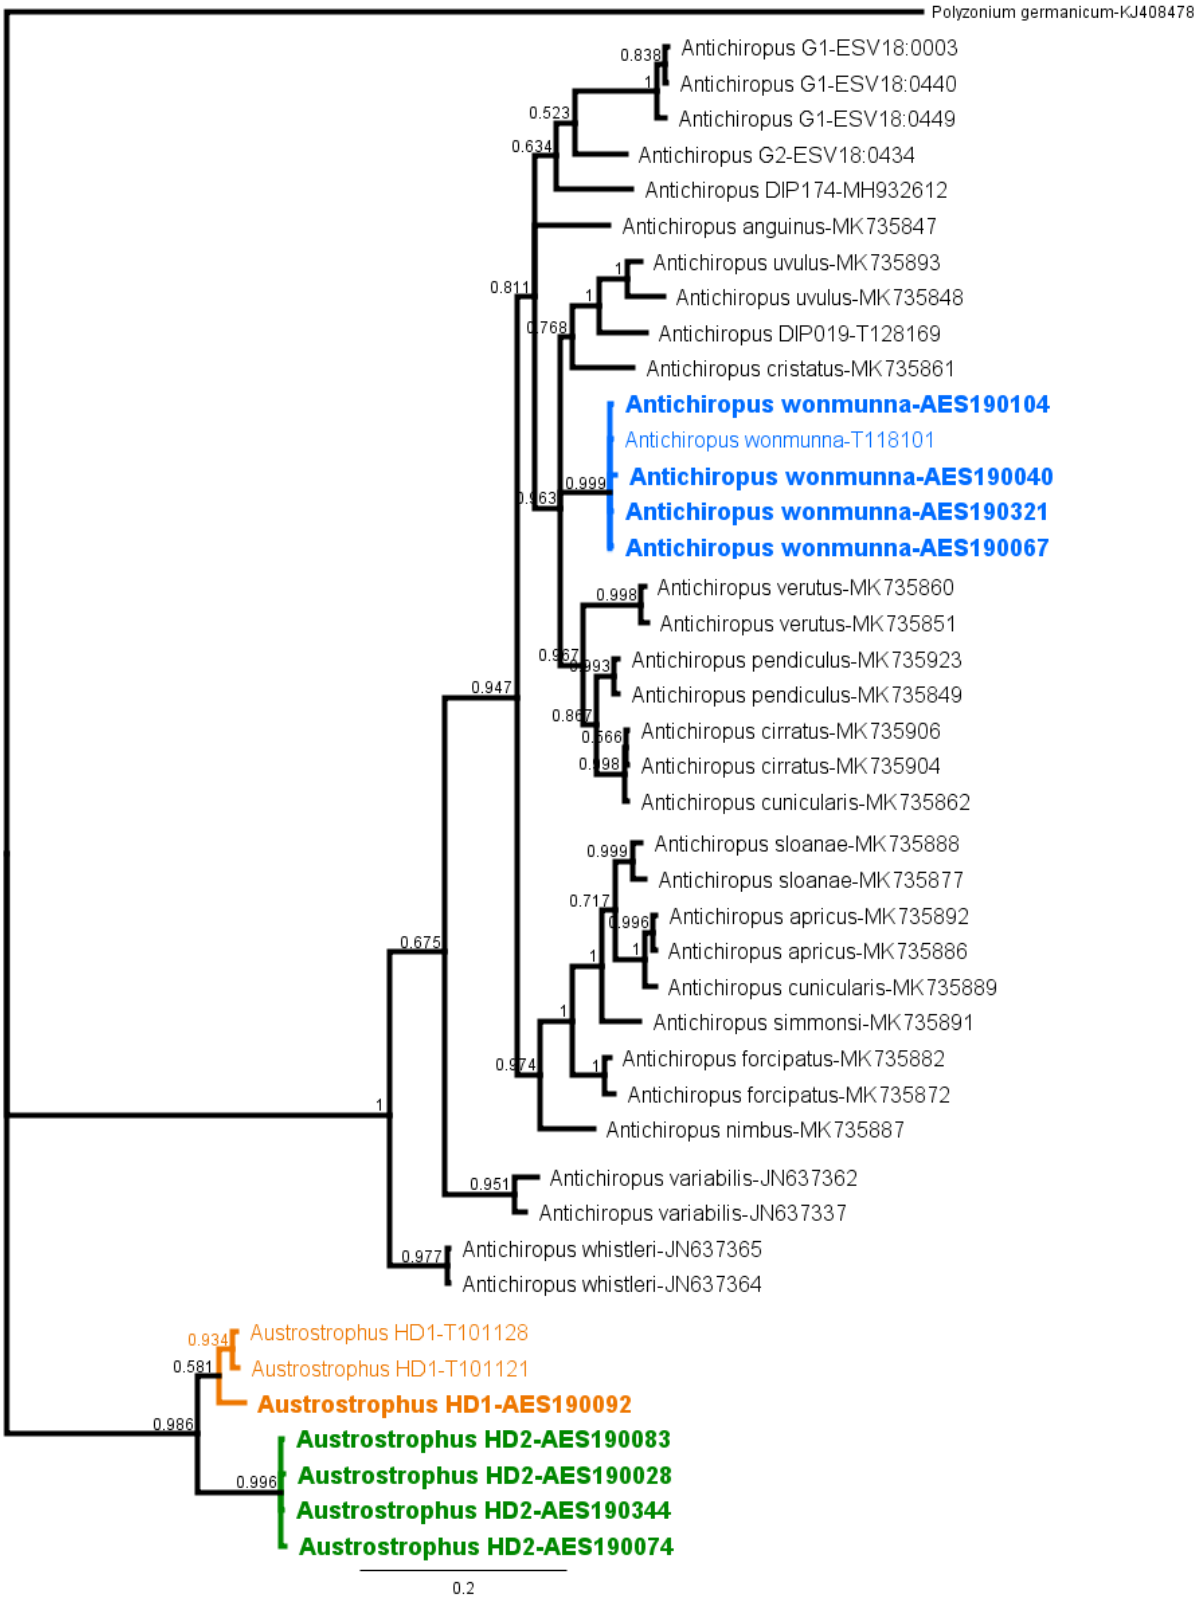

Figure 10. Phylogeny of millipedes included in this study with monophyletic clades shaded: target samples in bold; branch labels represent posterior probabilities; scale bar represents substitutions per site.

3.11 PARADOXOSOMATIDAE (POLYDESMIDA)

***Antichiropus* 'wonmunna'** (Figure 10)**.** The target samples differed from one another by 0% - 0.46% sequence divergence. These samples grouped with the sample of *Antichiropus* 'wonmunna' (T118101) and differed from it by between 0% - 0.45% sequence divergence, indicating that they are conspecific. These samples differed from all other *Antichiropus* samples in the analysis by 6.5% or more sequence divergence.

4 DISCUSSION

This study identified 30 species form 53 samples, of which 10 taxa represent species or morphospecies previously known from the Pilbara:

- *Karaops banyjima*: (AES190069, AES190099), a potential SRE: DD;
- *Aurecocrypta* 'MYG315' (AES190347), a potential SRE: DD;
- *Synothele* 'MYG311' (AES190039), a potential SRE: DD;
- *Synothele* 'MYG309' (AES190063), a potential SRE: DD;
- *Gaius tealei* (AES190072, AES190101), widespread;
- *Yilgarnia* 'MYG197' (AES190050), potential SRE: DD;
- 'Genus 7/4 PSE118' (T146562, T146561, T146559, AES190079), potential SRE: DD;
- *Lychas* 'bituberculatus cmplx' (AES190065), potential SRE: DD;
- *Lychas* 'multipunctatus cmplx' (AES190080), potential SRE: DD;
- *Antichiropus* 'wonmunna' (AES190321, AES190104, AES190067, AES190040), potential SRE: DD.

Twenty-two taxa identified here could not be matched with available sequences:

- *Aurecocrypta* 'HD1' (AES190082),
- *Beierolpium* 'HD1' (AES190331),
- *Beierolpium* 'HD2' (AES190341),
- *Beierolpium* 'HD3' (AES190012),
- *Indolpium* 'HD4'(AES190014),
- *Austrohorus* 'HD5' (T146556),
- *Euryolpium* 'HD6' (T146557),
- *Euryolpium* 'HD7' (T146564),
- *Tyrannochthonius* 'HD1' (T146555),
- *Tyrannochthonius* 'HD2'(AES190330),
- *Urodacus* 'HD1' (AES190076),
- *Mecistocephalus* 'HD1' (AES190336, AES190335, AES190308, AES190338),
- *Mecistocephalus* 'HD2' (AES190337),
- *Mecistocephalus* 'HD3' (AES190313, AES190322),
- *Sepedenophilous* 'HD1' (AES190305, AES190306, AES190077, AES190006, T146570, AES190007, AES190106),
- *Sepedenophilus* 'HD2' (AES190061),
- *Orphnaeus* 'HD1' (AES190103),
- *Cryptops* 'HD1' (AES190315, AES190318, AES190319),

- *Austrostrophus* 'HD1' (AES190092),
- *Austrostrophus* 'HD2' (AES190028, AES190344, AES190074, AES190083).

These taxa all have distribution and taxonomic characteristics that make them potential SREs. There is potential for the WA Museum to have sequences that could provide additional information regarding the relationships of the following taxa: *Aurecocrypta* 'HD1', *Beierolpium* 'HD1' (AES190331), *Beierolpium* 'HD2', *Beierolpium* 'HD3', *Indolpium* 'HD4', *Austrohorus* 'HD5', *Euryolpium* 'HD6', *Euryolpium* 'HD7', *Tyrannochthonius* 'HD1', and *Tyrannochthonius* 'HD2'.

Molecular identification of terrestrial arthropods from north west of Newman, Western Australia (project 1912)

Report to *Alacran Environmental Science*

11 October 2019

Nerida Wilson, Joel Huey, Mark Harvey

Molecular Systematics Unit & Department of Terrestrial Zoology,
Western Australian Museum,
Locked Bag 49, Welshpool DC, Western Australia 6986, Australia

Although identifications in this report were consistent with the best available information and current scientific thinking at the time of identification the use of this report is at the risk of the user. Any liability to users of this report for loss of any kind arising out of the use of this report or the information and identifications it contains is expressly disclaimed.

Summary

Alacran Environmental Science requested identification of mitochondrial COI sequences from specimens of terrestrial invertebrates from the Pilbara region of Western Australia. This comprised of 19 sequences from Barychelidae, Buthidae, Chthoniidae, Olpiidae, Selenopidae, Trigoniulidae and Urodacidae (see Table 1 and Appendix 1 for sequence and specimen details). The main objectives of the WA Museum's Molecular Systematics Unit (MSU) were to use these sequences to determine the taxonomic identity of the specimens.

Provided DNA sequences were each BLASTED against publically accessible sequences in GenBank and with data sets derived from current research projects at WA Museum. The top 20 blast hits for each major taxon were gathered, duplicates removed, and analysed with a Maximum Likelihood phylogenetic analysis using a GTR+G model of evolution and 100 bootstraps (RAxML). Distances were calculated via tree-based estimates of identical bases in Geneious Prime 2019.2.1.

A summary of sequences queried is in Table 1.

Table 1. Summary of queried sequences supplied to WA Museum.

FAMILY	Total no. sequences
Barychelidae	1
Buthidae	2
Chthoniidae	2
Olpiidae	7
Selenopidae	2
Trigoniulidae	4
Urodacidae	1

Results

The sequencing was undertaken by Xytogen at the request of Alacran and reconciled sequences were passed on to WAM for analysis. COI DNA barcodes were compared to existing data held by the Western Australian Museum, and the publically accessible GenBank database. A summary of the comparison (BLAST results) is provided in Table 2. Excised relevant parts of the resulting Maximum Likelihood trees are provided in Appendix 2 for visualisation of genetic relationships. The raw sequence data is supplied for reference in Appendix 3.

Table 2. Summary of identifications of queried specimens.

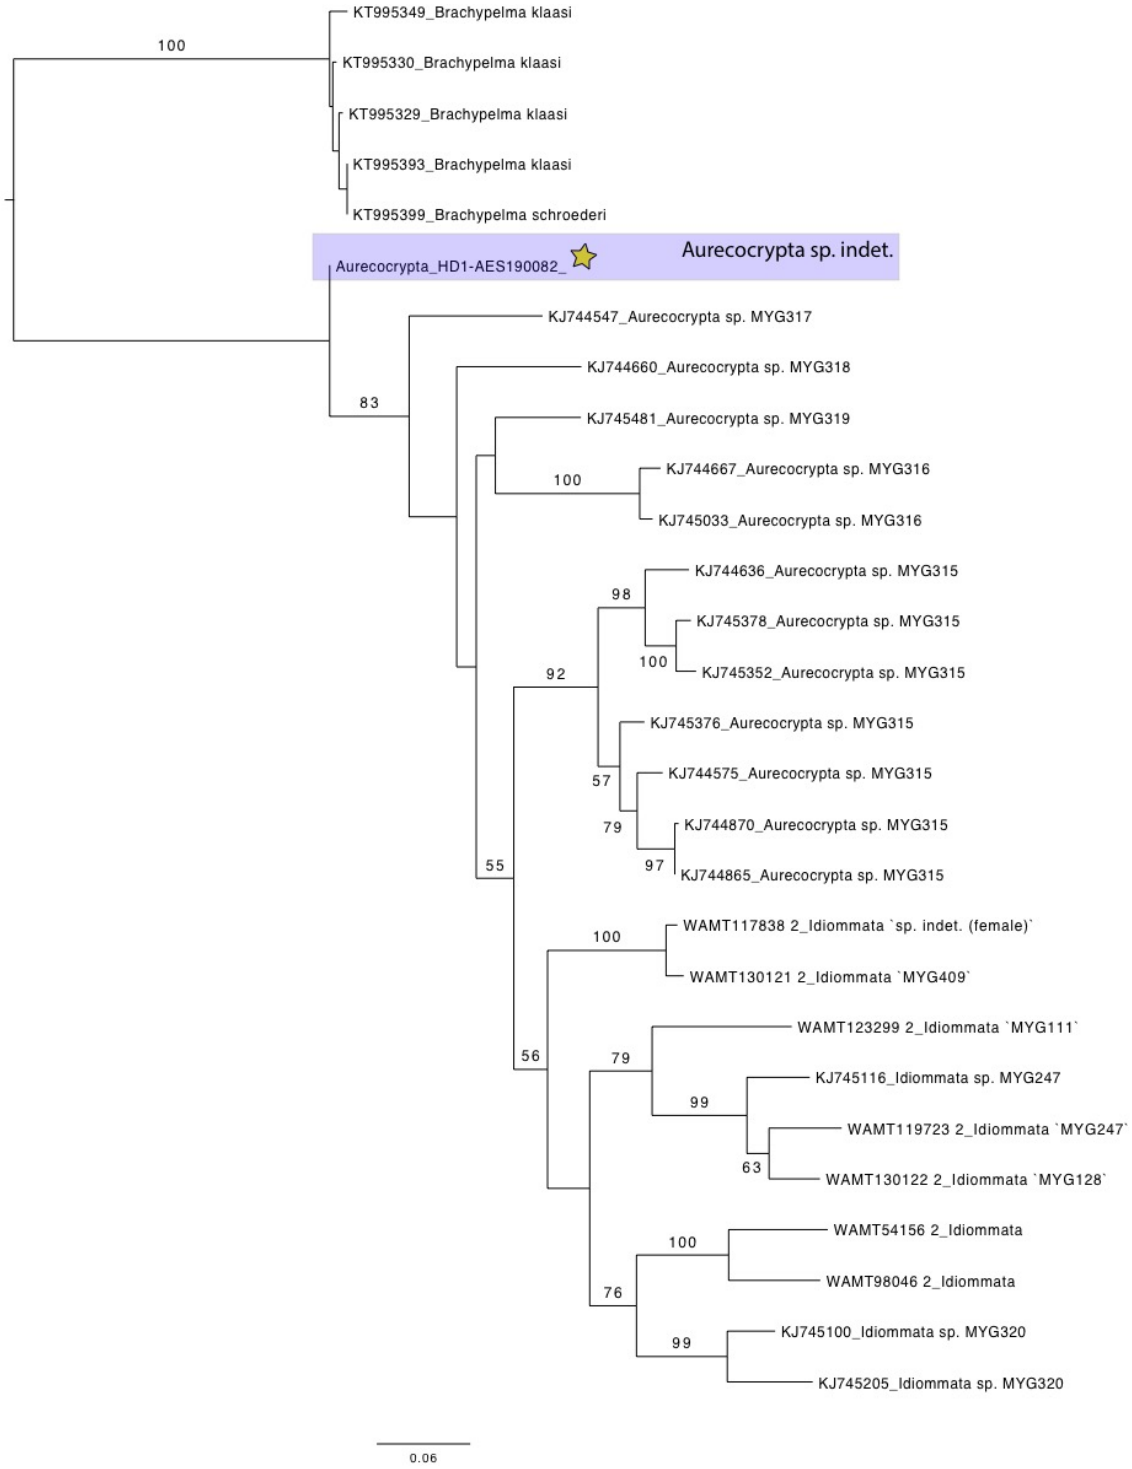
REGNO (FIELD NO)	FAMILY	SPECIES DESIGNATION	SUMMARY OF RESULTS
AES190082	Barychelidae	*Aurecocrypta* sp. indet.	This specimen forms a basal grade to many other *Aurecocrypta* species. It shares 89.60% genetic pairwise similarity with *Aurecocrypta* MYG317. It either represents a newly discovered species or a not-yet-sequenced species. It can be given a MYG code once registered at WAM
AES190065	Buthidae	*Lychas* `bituberculatus' complex	This specimen falls into a well-supported clade known as the *L. 'bituberculatus*' complex, which has not yet been resolved taxonomically. It shares 99.85% genetic pairwise similarity with WAMT91703.
AES190080	Buthidae	*Lychas* `multipunctatus' complex	This specimen falls into a well-supported clade known as the *L. 'multipunctatus*' complex, which has not yet been resolved taxonomically. It shares 99.70% genetic pairwise similarity with WAMT97367.

AES190330	Chthoniidae	*Tyrannochthonius* sp. indet.	This specimen forms a sister relationship with T146555. The pair share 87.00% genetic pairwise similarity, which does not allow a conclusion about whether the two are conspecific or not. Further work on the group is needed to establish even a code-based system of names. It either represents a newly discovered taxon or a not-yet-sequenced taxon.
T146555	Chthoniidae	*Tyrannochthonius* sp. indet.	This specimen forms a well-supported sister relationship with AES190330. The pair share 87.00% genetic pairwise similarity, which does not allow a conclusion about whether the two are conspecific or not. Further work on the group is needed to establish even a code-based system of names. It either represents a newly discovered taxon or a not-yet-sequenced taxon.
T146556	Olpiidae	*Austrohorus* sp. indet.	This specimen's nearest relative in the tree is WAMT132648. The pair share 85.54% genetic pairwise similarity, which does not allow a conclusion about whether the two are conspecific or not. The identity of WAMT132648 is PSE099.
AES190012	Olpiidae	*Beierolpium* sp. 8/4	This specimen is highly supported as conspecific with WAMT132648. The pair share 99.79% genetic pairwise similarity. The identity of WAMT122168 is sp. 8/4.

AES190331 AES190341	Olpiidae	*Beierolpium sp. indet.*	These two specimens are highly supported as sister taxa. They share 88.57% genetic pairwise similarity and are likely conspecific. These either represent a newly discovered species or a not-yet-sequenced species.
T146557	Olpiidae	*Euryolpium* sp. indet.	This specimen is highly supported as conspecific with WAMT127762. The pair share 96.86% genetic pairwise similarity. The identity of WAMT127762 is unknown, as it represents a juvenile from West Angelas.
T146564	Olpiidae	*Euryolpium* sp. indet.	This specimen's nearest relative in the tree is WAMT135503. The pair share 84.40% genetic pairwise similarity. It either represents a newly discovered taxon or a not-yet-sequenced taxon.
AES190014	Olpiidae	*Genus PSEAAA* sp. indet.	This specimen is poorly supported as sister to WAMT113765. The pair share 86.39% genetic pairwise similarity, which does not allow a conclusion about whether the two are conspecific or not. The identity of WAMT113765 is an undescribed genus *PSEAAA* sp. indet.
AES190099	Selenopidae	*Karaops nyangumarta*	This specimen is highly supported as conspecific with WAMT134063 (and others). The pair share 98.88% genetic pairwise similarity. The identity of WAMT134063 is *Karaops nyangumarta.*

AES190069	Selenopidae	*Karaops* sp 'ARA001'	This specimen is highly supported as conspecific with WAMT130402 (and others). The pair share 97.29% genetic pairwise similarity. The identity of WAMT130402 is *Karaops 'ARA001'.*
AES190074 AES190028 AES190083	Trigoniulidae	*Austrostrophus* clade E	This specimen is highly supported as conspecific with WAMT100768 (and others). The pair share 99.54% genetic pairwise similarity. The identity of WAMT100768 is *Austrostrophus* clade E.
AES190092	Trigoniulidae	*Austrostrophus* clade A	This specimen is supported as conspecific with WAMT122166 (and others). The pair share 99.09% genetic pairwise similarity. The identity of WAMT122166 is *Austrostrophus* clade A.
AES190076	Urodacidae	*Urodacus* sp. indet.	This specimen is highly supported as sister taxon to WAMT91922 (and others). The pair share 93.49% genetic pairwise similarity, which does not yet allow a conclusion about whether they are conspecific or not. The closely related specimens are also unidentified at present.

Conclusions



The 19 sequences supplied represent sixteen different taxa, from ten different genera. Fifteen of those species are currently undescribed. Only one specimen can be identified to a valid species name. Many others belong to known but unnamed taxa, and many remain to be clarified at the species-level, which would rely on further research in the respective taxonomic groups.

Appendix 1. Specimen data for all specimens.

Appendix E: Fauna Species Lists

This page has been left blank intentionally.

Table E.1: Amphibian species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			NatureMap / DBCA	EPBC PMST	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA						
HYLIDAE											
Cyclorana maini	Sheep Frog					X		X			X
Cyclorana platycephala	Water-holding Frog					X					
Litoria rubella	Little Red Tree Frog					X			X	X	X
LIMNODYNASTIDAE											
Neobatrachus aquilonius	Northern Burrowing Frog					X					
Neobatrachus sutor	Shoemaker Frog					X					
MYOBATRACHIDAE											
Pseudophryne douglasi	Gorge Toadlet					X					
Uperoleia russelli	Northwest Toadlet					X					
Uperoleia saxatilis	Pilbara Toadlet					X					

Table E.2: Reptile species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA						
CHELUIDAE											
Chelodina steindachneri	Flat-shelled Turtle					X					
AGAMIDAE											
Gowidon longirostris						X		X	X	X	X
Ctenophorus caudicinctus	Ring-tailed Dragon					X		X	X	X	X
Ctenophorus isolepis	Military Dragon					X				X	
Ctenophorus nuchalis	Central Netted Dragon					X					
Ctenophorus reticulatus	Western Netted Dragon					X		X			
Diporiphora amphiboluroides	Mulga Dragon							X			
Diporiphora valens	Southern Pilbara Tree Dragon					X		X			
Pogona minor						X		X	X	X	
Tympanocryptis cephalus	Pebble Dragon					X		X			
DIPLODACTYLIDAE											
Crenadactylus ocellatus	Clawless Gecko					X					
Diplodactylus conspicillatus	Fat-tailed Gecko					X					
Diplodactylus granariensis rex						X					
Diplodactylus pulcher						X		X	X		
Diplodactylus savagei	Southern Pilbara Beak-faced Gecko					X		X			
Lucasium stenodactylum						X		X	X		X
Lucasium wombeyi						X		X	X		
Oedura fimbria	Marbled Velvet Gecko					X		X	X	X	X
Rhynchoedura ornata	Western Beaked Gecko					X		X	X		X
Strophurus elderi						X		X	X		
Strophurus jeanae						X					
Strophurus wellingtonae						X		X	X	X	X
CARPHODACTYLIDAE											
Nephrurus wheeleri cinctus						X		X		X	X

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA						
Underwoodisaurus seorsus	Pilbara Barking Gecko				P2	X		X			
GEKKONIDAE											
Gehyra pilbara						X					
Gehyra punctata						X		X	X	X	X
Gehyra purpurascens						X					
Gehyra variegata						X		X	X	X	X
Heteronotia binoei	Bynoe's Gecko					X		X		X	X
Heteronotia spelea	Desert Cave Gecko					X		X	X	X	
PYGOPODIDAE											
Delma butleri											X
Delma elegans						X		X			
Delma haroldi						X					
Delma nasuta						X		X	X		X
Delma pax						X		X	X	X	X
Delma tincta						X		X			
Lialis burtonis						X		X	X		X
Pygopus nigriceps						X		X			X
SCINCIDAE											
Carlia munda						X		X	X	X	X
Carlia triacantha						X		X			
Cryptoblepharus buchananii						X		X			
Cryptoblepharus plagiocephalus						X					
Cryptoblepharus ustulatus						X		X	X	X	
Ctenotus duricola						X		X			
Ctenotus grandis						X			X		X
Ctenotus hanloni						X					
Ctenotus helenae						X		X	X		
Ctenotus leonhardii						X					
Ctenotus pallasotus	Western Pilbara Lined Ctenotus								X		X

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA						
Ctenotus pantherinus	Leopard Ctenotus					X		X	X	X	X
Ctenotus robustus						X		X			
Ctenotus rubicundus						X					
Ctenotus rutilans						X		X	X		
Ctenotus saxatilis	Rock Ctenotus					X		X	X	X	X
Ctenotus schomburgkii						X		X	X	X	
Ctenotus serventyi						X					
Ctenotus uber						X		X			X
Cyclodomorphus melanops	Slender Blue-tongue					X		X			
Egernia cygnitos	Western Pilbara Spiny-tailed Skink					X					
Egernia depressa	Southern Pygmy Spiny-tailed Skink					X					
Egernia formosa						X			X	X	X
Eremiascincus pallidus	Western Narrow-banded Skink					X					
Eremiascincus richardsonii	Broad-banded Sand Swimmer					X					
Lerista bipes						X					
Lerista labialis						X					
Lerista macropisthopus remota					P2	X					X
Lerista muelleri						X		X	X		
Lerista neander						X		X	X		
Lerista timida						X		X			
Lerista verhmens						X		X			
Lerista zietzi						X		X			
Menetia greyii						X		X		X	X
Menetia surda						X		X			
Morethia ruficauda exquisita						X		X		X	X
Proablepharus reginae						X					

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA						
Tiliqua multifasciata	Central Blue-tongue					X		X	X		X
VARANIDAE											
Varanus acanthurus	Spiny-tailed Monitor					X		X	X	X	X
Varanus brevicauda	Short-tailed Pygmy Monitor					X		X	X		
Varanus bushi	Pilbara Mulga Monitor					X		X	X		
Varanus caudolineatus						X			X		
Varanus eremius	Pygmy Desert Monitor					X					
Varanus gouldii	Bungarra or Sand Monitor					X			X		
Varanus giganteus	Perentie					X		X			X
Varanus hamersleyensis	Southern Pilbara Rock Goanna					X					
Varanus panoptes	Yellow-spotted Monitor					X		X	X	X	X
Varanus pilbarensis	Pilbara Rock Monitor					X					
Varanus tristis tristis	Racehorse Monitor					X		X	X		X
TYPHLOPIDAE											
Anilios ammodytes									X		
Anilios ganei					P1	X					
Anilios grypus								X	X		
Anilios hamatus								X	X		X
Anilios waitii								X			
BOIDAE											
Antaresia perthensis	Pygmy Python					X		X			
Antaresia stimsoni	Stimson's Python					X					
Aspidites melanocephalus	Black-headed Python					X					
Liasis olivaceus barroni	Pilbara Olive Python		VU	VU		X	X				
ELAPIDAE											
Acanthophis wellsi	Pilbara Death Adder					X		X	X		
Brachyurophis approximans						X		X	X		

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA						
Demansia psammophis cupreiceps	Yellow-faced Whipsnake					X		X			X
Demansia rufescens	Rufous Whipsnake					X		X			
Furina ornata	Moon Snake					X		X		X	
Parasuta monachus						X		X			
Pseudechis australis	Mulga Snake					X		X		X	X
Pseudonaja mengdeni	Western Brown Snake					X		X			
Pseudonaja modesta	Ringed Brown Snake					X		X			
Pseudonaja nuchalis	Gwardar; Northern Brown Snake					X				X	
Suta fasciata	Rosen's Snake					X		X			
Suta punctata	Spotted Snake					X					
Vermicelli snelli	Pilbara Bandy Bandy					X		X			

Table E.3: Bird species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Birdata	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA							
CASUARIIDAE												
Dromaius novaehollandiae	Emu					X		X	X		X	
PHASIANIDAE												
Coturnix ypsilophora	Brown Quail					X		X	X	X	X	
ANATIDAE												
Dendrocygna eytoni	Plumed Whistling-Duck					X		X				
Cygnus atratus	Black Swan							X				
Anas gracilis	Grey Teal							X				
Anas superciliosa	Pacific Black Duck					X		X				
Chenonetta jubata	Australian Wood Duck							X				
COLUMBIDAE												
Phaps chalcoptera	Common Bronzewing					X		X	X		X	X
Ocyphaps lophotes	Crested Pigeon					X		X	X	X	X	X
Geophaps plumifera	Spinifex Pigeon					X		X	X	X	X	X
Geopelia cuneata	Diamond Dove					X		X	X	X	X	X
Geopelia striata	Peaceful Dove					X		X				
PODARGIDAE												
Podargus strigoides	Tawny Frogmouth					X		X	X			X
EUROSTOPODIDAE												
Eurostopodus argus	Spotted Nightjar					X		X	X		X	X
AEGOTHELIDAE												
Aegotheles cristatus	Australian Owlet-nightjar					X		X	X	X		
APODIDAE												
Apus pacificus	Fork-tailed Swift		IA	IA		X			X			
ANHINGIDAE												
Anhinga novaehollandiae	Australasian Darter					X		X				
PHALACROCORACIDAE												
Microcarbo melanoleucos	Little Pied Cormorant							X				

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Birdata	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA							
Phalacrocorax varius	Pied Cormorant					X						
Phalacrocorax sulcirostris	Little Black Cormorant					X		X				
PELECANIDAE												
Pelecanus conspicillatus	Australian Pelican					X		X				
ARDEIDAE												
Ardea pacifica	White-necked Heron							X				
Ardea modesta	Eastern Great Egret						X	X				
Ardea ibis	Cattle Egret						X					
Egretta novaehollandiae	White-faced Heron					X		X	X			
THRESKIORNITHIDAE												
Threskiornis spinicollis	Straw-necked Ibis					X		X	X		X	
ACCIPITRIDAE												
Elanus axillaris	Black-shouldered Kite					X			X	X	X	
Elanus scriptus	Letter-winged Kite				P4						X	
Haliastur sphenurus	Whistling Kite					X		X	X	X	X	X
Lophoictinia isura	Square-tailed Kite					X		X	X			
Milvus migrans	Black Kite					X		X				
Accipiter fasciatus	Brown Goshawk					X		X	X	X		X
Accipiter cirrocephalus	Collared Sparrowhawk					X		X	X			
Circus assimilis	Spotted Harrier					X		X	X	X	X	X
Hamirostra melanosternon	Black-breasted Buzzard					X		X	X		X	
Aquila audax	Wedge-tailed Eagle					X		X	X		X	
Hieraaetus morphnoides	Little Eagle					X		X	X	X		
FALCONIDAE												
Falco cenchroides	Nankeen Kestrel					X		X	X	X	X	
Falco berigora	Brown Falcon					X		X	X	X	X	X
Falco subniger	Black Falcon							X				
Falco longipennis	Australian Hobby					X		X	X		X	
Falco hypoleucos	Grey Falcon			VU		X						

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Birdata	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA							
Falco peregrinus	Peregrine Falcon			OS		X		X				
RALLIDAE												
Gallirallus philippensis	Buff-banded Rail							X				
Porzana tabuensis	Spotless Crake					X						
OTIDIDAE												
Ardeotis australis	Australian Bustard					X		X	X	X	X	
BURHINIDAE												
Burhinus grallarius	Bush Stone-curlew					X		X	X			
RECURVIROSTRIDAE												
Himantopus himantopus	Black-winged Stilt					X		X				
CHARADRIIDAE												
Charadrius veredus	Oriental Plover		IA	IA			X					X
Elseyornis melanops	Black-fronted Dotterel					X		X				
Erythrogonys cinctus	Red-kneed Dotterel					X		X				
ROSTRATULIDAE												
Rostratula australis	Australian Painted Snipe		EN	EN			X					
SCOLOPACIDAE												
Tringa hypoleucos	Common Sandpiper		IA	IA			X					
Tringa nebularia	Common Greenshank		IA	IA		X						
Calidris melanotos	Pectoral Sandpiper		IA	IA			X					
Calidris acuminata	Sharp-tailed Sandpiper		IA	IA			X					
Calidris ferruginea	Curlew Sandpiper		CR	VU/ IA			X					
TURNICIDAE												
Turnix velox	Little Button-quail					X		X	X	X	X	X
CACATUIDAE												
Cacatua roseicapilla	Galah					X		X	X	X		
Cacatua sanguinea	Little Corella					X		X	X	X		X
Nymphicus hollandicus	Cockatiel					X		X	X	X		
PSITTACIDAE												

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Birdata	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA							
Platycercus zonarius	Australian Ringneck					X		X	X	X	X	X
Melopsittacus undulatus	Budgerigar					X		X	X	X	X	X
Neophema bourkii	Bourke's Parrot					X		X		X		
Platycercus varius	Mulga Parrot					X		X	X	X		
Pezoporus occidentalis	Night Parrot		EN	CR			X					
CUCULIDAE												
Centropus phasianinus	Pheasant Coucal							X				
Chrysococcyx basalis	Horsfield's Bronze-Cuckoo					X		X	X		X	X
Chrysococcyx osculans	Black-eared Cuckoo							X	X			
Cacomantis pallidus	Pallid Cuckoo					X		X	X		X	X
STRIGIDAE												
Ninox connivens	Barking Owl					X			X			
Ninox boobook boobook	Southern Boobook							X	X	X		
TYTONIDAE												
Tyto javanica	Eastern Barn Owl					X		X	X			
HALCYONIDAE												
Dacelo leachii	Blue-winged Kookaburra					X		X		X	X	
Todiramphus pyrrhopygius	Red-backed Kingfisher					X		X	X	X	X	X
Todiramphus sanctus	Sacred Kingfisher					X		X	X	X	X	
MEROPIDAE												
Merops ornatus	Rainbow Bee-eater					X	X	X		X	X	X
PTILONORHYNCHIDAE												
Ptilonorhynchus maculatus guttatus	Western Bowerbird					X		X	X	X	X	X
MALURIDAE												
Malurus leucopterus	White-winged Fairy-wren					X		X	X		X	X
Malurus lamberti assimilis	Variegated Fairy-wren					X		X	X	X	X	X
Stipiturus ruficeps	Rufous-crowned Emu-wren					X		X	X	X	X	X
Malurus splendens	Splendid Fairy-wren					X		X	X			
Amytornis striatus whitei	Striated Grasswren					X		X	X	X	X	X

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Birdata	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA							
ACANTHIZIDAE												
Pyrrholaemus brunneus	Redthroat					X		X	X			
Smicrornis brevirostris	Weebill					X		X	X	X	X	X
Gerygone fusca	Western Gerygone					X		X	X	X	X	X
Acanthiza robustirostris	Slaty-backed Thornbill					X		X	X	X		
Acanthiza chrysorrhoa	Yellow-rumped Thornbill					X		X	X			
Acanthiza uropygialis	Chestnut-rumped Thornbill					X		X	X		X	X
Acanthiza apicalis	Inland Thornbill					X		X	X	X	X	X
Aphelocephala nigricincta	Banded Whiteface							X				
Aphelocephala leucopsis	Southern Whiteface					X		X				
PARDALOTIDAE												
Pardalotus rubricatus	Red-browed Pardalote					X		X			X	
Pardalotus striatus	Striated Pardalote					X		X	X		X	
MELIPHAGIDAE												
Gavicalis virescens	Singing Honeyeater					X		X	X	X	X	X
Ptilotula keartlandi	Grey-headed Honeyeater					X		X	X	X	X	X
Ptilotula penicillata	White-plumed Honeyeater							X	X		X	X
Purnella albifrons	White-fronted Honeyeater					X			X			
Manorina flavigula	Yellow-throated Miner					X		X	X	X	X	X
Melithreptus gularis	Black-chinned Honeyeater					X		X	X			
Acanthagenys rufogularis	Spiny-cheeked Honeyeater					X		X	X	X	X	X
Conopophila whitei	Grey Honeyeater					X		X	X			
Epthianura tricolor	Crimson Chat					X		X	X			
Certhionyx variegatus	Pied Honeyeater					X		X				
Sugomel niger	Black Honeyeater							X				
Lichmera indistincta	Brown Honeyeater					X		X	X		X	X
POMATOSTOMIDAE												
Pomatostomus temporalis	Grey-crowned Babbler					X		X	X	X	X	X
Pomatostomus superciliosus	White-browed Babbler					X		X	X			

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Birdata	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA							
EUPATRIDAE												
Cinclosoma castaneothorax	Chestnut-breasted Quail-thrush					X		X				
Psophodes occidentalis	Chiming Wedgebill							X			X	
NEOSITTIDAE												
Daphoenositta chrysoptera	Varied Sittella					X		X				
CAMPEPHAGIDAE												
Coracina novaehollandiae	Black-faced Cuckoo-shrike					X		X	X	X	X	X
Coracina maxima	Ground Cuckoo-shrike					X		X	X			
Lalage tricolor	White-winged Triller					X		X	X	X	X	X
PACHYCEPHALIDAE												
Pachycephala rufiventris	Rufous Whistler					X		X	X	X		X
Colluricincla harmonica	Grey Shrike-thrush					X		X	X	X	X	X
Oreoica gutturalis	Crested Bellbird					X		X	X	X	X	X
ARTAMIDAE												
Artamus personatus	Masked Woodswallow					X		X	X			X
Artamus cinereus	Black-faced Woodswallow					X		X	X	X	X	X
Artamus minor	Little Woodswallow					X		X	X	X	X	
Cracticus torquatus	Grey Butcherbird					X		X	X	X	X	X
Cracticus tibicen	Australian Magpie					X		X	X	X	X	X
Cracticus nigrogularis	Pied Butcherbird					X		X	X	X	X	X
RHIPIDURIDAE												
Rhipidura albiscapa	Grey Fantail					X		X	X	X	X	X
Rhipidura leucophrys	Willie Wagtail					X		X	X	X	X	X
CORVIDAE												
Corvus bennetti	Little Crow					X		X	X		X	
Corvus orru	Torresian Crow					X		X	X	X	X	X
MONARCHIDAE												
Grallina cyanoleuca	Magpie-lark					X		X	X	X	X	X

Scientific name	Common name	Introduced	Conservation codes			Nature Map / DBCA	EPBC PMST	Birdata	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA							
PETROICIDAE												
Petroica goodenovii	Red-capped Robin					X		X	X		X	
Melanodryas cucullata	Hooded Robin					X		X	X		X	X
ALAUDIDAE												
Mirafra javanica	Horsfield's Bushlark					X		X	X		X	
ACROCEPHALIDAE												
Acrocephalus australis	Australian Reed-Warbler					X		X				
MEGALURIDAE												
Cincloramphus mathewsi	Rufous Songlark							X	X	X		X
Cincloramphus cruralis	Brown Songlark							X	X			
Eremiornis carteri	Spinifexbird					X		X	X	X		X
HIRUNDINIDAE												
Cheramoeca leucosterna	White-backed Swallow							X				
Hirundo rustica	Barn Swallow		IA	IA			X					
Hirundo neoxena	Welcome Swallow					X		X				
Petrochelidon ariel	Fairy Martin					X		X		X		
Petrochelidon nigricans	Tree Martin					X		X	X	X		
NECTARINIIDAE												
Dicaeum hirundinaceum	Mistletoebird					X		X	X			
ESTRILDIDAE												
Taeniopygia guttata	Zebra Finch					X		X	X	X	X	X
Neochmia ruficauda	Star Finch					X		X				
Emblema pictum	Painted Finch					X		X	X	X	X	X
MOTACILLIDAE												
Anthus novaeseelandiae	Australasian Pipit					X		X	X		X	
Motacilla flava	Yellow Wagtail		IA	IA			X					
Motacilla cinerea	Grey Wagtail		IA	IA			X					

Table E.4: Mammal species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			NatureMap / DBCA	EPBC PMST	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA						
TACHYGLOSSIDAE											
Tachyglossus aculeatus	Short-beaked Echidna								X	X	
DASYURIDAE											
Dasycercus blythi	Brush-tailed Mulgara				P4	X					
Dasykaluta rosamondae	Little Red Kaluta					X		X		X	X
Dasyurus hallucatus	Northern Quoll		EN	EN		X	X	X	X	X	X
Ningaui timealeyi	Pilbara Ningaui					X		X	X	X	X
Planigale ingrami	Long-tailed Planigale					X					
Planigale sp. 1'	Pilbara Planigale								X		X
Pseudantechinus roryi	Rory's Pseudantechinus					X					
Pseudantechinus woolleyae	Woolley's Pseudantechinus					X		X			
Sminthopsis macroura	Stripe-faced Dunnart					X		X	X	X	
Sminthopsis ooldea	Ooldea Dunnart					X		X			X
Sminthopsis youngsoni	Lesser Hairy-footed Dunnart					X					
THYLACOMYIDAE											
Macrotis lagotis	Bilby, Dalgyte		VU	VU		X	X				
MACROPODIDAE											
Macropus robustus erubescens	Euro, Biggada					X		X	X	X	X
Macropus rufus	Red Kangaroo, Marlu					X		X	X		X
Petrogale rothschildi	Rothschild's Rock-wallaby					X		X	X	X	X
MEGADERMATIDAE											
Macroderma gigas	Ghost Bat		VU	VU		X	X	X	X	X	X
HIPPOSIDERIDAE											
Rhinonicteris aurantia (Pilbara form)	Pilbara Leaf-nosed Bat		VU	VU		X	X	X		X	
EMBALLONURIDAE											

Scientific name	Common name	Introduced	Conservation codes			NatureMap / DBCA	EPBC PMST	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA						
Saccolaimus flaviventris	Yellow-bellied Sheathtail-bat					X		X	X	X	X
Taphozous georgianus	Common Sheathtail-bat					X		X	X	X	X
Taphozous hilli	Hill's Sheathtail-bat					X		X	X	X	
VESPERTILIONIDAE											
Chalinolobus gouldii	Gould's Wattled Bat					X		X	X	X	X
Chalinolobus morio	Chocolate Wattled Bat					X					
Nyctophilus daedalus	Northwestern Long-eared Bat					X					
Nyctophilus geoffroyi	Lesser Long-eared Bat					X		X	X	X	
Scotorepens greyii	Little Broad-nosed Bat					X		X	X	X	X
Vespadelus finlaysoni	Finlayson's Cave Bat					X		X	X	X	X
MOLOSSIDAE											
Chaerephon jobensis	Northern Freetail-bat					X		X	X	X	X
Mormopterus beccarii	Beccari's Freetail-bat							X			
Ozimops lumsdenae	Northern Freetail-bat					X		X	X	X	X
Austronomus australis	White-striped Freetail-bat							X		X	
MURIDAE											
Leggadina lakedownensis	Short-tailed Mouse				P4	X					
Mus musculus	House Mouse	*				X	X	X		X	
Notomys alexis	Spinifex Hopping-mouse					X					
Pseudomys chapmani	Western Pebble-mound Mouse				P4	X		X	X		X
Pseudomys delicatulus	Delicate Mouse					X		X			
Pseudomys desertor	Desert Mouse					X		X	X	X	
Pseudomys hermannsburgensis	Sandy Inland Mouse					X		X	X	X	
Pseudomys nanus	Western Chestnut Mouse					X					
Zyzomys argurus	Common Rock-rat					X		X	X	X	
LEPORIDAE											

Scientific name	Common name	Introduced	Conservation codes			NatureMap / DBCA	EPBC PMST	Previous surveys	Phase 1 survey	Phase 2 survey	Phase 3 survey
			EPBC Act	BC Act	DBCA						
Oryctolagus cuniculus	Rabbit	*				X	X	X	X	X	X
CANIDAE											
Canis familiaris dingo	Dingo, Dog	*				X	X	X	X	X	X
Vulpes vulpes	Red Fox	*					X				
FELIDAE											
Felis catus	Cat	*				X	X	X	X	X	X
EQUIDAE											
Equus asinus	Donkey	*				X	X			X	
Equus caballus	Horse	*				X	X				
CAMELIDAE											
Camelus dromedarius	Dromedary, Camel	*				X	X		X	X	
BOVIDAE											
Bos taurus	European Cattle	*				X			X	X	X

Table E.5: Amphibian species recorded during the current surveys. Numbers are those recorded in Phase 1, Phase 2 and Phase 3. X = the trap sites were not opened during that particular phase of fauna surveying.

Species name	TS01	TS02	TS03	TS04	TS05	TS06	TS07	TS08	TS09	TS10	TS11	TS12	TS13	TS14	TS15	TS16	TS17	TS18	TS19	Other
HYLIDAE																				
Cyclorana maini														x, x, 4						
Litoria rubella						1, 0, x	0, 2, x							x, x, 1						0, 11, 4

Table E.6: Reptile species recorded during the current surveys. Numbers are those recorded in Phase 1, Phase 2 and Phase 3. X = the trap sites were not opened during that particular phase of fauna surveying.

Species name	TS01	TS02	TS03	TS04	TS05	TS06	TS07	TS08	TS09	TS10	TS11	TS12	TS13	TS14	TS15	TS16	TS17	TS18	TS19	Other
AGAMIDAE																				
Gowidon longirostris						0, 1, x	0, 1, x													2, 0, 1
Ctenophorus caudicinctus	0, 1, x			3, 2, x	0, 3, x							0, 1, x			x, x, 1					2, 2, 0
Ctenophorus isolepis					0, 2, x															
Pogona minor			1, 0, x	0, 1, x																1, 0, 0
CARPHODACTYLIDAE																				
Nephrurus wheeleri cinctus	0, 1, x													x, x, 4						0, 0, 1
DIPLODACTYLIDAE																				
Diplodactylus pulcher	5, 0, x		5, 0, x																	
Lucasium stenodactylum				5, 0, x		3, 0, x										x, x, 1	x, x, 3			0, 0, 1
Lucasium wombeyi				1, 0, x		2, 0, x	1, 0, x													1, 0, 0
Oedura fimbria																				13, 3, 1
Rhynchoedura ornata				1, 0, x		2, 0, x										x, x, 3				
GEKKONIDAE																				
Gehyra punctata																				6, 2, 1
Gehyra variegata			1, 0, x			1, 0, x								x, x, 1						3, 2, 1
Heteronotia binoei																				0, 1, 1
Heteronotia spelea																				1, 1, 0
Strophurus elderi				1, 0, x																
Strophurus wellingtonae					1, 0, x															0, 1, 2
PYGOPODIDAE																				
Delma butleri															x, x, 1					
Delma nasuta							1, 0, x							x, x, 1						0, 0, 1
Delma pax						1, 0, x	0, 1, x									x, x, 1				
Lialis burtonis				2, 0, x			1, 0, x													1, 0, 1
Pygopus nigriceps														x, x, 1						
SCINCIDAE																				
Carlia munda	1, 0, x	5, 0, x			0, 1, x	6, 1, x	3, 5, x				1, 1, x			x, x, 3			x, x, 2	x, x, 1		
Cryptoblepharus ustulatus									1, 0, x											1, 1, 0
Ctenotus grandis	1, 0, x													x, x, 1		x, x, 1				
Ctenotus helenae				1, 0, x		3, 0, x														
Ctenotus pallasotus				2, 0, x													x, x, 1	x, x, 1		
Ctenotus pantherinus		2, 1, x		4, 0, x	6, 0, x	2, 0, x						0, 1, x			x, x, 2	x, x, 2				
Ctenotus rutilans					2, 0, x															
Ctenotus saxatilis							0, 1, x				1, 0, x		0, 2, x	x, x, 2	x, x, 3	x, x, 2	x, x, 3	x, x, 2		
Ctenotus schomburgkii	1, 0, x		1, 1, x																	0, 1, 0

Species name	TS01	TS02	TS03	TS04	TS05	TS06	TS07	TS08	TS09	TS10	TS11	TS12	TS13	TS14	TS15	TS16	TS17	TS18	TS19	Other
Ctenotus uber															x, x, 1	x, x, 1		x, x, 1		
Egernia formosa										1, 0, x	2, 1, x								x, x, 1	
Lerista macropisthopus remota																		x, x, 1		
Lerista muelleri	1, 0, x																			
Lerista neander	1, 0, x		1, 0, x																	
Menetia greyii							0, 3, x							x, x, 1			x, x, 1			
Morethia ruficauda exquisita					0, 1, x											x, x, 1				0, 0, 1
Tiliqua multifasciata				1, 0, x	1, 0, x											x, x, 3	x, x, 1	x, x, 2		
VARANIDAE																				
Varanus acanthurus				1, 0, x									0, 1, x		x, x, 2	x, x, 1				1, 0, 0
Varanus brevicauda					3, 0, x															
Varanus bushi																				1, 0, 0
Varanus caudolineatus																				1, 0, 0
Varanus giganteus																				0, 0, 1
Varanus gouldii																				1, 0, 0
Varanus panoptes	1, 0, x																			0, 1, 1
Varanus tristis tristis																				1, 0, 1
TYPHLOPIDAE																				
Anilios ammodytes					2, 0, x															
Anilios grypus				1, 0, x	1, 0, x															
Anilios hamatus				1, 0, x										x, x, 1						
ELAPIDAE																				
Acanthophis wellsi				1, 0, x																
Brachyurophis approximans						1, 0, x	1, 0, x													
Demansia psammophis																x, x, 1				
Furina ornata													0, 1, x							
Pseudechis australis																x, x, 1				0, 1, 0
Pseudonaja nuchalis												0, 1, x								

Table E.7: Bird species recorded during the current surveys. Numbers are those recorded in Phase 1, Phase 2 and Phase 3. X = the trap sites were not opened during that particular phase of fauna surveying.

Species name	TS01	TS02	TS03	TS04	TS05	TS06	TS07	TS08	TS09	TS10	TS11	TS12	TS13	TS14	TS15	TS16	TS17	TS18	TS19	Other
DROMAIIDAE																				
Dromaius novaehollandiae				0, 1, x																
PHASIANIDAE																				
Coturnix ypsilophora				1, 0, x		4, 0, x	1, 1, x													
COLUMBIDAE																				
Geopelia cuneata				3, 0, x								0, 1, x		x, x, 1						1, 1, 0
Geophaps plumifera										0, 1, x										1, 1, 2
Ocyphaps lophotes			0, 1, x	2, 3, x	1, 1, x	1, 0, x													x, x, 2	1, 1, 1
Phaps chalcoptera																			x, x, 1	0, 1, 2
CAPRIMULGIDAE																				
Eurostopodus argus																				0, 2, 3
AEGOTHELIDAE																				
Aegotheles cristatus											1, 0, x									4, 0, 0
THRESKIORNITHIDAE																				
Threskiornis spinicollis																				0, 1, 0
ACCIPITRIDAE																				
Elanus caeruleus axillaris																				1, 1, 0
Elanus scriptus																				0, 1, 0
Haliastur sphenurus						2, 0, x									x, x, 1					2, 4, 0
Accipiter fasciatus																				1, 0, 1
Circus assimilis	1, 0, x																			1, 2, 2
Aquila audax																				0, 2, 0
Hamirostra melanosternon																				0, 4, 0
Hieraaetus morphnoides																				1, 0, 0
FALCONIDAE																				
Falco cenchroides				1, 0, x		1, 0, x														0, 2, 0
Falco berigora				1, 0, x																0, 1, 1
Falco longipennis							0, 1, x													
OTIDIDAE																				
Ardeotis australis																				1, 1, 0
CHARADRIIDAE																				
Charadrius veredus																				0, 0, 1
TURNICIDAE																				
Turnix velox				1, 0, x		1, 1, x	1, 0, x						0, 2, x			x, x, 1				
CACATUIDAE																				
Cacatua roseicapillus				1, 0, x		1, 0, x														

Species name	TS01	TS02	TS03	TS04	TS05	TS06	TS07	TS08	TS09	TS10	TS11	TS12	TS13	TS14	TS15	TS16	TS17	TS18	TS19	Other
Cacatua sanguinea		1, 0, x					1, 0, x												x, x, 1	
Nymphicus hollandicus						1, 0, x														
PSITTACIDAE																				
Melopsittacus undulatus								2, 0, x												0, 1, 1
Neophema bourkii																				11, 0, 0
Platycercus varius																				2, 0, 0
Platycercus zonarius	1, 0, x		3, 0, x		1, 1, x	2, 0, x	1, 2, x		0, 1, x							x, x, 3	x, x, 1		x, x, 2	1, 4, 1
CUCULIDAE																				
Chrysococcyx basalis							0, 1, x		0, 2, x		0, 1, x					x, x, 1	x, x, 1	x, x, 1		
Cacomantis pallidus			0, 2, x						0, 1, x					x, x, 1			x, x, 1			0, 1, 0
STRIGIDAE																				
Ninox boobook boobook										1, 0, x	1, 0, x									2, 0, 0
Podargus strigoides																				0, 0, 1
ALCEDINIDAE																				
Dacelo leachii						2, 1, x														
Todiramphus pyrrhopygius																				1, 2, 1
Todiramphus sanctus		1, 0, x				4, 1, x														1, 0, 0
MEROPIDAE																				
Merops ornatus				1, 2, x	0, 1, x	0, 1, x								x, x, 1		x, x, 1		x, x, 1		1, 4, 2
PTILONORHYNCHIDAE																				
Ptilonorhynchus guttatus										1, 0, x										2, 3, 3
MALURIDAE																				
Amytornis striatus				0, 1, x						0, 2, x	0, 1, x									1, 2, 1
Malurus lamberti assimilis		2, 2, x		0, 2, x		1, 0, x	0, 3, x	0, 1, x						x, x, 2		x, x, 1				0, 0, 1
Malurus leucopterus		0, 1, x														x, x, 1		x, x, 1		0, 1, 1
Stipiturus ruficeps					2, 1, x								0, 1, x		x, x, 3	x, x, 3	x, x, 1			
ACANTHIZIDAE																				
Acanthiza apicalis	1, 0, x	1, 0, x						0, 2, x										x, x, 1		0, 0, 1
Acanthiza robustirostris	2, 0, x		1, 0, x																	
Acanthiza uropygialis									0, 1, x											0, 1, 1
Gerygone fusca	4, 0, x		1, 0, x															x, x, 1		0, 1, 1
Smicrornis brevirostris	1, 2, x	0, 2, x		2, 2, x	1, 2, x	1, 3, x	1, 4, x	1, 2, x	2, 6, x	1, 0, x	1, 1, x			x, x, 1		x, x, 1			x, x, 1	2, 7, 3
PARDALOTIDAE																				
Pardalotus rubricatus										0, 2, x										0, 1, 0
Pardalotus striatus								0, 1, x												
MELIPHAGIDAE																				
Acanthagenys rufogularis			1, 0, x	0, 4, x			0, 1, x				0, 1, x			x, x, 1		x, x, 2		x, x, 1		1, 3, 1

Species name	TS01	TS02	TS03	TS04	TS05	TS06	TS07	TS08	TS09	TS10	TS11	TS12	TS13	TS14	TS15	TS16	TS17	TS18	TS19	Other
Gavicalis virescens	2, 2, x	1, 2, x		3, 1, x	0, 1, x		4, 1, x	0, 2, x	0, 3, x	0, 3, x	0, 1, x			x, x, 2	x, x, 1	x, x, 2	x, x, 1	x, x, 3	x, x, 2	2, 1, 3
Lichmera indistincta							0, 1, x	0, 1, x										x, x, 2		0, 1, 1

Appendix F: Threatened and Priority Fauna Species Likelihood of Occurrence within the Survey Area

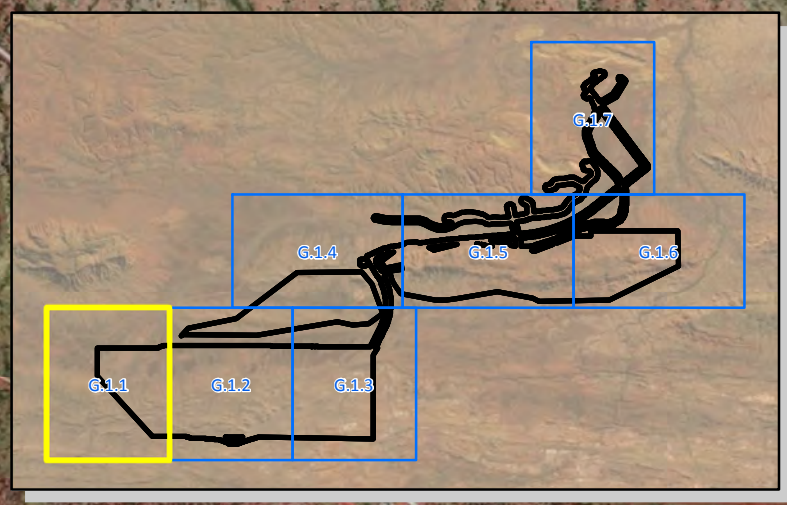
This page has been left blank intentionally.

Table F.1: Likelihood of occurrence of conservation listed vertebrate fauna species listed as potentially occurring in the vicinity of the survey area.

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	BC Act	DBCA		Pre-survey	Post-survey
Reptiles						
Underwoodisaurus seorsus (Pilbara Barking Gecko)			P2	Confined in the Pilbara to the Hamersley Ranges from Tom Price to Newman. Occurs in rocky areas with spinifex and low tree cover.	High	High
Lerista macropisthopus remota			P2	This subspecies occurs in woodlands and semi-arid shrublands where animals shelter under leaf litter. This species is generally found in the central interior particularly the Ashburton region.	High	**Recorded**
Anilios ganei			P1	Little information is available on this species but it is believed to be associated with moist gorges and gullies.	High	High
Liasis olivaceus barroni (Pilbara Olive Python)	VU	VU		Generally rocky habitats in close association to permanent and semi-permanent water sources.	High	High
Birds						
Apus pacificus (Fork-tailed Swift)	IA	IA		Largely aerial species independent of the terrestrial environment.	Moderate	Moderate
Elanus scriptus (Letter-winged Kite)			P4	The Letter-winged Kite is a bird of open country and grasslands in arid and semi-arid Australia, where there are tree-lined streams or water courses.	Low	**Recorded**
Falco hypoleucos (Grey Falcon)		VU		Open habitats: semi-deserts, grassy inland plains, timbered watercourses, pastoral lands.	Moderate	Moderate
Falco peregrinus (Peregrine Falcon)		OS		Cosmopolitan, will hunt in any habitat, soaring at height or from a perch; often near cliffs. Nests on rocky ledges in tall, vertical cliff faces and tall trees associated with drainage lines.	Moderate	Moderate
Charadrius veredus (Oriental Plover)	IA	IA		Breeding habitat includes arid grasslands, saltpans; non-breeding habitat includes grasslands, salt-fields, and coastal regions.	Moderate	**Recorded**

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	BC Act	DBCA		Pre-survey	Post-survey
Rostratula australis (Australian Painted Snipe)	EN	EN		Inhabits shallow terrestrial freshwater wetlands, lakes, swamps and claypans. Also found in waterlogged grassland and saltmarsh. Typical sites include areas with emergent tussocks of grass, sedges or samphire; often scattered with clumps of lignum *Muehlenbeckia*, or canegrass or sometimes with tea-tree (*Melaleuca*).	Low	Low
Actitis hypoleucos (Common Sandpiper)	IA	IA		Non-breeding migrant to a wide variety of habitats, such as riverbanks, estuaries, freshwater seeps on coastal shores, tidal creeks, mangrove swamps and saltmarshes.	Low	Low
Tringa nebularia (Common Greenshank)	IA	IA		A variety of freshwater, marine and artificial wetlands, including swamps, open muddy or rocky shores of lakes and large rivers, sewerage farms, saltworks, muddy coastal flats, mangroves and estuaries.	Low	Low
Calidris melanotos (Pectoral Sandpiper)	IA	IA		Mainly swamps, lagoons, river pools, irrigation channels and sewerage ponds. Also in samphire flats around estuaries and salt lakes.	Low	Low
Calidris acuminata (Sharp-tailed Sandpiper)	IA	IA		Muddy edges of shallow fresh/brackish wetlands with emergent sedges, saltmarsh, grass and low vegetation.	Low	Low
Calidris ferruginea (Curlew Sandpiper)	CR/IA	VU/IA		This species mainly occurs on intertidal mudflats in sheltered coastal areas and also around non-tidal swamps, lakes and lagoons near the coast. They are also recorded inland, though less often, including around ephemeral and permanent lakes, dams, waterholes and bore drains, usually with bare edges of mud or sand.	Low	Low

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	BC Act	DBCA		Pre-survey	Post-survey
Pezoporus occidentalis (Night Parrot)	EN	CR		Most habitat records are from *Triodia* grasslands and/or chenopod shrublands in the arid and semi-arid zones. *Astrebla* spp. (Mitchell grass), shrubby samphire and chenopod associations, scattered trees and shrubs, *Acacia aneura* (Mulga) woodland, treeless areas and bare gibber as associated with sightings of the species.	Low	Low
Hirundo rustica (Barn Swallow)	IA	IA		Coastal open country generally, especially near surface water and man-made structures such as bridges and power wires.	Low	Low
Motacilla cinerea (Grey Wagtail)	IA	IA		Damp short-grass flats, rice stubbles and edge of swamps, sewage ponds, bore overflows, grazed or mowed grass and irrigated areas.	Low	Low
Motacilla flava (Yellow Wagtail)	IA	IA		Mainly banks and rocks in fast-running freshwater habitats such as rivers, creeks, streams and around waterfalls.	Low	Low
Mammals						
Dasycercus blythi (Brush-tailed Mulgara)			P4	Common in a range of habitats – tussock/hummock grasslands and sparse shrubs and low open woodlands on ridge tops, cliffs, scree slopes, hills and valley floors.	Moderate	Low
Dasyurus hallucatus (Northern Quoll)	EN	EN		Northern Quoll habitat generally encompasses some form of rocky area for denning purposes with surrounding vegetated habitats used for foraging and dispersal.	High	**Recorded**
Macrotis lagotis (Greater Bilby, Dalgyte)	VU	VU		Sand or sandy-loam in hummock grassland (*Triodia* species) and or *Acacia* shrublands.	Low	Low



Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	BC Act	DBCA		Pre-survey	Post-survey
Macroderma gigas (Ghost Bat)	VU	VU		A wide range from rainforest, monsoon and vine scrub in the tropics to open woodlands and arid areas.	High	**Recorded**
Rhinonicteris aurantia (Pilbara form) (Pilbara Leaf-nosed Bat)	VU	VU		Roosts in deep warm, humid caves or rock cracks, especially in proximity to water pools. Forages while flying low along watercourses and gorges and over *Triodia* grassland.	High	**Recorded**
Leggadina lakedownensis (Short-tailed Mouse, Karekanga)			P4	Open tussock and hummock grassland, *Acacia* shrubland and savannah woodland on alluvial clay/sandy soils.	Moderate	Moderate
Pseudomys chapmani (Western Pebble-mound Mouse)			P4	Gentle rocky slopes, hills and spurs with small pebble surface cover and sparse vegetation.	High – previously recorded within survey area	**Recorded**

Table G.1: Location of significant areas recorded during the Astron surveys.

Site ID	MGA Zone 50 K		Reason	Photograph
	Easting (mE)	Northing (mE)		
Cave 1	712281	7450651	Cave that is likely to support Matters of National Environmental Significance (MNES) bat species and other conservation significant fauna species. Confirmed Ghost Bat nocturnal roost (possible diurnal roost).	
Cave 2	716905	7450075	Cave that is likely to support MNES bat species and other conservation significant fauna species.	
Cave 4	712487	7451071	Cave that is likely to support MNES bat species and other conservation significant fauna species. Confirmed Ghost Bat nocturnal roost (feed cave, five scats found).	No photo available

Site ID	MGA Zone 50 K		Reason	Photograph
	Easting (mE)	Northing (mE)		
Cave 5	710766	7450668	Cave that is likely to support MNES bat species and other conservation significant fauna species. Confirmed Ghost Bat nocturnal roost (possible diurnal roost).	
Cave 6	710715	7450850	Cave that is likely to support MNES bat species and other conservation significant fauna species.	No photo available
Cave 7	697235	7444586	Cave that is likely to support MNES bat species and other conservation significant fauna species. Confirmed Ghost Bat nocturnal roost (scats recorded)	

Site ID	MGA Zone 50 K		Reason	Photograph
	Easting (mE)	Northing (mE)		
Cave 8	699012	7444982	Cave that is likely to support MNES bat species and other conservation significant fauna species.	
PMM 1	713863	7450216	Active pebble mound that provides refuge for the Western Pebble-mound Mouse.	
PMM 2	704489	7449512	Inactive pebble mound that may provide refuge for the Western Pebble-mound Mouse.	

Site ID	MGA Zone 50 K		Reason	Photograph
	Easting (mE)	Northing (mE)		
PMM 4	704548	7449901	Active pebble mound that provides refuge for the Western Pebble-mound Mouse.	
PMM 5	704660	7449555	Active pebble mound that provides refuge for the Western Pebble-mound Mouse.	
PMM 6	704605	7449461	Recently inactive pebble mound that provides refuge for the Western Pebble-mound Mouse.	

Site ID	MGA Zone 50 K		Reason	Photograph
	Easting (mE)	Northing (mE)		
Cave 3*	708388	7450375	Cave that is likely to support MNES bat species and other conservation significant fauna species.	
Cave 9*	701453	7448445	Cave that is likely to support MNES bat species and other conservation significant fauna species. Confirmed Ghost feed cave (scats recorded)	
PMM 3*	700562	7448214	Recently inactive/active pebble mound that provides refuge for the Western Pebble-mound Mouse.	

*Recorded just outside the survey area due to post-survey boundary changes.

3	27 March 2019	Third issue incorporating Phase 3 data

Summary
Bat and Night Parrot (*Pezoporus occidentalis*) presence is reported for 28 sites in the Hope Down 2 and Bedded Hilltop areas, in the Pilbara, WA. Astron Environmental Services (Astron) carried out an echolocation based survey in three phases in November 2017, May 2018 and March 2019. 24 sites were surveyed for all bats present including Ghost bat social and ultrasonic calls. Four were surveyed using acoustic detectors set to record Night Parrot and Ghost bat social calls. Bat Call WA has reviewed the recordings made and provided species lists and activity levels for the bats present.

Twelve species of echolocating bats were confirmed present including both EPBC Act listed species in the Pilbara, the Pilbara leaf-nosed bat (*Rhinonicteris aurantia*) (PLNb) and the Ghost bat (*Macroderma gigas*) (PGb). PLNb calls were detected in low numbers at three sites in May 2018. PGb were detected ultrasonically at three sites and their presence was confirmed by observation by Astron ecologists of either bats or middens in caves at a further seven.

PLNb calls were detected at three sites during May 2018 but were not detected in November 2017 or March 2019. The calls at all three sites were at least three hours after dusk and are not consistent with the presence of a permanent roost cave nearby.

PGb presence during all three phases is consistent with the known population and dispersal of PGb in the district. The number of observations recorded indicates that additional targeted survey work is required to fully define the usage and categorisation of caves in the area by this species.

No Night Parrot calls were detected.

Habitats
The sites for the survey were chosen by Astron. Details of the sites are presented in table 1. The bat sites included each type of habitat present in the study area including gorges, breakaways. drainage lines and stony plains. All the Night Parrot sites are on stony plains. The locations are shown in relation to local features in figures 1 and 2.

Timing, Moon Phase and Weather
The echolocation survey was conducted between 24th to 30th November 2017, 18th to 26th May 2018 and 11th to 17th March 2019.

The November sampling evenings were hot with minimum overnight temperatures between 20 and 25^{O}C. The moon in this period was first quarter to full. The May sampling evenings were cool to cold with minimum overnight temperatures between 5 and 15^{O}C. The moon in this period was first quarter. No rain fell during these survey periods. The March sampling evenings were hot and humid with minimum overnight temperatures between 25 and 30^{O}C typical of northern wet season. Some seasonal rain fell during this period. The moon was at first quarter.

Survey Team
Sites were chosen and detectors placed by Astron ecologists. Bob Bullen of Bat Call WA completed analysis of audio and echolocation recordings.

Sampling
The survey consisted of completing a total of forty overnight ultrasonic bat sound recordings in November, thirty seven in May and twenty four in March, beginning at twilight, at twenty four locations within the survey area. A total of eleven acoustic survey nights were completed at two sites for Night Parrot in May and a further twelve in March. The recordings were "continuous"

(Hyder *et al.* 2010) made using ultrasonic SM2BAT+ SongMeter and acoustic SM4A SongMeter (both by Wildlife Acoustics Inc., USA) detectors. The audio settings used followed the manufacturer's recommendations contained in the user manuals.

For the ultrasonic recordings, once reformatted as .wav files, COOL EDIT 2000 (now available as AUDITION from Adobe Systems Inc.) was used to display each sequence for identification. Calls were identified manually. Only good quality call sequences were used. Details of calls analysed are provided in Table 2 as recommended by Australasian Bat Society (ABS 2006). Reference data for the species identified are available in Bullen and McKenzie 2002, McKenzie and Bullen 2003 and McKenzie and Bullen 2009.

For the acoustic recordings, each was reviewed both manually and using an automatic scan technique for Night Parrot calls. Candidate calls were compared with the author's confirmed reference calls from two Western Australian arid zone locations.

Survey Limitations

The sites surveyed were accessible on foot and the detectors, using omnidirectional microphones, were set on the ground with the microphone horizontal. Species are unlikely to be under-represented as a result.

Bat species density away from cave or adit entrances is impossible to estimate from echolocation records. Bat activity is therefore substituted as an approximate guide to the relative numbers of each species using the study area.

Results of bat fauna survey

An assemblage of twelve echolocating bat species was confirmed as present at the study sites including both the PLNb and PGb, table 4. Species activity levels were low to very high, which is expected for the study area habitat and the times of year.

PLNb detections

PLNb were detected at three widespread locations, two breakaway sites and a gorges site, table 4 and figure 3. Call numbers at all three were low with the maximum number of calls being eight at BAT 13 on the 22nd May, figure 4. The temporal pattern of calls at all three sites, figure 4, is consistent with PLNb foraging away from their roost with timing gaps from civil twilight of approximately three hours and being wide spread. This result is consistent with author's unpublished data that indicates that PLNb are only active across the study area in autumn. The closest confirmed permanent diurnal roosts are over 55 km to the north, west and south and over 80 km to the east (author's unpublished data). These distances suggest that the PLNb are possibly using temporary or satellite roosts in the district, as their usual foraging range is under 30 km (Bullen 2013). However the pattern of the data, the three hour time gap together with the low number of calls, is inadequate to indicate whether any potential satellite is within or outside the study area boundary. A more probable suggestion is that bats from existing permanent colonies take advantage of the benign conditions in autumn and spread across the country temporarily in search of additional foraging and roosting opportunities.

PGb detections

Ghost bats were detected ultrasonically at three sites, Bat 4 in November, BAT 21 in May and BAT 25 in March, table 4, figure 5. Additional observations were made by the field survey team, Table 5. Five caves containing PGb middens were located and a foraging PGb was seen at an opportunistic site, Table 5. Also a scat pile was observed under a highway bridge at site BAT 9. Two caves were assessed by the team as potential diurnal roosts and the other three caves and the

bridge as nocturnal feeding sites. These records are consistent with the PGB being present on both the Hope Down 2 and Bedded Hilltops study area ridges year round. This result is consistent with the known presence of the PGb across the central Pilbara in general and on the major ridges immediately to the north of the study area and west of the Hope Downs 1 mining area.

Common bat species detections
Four common species, *Austronomus australis*, *Chaerephon jobensis*, *Chalinolobus gouldii*, *Taphozous georgianus* and *Vespadelus finlaysoni* dominated bat presence in the area. Both Taphozous species were detected

Taxonomy presented herein is after Reardon *et al.* (2014) and Jackson and Groves (2015).

Results of Night Parrot survey.

No Night Parrot calls were detected.

Recommendations.

PLNb
The results of the survey are consistent with the author's existing data on the autumn dispersal of this species from its permanent roosts. No further specific targeted survey effort is indicated by these results.

PGb
The results of the survey are consistent with the use of the ridge lines within the study areas by PGb on a year round basis. Additional targeted survey effort is recommended to confirm potential maternity roost caves, groupings of caves that are important for the persistence of PGb, and other important diurnal roosting sites.

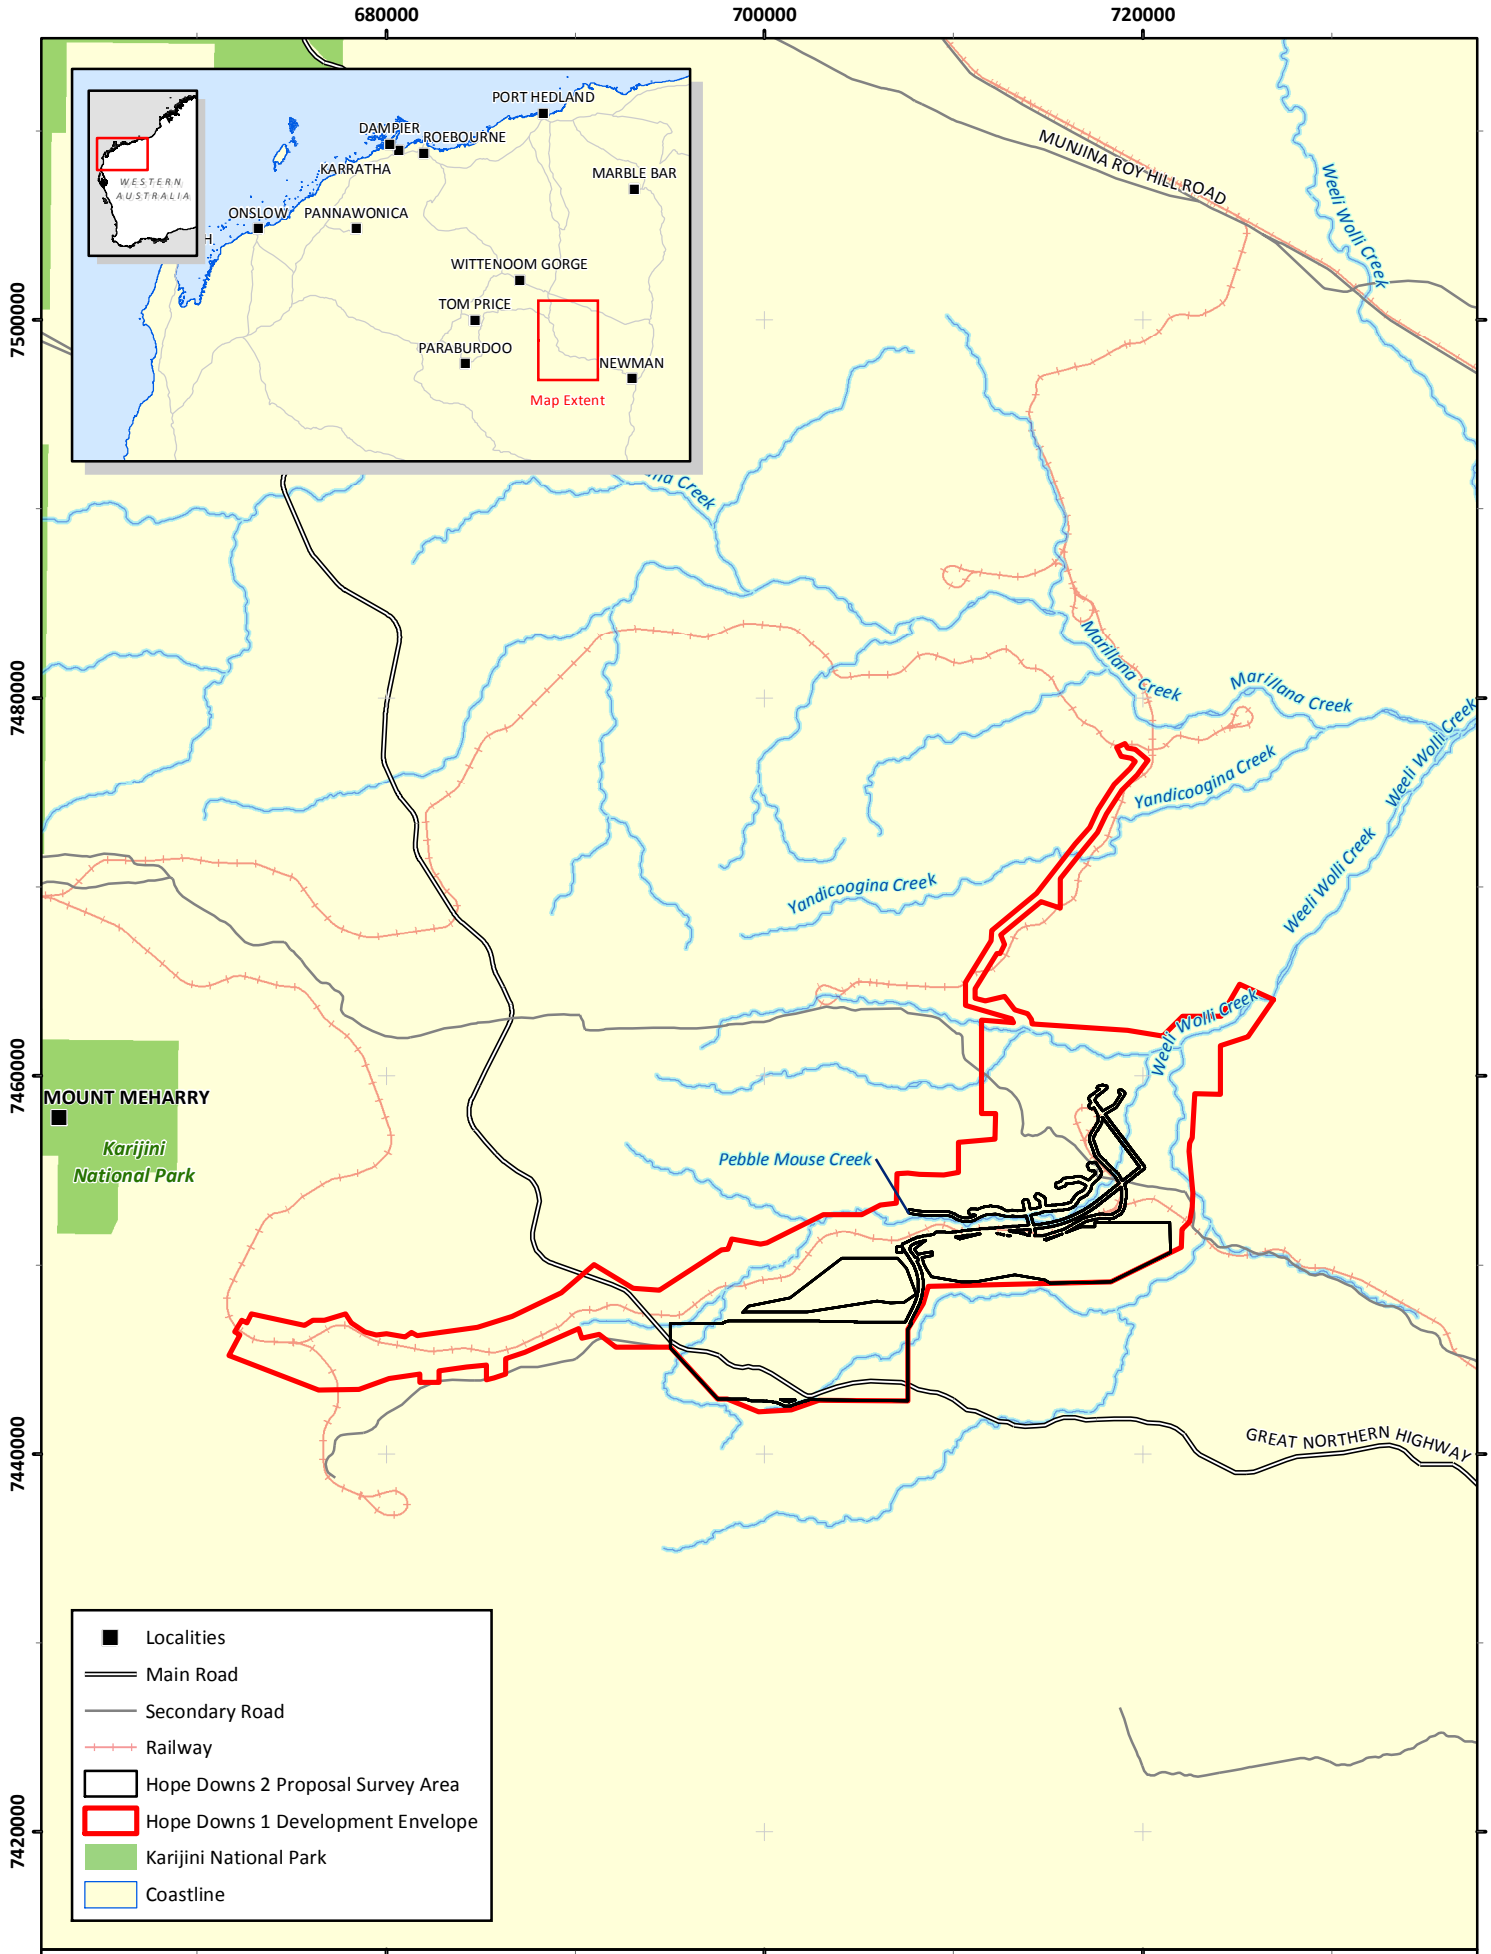
Dear Michelle,

Re: Hope Downs Development Envelope – Fauna Habitat Mapping

1 Introduction



Early in 2019 Rio Tinto commissioned a consolidation of all previous fauna habitat mapping across the Hope Downs 1 (HD1) Development Envelope. The HD1 Development Envelope encompasses the Hope Downs 2 Proposal area and the existing approved and operational Hope Downs 1 and Baby Hope mine sites, and corridors linking the West Angelas and Yandicoogina operations (36,944 ha) (Figure 1). A single, consolidated fauna habitat mapping GIS layer for the HD1 Development Envelope is presented in this letter.

2 Methods

Any previous fauna habitat mapping across the HD1 Development Envelope was consulted and incorporated into the final fauna habitat mapping layer ensuring fauna habitats aligned with those reported by Astron Environmental Services (2019a) as part of the Level 2 fauna surveys for the Hope Downs 2 proposal.

Forty-two fauna habitat assessments were conducted within the HD1 Development Envelope to consolidate or sample previously un-surveyed areas (Table A.1, Attachment A). A small area in the northern portion (319 ha) of the HD1 Development Envelope under Fortescue Metals Group (FMG) tenure was not able to be ground-truthed. Habitat mapping of this area was extrapolated using aerial imagery and available vegetation mapping (Astron Environmental Services 2019b). The locations of all the fauna habitat assessments within the HD1 Development Envelope are shown in Figure B.1 (Attachment B) and the following information was collected at each site:

- location – coordinates measured using a handheld GPS (GDA94)
- recorder and date – personnel involved in undertaking the fauna habitat assessment and the survey date

N

- habitat/landform – position in the landscape - major fauna habitat types were described based on the landform and vegetation
- vegetation type – a broad description of vegetation type and structure
- soils – a brief description of soil type
- microhabitat – presence of specific microhabitat features, for example, leaf litter, logs, burrows, rocky outcrops, rock crevices, hollows, permanent or semi-permanent water
- condition – habitat condition was assessed based on the presence of anthropogenic (human-induced) disturbances, and using the condition ratings suggested by Thompson and Thompson (2010)
- disturbance – any disturbance such as clearing, fire, weeds, flooding, vehicular, machinery, tracks or grazing
- photographs – a representative photograph was taken of each habitat assessment site.

The information derived from the fauna habitat assessments was used to delineate fauna habitats throughout the HD1 Development Envelope, which were then mapped accordingly. The potential for the mapped habitats to provide suitable habitat for MNES species Northern Quoll (*Dasyurus hallucatus*) (EN, EN), Ghost Bat (*Macroderma gigas*) (VU, VU), Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) (VU, VU), Night Parrot (*Pezoporus occidentalis*) (EN, CR) and Pilbara Olive Python (*Liasis olivaceus barroni*) (VU, VU) were ranked according to the criteria listed in Table 1.

Table 1: Suitability/significance of habitat ranking criteria for the target Matters of National Environmental Significance (MNES) species.

Species	Probable shelter and foraging habitat	Potential shelter and foraging habitat	Suitable foraging and dispersal habitat	Limited foraging and dispersal habitat
Pilbara Olive Python (*Liasis olivaceus barroni*)	N/A	Rocky habitat such as gorges, escarpments and breakaways along with drainage lines including or near permanent or semi-permanent water holes.	Drainage lines with dense vegetation enabling transitory behaviours and/or providing foraging potential. Rocky habitats that are not near water.	Habitat that has limited sheltering and foraging capacity with no permanent or semi-permanent water.
Northern Quoll *(Dasyurus hallucatus)*	Habitat as described in potential shelter and foraging habitat but is considered core habitat critical to the Northern Quoll. This was determined by proximity to known records and microhabitat features, such as south-facing, extent of habitat and whether it was in close association with a gorge or gully.	Rocky habitats such as ranges, escarpments, mesas, gorges, breakaways and boulder fields. Also major drainage lines or tree-lined drainage systems that are structurally diverse and contain large diameter trees, termite mounds or hollow logs.	Habitat important for foraging, dispersal and buffering of the species including moderate to small sized drainage lines and native vegetation in proximity (within 2 km) denning or shelter habitat.	Habitat that has limited sheltering and foraging capacity and not connected to potential denning/shelter and foraging habitat.
Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) and Ghost Bat (*Macroderma gigas*)	N/A	Rocky habitat that contains caves suitable as diurnal or maternity roosts sites, or potentially contains these caves and has not been adequately surveyed OR Areas highly suitable for foraging that are likely to be used on a regular basis.	Habitat important for foraging including diverse rocky terrain, moderately sized drainage lines and dense complex vegetation stands.	Habitat that has limited ecological value but may provide capacity for transitory movement across the landscape and/or limited foraging potential.

Species	Probable shelter and foraging habitat	Potential shelter and foraging habitat	Suitable foraging and dispersal habitat	Limited foraging and dispersal habitat
Night Parrot (*Pezoporus occidentalis*)	N/A	Isolated habitat not subjected to predation pressure, fire pressure, and altered habitat from pastoralism and mining activities. Generally roosting habitat that contains old and large spinifex clumps (>50 years unburnt), particularly ring-forming hummocks. OR Areas highly suitable for foraging in close association (<10 km) to potential roosting habitat, including *Triodia* (particularly at times of mass flowering and seeding) and chenopod communities dominated by *Sclerolaena*.	Very little is known on the foraging requirements of the Night Parrot. Habitat within 40 km of potential roosting and nesting sites, potentially important for foraging, including chenopod communities (particularly those dominated by *Sclerolaena*), *Triodia* and areas rich in herbs, including forbs, grasses and grass-like plants.	Habitat that has limited roosting and foraging potential for the Night Parrot.

3 Results and Discussion

3.1 Fauna Habitats

Nine broad fauna habitat types were recorded in the HD1 Development Envelope including: Major Drainage, Minor Drainage, Gorge/Gully, Breakaway, Rocky Hill, Low Hill and Slopes, Alluvial Plain, Mulga Woodland and Stony Plain (Table 2 and Figure B.1, Attachment B).

Areas of cleared habitat were prevalent throughout the operational mining areas within the HD1 mine site and Baby Hope deposit. These areas were associated with active mining and infrastructure and nearby mineral drilling programs such as drill pads and drill access tracks. These areas totalled 4,891.1 ha (13.2%) and were considered in 'disturbed' condition (Table 2). The fauna habitats surrounding these areas have been impacted by edge effects, lack of connectivity, grazing and the vegetation is often covered in dust. Most of the habitats away from the mining operations were considered 'very good' to 'high quality' condition owing to the lack of disturbances from fire, weeds and grazing. The Minor and Major Drainage habitats were heavily impacted by weed species such as **Cenchrus ciliaris* (Buffel Grass) and **Malvastrum americanum* (American Malvastrum), as well as impacts through extensive grazing and erosion from livestock. The Gorge and Breakaway habitats generally had the highest quality fauna habitat condition due to isolation from these threatening processes.

Major Drainage habitat is of high importance to fauna species providing a range of ecological values to a wide suite of species. This habitat type was often narrow linear isolated pockets of riparian vegetation, which is usually denser, taller and more diverse than the adjacent Minor Drainage habitat. The vegetation was complex and provided a range of micro niches for fauna species to exploit, such as for shelter and foraging. There were also a significant number of permanent and semi-permanent water bodies that provide drinking opportunities for a range of species and attract prey for predators. This habitat potentially supports conservation listed fauna species such as Northern Quoll and provides foraging sites for Ghost Bats and Pilbara Leaf-nosed Bats.

Minor Drainage habitat is a commonly recorded habitat for the Pilbara region and considered to be of moderate value to a wide spectrum of fauna species. The Minor Drainage habitat comprised a reduced diversity and density in vegetation species and communities, particularly when in the creek bed, and particularly when compared to riparian habitats, such as Weeli Wolli Creek located to the east of the survey area. When present, vegetation typically exhibited a moderate diversity of microhabitats, with some tree hollows and woody debris such as logs and leaf litter. The woody debris provides foraging and sheltering potential to ground dwelling reptiles and mammals. There were limited locations in this habitat that supported the potential for semi-permanent water bodies to form. Ground dwelling fauna are likely to utilise the linear nature of this habitat to traverse between habitats.

Gorge/Gully habitat is one of the more restricted habitats in the survey area. Gorges are a common feature of the Pilbara; however, as they tend to be narrow, linear features, gorges represent a small proportion of the total land area. In addition, they represent important shelter or roosting habitat for a number of MNES species, including the Pilbara Olive Python, Ghost Bat, Pilbara Leaf-nosed Bat and Northern Quoll. They may also support Priority listed species such as the blind snake *Anilios ganei* (P1). Occasional deep caves and semi-permanent rock pools are features within this habitat that can provide refuge and foraging opportunities for fauna during harsher drier seasonal conditions. There was one permanent/semi-permanent pool present during the survey at HA40. In addition, there are a number of locations where water could potentially pool after significant rain events, particularly within the Bedded Hilltop (BHT) area. This habitat was considered of high value

as it contains a complexity of microhabitats and potentially supports conservation significant fauna species.

Breakaway habitat is a common feature of the Pilbara; however, they tend to be narrow, linear features that represent a small proportion of the total land area. The breakaways of the survey area were often associated with the drop off areas of the Rocky Hill habitat and were specifically pertinent to BHT. Breakaway habitat contained microhabitats such as crevices, overhangs and shallow caves that provide shelter opportunities for MNES species. The caves have the potential to be used as diurnal roosts and nocturnal feeding roosts for the Ghost Bat, potential den sites for the Northern Quoll and Pilbara Olive Python. The Breakaway habitat provides important habitat values to a number of conservation listed species including MNES; therefore, it was considered of high importance for fauna.

Rocky Hill habitat is common and widespread throughout the Pilbara. This habitat generally has low vegetation complexity and low diversity of microhabitats; however, MNES species (such as the Northern Quoll) are likely to traverse and forage within these habitats. Other conservation significant species such as the Western Pebble-mound Mouse, *Anilios ganei* and the Pilbara Barking Gecko may also utilise this habitat. The soils are generally stony and compact, reducing the potential opportunities for burrowing species. Therefore, this habitat was considered of moderate value for fauna.

Low Hill and Slopes habitat is widespread and common throughout the Pilbara region and although there are a few conservation listed species that may utilise this habitat, they are unlikely to be restricted to it, except for the Western Pebble-mound Mouse. This habitat generally has low vegetation complexity and low diversity of microhabitats available for fauna species to exploit. The soils were generally stony and compact, reducing potential opportunities for burrowing species. This habitat was of low value to a broad spectrum of fauna species.

Alluvial Plain habitat is associated closely with drainage landforms of the Pilbara as it is often formed from the sediment overflow from drainage systems during flooding events. The Alluvial Plain habitat was of moderate value to a wide spectrum of fauna species as this habitat typically exhibited a moderate diversity of microhabitats, with some tree hollows and logs, and some areas of sandy soils suitable for burrowing. At the time of the survey, the tree hollows of this habitat supported nesting potential for small passerines such as pardalotes, thornbills and multiple species of honeyeaters. Within the survey area the vegetation of this habitat was generally less complex when compared to Minor Drainage habitat, with an absence of large eucalypts. This habitat may provide some limited foraging opportunities for Ghost Bats and Pilbara Leaf-nosed Bats.

Mulga Woodland habitat is characterised by vegetation communities dominated by Mulga (*Acacia aneura*) on a stony mantle. The open to moderately dense woodlands consisted of an understorey composed of sparse tussock or hummock grasses. The woodlands provide nesting and shelter habitats for birds and reptiles and the tussocks and hummocks provide habitat for small birds, reptiles and mammals. Mulga Woodlands are also subject to sheet water flow after rainfall and vegetation is often densely clumped or banded due to the sheet flow, often forming large groves. However due to a low diversity of microhabitats present (generally the understorey and leaf litter were considered sparse), this habitat type was considered of low value to a wide spectrum of fauna species.

Stony Plain habitat is widespread and common throughout the Pilbara region and although there are a few species of conservation significance that may utilise it, they are not restricted to this habitat type. Conservation significant fauna likely to occur in this habitat type include the Western

Pebble-mound Mouse. This habitat generally had low vegetation complexity and microhabitat diversity and was of low value for fauna.

3.2 Habitat Suitability for MNES Species

3.2.1 Northern Quoll

Approximately 665.4 ha (2%) of the HD1 Development Envelope, comprising Gorge/Gully and some Breakaway habitats, was considered probably shelter and foraging habitat (or core habitat as per the referral guidelines (Department of the Environment and Energy 2016)), based on proximity to known quoll records, microhabitat features and orientation aspect (Figure B.2, Attachment B). Approximately 255 ha (1%) of the survey area was considered potential shelter and foraging habitat, comprising mainly smaller Breakaway habitat (Figure B.2, Attachment B). The Gorge/Gully and Breakaway habitats contain rocky environments of high relief that are particularly important for Northern Quolls in the Pilbara as they provide potential denning sites for breeding and shelter and diverse microhabitats for foraging.

Approximately 4,814.2 ha (13%) of the HD1 Development Envelope was considered suitable foraging and dispersal habitat (Major and Minor Drainage, and Rocky Hill habitats), particularly where these habitats were in close association with the Gorge/Gully and Breakaway habitats as they provided microhabitats such as crevices and cracks for foraging (Figure B.2, Attachment B). The remaining 31,209 ha (84%) of the HD1 Development Envelope was considered to provide limited foraging and dispersal habitat, consisting of Alluvial Plain, Low Hills and Slopes, Mulga Woodland, Stony Plain and Disturbed habitats (Figure B.2, Attachment B).

3.2.2 Pilbara Leaf-nosed Bat

Approximately 920.4 ha (3%) of the HD1 Development Envelope, comprising the Gorge/Gully and Breakaway habitat, was considered potential shelter and foraging habitat for this species due to the presence of nocturnal refuge caves (Figure B.3, Attachment B). Approximately 31,132 ha (84%) of the HD1 Development Envelope, which consisted of Alluvial Plain, Major and Minor Drainage, Low Hills and Slopes, Mulga Woodland, Rocky Hill and Stony Plain habitats was considered suitable foraging and dispersal habitat (Figure B.3, Attachment B). The remaining 4,891.1 ha (13%) of the HD1 Development Envelope, comprising Disturbed areas, was considered to provide limited foraging and dispersal habitat (Figure B.3, Attachment B).

3.2.3 Ghost Bat

Approximately 920.4 ha (3%) of the HD1 Development Envelope, comprising the Gorge/Gully and Breakaway habitat, was considered potential shelter and foraging habitat (Figure B.4, Attachment B), due to the presence of caves that potentially support roost sites. Often Gorge/Gully and Breakaway habitats contain caves and deep shelters that are used as nocturnal feeding roosts by Ghost Bats.

Approximately 4,814.2 ha (13%) of the HD1 Development Envelope, which consisted of Major and Minor Drainage, and Rocky Hill habitats, was considered suitable foraging and dispersal habitat (Figure B.4, Attachment B). The taller trees provide ideal foraging/hunting perches particularly in areas that have, or have the potential for, semi-permanent surface water and contain thick vegetation. The Rocky Hill habitat contains microhabitats such as boulder piles, cracks and crevices that support a wide range of prey species for the Ghost Bat. The remaining 31,209 ha (84%) of the HD1 Development Envelope, comprising the Alluvial Plain, Low Hills and Slopes, Mulga Woodland,

Stony Plain and Disturbed habitats, was considered to provide limited foraging and dispersal habitat (Figure B.4, Attachment B).

3.2.4 Night Parrot

None of the habitats of the HD1 Development Envelope supported old, large and unburnt *Triodia* clumps that are considered the primary habitat requirement for the Night Parrot (Department of Parks and Wildlife 2017). The Alluvial Plain, Major and Minor Drainage, Mulga Woodland and Stony Plain habitats (11,738.2 ha, 32%) within the HD1 Development Envelope were mapped as suitable foraging and dispersal habitat (Figure B.5, Attachment B). However, most of these habitats have been impacted by recent fires (less than 10 years old), pastoral and mining impacts over a long duration, very sparse ground cover vegetation and a lack of chenopod communities or suitable size/age *Triodia* hummocks and are unlikely to support the Night Parrot. The remaining 25,205.4 ha (68%) was considered to provide limited foraging and dispersal habitat (Figure B.5, Attachment B).

3.2.5 Pilbara Olive Python

Approximately 920.4 ha (3%) of the HD1 Development Envelope, comprising the Gorge/Gully and Breakaway habitats, was considered as potential shelter and foraging habitat for the Pilbara Olive Python (Figure B.6, Attachment B). The caves and overhangs of the Gorge and Breakaway habitats are likely to provide denning sites and ambush locations frequented by this species.

Approximately 1,893 ha (5%) of the HD1 Development Envelope was considered suitable foraging and dispersal habitat, which consisted of Major and Minor Drainage habitats (Figure B.6, Attachment B). The remaining 34,130.2 ha (92%) of the HD1 Development Envelope was considered to provide limited foraging and dispersal habitat, consisting of Alluvial Plain, Low Hills and Slopes, Mulga Woodland, Rocky Hill, Stony Plain and Disturbed habitats (Figure B.6, Attachment B).

Table 2: Fauna habitat types recorded in the Hope Downs 1 Development Envelope.

Habitat type	Extent in HD1 Development Envelope (proportion)	Broad habitat description	Vegetation description	Microhabitats	Sites	Habitat condition	Value (broad faunal assemblage and MNES species)	Representative photo
Major Drainage	244.2 ha (0.7%)	Closed drainage areas on stony soils. Water bodies only present during times of heavy inundation	*Eucalyptus victrix* (*Eucalyptus camaldulensis*) woodland over *Melaleuca argentea* tall shrubland over *Petalostylis labicheoides* and *Acacia* spp. tall open shrubland over tussock grassland	Water bodies, hollow bearing trees and logs, thick ground cover/ vegetation, deep leaf litter	HA21, HA23, HA26	Very Good	Primary high value habitat for target MNES species. Provides significant shelter sites and supports a diversity of fauna species.	
Minor Drainage	1,648.9 ha (4.5%)	Open drainage areas on stony soils. Water bodies only present during times of heavy inundation	Scattered *Eucalyptus victrix* woodland over *Petalostylis labicheoides* and *Acacia* spp. tall open shrubland over tussock grassland	Hollow bearing trees and logs, thick ground cover/ vegetation, deep leaf litter	HA14, HA20, HA31	Good to High Quality	Moderate value to a wide spectrum of fauna species that are likely to reside in Minor Drainage habitats. Low value to target MNES species as they do not provide significant shelter.	
Gorge/ Gully	622 ha (1.7%)	Deep often rocky gorges, sometimes with ephemeral or semi-permanent pools	*Eucalyptus leucophloia* subsp. *leucophloia* and *Corymbia ferriticola* scattered low trees or *Eucalyptus repullulans* scattered low mallee over *Triodia pungens*, *T. vanleeuwenii* very open hummock grassland and scattered tussock grasses	Overhangs, crevices, caves, tree hollows, ephemeral, semi-permanent water	HA1, HA8, HA33, HA35, HA40	Very Good to High Quality	Primary high value habitat for target MNES species. Provides significant shelter sites and supports a diversity of fauna species.	
Breakaway	298.5 ha (0.8%)	Breakaway or ridge line, falling away to steep scree slope or drainage	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Acacia* spp. tall shrubs over *Triodia pungens* very open hummock grassland, sometimes with scattered tussock grasses	Caves (roost/feed caves), cracks and crevices, sheltered leaf litter	HA4, HA5, HA9, HA24, HA38	Very Good to High Quality	High value to a low diversity of fauna species that are likely to reside in Breakaway habitats. High value to target MNES species as they are likely to roost and den within this habitat type.	

Habitat type	Extent in HD1 Development Envelope (proportion)	Broad habitat description	Vegetation description	Microhabitats	Sites	Habitat condition	Value (broad faunal assemblage and MNES species)	Representative photo
Rocky Hill	2,921.2 ha (7.9%)	Stony hills on high ranges with dissected valleys and gorges	*Eucalyptus leucophloia* subsp. *leucophloia* and *Corymbia hamersleyana* scattered low trees to low open woodland over mixed open shrubland over open *Triodia wiseana, T. pungens, T. vanleeuwenii* hummock grassland	Shallow overhangs, boulders and crevices	HA3, HA7, HA10, HA11, HA12, HA13, HA34, HA39	Good to High Quality	Moderate value for target MNES species as they are likely to traverse and forage within these habitats. Moderate value to a low diversity of fauna species that are rocky habitat specialists.	
Low Hills and Slopes	16,472.6 ha (44.6%)	Low stony hills and slopes with dissected valleys and drainage on stony soils	*Eucalyptus leucophloia* subsp. *leucophloia* and/or *Corymbia hamersleyana* scattered low trees over mixed *Acacia* spp. open shrubland over open *Triodia pungens, T. vanleeuwenii* hummock grassland	Termite mounds, *Triodia* hummocks, minimal leaf litter	HA2, HA17, HA19, HA22, HA25, HA36, HA37, HA41, HA42	Very Good to High Quality	Low value to a wide spectrum of fauna species that are likely to reside within these habitats. Low value to target MNES species as this habitat type offers minimal ecological value to these species.	
Alluvial Plain	1,332.7 ha (3.6%)	Flood plain surrounding drainage areas	*Acacia pruinocarpa, A. aptaneura, Eremophila longifolia* tall open shrubland over tussock grassland	Dense leaf litter, termite mounds and spinifex clumps, cracking clays	None	Very Good	Low value to a wide spectrum of fauna species that are likely to reside within these habitats. Low value to target MNES species as this habitat type offers minimal ecological value to these species.	
Mulga Woodland	5,818.8 ha (15.7%)	Stands of Mulga groves on clay based stony plains	*Acacia catenulata*, (*A. pruinocarpa*) tall shrubland over *Eremophila fraseri* scattered tall shrubs over *Triodia pungens* very open hummock grassland	Limited microhabitats, termite mounds, minimal leaf litter	HA6, HA18, HA28, HA29, HA30, HA32	Disturbed to High Quality	Low value to a wide spectrum of fauna species that are likely to reside within these habitats. Low value to target MNES species as this habitat type offers minimal ecological value to these species.	

Habitat type	Extent in HD1 Development Envelope (proportion)	Broad habitat description	Vegetation description	Microhabitats	Sites	Habitat condition	Value (broad faunal assemblage and MNES species)	Representative photo
Stony Plain	2,693.8 ha (7.3%)	Broad flat low-lying plains to undulating plains on soft loamy soils	*Acacia aptaneura, A. pruinocarpa, A. catenulata* tall shrubland over *Triodia pungens* (and sometimes *T. vanleeuwenii)* hummock grassland or tussock grassland	Limited leaf litter, termite mounds and spinifex clumps	HA15, HA16, HA27	Very Good	Low value to a wide spectrum of fauna species that are likely to reside within these habitats. Low value to target MNES species as this habitat type offers minimal ecological value to these species.	
Disturbed	4,891.1 ha (13.2%)	Cleared areas from mining and pastoralism activities	Vegetation structure disturbed or absent.	None	None	Highly Degraded	Little value as fauna habitat.	

This letter was prepared by Principal Environmental Scientist Dr Jessica Johnston and was technically reviewed by Senior Environmental Scientist Matthew Love. If you would like to discuss this further, please feel free to contact me on 9421 9600.

C.3: Hope Downs 2 Proposal – Ghost Bat Cave Characteristics Report

19 May 2020

Our Reference: 14292B-20-BILR-1Rev0_200519

Michelle Doak
Senior Advisor Environmental Approvals
Rio Tinto
Central Park
152-158 St Georges Terrace
Perth WA 6000

Dear Michelle,

Re: Hope Downs 2 Proposal – Ghost Bat Cave Characteristics, February/March 2020

1 Introduction

Rio Tinto required additional assessment to be made of previously recorded caves by Astron Environmental Services (Astron) within the Hope Downs 2 (HD2) Proposal survey area. Astron was commissioned to confirm the GPS coordinates and record cave characteristics, including estimated number of Ghost Bat (*Macroderma gigas*) (VU; VU) scats, external and internal dimensions, entrance orientation and any other annotations, of the previously recorded Ghost Bat caves 1, 2, 4, 5, 6 and 8.

2 Methods

Astron previously recorded six Ghost Bat caves (Cave 1, 2, 4, 5, 6 and 8) within the HD2 Proposal survey area in 2017 (Astron Environmental Services 2020), prior to being permitted to enter caves to record internal dimensions. Astron zoologists Matthew Love and Lucy Dadour revisited the six Ghost Bat caves between 25 February and 2 March 2020 to confirm the GPS coordinates and record the following:

- external and internal dimensions of the cave, including annotations
- cave entrance orientation
- the number of Ghost Bat scats present and any other evidence of Ghost Bats
- photographs.

3 Results

The GPS coordinates and physical characteristics of the six previously recorded Ghost Bat caves are provided in Table 1. In addition to the six previously recorded caves, Astron zoologists located an additional Ghost Bat cave within the HD2 Proposal survey area that had not previously been recorded. The location and characteristics of this cave (Cave 10) are also provided in Table 1.

Table 1: Location of caves within Hope Downs 2 Proposal Survey Area.

C.4: Hope Downs 2 Proposal – Ghost Bat Memo

9 August 2023

Our Reference: 14200-009-22-BILR-2Rev0_220809

Sally Pickard
Senior Environmental Approvals Advisor
Rio Tinto
Central Park
158 St Georges Terrace
Perth WA 6000

Dear Sally,

Re: Hope Downs 2 Proposal – Ghost Bat Memo, August 2023

1 Introduction

Rio Tinto has referred to the Environmental Protection Authority (EPA) the potential development of two above water table iron ore deposits, Hope Downs (HD) 2 and Bedded Hilltop (together referred to as the 'HD2 Survey Area'), located within the Greater Hope Downs area in the Pilbara region of Western Australia. A Preliminary Feasibility Study (PFS) has commenced. Based on the outcome of the PFS, the Project is expected to progress into a Feasibility Study in late 2022/23. The environmental approvals process commenced in 2021 with referral under both the State *Environmental Protection Act 1986* and Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) being undertaken. The EPA set a Public Environmental Review level of assessment.

The Banjima Native Title Aboriginal Corporation commissioned Strategen JBS&G (Strategen) (2021) to undertake a peer review of the baseline survey reports that had been undertaken to date to support the previous environmental review document. Rio Tinto is committed to providing a response to the peer review conclusions and recommendations.

The Scope of Work was to provide a letter summarising the work undertaken to date on the Ghost Bat (*Macroderma gigas;* Vulnerable) within the HD2 Survey Area in response to the recommendations provided by Strategen's (2021) review of the following reports:

- Hope Downs 2 Proposal Fauna Survey (Astron Environmental Services 2020a)
- Hope Downs 2 Proposal Matters of National Environmental Significance Fauna Assessment (Astron Environmental Services 2020b)
- Hope Downs 2 Proposal – Ghost Bat Cave Characteristics, February/March 2020 (Astron Environmental Services 2020c)

With respect to Ghost Bats, Strategen (2021) made the following recommendations:

Survey Effort

- Clearly demonstrate that all potential roost caves have been adequately surveyed. Demonstrate survey effort overlain with habitat mapping.
- The report (Astron Environmental Services 2020b) states that "areas not traversed were assessed visually from a distance where possible and considered a low probability of containing caves". Give further consideration to undertaking additional targeted survey effort to demonstrate suitable roost caves are unlikely to occur in areas not traversed in the targeted Matters of National Environmental Significance survey. Consider the benefit of adopting techniques such as drones to adequately cover the development envelope and determine if any potential roost caves occur which may require additional survey.

Ghost Bat Records within the Survey Area

- Show category of Ghost Bat roost on the figure displaying locations of Ghost Bat roost caves.

Regional Context of Ghost Bat Records

- Provide greater detail as to the regional context/ importance of the development envelope with respect to the Ghost Bat, i.e. proximity and location of nearest known significant roosts.

2 Survey Effort

There were no specific instructions for survey effort within relevant guidelines at the time of the surveys (Department of the Environment, Water, Heritage and the Arts 2010), except to focus selective searches and sampling procedures within large survey areas. The most recent publication on Ghost Bats (Bat Call WA 2021), which was published following completion of surveys within the HD2 Survey Area, states that surveys should focus on the most likely areas within a study area; that is, in gorges, deep gullies flanked by rocky outcrop and beneath ephemeral waterfalls, focusing on landscapes composed primarily of Brockman and Marra Mamba banded iron formation.

Searches were focused within the Brockman Iron Formation and Marra Mamba Iron Formation geological units of the HD2 Survey Area that were mapped as Breakaway and Gorge/Gully habitats. Astron considers that suitable habitat within the HD2 Survey Area has been adequately surveyed to record potential roost caves and that there are no areas considered to require further search effort. Echolocation recording sites were sampled across four phases – November 2017, May 2018, March 2019 and September 2019. When all survey effort (Astron Environmental Services 2020c, 2020b, 2020a) is combined, including track logs and 27 echolocation bat recording sites, Astron considers that the HD2 Survey Area has been adequately surveyed. Other targeted assessments for the Northern Quoll (*Dasyurus halluctus*; Endangered) (Astron Environmental Services 2023a, 2023b, 2023c) have also been undertaken since Strategen's (2021) review, which covered similar habitats to those that support Ghost Bat roosts and would classify as additional search effort. Figure 1 shows survey effort to date overlain with fauna habitat mapping to demonstrate that the Gorge/Gully and Breakaway habitats have been thoroughly surveyed throughout the Survey Area. It was concluded by Bat Call WA (2019) that targeted survey effort for groupings of caves important for the persistence of Ghost Bat had been carried out at both the eastern and western ends of the HD2 Proposal Survey Area.

There are some areas of Gorge/Gully and Breakaway habitats deemed to be less suitable roosting habitat (did not contain overhangs or shallow caves) and not to contain roost caves suitable for Ghost Bats. These areas were not ground-truthed, as they were visually assessed as not suitable roosting habitat in the field by highly experienced personnel with over 10 years of experience.

3 Ghost Bat Records within the Survey Area

The Ghost Bat has been recorded on 12 occasions within the HD2 Survey Area during previous Astron surveys, through acoustic recordings/calls (BAT4, BAT21 and BAT25), scats (seven records) and sighting of two individuals (one during spotlighting and one within Cave 8 during a cave assessment) (Astron Environmental Services 2020c, 2020b, 2020a) (Figure 2 and Table 1.1, Attachment 1).

Nine Ghost Bat caves have been recorded within the Survey Area (Figure 2 and Table 1.2, Attachment 1). One cave (Cave 10) was deemed to be a Category 2 maternity/diurnal roost cave with regular occupancy according to Bat Call WA (2021). Because of current insufficient data to identify any trends, any cave that has regular occupancy must be assumed to be capable of supporting one or more reproducing females and their offspring, and is therefore considered critical habitat (Bat Call WA 2021).

Two caves (Caves 1 and 5) were deemed to be Category 3 roost caves with occasional occupancy. When adjacent to Category 2 caves, these are considered to be a part of an 'apartment block' and are therefore critical habitat important for the ongoing presence of the species in the area (Bat Call WA 2021). In contrast, isolated Category 3 caves are not considered critical habitat essential to the long-term viability of a local population (Bat Call WA 2021). However, these caves may enable the long-distance movement of individuals across a landscape, and therefore contribute to genetic exchange between neighbouring colonies (Bat Call WA 2021).

The remaining six caves (Caves 2, 3, 4, 6, 7 and 8) were deemed to be Category 4 nocturnal roost caves (opportunistic usage) and are not considered significant (Bat Call WA 2021). These Category 4 caves are common in the landscape and numerous observations suggest that the majority of caves and adits in the Pilbara are used in at least an opportunistic manner by itinerant Ghost Bats (Bat Call WA 2019).

4 Regional Context of Ghost Bat Records

The number of Ghost Bats within the Hamersley Range of the Pilbara region has been estimated at 350 individuals, with Ghost Bats mostly being encountered as groups of one to 15 individuals roosting in caves in ironstone strata (Bat Call WA 2021). In the wet season, these groups have been observed to include reproducing females (Bat Call WA 2021). The records of Ghost Bats within the HD2 Proposal Survey Area indicate that the Ghost Bat forages in low numbers on the HD2 and Bedded Hilltop ridges, with only one to two calls recorded across four phases of survey (November 2017, May 2018, March and September 2019) (Bat Call WA 2019). No evidence of activity consistent with reproducing bats was detected (Bat Call WA 2019). The records are consistent with the known regional presence of the Ghost Bat across the central Pilbara region (Hamersley subregion), as well as locally on the major ridges immediately to the north of the survey area and west of the HD1 mining area (Bat Call WA 2019).

There are a number of Pilbara caves and adits that are considered Category 2 roosts, where Ghost Bats have regular, but not continuous, presence over long periods (Bat Call WA 2021). The longest continuous monitoring programs have been at Rio Tinto's West Angelas project, just west of the HD2 Survey Area, and at BHP's Mining Area C and South Flank projects, immediately to the north of the HD2 Survey Area (Bat Call WA 2021). At all three locations there are several caves with roosting Ghost Bat records but none of these have had either permanent presence or consistently high numbers present (Bat Call WA 2021). Numbers have varied between zero and five individuals, with very occasional counts of 20 or more (Bat Call WA 2021). Based on recent monitoring of several Hamersley Range caves using ultrasonic call detectors, Ghost Bats may be present for 25% to 75% of nights over periods of up to several months, but then may abandon the caves for weeks or even months at a time (Bat Call WA 2021). At present, there is insufficient data to determine if there are any seasonal trends in these occupancy rates (Bat Call WA 2021). These caves typically have several other caves, shelters, and overhangs within a few hundred metres and together they make up an 'apartment block' grouping (Threatened Species Scientific Committee 2016) that supports the ongoing presence of the bats.

Other caves and/or shelters have not been recorded within proximity to the Category 2 Ghost Bat roost cave (Cave 10) within the HD2 Survey Area, and all suitable Gorge/Gully habitat within a 500 m radius of Cave 10 has been searched. The nearest caves are approximately 1.25 km (Cave 2 – Category 4), 3.26 km (Cave 4 – Category 4) and 3.43km (Cave 1 – Category 3) from Cave 10. No groupings of caves with regular calls, suggesting a more heavily used 'apartment block', have been identified to date within the HD2 Survey Area. However, ultrasonic detector units have not been placed within Cave 10, so the number of Ghost Bats utilising the cave and the frequency of usage is currently unknown.

This letter was prepared by Principal Zoologist Dr Jessica Johnston and technically reviewed by Principal Environmental Scientist Janelle Atkinson. If you have any queries please contact Senior Project Coordinator, Melissa Ford on (08) 9421 9600.

Central Park
158 St Georges Terrace
Perth WA 6000

Dear Sally,

Re: Hope Downs 2 Proposal – Grey Falcon Environmental Impact Assessment, August 2023

1 Introduction

1.1 Background

Rio Tinto has referred to the Environmental Protection Authority (EPA) the potential development of two above water table iron ore deposits, Hope Downs 2 (HD2) and Bedded Hilltop (referred to as the 'HD2 survey area'), located within the Greater Hope Downs area, in the Pilbara region of Western Australia. A Preliminary Feasibility Study (PFS) Study has commenced. Based on the outcome of the PFS, the Project is expected to progress into Feasibility Study in late 2022/23. The environmental approvals process commenced in 2021 with referral under both the State *Environmental Protection Act 1986* and Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) being undertaken. The EPA set a Public Environmental Review level of assessment.

The Department of Agriculture, Water and the Environment (DAWE) determined the project a controlled action under the EPBC Act, with an accredited assessment pathway. DAWE identified that the proposed action is likely to have a significant impact on Matters of National Environmental Significance species, including the Grey Falcon (*Falco hypoleucos*), which has been listed as Vulnerable since the baseline surveys were undertaken (Astron Environmental Services 2020).

1.2 Scope of Work

The Scope of Work was to undertake a review of the Grey Falcon's occurrence within the HD2 survey area based on the records captured during the baseline survey and any local surveys that have been completed in adjacent areas, to inform environmental impact assessment.

2 Grey Falcon

The Grey Falcon (*Falco hypoleucos*) is specially protected under both State and Federal legislation. The species is listed as Criterion 4 ('Vulnerable') under the Western Australian *Biodiversity Conservation Act 2016* and as 'Vulnerable' under the Commonwealth EPBC Act.

The Grey Falcon is an elusive species endemic to mainland Australia. It is the rarest of six Australian falcons and one of the least common raptors (Olsen and Olsen 1986; Marchant and Higgins 1993). The Grey Falcon is a medium-sized raptor (400 g – 500 g) with females weighing on average about 30% more than males (Schoenjahn 2011). The Grey Falcon is a compact, pale grey falcon with a heavy thick chest, long wings and dark wing tips (Debus 2019; Schoenjahn 2010).

The species occurs in arid and semi-arid Australia, including the Murray-Darling Basin, Eyre Basin, central Australia and Western Australia (Marchant and Higgins 1993). The species is mainly found where annual rainfall is less than 500 mm, except when wet years are followed by drought when the species might become marginally more widespread, although it is essentially confined to the arid and semi-arid zones at all times (Schoenjahn 2018). The species appears to be absent from Cape York Peninsula, areas east of the Great Dividing Range in Queensland and New South Wales, south of the Great Dividing Range in Victoria, and south of latitude 26°S in Western Australia (Barrett et al. 2003; Schoenjahn 2018).

The Grey Falcon occurs at low densities across inland Australia (Birdlife Australia 2019). The species frequents timbered lowland plains, particularly *Acacia* shrublands that are crossed by tree-lined water courses (Garnett et al. 2011, Watson 2011, Janse et al. 2015, Ley and Tynan 2016, Schoenjahn 2018). The species has been observed hunting in treeless areas and frequents tussock grassland and open woodland, especially in winter (Janse et al. 2015, Schoenjahn 2018). While breeding, Grey Falcons feed almost exclusively on birds (Cupper and Cupper 1980, 1981, Schoenjahn 2013, Janse et al. 2015, Ley and Tynan 2016). Prey species include doves, pigeons, small parrots and cockatoos, and finches, but a variety of other bird prey species has been recorded (Marchant and Higgins 1993, Deebus and Rose 2000, Hollands 2003, Schoenjahn 2013). Grey Falcons have also been observed predating small mammals and lizards (Czechura 1981, Moore 2016).

Breeding occurs from June to November. Clutch size can vary from one to four eggs (Olsen and Olsen 1986, Garnett et al. 2011, Schoenjahn 2013). Data on laying dates and breeding events suggests that above average rainfall in the first half of the year may encourage breeding (Sutton 2010). Eggs are laid in the old nests of other birds, particularly those of other raptors or corvids. The nests chosen are usually in the tallest trees along watercourses, particularly River Red Gum (*Eucalyptus camaldulensis*) and Coolibah (*E. coolabah*), but falcons also nest in telecommunication towers (Marchant and Higgins 1993, Schoenjahn 2013, Schoenjahn 2018). Therefore, the critical breeding habitat for this species includes major drainage lines with established tall trees. The incubation period is 34 to 35 days (Cupper and Cupper 1980, Hollands 2003, Sutton 2010, Ley and Tynan 2016), with the nesting period between 40 to 50 days (Hollands 2003). Young falcons typically remain with their parents up to at least 12 months after fledging (Schoenjahn 2018).

Schoenjahn (2018) identified 10 plausible threats to the Grey Falcon and ranked them according to severity. These threats were extrapolated from closely related species since there is little data on specific threats to the Grey Falcon. The main threats (threat status equal to high or very high) identified were predation by cats, increased temperatures due to climate change, grazing by exotic herbivores, small population size and nest shortage (Garnett et al. 2011, Schoenjahn 2013).

3 Methods

The primary method of recording Grey Falcon is via opportunistic sightings. Targeted searches for this species are difficult due to their rarity, nomadic nature, and potential to range across a variety of habitats. Historical surveys within and surrounding the project area relied mainly on opportunistic sightings to detect this species. This species could have also been detected during targeted searches for other conservation significant species such as the Northern Quoll (*Dasyurus hallucatus*) and Pilbara

Olive Python (*Liasis olivaceus barroni*). Targeted searching for Grey Falcon involves intensive area searches on foot, involving detection by sight, call and signs of occupancy, especially nests.

Astron completed a Department of Biodiversity, Conservation and Attractions (DBCA) threatened and priority fauna search to identify any new records of this species within 75 km of the HD2 survey area (Department of Biodiversity, Conservation and Attractions 2022) and reviewed known information on this species, the survey effort completed in previous surveys and sightings recorded to date within the vicinity of the survey area.

The likelihood of the species being present within the survey area and the likely impacts to this species from the Project in accordance with the Commonwealth significant impact guidelines (Department of Environment 2013) were assessed.

4 Results

A DBCA database search returned four Grey Falcon records within 50 km of the HD2 survey area. Three of these records were from Area C South Flank deposit in 2008 within approximately 8 km from the HD2 survey area. The three records were of one individual each, all within 5 km of each other and four days apart, suggesting it was likely the same individual on all three occasions. The fourth record was from West Angelas in June 1997, within 22 km of the HD2 survey area. The record was of two individuals and given the record was from June and breeding occurs from June to November, it is possible that this was a record of a breeding pair.

Nine previous fauna surveys within 50 km of the HD2 survey area returned only one (1 record from 1,239 person days) Grey Falcon record (Table 1). During detailed fauna surveys at Rhodes Ridge, two adults were sighted opportunistically together on powerlines leading from Hope Downs 4 camp within Low Hills and Slopes habitat, approximately 45 km south-east from the HD2 survey area (Astron Environmental Services 2020). The record was from August and since breeding occurs from June to November, it is possible that this was a record of a breeding pair.

All habitats previously identified within the HD2 survey area (Astron Environmental Services 2020) could be utilised by the Grey Falcon for foraging, particularly areas where prey bird species are found. However, no Major Drainage Line habitat (preferred breeding habitat) is present within the HD2 survey area. Minor Drainage Line habitat is not considered suitable breeding habitat due to the lack of mature trees within this habitat. The closest potential breeding habitat for the Grey Falcon is the sections of Weeli Wolli Creek near discharge points that support riparian vegetation with larger trees, approximately 5 km north-east of the HD2 survey area, since it provides tall, established trees for breeding.

Table 1: Summary of literature review results from surveys conducted within the vicinity of the survey area.

Author (year)	Survey area; size (ha)	Survey level	Survey timing	Survey effort	Grey Falcon records
Astron (unpublished)	Rhodes Ridge survey area 110,745 ha	Level 2 (2 phases)	June 2019 -present (ongoing)	Baseline fauna assessment of terrestrial vertebrate fauna and short-range endemic (SRE) invertebrate fauna species within the survey area. Habitat assessments, 60 trapping sites, avifauna censuses at each trapping site, foot traverses, nocturnal searches, targeted searches for both vertebrates and SRE invertebrates, and the use of SM2 acoustic bat echolocation recorders and motion sensor cameras.	12 fauna sampling surveys 4 people per survey. Two phases, 21 days total. 134 person days. 46 hours of searching with the potential to encounter this species. Considered to have moderate potential to occur. Not recorded during survey. **0 records/ 134 person days.**
Ninox Wildlife Consulting (2009a)	Hope Downs 4 Option 1 Infrastructure Corridor Size not stated	Level 2 (1 phase)	May 2008	Four trapping sites, Anabat ultrasonic call detector, avifauna census, SRE sampling and opportunistic searches.	8 days 6 people. 48 person days. 10.5 hours of survey. Considered to have moderate potential to occur. Not recorded during survey. **0 records/ 48 person days.**
Ninox Wildlife Consulting (2009b)	Hope Downs 4 Option 6 Infrastructure Corridor Size not stated	Level 2 (2 phases)	September 2008 April 2009	Six trapping sites, Anabat ultrasonic call detector, avifauna census, SRE sampling and opportunistic searches.	14 days 6 people. 84 person days. 21 hours of avifauna survey. Considered to have moderate potential to occur. Not recorded during survey. **0 records/ 84 person days.**

5 Discussion

Major Drainage Line habitats represent the most suitable breeding and foraging habitat for Grey Falcons since they provide large trees for nesting and waterbodies which act as attractants for prey.

The closest major drainage line is the sections of Weeli Wolli Creek near discharge points that support riparian vegetation with larger trees, approximately 5 km north-east of the HD2 survey area. Since Major Drainage Line habitat does not lie within the HD2 survey area, it is unlikely that the Project will have significant impacts on breeding/nesting success.

The sighting of two individuals near HD4 camp (approximately 45 km from HD2 survey area) shows the species occurs in the general vicinity of the survey area. Given the time of year (August) and the maturity of the individuals, they were likely to be a breeding pair. Since the individuals were observed away from nesting habitat (within Low Hills and Slopes habitat), it is likely that they were foraging at the time of observation.

Grey Falcons forage across a variety of habitats. While suitable foraging habitat exists within the HD2 survey area and the Grey Falcon is likely to utilise the survey area for foraging, they are unlikely to rely solely on habitat within the survey area. Given the nomadic nature of the Grey Falcon, they tend not to be reliant on a specific habitat or area. The lack of fidelity to a set home range means that the species is less likely to be reliant on the habitats of the HD2 survey area and less likely to be impacted by the Project. The fauna habitats within the HD2 survey area are also not considered unique, and similar habitat is found in the surrounding area. Consequently, the HD2 survey area does not represent critical foraging or breeding habitat for this species.

The records of potential breeding pairs and individual records within 50 km of the HD2 survey area suggests a population of Grey Falcons exist in the surrounding area and may utilise the HD2 survey area for foraging.

6 Conclusions

Based on few previous records within 50 km of the HD2 survey area, the lack of historical records within the HD2 survey area despite a large amount of survey effort (1 record from 1,239 person days), lack of preferred breeding habitat within the survey area, and the nature of Grey Falcons to forage across a variety of habitats, it is unlikely that the Project will have a significant impact on this species.

This letter was prepared by Zoologist Brittany Osborn and technically reviewed by Principal Zoologist Dr Jessica Johnston. If you have any queries please contact Senior Project Coordinator, Melissa Ford on (08) 9421 9600.

Yours sincerely

Executive Summary

Rio Tinto is evaluating the potential development of additional iron ore deposits at Hope Downs 2 (HD2) in the Pilbara region of Western Australia. Astron Environmental Services was commissioned to undertake an assessment of Matters of National Environmental Significance (MNES) fauna species within the Hope Downs 2 Development Envelope (the survey area, which is 10,817.7 hectares). This MNES assessment was completed by undertaking:

- a review of a previously completed three phase Level 2 vertebrate fauna assessment of the survey area
- a targeted MNES field survey to better understand the distribution of MNES species within the survey area and to address the gaps in effort and coverage of the previously completed surveys.

Eight broad fauna habitat types have been recorded in the survey area: Minor Drainage; Gorge/Gully; Breakaway; Rocky Hill; Low Hill and Slopes; Alluvial Plain; Mulga Woodland; and Stony Plain. Areas of cleared habitat were present within the HD2 and Bedded Hilltop areas where exploration drilling had occurred in the form of drill pads and drill access tracks. The Gorge/Gully and Breakaway habitats in the survey area were considered important habitat for the MNES fauna species: Northern Quoll; Ghost Bat; Pilbara Leaf-nosed Bat; and Pilbara Olive Python. This is due to the microhabitats they provide such as caves and semi-permanent water pools that can exist in these refuge type areas and are important for species foraging and sheltering requirements.

Four MNES fauna species have been recorded within the survey area: Northern Quoll (*Dasyurus hallucatus*) (Endangered; Endangered); Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) (Vulnerable; Vulnerable); Ghost Bat (*Macroderma gigas*) (Vulnerable; Vulnerable); and Oriental Plover (*Charadrius veredus*) (Migratory; Migratory). No further records of any MNES fauna species were obtained during the targeted MNES survey.

The recent Northern Quoll records previously documented within the survey area are significant given that the survey area is at the edge of this species' regional distribution and there has been a paucity of previous local and regional records. These recent quoll records suggested that a resident population may exist in the survey area. No Northern Quolls were recorded during the targeted MNES survey, despite utilising sampling methods specifically designed to target this species. The conditions were considered poor due to dry conditions preceding the survey. The seasonal conditions, along with a high feral cat (*Felis catus*) activity recorded within the survey area, may have contributed to the lack of Northern Quoll records during the targeted MNES survey.

The nine previous records of Ghost Bats within the survey area, as well as two Category 3 roost caves with occasional occupancy and five Category 4 nocturnal roost caves, are consistent with the Ghost Bat foraging in low numbers on the HD2 and Bedded Hilltop. It is consistent with the known regional presence of the Ghost Bat across the central Pilbara region as well as locally on the major ridges immediately to the north of the survey area and west of the Hope Downs 1 mining area.

The Pilbara Leaf-nosed Bat has only been detected by calls at three locations during one previous field survey in May 2018 within the survey area and recordings were deemed to indicate low activity levels. The Pilbara Leaf-nosed Bat records were from foraging individuals in Gorge/Gully and Breakaway fauna habitats with all calls at least three hours after dusk and not consistent with presence of a permanent roost cave nearby.

One Oriental Plover individual was opportunistically sighted during the recent Level 2 surveys (Astron Environmental Services 2019) at the Hope Downs 1 village camp, likely due to the presence

of water at the camp. This species is unlikely to occur on a permanent basis within the unaltered habitats of the survey area.

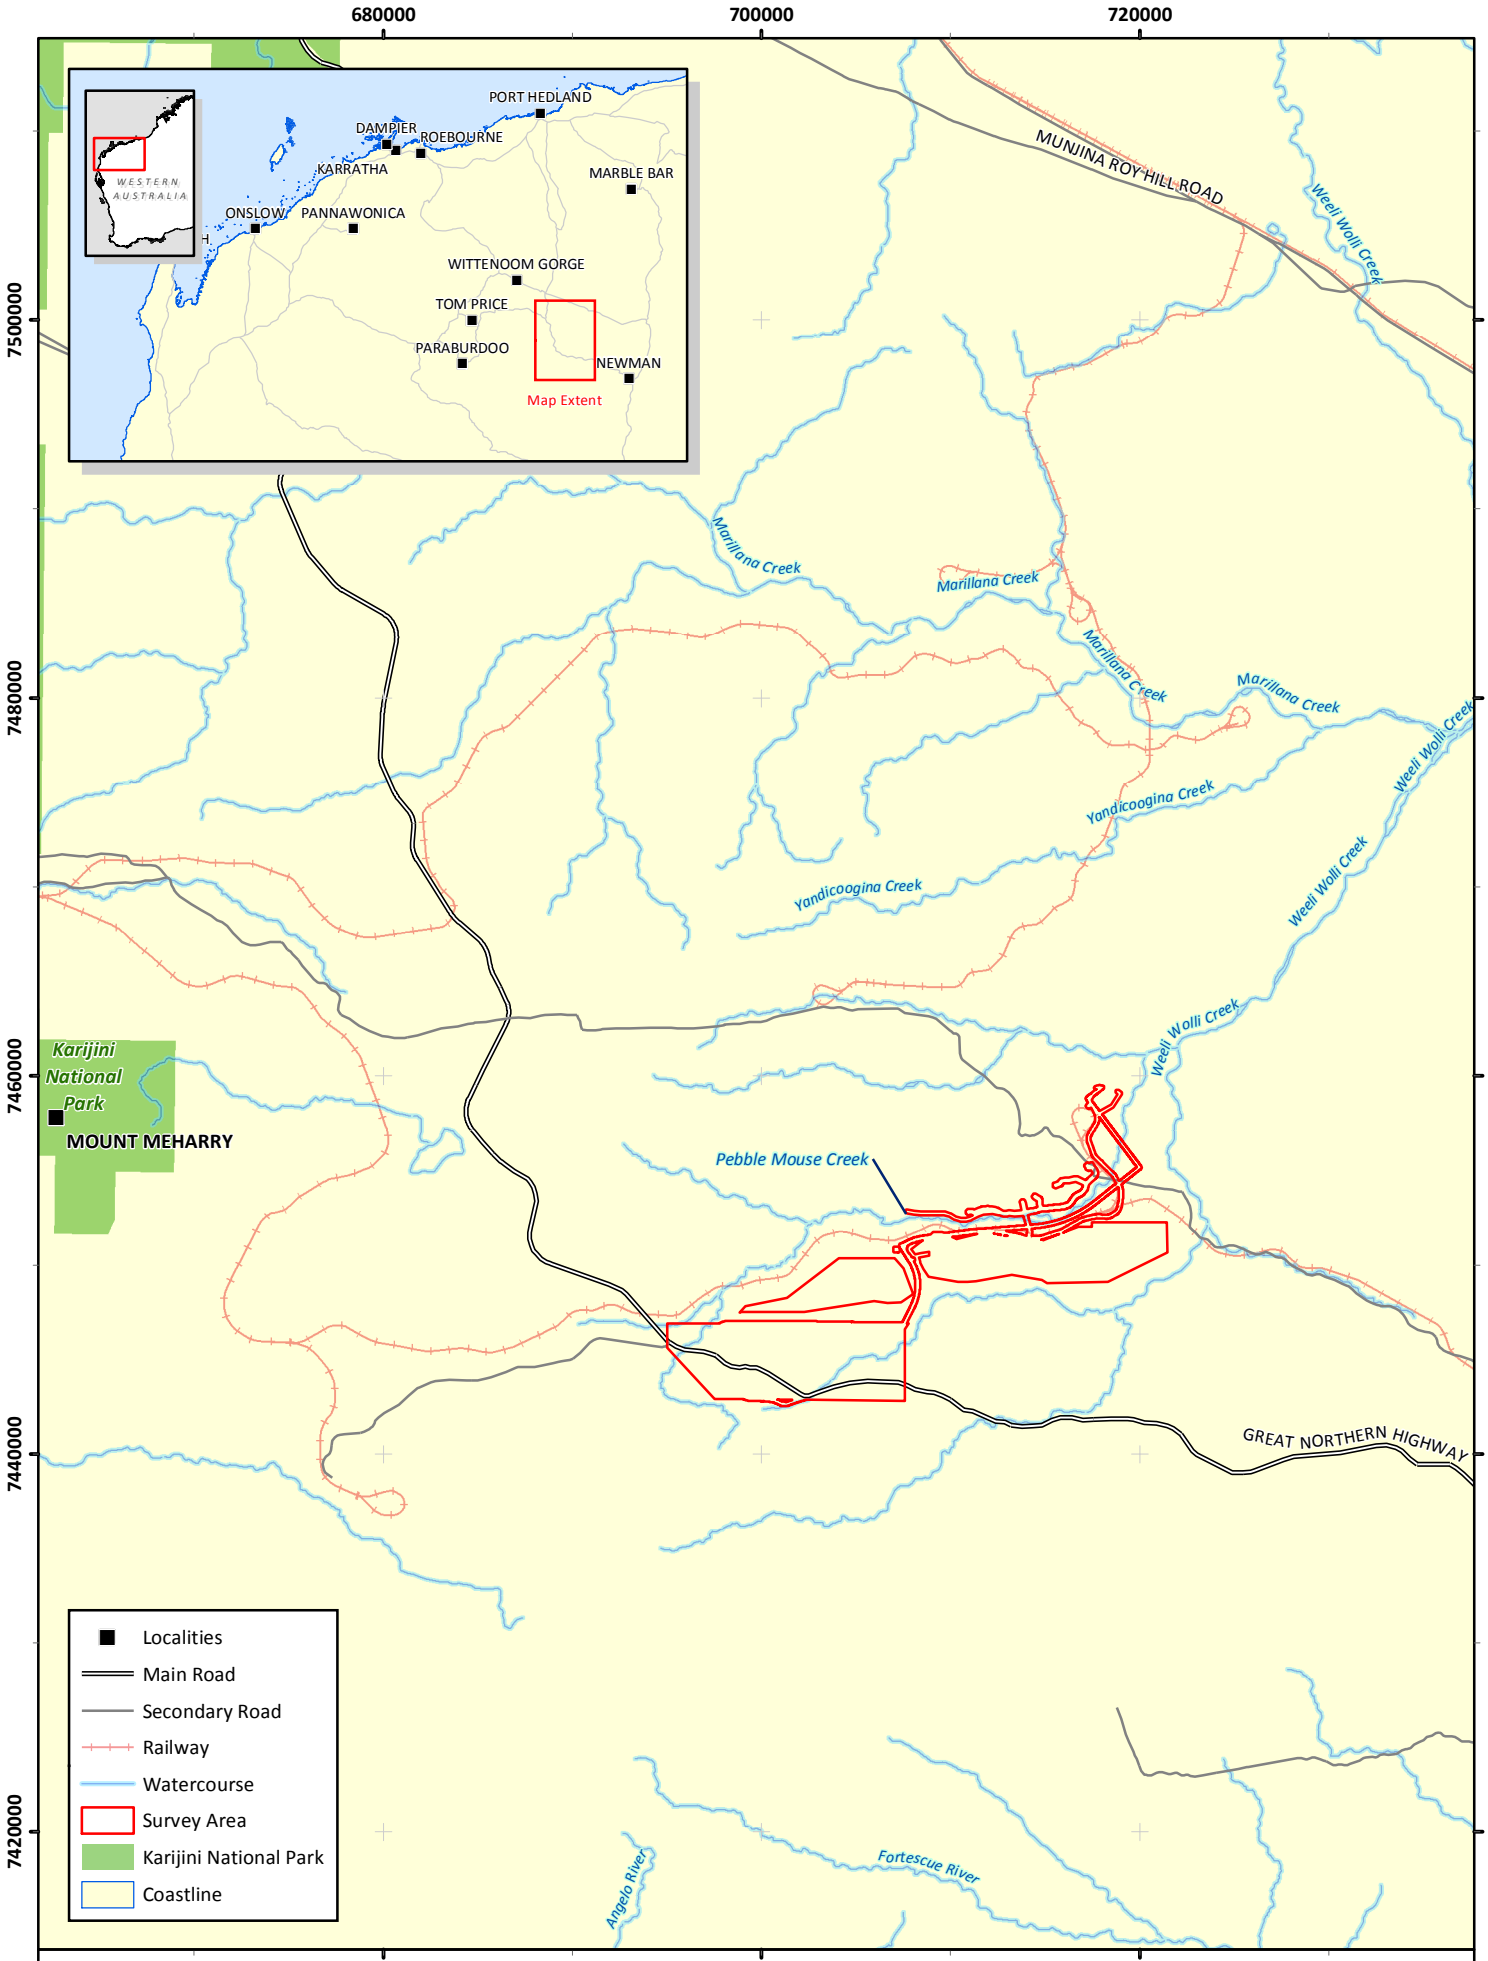
1 Introduction

1.1 Project Background

Rio Tinto is evaluating the potential development of additional iron ore deposits at Hope Downs 2 (HD2) in the Pilbara region of Western Australia, approximately 68 km north-west of Newman. Astron Environmental Services (Astron) was commissioned to undertake an assessment of Matters of National Environmental Significance (MNES) fauna species within the 10,817.7 ha HD2 Development Envelope (which includes two deposits: HD2 and Bedded Hilltop) and herein is referred to as the survey area (Figure 1).

1.2 Scope and Objectives



Astron previously completed a three phase Level 2 vertebrate fauna assessment of the survey area, in which four species of MNES were recorded (Astron Environmental Services 2019). These species included: Northern Quoll (*Dasyurus hallucatus*) (EN; EN); Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) (VU; VU); Ghost Bat (*Macroderma gigas*) (VU; VU); and Oriental Plover (*Charadrius veredus*) (IA; IA). Rio Tinto commissioned a targeted MNES survey to better understand the distribution of MNES species within the survey area that was required from the previous surveys conducted and to address the gaps in survey effort and coverage from the previous surveys conducted (Astron Environmental Services 2019).

The objective was to undertake a targeted MNES fauna assessment through a desktop assessment and field survey, and to incorporate data from previous biological surveys conducted in the vicinity of the survey area. The resultant data have been utilised to produce this report, which is intended to support and inform the environmental assessment process in accordance with the requirements of the *Environmental Protection and Biodiversity Act 1999* (EPBC Act). Astron conducted the targeted MNES survey in accordance with the regulatory guidance detailed in Table 1.

The scope and key limitations of the targeted MNES survey are outlined in Table 1 and further detail is provided in Section 3.3 of this report.

Table 1: Summary of Astron's vertebrate MNES fauna assessment.

Level of survey	Survey area size	Survey timing	Relevant regulatory guidance documents	Key survey limitations
Targeted terrestrial MNES vertebrate fauna survey	10,817.7 ha (survey area)	17 – 27 September 2019	• EPBC Act referral guideline for the Endangered Northern Quoll *Dasyurus hallucatus* (Department of the Environment and Energy 2016) • Survey Guidelines for Australia's Threatened Reptiles, Birds, Mammals and Bats Technical Guidance - Sampling Methods for Terrestrial Fauna (Department of the Environment, Water, Heritage and the Arts 2010a, 2010b, Department of Sustainability Environment Water Population and Communities 2011a, 2011b) **Other supporting guidance documents:** • Position Statement No. 3 (Environmental Protection Authority 2002) • Technical Guidance - Terrestrial Fauna Surveys (Environmental Protection Authority 2016a) • Technical Guidance - Sampling Methods for Terrestrial Fauna (Environmental Protection Authority 2016b) • Pilbara Northern Quoll Project: Surveying and Monitoring *Dasyurus hallucatus* in the Pilbara, Western Australia (Dunlop et al. 2014) • Interim Guidelines for Preliminary Surveys of the Night Parrot (*Pezoporus occidentalis*) in Western Australia (Department of Parks and Wildlife 2017)	• Rainfall in the three months preceding the targeted MNES survey was 52% below average. • Feral cat (*Felis catus*) activity appeared to be high in the area at the time of survey. • This is classified as a potentially major limitation for the lack of detection of any MNES species, particularly the Northern Quoll that had previously been recorded.

2 Environmental Context

2.1 Physical Environment

2.1.1 Climate

The climate of the Pilbara region of Western Australia is classified as arid tropical with two distinct seasons: a hot, wet summer (October – April) and a mild, dry winter (May – September) (Bureau of Meteorology 2019)

Based on long-term climatic data from the nearest Bureau of Meteorology weather station at Newman Aero (Station 007176) (approximately 90 km south-east of the survey area) the mean annual rainfall since 1971 is 329.5 mm. The mean maximum daily temperatures since 1996 range between 23.0°C and 39.2°C, and range above 30°C for much of the year (Figure 2) (Bureau of Meteorology 2019).

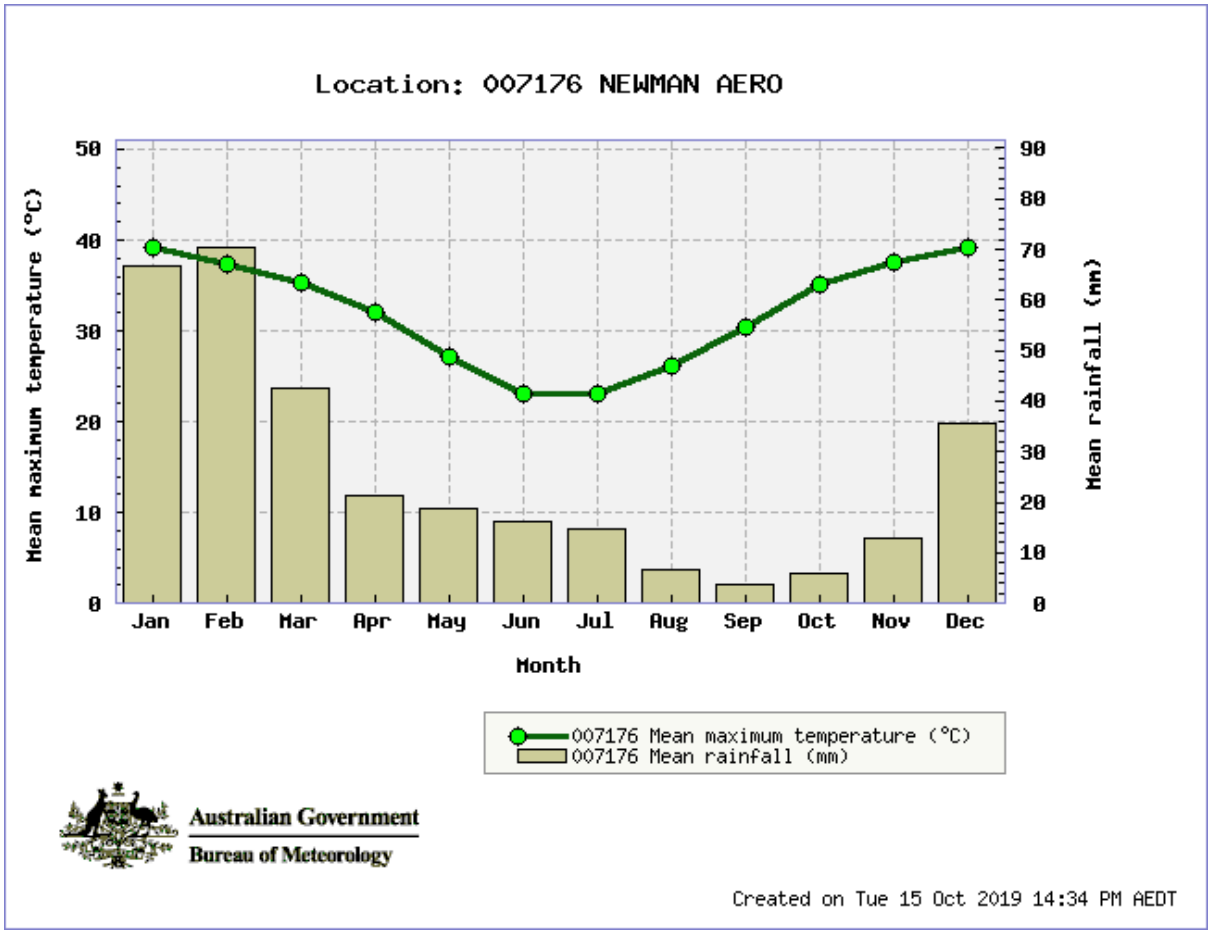

Figure 2: Climate data for Newman Aero Station (Station 007176). Mean annual rainfall data has been calculated from 1971 – 2019 and mean maximum temperature has been calculated from 1996 – 2019 (Bureau of Meteorology 2019).

2.1.2 Geology and Soils

The surface geology of the survey area is comprised of 10 units (Stewart et al. 2008), with Colluvium 3841 being the most dominant (Table 2). Geological mapping of the survey area and surrounds is presented in Figure A.1 (Appendix A).

Table 2: Geological units of the survey area (Stewart et al. 2008).

Geological name	Label	Area (ha)
Alluvium 38485: Channel and flood plain alluvium; gravel, sand, silt, clay, locally calcreted.	Qa	431.4
Brockman Iron Formation: banded iron-formation, chert, mudstone and siltstone.	Lchk	681.7
calcrete 38497 - Pisolitic, nodular or massive calcrete; ferruginous inclusions; calcareous cementing of bedrock and transported materials; locally with intercalated chalcedony; as low mounds, in playa lakes, or as valley calcrete; locally dissected and karstified	Czk	18.1
Colluvium 38491: Colluvium, sheetwash, talus; gravel piedmonts and aprons over and around bedrock; clay-silt-sand with sheet and nodular kankar; alluvial and aeolian sand-silt-gravel in depressions and broad valleys in Canning Basin; local calcrete, reworked laterite.	Qrc	2,587.8
Fortescue Group: Metadolerite, dolerite, gabbro; medium to coarse grained, massive grey-green rock, usually foliated.	Adf	763.6
Jeerinah Formation: Shale, sandstone, siltstone, mudstone, dolomite, local microbanded chert, jaspilite, conglomerate; fine-grained massive rhyolite; mafic tuff with local accretionary lapilli and agglomerate; thin basalt/dolerite and andesitic basalt flows.	Awfj	1,443.9
Marra Mamba Iron Formation: Chert, ferruginous chert, jaspilite, banded iron-formation, minor shale, siltstone, mudstone.	Achm	2,328.3
Mount McRae Shale and Mount Sylvia Formation: Interbedded shale, chert, banded iron-formation.	Ashm	1,212.5
Weeli Wolli Formation: Banded iron-formation (commonly jaspilitic), mudstone, siltstone; common interlayered metadoleritic sills.	Lchw	1,036.1
Wittenoom Formation: Calcitic dolomite, interbedded chert and shale in upper and lower parts, volcaniclastic sandstone.	Alhw	314.3

2.1.3 Surface Water and Hydrology

No Wetlands of International Importance (i.e. Ramsar wetlands) or Nationally Important Wetlands occur within the survey area (Department of the Environment and Energy 2019a). The nearest Nationally Important Wetland is Fortescue Marshes, located 40 km north of the survey area, which has been nominated as a proposed Ramsar site. Pebble Mouse Creek passes through a large proportion of the survey area. One of the upper tributaries of Weeli Wolli Creek passes through the survey area.

2.2 Biological Environment

2.2.1 Interim Biogeographic Regionalisation of Australia

The Interim Biogeographic Regionalisation for Australia (IBRA version 7) divides the Australian continent into 89 bioregions and 419 subregions (Department of the Environment and Energy 2019b). The IBRA regions represent a landscape-based approach to classifying the land surface, including attributes of climate, geomorphology, landform, lithology, and characteristic flora and fauna. The survey area occurs in the Pilbara bioregion, of which 8.4% is represented in the national reserve system (Department of the Environment 2018).

The biodiversity of the 53 subregions recognised in Western Australia was documented as part of a national audit to provide priorities for conservation action (Department of Conservation and Land Management 2002). The survey area occurs within the Hamersley subregion of the Pilbara region and is described in the audit as:

- Hamersley PIL3 – dissected bold plateaux and ranges of flat lying, moderately folded sandstone and quartzite with vegetation described as Mulga low woodland over tussock grasses occurring on fine textured soils in valley floors, with scattered Snappy gum (*Eucalyptus leucophloia*) over *Triodia brizoides* on skeletal soils of the ranges (Kendrick 2001).

2.2.2 Land Systems

Land systems of the Western Australian rangelands have been mapped and described by the Department of Primary Industries and Regional Development (formerly the Department of Agriculture and Food WA) outlining the distributions and providing comprehensive descriptions of biophysical resources, including soil and vegetation condition. A total of 102 land systems occur in the Pilbara bioregion covering 181,723 km^2. Nine land systems occur in the survey area (Table 3). The layout of these land systems within the survey area is shown in Figure A.2 (Appendix A).

Table 3: Distribution of land systems within the survey area.

Land system	Total area within bioregion (ha)	Total area (ha) (proportion of survey area (%))
Boolgeeda - stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands.	961,847	1,486.0 (13.7)
Calcrete - low calcrete platforms and plains supporting shrubby hard spinifex grasslands.	134,834	4.9 (<0.1)
Egerton - highly dissected plains and slopes with sparse mulga shrublands or shrubby hard spinifex grasslands.	66,849	1.4 (<0.1)
McKay - hills, ridges, plateaux remnants and breakaways of meta sedimentary and sedimentary rocks supporting hard spinifex grasslands with acacias and occasional eucalypts.	426,124	326.7 (3.0)
Newman - rugged jaspilite plateaux, ridges and mountains with hard spinifex.	1,994,339	4,647.2 (43.0)
Pindering - gravelly hardpan plains supporting groved mulga shrublands with hard and soft spinifex.	38,738	410.5 (3.8)
Platform - dissected slopes and raised plains supporting shrubby hard spinifex grasslands.	236,390	2,522.2 (23.3)
Rocklea - basalt hills, plateaux, lower slopes and minor stony plains supporting hard spinifex and occasionally soft spinifex grasslands with scattered shrubs.	2,880,288	1,314.1 (12.1)
Wannamunna - hardpan plains and internal drainage tracts supporting mulga shrublands and woodlands and occasionally eucalypt woodlands.	63,004	104.5 (1.0)

2.2.3 Pre-European Vegetation

Beard (1975) completed broad-scale (1:1,000,000) pre-European vegetation mapping at an association level. The Beard mapping was later used by the Department of Agriculture and Food WA (Shepherd et al. 2002) to compile vegetation units that assisted with identifying pre-European and current extents of vegetation throughout Western Australia.

Three pre-European vegetation units, 82, 18 and 29 (Shepherd et al. 2002), are associated with the survey area (Figure A.3, Appendix A). Table 4 summarises the current and pre-European extent of these three vegetation units in the Pilbara bioregion and the survey area.

2.3 Commonwealth Conservation Categories

The EPBC Act provides a legal framework to protect and manage MNES including listed flora, fauna and ecological communities. These listed flora, fauna and ecological communities are allocated a conservation category, which are outlined in Tables B.1 and B.2 (Appendix B).

Ecological communities may be subject to processes that threaten to destroy or significantly modify it across much of its range. These communities are identified as threatened ecological communities (TECs) that are listed at both Commonwealth level under the EPBC Act (Table B.1, Appendix B).

2.4 Land Use and Tenure

The survey area is located within the Shire of East Pilbara. The local area is mainly used for mineral exploration and mining activity. Karijini National Park is the nearest conservation reserve, located approximately 35 km to the west of the survey area (Figure 1).

Table 4: Extent of pre-European vegetation within the survey area (Department of Biodiversity, Conservation and Attractions 2018a).

Vegetation association	Mapping unit (Beard 1975)	Description	Total area (ha) (proportion of survey area (%))	Pre-European extent (ha)	Current extent in bioregion (ha)	Proportion of pre-European extent remaining (%)	Pre-European extent with formal protection (%)
82	e16Lr t3Hi	Hummock grasslands, low tree steppe; snappy gum over *Triodia wiseana*	5,452.2 (50.4)	2,168,702	2,156,558	99.4	13.7
18	a1Li	Low woodland, open low woodland or sparse woodland; mulga (*Acacia aneura*)	5,339.0 (49.4)	580,512	576,389	99.3	29.6
29	a1Lp	Mulga (*Acacia aneura*) and associated species.	26.5 (0.2)	172,083	171,975	99.9	12.8

3 Methods

3.1 Desktop Assessment

3.1.1 Database Searches

A desktop assessment was previously undertaken as part of the Level 2 survey report (Astron Environmental Services 2019) to assess whether any conservation listed vertebrate and invertebrate species, Short Range Endemic (SRE) invertebrate species or communities were likely to occur within the survey area. The review focused on key habitats for conservation listed fauna and MNES species; the targeted MNES assessment was specific to federal referral under the EPBC Act and so an updated Protected Matters database search was also undertaken (Table 5).

Table 5: Database searches requested.

Database name	Date search results received	Search focus	Search area
Protected Matters Search Tool (Department of the Environment and Energy 2019c)	04/09/2019	Matters of National Environmental Significance	40 km radius from a central point defined by the coordinates: 23°04'04" S, 119°01'56" E

3.1.2 Literature Review

Fauna surveys that have been previously commissioned by Rio Tinto within the vicinity of the survey area and supplied to Astron were incorporated within the desktop assessment. Astron (2019) completed the only baseline systematic fauna survey that have been conducted within the survey area. Other survey areas in relation to the current survey area are shown in Figure 3 and include:

- Biota Environmental Sciences (2006) Hope Downs Rail Corridor (Juna Downs Section) Fauna Survey
- Biota Environmental Sciences (2009) Hope Downs Section 45C Targeted Fauna Review
- Biota Environmental Sciences (2011) Hope Downs Project Life of Mine Targeted Fauna Survey
- Biota Environmental Sciences (2014) Hope Downs South West Marra Mamba Development Targeted Fauna Survey
- Ecologia Environment (2014) Greater West Angelas Terrestrial Fauna Assessment
- Ninox Wildlife Consulting (2009a) A Vertebrate Fauna Survey of the Proposed Hope Downs 4 Infrastructure Corridor Option 1 Near Newman Western Australia
- Ninox Wildlife Consulting (2009b) A Vertebrate Fauna Survey of the Proposed Hope Downs 4 Infrastructure Corridor Option 6 Near Newman Western Australia

3.1.3 Conservation Assessment

Threatened and Migratory MNES listed vertebrate fauna species that were returned from the database searches were categorised for likelihood of occurrence within the survey area according to the criteria listed in Table B.3 (Appendix B). Post survey, the likelihood table was re-assessed utilising the information obtained during the field survey. The additional criteria used for the assessment are

outlined in Table B.3 (Appendix B). The likelihood table was then updated to reflect an improved understanding of the likelihood that a species would actually occur in the survey area.

The potential for the habitats to provide suitable habitat for MNES species Northern Quoll, Ghost Bat, Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*), Night Parrot (*Pezoporus occidentalis*) and Pilbara Olive Python (*Liasis olivaceus barroni*) were ranked according to the criteria listed in Table B.4 (Appendix B). The shelter and foraging habitat suitability category for the Northern Quoll was further refined and split into 'probable shelter and foraging habitat' (or core habitat as per the referral guidelines (Department of the Environment and Energy 2016)) and 'potential shelter and foraging habitat'. The criteria for these categories are also listed in Table B.4 (Appendix B).

Given the presence of Ghost Bats within the region and survey area, each cave assessed was categorised as:

- Category 1 – diurnal roost caves with permanent occupancy
- Category 2 – diurnal roost caves with regular occupancy
- Category 3 – roost caves with occasional occupancy
- Category 4 – nocturnal roost caves (opportunistic usage).

These categories are based on definitions for Ghost Bat usage according to Bat Call WA (2019) (Appendix G).

3.2 Field Survey

3.2.1 Survey Timing and Personnel

The MNES fauna assessment was undertaken by Matthew Love, David Keirle, Brittany Osborn and Sean Smithies. The fauna team leader (Matthew Love) has over 10 years of experience conducting vertebrate fauna surveys within the Pilbara region of Western Australia.

The targeted MNES field survey was conducted from 17 to 27 September 2019 under "Fauna Taking (Biological Assessment) Licence" No. BA27000015-2 and "Authorisation to Take or Disturb Threatened Species" No. TFA 2019-0006.

3.2.2 Weather

Daily observations for rainfall and temperature were recorded by Rio Tinto at the Hope Downs 1 (HD1) Weather Station, with long term rainfall and temperature observations being sourced from the Newman Aero BoM station (number 007176), approximately 87 km south-east of the HD1 Weather Station. Local rainfall and temperatures preceding the survey are presented in Figure 4.

The daily maximum temperatures during the targeted MNES survey averaged 28.4°C ± 4°C and daily minimum temperatures averaged 16.1°C ± 4°C. Mean maximum daily temperatures during the targeted MNES survey were approximately 2°C warmer than the long-term mean for September and the mean minimum daily temperatures were approximately 2°C cooler than the long-term mean for September. Rainfall in the 12 months preceding the targeted MNES survey was 204.7 mm (38%) below the long-term mean of 329.5 mm. Rainfall in the 12 weeks preceding the targeted MNES survey was 18 mm (52%) below the mean rainfall for the same period.

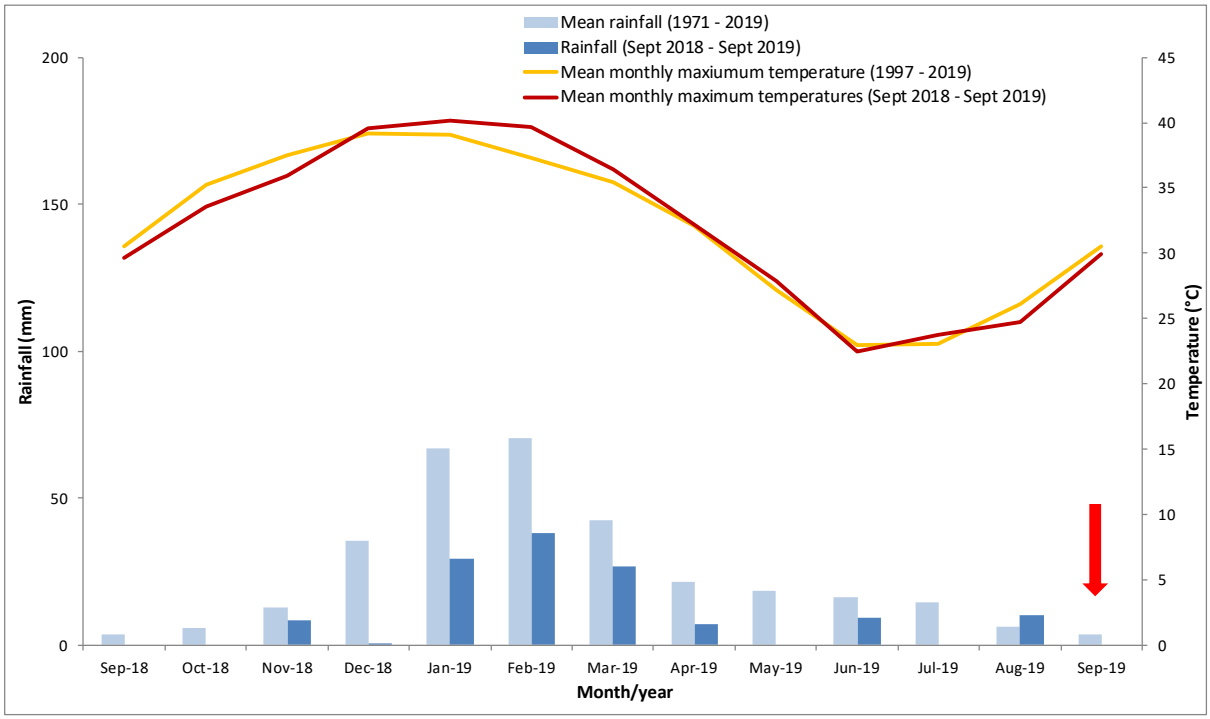

Figure 4: Mean monthly and recorded monthly rainfall (mm) and mean monthly and recorded monthly maximum temperatures (°C). Daily records supplied by Rio Tinto and long term records supplied by the Bureau of Meteorology from the Newman Aero station (number 007176). The red arrow displays the timing for the targeted MNES survey.

3.2.3 Vertebrate Fauna

3.2.3.1 Northern Quoll Trapping

A trapping program, designed to detect the presence of the Northern Quoll was implemented within the survey area. Four sites, each with 50 wire cage traps spaced at approximately 50 m intervals, were set within the survey area in line with the standardised regional monitoring protocol. This methodology is designed by the Department of Biodiversity, Conservation and Attractions (DBCA) and referral guidelines (Dunlop et al. 2014, Department of the Environment and Energy 2016). The cage traps were set for seven nights, covered with hessian for shade and protection, and baited with peanut butter, oats and sardines (Dunlop et al. 2014). The locations of the cage traps are shown in Figure C.1 and detailed in Table C.1 (Appendix C).

3.2.3.2 Motion Sensitive Cameras

Motion sensitive cameras (Moultrie and Reconyx HC600 HyperFire) were set at three locations as per methods set out in the referral guidelines (Department of the Environment and Energy 2016). Three targeted camera transects each consisting of 10 motion sensitive cameras spaced at approximately 100 m intervals, were set for between four and six nights with a combined trapping effort of 140 camera trap nights. The cameras were baited and placed in prospective/suitable habitat such as cave entrances aimed at targeting MNES species, specifically the Northern Quoll. Camera locations are shown in Figure C.1 and detailed in Table C.1 (Appendix C).

3.2.3.3 Acoustic Bat Surveys

Acoustic ultrahigh frequency equipment was used to record the presence of bats, in particular the Pilbara Leaf-nosed Bat and Ghost Bat. Acoustic recording devices (Song Meter (SM) 2 SM2BAT+ and SM4) were positioned in a total of five locations to achieve a broad coverage of the survey area, and to target potential flyways for the Pilbara Leaf-nosed Bat. The detectors were set for between four and five nights, resulting in a total of 17 recording nights. One unit failed to operate (BAT32). The locations are depicted in Figure C.1 and detailed in Table C.1 (Appendix C). The bat echolocation data collected in the field was analysed by Robert Bullen (Bat Call WA 2019).

3.2.3.4 Audio Night Parrot Survey

Due to the recent discovery of Night Parrot populations in Western Australia, DBCA have published Interim Guidelines for Preliminary Surveys of Night Parrots in Western Australia (Environmental Protection Authority 2016a, 2016b). The survey area location is mapped as 'high priority for survey' for this species so passive acoustic surveys were undertaken and Autonomous Recording Units (ARUs) used in the most prospective habitats (Stony Plain habitat containing *Triodia*).

The ARUs were set at two locations for five and six nights each and recorded from 1 hour pre-sunset to 1 hour post-dawn. The audio data was recorded at 44.1 k bits and covered the frequency range 100 kHz to 21,000 kHz, which brackets the Night Parrot call frequency range of 1,500 kHz to 3,500 kHz. The audio data collected in the field was analysed by Robert Bullen (Bat Call WA 2019). The ARU locations are depicted in Figure C.1 and detailed in Table C.1 (Appendix C).

3.2.3.5 Targeted Searches

The aim of the targeted searches was to identify areas of potentially suitable habitat for conservation significant fauna, such as caves, and secondary signs including tracks, scats, diggings and burrows. Visual observation for conservation significant fauna habitat was ongoing whilst moving through the survey area. Track logs were recorded using a handheld GPS and are shown in

Figure C.1 (Appendix C). Any opportunistic sightings of fauna species were recorded whilst traversing the survey area.

3.3 Limitations

Following completion of the desktop assessment and targeted MNES survey, a review of any limitations that may affect a complete assessment of the data collected was conducted. The limitations listed in Table 6 are based on those suggested as considerations in Technical Guidance - Terrestrial Fauna Surveys (Environmental Protection Authority 2016b, 2016a); however, still have relevance for this targeted MNES fauna assessment. Due to the number of fauna surveys conducted in the survey area, the populations of conservation significant fauna are considered to be relatively well documented.

Table 6: Statement of limitations for the targeted vertebrate fauna assessment.

Potential limitation	Degree of limitation	Statement regarding potential limitations
(i) Competency/experience	No limitation	The two senior zoologists leading the survey teams have over 10 years' experience conducting fauna surveys in the Pilbara.
(ii) Scope What faunal groups were sampled and were some sampling methods not able to be employed because of constraints such as weather conditions.	No limitation	The survey scope was able to be completed and all sampling methods were adequately employed. The fauna observed and identified are likely to represent a portion of the suite of species that utilise the survey area.
(iii) Proportion of fauna identified, recorded and/or collected	Minor limitation	Ghost Bats are notoriously difficult to detect as their echolocation calls show wide variation and they do not always call (utilising ultrasonic calls) when exiting and entering caves (McKenzie and Bullen 2009). In addition acoustic recording devices are not always successful in picking up the vocal calls (audible sound) when Ghost Bats utilise certain feeding strategies. However, searches of fauna habitat with the potential to support roost caves were also undertaken to record feeding evidence or individuals roosting in caves.
(iv) Sources of information Previously available information (whether historic or recent) as distinct from new data.	No limitation	Adequate information was available from database searches and previous studies in the survey area and region.
(v) Proportion of task achieved. Further work which might be needed?	No limitation	The survey scope was able to be completed and all sampling methods were adequately employed.
(vi) Timing/weather/season/cycle	Minor limitation	Rainfall in the three months preceding the targeted MNES survey was 18 mm (52%) below the mean rainfall for the same period; therefore, the seasonal conditions were considered to be dry. This may have contributed to the lack of MNES species, particularly the Northern Quoll, detected during the survey. However, a three-phase Level 2 survey has recently been completed within the survey area, with Phase 3 experiencing good seasonal conditions. Therefore, this limitation is considered minor when these surveys are also considered.
(vii) Disturbances For example fire, flood, accidental human intervention which affected results of survey	Potentially major limitation	Large areas of the Bedded Hilltop area were affected by recent fires and therefore were not suitable for sampling. Feral cat activity appeared to be high in the area at the time of survey and may have contributed to the lack of MNES species, particularly the Northern Quoll, detected during the survey.
(viii) Intensity In retrospect, was the intensity adequate?	No limitation	The intensity of the surveys was considered adequate for a targeted MNES fauna survey.

Potential limitation	Degree of limitation	Statement regarding potential limitations
(ix) Completeness Was the relevant area fully surveyed?	No limitation	All target habitats considered suitable for MNES species within the survey area were adequately surveyed.
(x) Resources Degree of expertise available in animal identification to taxon level.	No limitation	Adequate resources were available to identify fauna species. All technical personnel involved in identification have extensive experience in conducting vertebrate fauna surveys in the Pilbara.
(xi) Remoteness and/or access problems	No limitation	No access constraints affected the survey outcomes.
(xii) Availability of contextual information For example biogeographic information on the region.	No limitation	Database searches and previous vertebrate fauna surveys in the vicinity of the survey area provided contextual information.

4 Results

4.1 Desktop Assessment

A Protected Matters database search revealed 17 MNES species, specifically listed Threatened and Migratory species. Fauna species listed as Marine and Invasive were not considered in this assessment. These 17 species comprised of one reptile species, 12 bird species and four mammal species (Table D.1 Appendix D). Of these, four species were considered to have a 'high' likelihood (inclusive of those recorded within the survey area), two species were considered to have a 'moderate' likelihood and 11 were considered to have a 'low' likelihood of occurrence within the survey area (Table D.1, Appendix D). This is based on their respective ecology, habitats considered likely to be present and any previous records from historic survey and database records.

Previous surveys undertaken for Rio Tinto in the vicinity of the survey area recorded five MNES fauna species: Fork-tailed Swift (*Apus pacificus*) (IA; IA); Oriental Plover; Northern Quoll*;* Pilbara Leaf-nosed Bat; and Ghost Bat (Table 7). Astron (2019) completed a three phase Level 2 vertebrate fauna assessment of the survey area, in which four MNES species were recorded: Northern Quoll; Pilbara Leaf-nosed Bat; Ghost Bat; and Oriental Plover.

Table 7: Summary of literature review results from surveys conducted within the vicinity of the survey area.

Author (year)	Survey area; size (ha)	Survey level	Survey timing	Survey effort	MNES vertebrate fauna recorded
Astron (2019)	Hope Downs 2 survey area 10,817.7 ha	Level 2 (3 phases)	November 2017 May 2018 March 2019	Baseline fauna assessment of terrestrial vertebrate fauna and SRE invertebrate fauna species within the survey area. 4.2 Field Survey

4.2.1 Fauna Habitat

Eight broad fauna habitat types have been previously detailed within the survey area: Minor Drainage; Gorge/Gully; Breakaway; Rocky Hill; Low Hill and Slopes; Alluvial Plain; Mulga Woodland; and Stony Plain (Astron Environmental Services 2019).

4.2.2 Habitat Suitability for MNES Species

Northern Quoll

Approximately 107 ha (1%) of the survey area, comprising Gorge/Gully and some Breakaway habitats, was considered 'probable shelter and foraging habitat' (or core habitat as per the referral guidelines (Department of the Environment and Energy 2016)), based on proximity to known quoll records, microhabitat features and orientation aspect (Figure E.1, Appendix E). Approximately 200 ha (2%) of the survey area was considered 'potential shelter and foraging habitat', comprising mainly smaller Breakaway habitats (Figure E.1, Appendix E). The Gorge/Gully and Breakaway habitats contain rocky environments of high relief that are particularly important for Northern Quolls in the Pilbara as they provide denning sites for breeding and shelter and diverse microhabitats for foraging.

Approximately 1,858 ha (17%) of the survey area was considered suitable foraging and dispersal habitat (Minor Drainage and Rocky Hill habitats), particularly where these habitats were in close association with the Gorge/Gully and Breakaway habitats as they provided microhabitats such as crevices and cracks for foraging (Figure E.1, Appendix E).

The remaining 8,653 ha (80%) of the survey area was considered to provide limited foraging and dispersal habitat, consisting of Alluvial Plain, Low Hills and Slopes, Mulga Woodland, Stony Plain and Disturbed habitats (Figure E.1, Appendix E).

Pilbara Leaf-nosed Bat

Approximately 307 ha (3%) of the survey area, comprising the Gorge/Gully and Breakaway habitat, was considered potential shelter and foraging habitat for this species due to the presence of nocturnal refuge caves (Figure E.2, Appendix E). No permanent roosts for this species have been recorded in the survey area.

Approximately 9,678 ha (89%) of the survey area, which consisted of Alluvial Plain, Minor Drainage, Low Hills and Slopes, Mulga Woodland, Rocky Hill and Stony Plain habitats was considered suitable foraging and dispersal habitat (Figure E.2, Appendix E). This species is likely to forage only occasionally within the survey area based on recorded calls, taking advantage of benign conditions and dispersing temporarily in search of additional foraging and roosting opportunities (Bat Call WA 2019).

The remaining 833 ha (8%) of the survey area, comprising Disturbed areas, was considered to provide limited foraging and dispersal habitat (Figure E.2, Appendix E).

Ghost Bat

Approximately 307 ha (3%) of the survey area, comprising the Gorge/Gully and Breakaway habitat, was considered potential shelter and foraging habitat (Figure E.3, Appendix E), due to the presence

of caves that potentially support roost sites. Often Gorge/Gully and Breakaway habitats contain caves and deep shelters that are used as nocturnal feeding roosts by Ghost Bats.

Previously, seven caves have been recorded within the survey area (Table F.1, Appendix F) (Astron Environmental Services 2019). Two caves (Caves 1 and 5) were categorised as Category 3 roost caves with occasional occupancy due to the presence of Ghost Bat feeding evidence (scats) and/or the physical properties of the caves were conducive to diurnal roosting (Astron Environmental Services 2019).

The remaining five caves (Cave 2, 4, 6, 7 and 8) were categorised as Category 4 nocturnal roost caves (opportunistic usage) given the physical properties of the caves (Table F.1, Appendix F). Ghost Bat feeding evidence was recorded in Caves 4 and 7; however, these sites were more overhangs rather than caves and not conducive to diurnal roosting for this species (Astron Environmental Services 2019).

No additional caves were recorded during the targeted MNES survey. It is considered unlikely that additional significant caves exist within the survey area; however, the possibility cannot be discounted as the survey area was not searched in its entirety. If present, they are likely to be found within the Gorge/Gully and Breakaway habitats only. Both habitats also contain complex vegetation structures and microhabitats that support prey species and foraging sites for the Ghost Bat.

Approximately 1,858 ha (17%) of the survey area, which consisted of Minor Drainage and Rocky Hill habitats, was considered suitable foraging and dispersal habitat (Figure E.3, Appendix E). The taller trees found in the Minor Drainage habitats provide ideal foraging/hunting perches particularly in areas that have the potential for semi-permanent surface water and contain thick vegetation. The Rocky Hill habitat contains microhabitats such as boulder piles, cracks and crevices that support a wide range of prey species for the Ghost Bat.

The remaining 8,653 ha (80%) of the survey area, comprising the Alluvial Plain, Low Hills and Slopes, Mulga Woodland, Stony Plain and Disturbed habitats, was considered to provide limited foraging and dispersal habitat (Figure E.3, Appendix E).

Night Parrot

None of the habitats of the survey area supported old, large and unburnt *Triodia* clumps that are considered the primary habitat requirement for the Night Parrot (Department of Parks and Wildlife 2017). The Alluvial Plain, Minor Drainage, Mulga Woodland and Stony Plain habitats (3,230 ha, 30%) within the survey area were mapped as suitable foraging and dispersal habitat but the Night Parrot is unlikely to occur within the survey area (Figure E.4, Appendix E). Most of these habitats (particularly within the Bedded Hilltop (BHT) and HD2 areas) were impacted by recent fires (less than 10 years old), pastoral and mining impacts over a long duration, very sparse ground cover vegetation and a lack of chenopod communities or suitable size/age *Triodia* hummocks and are unlikely to support the Night Parrot.

The remaining 7,587 ha (70%) was considered to provide limited foraging and dispersal habitat (Figure E.4, Appendix E).

Pilbara Olive Python

Approximately 307 ha (3%) of the survey area, comprising the Gorge/Gully and Breakaway and habitats, was considered as potential shelter and foraging habitat for the Pilbara Olive Python

(Figure E.5, Appendix E). The caves and overhangs of the Gorge and Breakaway habitats are likely to provide denning sites and ambush locations frequented by this species.

Approximately 870 ha (8%) of the survey area was considered suitable foraging and dispersal habitat, which consisted of Minor Drainage habitats (Figure E.5, Appendix E).

The remaining 9,641 ha (89%) of the survey area was considered to provide limited foraging and dispersal habitat, consisting of Alluvial Plain, Low Hills and Slopes, Mulga Woodland, Rocky Hill, Stony Plain and Disturbed habitats (Figure E.5, Appendix E).

4.2.3 Fauna Species

4.2.3.1 MNES Species Recorded

Four MNES fauna species have been recorded within the survey area. The locations of these species records are shown in Figure F.1 (Appendix F).

Northern Quoll (*Dasyurus hallucatus*) (EN; EN)

The Northern Quoll occurs in a variety of habitats (Oakwood 2008) but is commonly found in open lowland savannah forest and rocky escarpments. Rocky areas are a particularly important zone for Northern Quolls in the Pilbara as these areas retain water and provide a diversity of microhabitats. These areas also tend to have greater floristic diversity and productivity resulting in greater prey density compared to non-rocky areas. These rocky areas also provide refuge from feral cats, fire and livestock (Hill and Ward 2010) and provide breeding potential (Department of the Environment and Energy 2016).

The Northern Quoll was recorded 14 times during the previous Astron surveys (Astron Environmental Services 2019) (Appendix F.1, Appendix F). The majority of the records were made within Gorge/Gully and Breakaway habitats via motion camera detection (10 records), followed by scat recordings (three records) and a solitary male individual was captured. Most of the records were made at BHT (10 recordings), followed by four records at the Wonmunna (WM) area. No records of the Northern Quoll were made within the HD2 deposit. The capture of an individual sub-adult male as well as multiple motion camera recordings at separate locations suggested that a resident population may exist in the survey area, particularly within the BHT area. However, no Northern Quolls were recorded during the current targeted MNES survey, despite utilising sampling methods such as cage traps and motion sensitive cameras, specifically designed to target this species.

Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) (VU; VU)

Pilbara Leaf-nosed Bats are known to require deep caves characterised by high levels of humidity and stable temperatures (Churchill 2008). This is a result of their limited ability to conserve heat and water (Armstrong 2001, Churchill 2008). Caves deep enough to create this environment are relatively uncommon in the Pilbara, with only 20 to 25 roost sites being known (R. Bullen 2014, pers. comm. 20 Oct 2014). Foraging habitat for the Pilbara Leaf-nosed Bat is diverse and includes riparian vegetation, hummock grassland, and sparse tree and shrub savannah (Duncan et al. 1999). Roost sites for the Pilbara Leaf-nosed Bat can be classified (Department of the Environment 2017) based on the following criteria:

- Permanent diurnal roosts—occupied year-round and likely the focus for some part of the nine-month breeding cycle; considered as critical habitat that is essential for daily survival.

- Non-permanent breeding (maternal) roosts—evidence of usage during some part of the nine-month breeding cycle (July to March), but not occupied year-round; considered as critical habitat that is essential for both daily and long-term survival.
- Transitory diurnal roosts—occupied for part of the year only, outside the breeding season (i.e. April to June), and which could facilitate long distance dispersal in the region; considered as critical habitat that is essential for both daily and long-term survival.
- Nocturnal refuge—occupied or entered at night for resting, feeding or other purposes, with perching not a requirement. Excludes overhangs. Not considered critical habitat but are important for persistence in a local area.

Pilbara Leaf-nosed Bats have also been recorded flying over small watercourses amongst granite boulder terrain, over pools and low shrubs in ironstone gorges, and above low shrubs and around pools in gravelly watercourses with *Melaleuca leucadendron*, such as in Barlee Range Nature Reserve (Armstrong 2001). In the Pilbara, the species has been observed in *Triodia* hummock grasslands covering low rolling hills and shallow gullies, with scattered *Eucalyptus camaldulensis* along the creeks (Armstrong 2001, Churchill 2008).

The Pilbara Leaf-nosed Bat was not recorded during the current survey but was recorded at three locations at low activity levels within the survey area during previous Astron surveys (Astron Environmental Services 2019) (Table F.1, Appendix F). The Pilbara Leaf-nosed Bat records were from foraging individuals in Gorge/Gully and Breakaway fauna habitats, as the calls at all three sites were at least three hours after dusk and are not consistent with the presence of a permanent roost cave nearby (Astron Environmental Services 2019). This species is likely to forage only occasionally within the survey area taking advantage of benign conditions and dispersing temporarily in search of additional foraging and roosting opportunities (Bat Call WA 2019).

Ghost Bat (*Macroderma gigas*) (VU; VU)

The preferred habitat of Ghost Bats is considered to be rocky gorges and breakaways that support caves and crevices used as maternity roosts. The Ghost Bat uses different natural formations for various purposes and for groups to persist they generally require habitats that provide:

- a selection of roosting opportunities with night roosts or feeding sites, day roosts and at least one deep cave with characteristics of a maternity roost
- nearby gullies and gorges with vegetation of vertical complexity (diverse vegetation heights and density) and presence of water that would attract prey species
- a productive foraging area within a 5 km to 10 km radius, usually including a good quality riparian drainage line.

Transient roosts and feeding sites are used by small numbers of Ghost Bats, whereas maternity roosts are used by larger colonies (Armstrong and Anstee 2000). Night feeding roosts (feed caves) are typically shallow caves and shelters/overhangs high in the strata and poorly insulated from the elements (Armstrong and Anstee 2000). Transient day roosts are deeper and more complex, have more insulation providing a more stable temperature and typically have one or more large chambers high enough to avoid predators. Maternity roosts provide additional features to support a reproducing population including high temperature (27°C to 33°C) and humidity (>85%) (Armstrong and Anstee 2000). The Ghost Bat can have a relatively small nightly foraging range (up to 2 km from the roost where it has been studied in Queensland) (Tidemann et al. 1985, Pettigrew et al. 1986), but has the flight capability to range widely (Bullen and McKenzie 2002) perhaps tens of kilometres

in a night. This is evident from genetic markers, which suggest that males are particularly likely to disperse long distances throughout the landscape (Worthington Wilmer et al. 1994, 1999).

Ghost Bats require caves of varying shapes and sizes to fulfil each of its ecological requirements. Cave usage can be classified into three categories: feed caves, day roosts and maternal roosts.

- Feed caves are typically shallow caves or overhangs high in the strata that are poorly insulated from the elements (Armstrong and Anstee 2000). Ghost Bats hunt at night and use feed caves to consume prey they have captured in the surrounding area. Feed caves often contain Ghost Bat scats and/or feeding remnants (typically feathers and small animal bones).
- Day roosts are generally deep, complex caves or disused mines that contain domed ceilings, fissures or passages which create a stable microclimate. These caves are usually lower in the strata making them well insulated. The stable temperature and elevated humidity of these caves relative to the ambient conditions create physiologically benign conditions (Leitner and Nelson 1967, Hall et al. 1997, Armstrong and Anstee 2000, McKenzie and Bullen 2009).
- Maternal roosts like day roosts are generally deep, complex caves or disused mines that contain domed ceilings, fissures or passages which create a stable microclimate and often contain multiple entrances (McKenzie and Hall 2008). Maternal roosts have a stable temperature of 23°C to 28°C and moderate to high relative humidity of 50% to 100% (Pettigrew et al. 1986, Churchill and Helman 1990, Armstrong and Anstee 2000, Churchill 2008).

The Ghost Bat was recorded on nine occasions within the survey area during the previous Astron surveys, through acoustic recordings (calls), scats recorded in nocturnal feed caves and an individual sighted during spotlighting within the HD2 area (Astron Environmental Services 2019) (Table F.1, Appendix F). Two of seven caves previously recorded within the survey area (Caves 1 and 5) were deemed to be Category 3 roost caves with occasional occupancy. These caves are not considered significant to the long-term presence of the species (Bat Call WA 2019). The other five previously recorded caves were deemed to be Category 4 nocturnal roost caves (opportunistic usage) and are not considered significant. These Category 4 caves are common in the landscape as numerous observations suggest that the majority of caves and adits in the Pilbara are used in at least an opportunistic manner by itinerant Ghost Bats (Bat Call WA 2019). No further observations of the Ghost Bat or additional caves were recorded during the targeted MNES survey. It is considered unlikely that additional significant caves exist within the survey area; however, the possibility cannot be discounted as the survey area was not searched in its entirety. The areas not traversed were assessed visually from a distance where possible and considered a low probability of containing caves. If present, they are likely to be found within the Gorge/Gully and Breakaway habitats only.

Oriental Plover (*Charadrius veredus*) (IA; IA)

The Oriental Plover is a non-breeding visitor to Australia, where the species occurs in both coastal and inland areas, mostly in northern Australia. Most records are along the north-western coast, between the Exmouth Gulf and Derby in Western Australia (Department of the Environment and Energy 2019d). This species occupies sparsely vegetated plains, beaches and tidal flats, saltworks and sometimes sewage ponds.

One individual was opportunistically sighted during a previous survey at the HD1 village camp, likely due to the presence of water at the camp (Astron Environmental Services 2019) (Table F.1, Appendix F). It was not recorded during the targeted MNES survey.

4.2.3.1 MNES Species Potentially Occurring

Pilbara Olive Python (*Liasis olivaceus barroni*) (VU; VU)

The Pilbara Olive Python prefers escarpments, deep gorges, water holes and rock piles associated with permanent pools in rocky areas in the ranges of the Pilbara region (Pearson 1993, Wilson and Swan 2010). Microhabitat preferences of the Pilbara Olive Python are under rock piles, on top of rocks or under spinifex (Tutt et al. 2004). Individuals spend the cooler winter months within caves and rock crevices away from water sources. In the warmer summer months, the pythons are found to move around widely, usually in close proximity to water and rock outcrops (Wilson and Swan 2010).

This species was not recorded during the targeted MNES survey or during previous surveys (Astron Environmental Services 2019). Despite this it is still considered likely to be found within the Gorge/Gully, Breakaway and Minor Drainage habitats given there are 14 previous records of this species in the vicinity of the survey area (Department of Biodiversity, Conservation and Attractions 2018b) and suitable habitat exists within the survey area.

5 Discussion

5.1 MNES Habitat

Habitats within the survey area were not restricted at the local or subregional scale and no uncommon geological units or land systems occurred within the survey area. In a regional context, the Gorge and Breakaway habitats in the Pilbara are restricted to the Chichester and Hamersley Ranges, but they are well represented in these areas. The Gorge/Gully and Breakaway habitats in the survey area were considered important habitat for MNES fauna species. This is due to the microhabitats they provide such as caves and semi-permanent water pools that can exist in these refuge type areas and are important for species foraging and sheltering requirements. Gorge/Gully and Breakaway habitats were considered suitable for the MNES species Northern Quoll, Ghost Bat, Pilbara Leaf-nosed Bat and Pilbara Olive Python. With respect to the Northern Quoll, these habitats were divided into 'probable shelter and foraging habitat' (or core habitat), which comprised most of the Gorge/Gully habitat within the survey area and Breakaway habitats within the BHT area; and 'potential shelter and foraging habitat', comprising the smaller Breakaway habitats, particularly within the HD2 area.

The Rocky Hill habitat within the survey area has been impacted by fire. It is widespread and common throughout the Pilbara bioregion and is not restricted to the Chichester and Hamersley Ranges. This habitat generally had low vegetation complexity and low diversity of microhabitats; however, the MNES species Northern Quoll, Pilbara Leaf-nosed Bat and Ghost Bat are likely to traverse and forage within these habitats.

The Minor Drainage habitats within the survey area were generally devoid of vegetation and impacted from pastoral activities, and are unlikely to provide significant refuge for species, but may provide dispersal and/or foraging habitat for MNES species Northern Quoll, Pilbara Leaf-nosed Bat, Ghost Bat and Pilbara Olive Python. Minor drainage line habitats, although not necessarily large in terms of area, are also common and well-represented habitats within the immediate vicinity of the survey area and the wider Pilbara region.

The Low Hills and Slopes, Alluvial Plain, Mulga Woodland and Stony Plain habitat in the survey area provide fewer microhabitat opportunities for MNES fauna species and are also more widespread in the immediate vicinity as well as the Hamersley subregion and wider bioregion.

5.2 MNES Species

Four MNES fauna species have previously been recorded within the survey area. No further records of any MNES fauna species were obtained during the targeted MNES survey.

The recent Northern Quoll records documented within the survey area (Astron Environmental Services 2019) are significant given that the survey area is at the edge of this species' regional distribution and there has been a paucity of previous local and regional records. The records, which included capture of an individual sub-adult male and multiple motion camera recordings at separate locations suggest that a resident population may exist in the survey area, particularly within the BHT area (Astron Environmental Services 2019). However, no Northern Quolls were recorded during the targeted MNES survey, despite utilising sampling methods specifically designed to target this species in accordance with Commonwealth referral guidelines (Department of the Environment and Energy 2016) and standardised regional monitoring protocols (Dunlop et al. 2014). The conditions preceding the targeted MNES survey were considered poor due to dry conditions. The seasonal conditions, along with a high feral cat (*Felis catus*) activity recorded within the survey area, may have contributed to the lack of Northern Quoll records during the targeted MNES survey. Three individual

cats were captured at three different cage trapping sites across the survey area. Another individual cat was observed on a motion sensitive camera within the HD2 area and the field team observed cat sightings in and around both the HD1 and Hope Downs 4 villages during the survey (Matthew Love, pers. obs.), indicating a potentially high level of cat activity within the survey area at the time of the survey.

The Ghost Bat was previously recorded on nine occasions within the survey area through acoustic recordings (calls), scats recorded in nocturnal feed caves and an individual sighted during spotlighting within the HD2 area (Astron Environmental Services 2019). Two of seven caves previously recorded within the survey area (Caves 1 and 5) were deemed to be Category 3 roost caves with occasional occupancy based on their size and depth; however, no ultrasonic detections were recorded. The other five previously recorded caves were deemed to be Category 4 nocturnal roost caves (opportunistic usage). These Category 4 caves are common in the landscape as numerous observations suggest that the majority of caves and adits in the Pilbara are used in at least an opportunistic manner by itinerant Ghost Bats (Bat Call WA 2019). The caves recorded within the survey area are not considered significant to the long-term presence of the species (Bat Call WA 2019). The records are consistent with the Ghost Bat foraging in low numbers on the HD2 and BHT ridges (Bat Call WA 2019). It is also consistent with the known regional presence of the Ghost Bat across the central Pilbara region as well as locally on the major ridges immediately to the north of the survey area and west of the HD1 mining area (Bat Call WA 2019). The targeted MNES survey failed to further record the Ghost Bat or additional caves within the survey area. It is highly unlikely that additional significant caves (Category 1 or 2) exist within the survey area.

The Pilbara Leaf-nosed Bat has been detected by calls at three locations during one previous field survey in May 2018 (Astron Environmental Services 2019), but were not detected in November 2017, March 2019 (Astron Environmental Services 2019) or the targeted MNES survey. The calls recorded were at least three hours after dusk and are not consistent with the presence of a permanent roost cave nearby (Bat Call WA 2019). This species is likely to forage only occasionally within the survey area taking advantage of benign conditions and dispersing temporarily in search of additional foraging and roosting opportunities (Bat Call WA 2019).

One Oriental Plover individual was opportunistically sighted during a previous survey at the HD1 village camp (Astron Environmental Services 2019), likely due to the presence of water at the camp. This species is unlikely to occur on a permanent basis within the unaltered habitats of the survey area.

Appendix B: Conservation Categories, Habitat Suitability and Likelihood Criteria

This page has been left blank intentionally.

Table B.1: Definitions and criteria for Threatened Ecological Communities (Department of Environment and Conservation 2013).

Three categories exist for listing Threatened Ecological Communities under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act). An ecological community may be categorised as:

Categories of ecological communities	
Critically endangered	If, at that time, it is facing an extremely high risk of extinction in the wild in the immediate future.
Endangered	If, at that time, it is not critically endangered and is facing a very high risk of extinction in the wild in the near future.
Vulnerable	If, at that time, it is not critically endangered or endangered, and is facing a high risk of extinction in the wild in the medium-term future.

Reference: Department of Environment and Conservation 2013, Definitions, Categories and Criteria for Threatened and Priority Ecological Communities DEC (Parks and Wildlife), <https://www.dpaw.wa.gov.au/images/plants-animals/threatened-species/definitions_categories_and_criteria_for_threatened_and_priority_ecological_communities.pdf.>

Table B.2: Categories and definitions for EPBC Act listed fauna species.

Conservation category	Definition
Extinct	Taxa with no reasonable doubt that the last member of the species has died.
Extinct in the wild	Taxa known to survive only in cultivation, in captivity or as a naturalized population well outside its past range; or it has not been recorded in its known and/or expected habitat, at appropriated seasons, anywhere in its past range, despite exhaustive surveys over a time frame appropriate to its life cycle and form.
Critically endangered (CR)	Taxa facing an extremely high risk of extinction in the wild in the immediate future, as determined in accordance with the prescribed criteria.
Endangered (EN)	Taxa are not critically endangered; and are facing a very high risk of extinction in the wild in the near future, as determined in accordance with the prescribed criteria.
Vulnerable (VU)	Taxa are not critically endangered or endangered; and are facing a high risk of extinction in the wild in the medium-term future, as determined in accordance with the prescribed criteria.
Conservation dependent (CD)	Taxa are the focus of a specific conservation program the cessation of which would result in the species becoming vulnerable, endangered or critically endangered; or the following subparagraphs are satisfied: i) the taxa is a species of fish; ii) the taxa is the focus of a management plan that provides management actions necessary to stop the decline of, and support the recovery of, the taxa so that its chances of long term survival in nature are maximized; iii) the management plan is in force under a law of the Commonwealth or of a State or Territory; iv) Cessation of the management plan would adversely affect the conservation status of the taxa Fish includes all taxa of bony fish, sharks, rays, crustaceans, molluscs and other marine organisms, but does not include marine mammals/reptiles.
Migratory (IA)	Taxa are considered migratory species on International Agreements; i) if they are native to Australia and are included in the appendices to the Bonn Convention (Convention on the Conservation of Migratory Species of Wild Animals Appendices I and II); ii) all migratory species included in annexes established under the Japan-Australia Migratory Bird Agreement (JAMBA) and the China-Australia Migratory Bird Agreement (CAMBA); and iii) Are native, migratory species identified in a list established under, or an instrument made under, an international agreement approved by the Minister, such as the Republic of Korea-Australia Migratory Bird Agreement (ROKAMBA).

Note: CD and IA are only related to conservation significant fauna

Table B.3: Criteria used to define likelihood occurrence of conservation significant fauna species.

Likelihood of occurrence	Pre-survey	Post-survey
Recorded	N/A	Species or evidence of species recorded during survey.
High	Species has been recorded within the survey area or within 20 km of the survey area and preferred habitat appears to be present.	Core or preferred habitats present in the survey area which are abundant and/or high quality condition. OR Species is known to be cryptic and may not have been detected despite adequate survey effort and suitable habitat present within the survey area. OR Species or evidence of species recorded within the survey area however doubt remains over the taxonomic identification, validity of record.
Moderate	Species has not been recorded from within the survey area, however species has been recorded within the prescribed database search area and suitable habitat appears to be present.	Core or highly suitable habitats present in the survey area, however non-cryptic species that was not detected despite adequate survey effort. OR Core or preferred habitats present in the survey area are mainly in poor or modified condition.
Low	Species recorded from within the prescribed database search area but suitable habitat does not appear to be present.	Species has not been recorded in the survey area despite adequate survey effort. OR Species dependent on specific habitats that do not occur in the survey area. OR Species considered locally extinct.

Table B.4: Suitability/significance of habitat ranking criteria for the target Matters of National Environmental Significance (MNES) species.

Species	Probable shelter and foraging habitat	Potential shelter and foraging habitat	Suitable foraging and dispersal habitat	Limited foraging and dispersal habitat
Pilbara Olive Python (*Liasis olivaceus barroni*)	N/A	Rocky habitat such as gorges, escarpments and breakaways along with drainage lines including or in close proximity to permanent or semi-permanent water holes.	Drainage lines with dense vegetation enabling transitory behaviours and/or providing foraging potential. Rocky habitats that are not in close proximity to water.	Habitat that has limited sheltering and foraging capacity with no permanent or semi-permanent water.
Northern Quoll *(Dasyurus hallucatus)*	Habitat as described in potential shelter and foraging habitat but is considered core habitat critical to the Northern Quoll. This was determined by proximity to known records and microhabitat features, such as south-facing, extent of habitat and whether it was in close association with a gorge or gully.	Rocky habitats such as ranges, escarpments, mesas, ranges, gorges, breakaways and boulder fields. Also major drainage lines or tree-lined drainage systems that are structurally diverse and contain large diameter trees, termite mounds or hollow logs.	Habitat important for foraging, dispersal and buffering of the species including moderate to small sized drainage lines and native vegetation in close proximity (within 2 km) denning or shelter habitat.	Habitat that has limited sheltering and foraging capacity and not connected to potential denning/shelter and foraging habitat.
Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) and Ghost Bat (*Macroderma gigas*)	N/A	Rocky habitat that contains caves suitable as diurnal or maternity roosts sites, or potentially contains these caves and has not adequately surveyed OR Areas highly suitable for foraging that are likely to be used on a regular basis.	Habitat important for foraging including diverse rocky terrain, moderately sized drainage lines and dense complex vegetation stands.	Habitat that has limited ecological value but may provide capacity for transitory movement across the landscape and/or limited foraging potential.

Species	Probable shelter and foraging habitat	Potential shelter and foraging habitat	Suitable foraging and dispersal habitat	Limited foraging and dispersal habitat
Night Parrot (*Pezoporus occidentalis*)	N/A	Isolated habitat not subjected to predation pressure, fire pressure, and altered habitat from pastoralism and mining activities. Generally roosting habitat that contains old and large spinifex clumps (>50 years unburnt), particularly ring-forming hummocks. OR Areas highly suitable for foraging in close association (<10 km) to potential roosting habitat, including *Triodia* (particularly at times of mass flowering and seeding) and chenopod communities dominated by *Sclerolaena*.	Very little is known on the foraging requirements of the Night Parrot. Habitat within 40 km of potential roosting and nesting sites, potentially important for foraging, including chenopod communities (particularly those dominated by *Sclerolaena*), *Triodia* and areas rich in herbs, including forbs, grasses and grass-like plants.	Habitat that has limited roosting and foraging potential for the Night Parrot.

Appendix D: MNES Species Likelihood of Occurrence within the Survey Area

This page has been left blank intentionally.

Table D.1: Likelihood of occurrence of conservation listed vertebrate fauna species listed as potentially occurring in the vicinity of the survey area.

Scientific name (common name)	Conservation codes		Preferred habitat	Likelihood of occurrence	
	EPBC Act	BC Act		Pre-survey	Post-survey
Reptiles					
Liasis olivaceus barroni (Pilbara Olive Python)	VU	VU	Generally rocky habitats in close association to permanent and semi-permanent water sources.	High	High
Birds					
Apus pacificus (Fork-tailed Swift)	IA	IA	Largely aerial species independent of the terrestrial environment.	Moderate	Moderate
Charadrius veredus (Oriental Plover)	IA	IA	Breeding habitat includes arid grasslands, saltpans; non-breeding habitat includes grasslands, salt-fields, and coastal regions.	Moderate	High - previously recorded
Rostratula australis (Australian Painted Snipe)	EN	EN	Inhabits shallow terrestrial freshwater wetlands, lakes, swamps and claypans. Also found in waterlogged grassland and saltmarsh. Typical sites include areas with emergent tussocks of grass, sedges or samphire; often scattered with clumps of lignum *Muehlenbeckia*, or canegrass or sometimes with tea-tree (*Melaleuca*).	Low	Low
Actitis hypoleucos (Common Sandpiper)	IA	IA	Non-breeding migrant to a wide variety of habitats, such as riverbanks, estuaries, freshwater seeps on coastal shores, tidal creeks, mangrove swamps and saltmarshes.	Low	Low
Tringa nebularia (Common Greenshank)	IA	IA	A variety of freshwater, marine and artificial wetlands, including swamps, open muddy or rocky shores of lakes and large rivers, sewerage farms, saltworks, muddy coastal flats, mangroves and estuaries.	Low	Low
Calidris melanotos (Pectoral Sandpiper)	IA	IA	Mainly swamps, lagoons, river pools, irrigation channels and sewerage ponds. Also in samphire flats around estuaries and salt lakes.	Low	Low
Calidris acuminata (Sharp-tailed Sandpiper)	IA	IA	Muddy edges of shallow fresh/brackish wetlands with emergent sedges, saltmarsh, grass and low vegetation.	Low	Low

Scientific name (common name)	Conservation codes		Preferred habitat	Likelihood of occurrence	
	EPBC Act	BC Act		Pre-survey	Post-survey
Calidris ferruginea (Curlew Sandpiper)	CR/IA	VU/IA	This species mainly occurs on intertidal mudflats in sheltered coastal areas and also around non-tidal swamps, lakes and lagoons near the coast. They are also recorded inland, though less often, including around ephemeral and permanent lakes, dams, waterholes and bore drains, usually with bare edges of mud or sand.	Low	Low
Pezoporus occidentalis (Night Parrot)	EN	CR	Most habitat records are from *Triodia* grasslands and/or chenopod shrublands in the arid and semi-arid zones. *Astrebla* spp. (Mitchell grass), shrubby samphire and chenopod associations, scattered trees and shrubs, *Acacia aneura* (Mulga) woodland, treeless areas and bare gibber as associated with sightings of the species.	Low	Low
Hirundo rustica (Barn Swallow)	IA	IA	Coastal open country generally, especially near surface water and man-made structures such as bridges and power wires.	Low	Low
Motacilla cinerea (Grey Wagtail)	IA	IA	Damp short-grass flats, rice stubbles and edge of swamps, sewage ponds, bore overflows, grazed or mowed grass and irrigated areas.	Low	Low
Motacilla flava (Yellow Wagtail)	IA	IA	Mainly banks and rocks in fast-running freshwater habitats such as rivers, creeks, streams and around waterfalls.	Low	Low
Mammals					
Dasyurus hallucatus (Northern Quoll)	EN	EN	Northern Quoll habitat generally encompasses some form of rocky area for denning purposes with surrounding vegetated habitats used for foraging and dispersal.	High	High - previously recorded
Macrotis lagotis (Greater Bilby, Dalgyte)	VU	VU	Sand or sandy-loam in hummock grassland (*Triodia* species) and or *Acacia* shrublands.	Low	Low

Scientific name (common name)	Conservation codes		Preferred habitat	Likelihood of occurrence	
	EPBC Act	BC Act		Pre-survey	Post-survey
Macroderma gigas (Ghost Bat)	VU	VU	A wide range from rainforest, monsoon and vine scrub in the tropics to open woodlands and arid areas.	High	High - previously recorded
Rhinonicteris aurantia (Pilbara form) (Pilbara Leaf-nosed Bat)	VU	VU	Roosts in deep warm, humid caves or rock cracks, especially in proximity to water pools. Forages while flying low along watercourses and gorges and over *Triodia* grassland.	High	High - previously recorded

Summary
Bat and Night Parrot (*Pezoporus occidentalis*) presence is reported for thirty-three sites in the Hope Down 2 and Bedded Hilltop areas, in the Pilbara, WA. Astron Environmental Services (Astron) carried out an acoustic survey in four phases in November 2017, May 2018, March and September 2019. Twenty-seven sites were surveyed ultrasonically for all bats present including Ghost bat social and ultrasonic calls. Six sites were surveyed using acoustic detectors set to record Night Parrot and Ghost bat social calls. Bat Call WA has reviewed the recordings made and provided species lists and activity levels for the bats present.

Twelve species of echolocating bats were confirmed present including both EPBC Act listed species in the Pilbara, the Pilbara leaf-nosed bat (*Rhinonicteris aurantia*) (PLNb) and the Ghost bat (*Macroderma gigas*) (PGb). PLNb calls were detected in low numbers at three sites in May 2018. PGb were detected ultrasonically at three sites and their presence was confirmed by observation by Astron ecologists of either bats or middens at a further six.

PLNb calls were detected at three sites during May 2018 but were not detected in November 2017 or in 2019. The calls at all three sites were at least three hours after dusk, were well scattered, and are not consistent with the presence of a permanent roost cave nearby.

PGb presence, detected in very low numbers in phases 1, 2 and 3 (November 2017, May 2018 and March 2019, but not in September 2019), is consistent with the known regional population and dispersal for foraging of PGb in the district. No evidence of activity consistent with reproducing bats was detected.

No Night Parrot calls were detected.

Habitats
The sites for the survey were chosen by Astron. Details of the sites are presented in table 1. The bat sites included each type of habitat present in the study area including cave entrances, gorges, breakaways. drainage lines and stony plains. All the Night Parrot sites are on stony plains. The locations are shown in relation to local features in figures 1 and 2.

Given the presence of PGb in the district, each cave assessed during the survey has been categorised according to the following definitions based on PGb usage:

Category 1 diurnal roost caves with permanent occupancy.
There are several documented permanent roost caves and underground mines in northern Australia, e.g. Tunnel Creek in the Kimberley and Kohinoor Adit in the NT. These tend to have large but variable populations, e.g. Kohinoor's colony has grown from 300+ in 1981 to ~1,500 in 1990 and then reduced to 550 in 2013 (Woinarski *et al*. 2014). In the Pilbara, other than a few historical underground mines e.g. Klondyke Queen, Lalla Rookh and Bamboo Creek which do have large populations of over 100 PGb, very few such roosts in natural caves are documented. Those that may be permanently occupied have been observed with variable populations present.

Where permanent presence at these sites is proven, they must all be assumed to be maternity caves. There are no previously documented Cat 1 caves in the central Hamersley Ranges.

Category 2 diurnal roost caves with regular occupancy.
There are a number of Pilbara caves and adits where PGb have regular, but not continuous, presence over long periods. The longest continuous monitoring programs have been at Rio Tinto's West Angelas project and at BHPs MAC and South Flank projects. At all three locations there are several caves with roosting PGb records but none of these have had either permanent presence or consistently high numbers present. Numbers have varied between zero and five with very occasional counts of 20 or more. Based on recent monitoring of caves using ultrasonic call detectors, these caves have PGb present for 25% to 75% of nights for mid to long periods but then may be abandoned for periods. There is insufficient data at present to see if there are any seasonal trends in these occupancy rates. These caves typically have a number of other caves, shelters and overhangs within a few hundred meters. Together they make up an "apartment block" grouping (TSSC 2016, Bat Call 2017, Bat Call 2019) that supports the ongoing presence of the bats.

Recent analysis at West Angelas based on genetic sampling at five monitored caves in 2015 and 2017 (Ottwell *et al*. 2018) suggests that some PGb tend to use particular caves regularly over a season or year but others move between caves in the same period. Their analysis identifies 34 unique individuals at caves over those two years and indicated that the "genetic effective population size" was 12 individuals. Two of the five caves have been shown by the long-term observations to have regular occupancy (Biologic 2016). These are AA1 and A1. In all surveys undertaken, PGb have been either roosting in low numbers or there was evidence of recent roosting at the former and, with the exception of one survey, at the latter. The genetic analysis also supports this conclusion with presence of multiple bats over the two years of that study at these caves. Similar occupancy patterns have been recorded at several caves at the BHP projects. There are an increasing number of observations becoming available of pregnant PGb or PGb carrying pups at some of these caves although again there is insufficient data to identify any trends other than to say that any cave that has regular occupancy must be assumed to be capable of supporting one or more reproducing females and their offspring. There are no caves at HD2/Bedded Hilltops (see below) that the data indicates fall into this category.

Category 3 roost caves with occasional occupancy.
There are many caves and adits where PGb occasionally or rarely roost diurnally in small numbers of one to a few. Surveys in recent years have identified numerous caves that have PGb scats or small food middens present but either no evidence of roosting bats or with rarely repeated presence observations, e.g. five of the seven monitored caves at West Angelas (Biologic 2016) show such a pattern with occasional PGb present and/or intermittent evidence of recent occupancy. Reproducing females have been reported from at least two caves that ongoing observations indicate fall into this category. However, the ongoing observations show opportunistic occupation only. These caves are therefore not considered significant to the long-term presence of the species.

Category 4 nocturnal roost caves, opportunistic usage.
Numerous observations suggest that the majority of caves and adits in the Pilbara are used in at least an opportunistic manner by itinerant Ghost bats. This may be anything from a single foraging visit to a longer visit with a resting period or possibly a feeding session. Evidence of such visits is the widespread presence of small numbers of scats or occasionally recorded echolocation calls during surveys. These visits may or may not be repeated depending whether the bat is passing through a district or is a more permanent resident nearby.

Timing, Moon Phase and Weather
The echolocation survey was conducted between 24th to 30th November 2017, 18th to 26th May 2018, 11th to 17th March 2019 and 20th to 26th September 2019.

The November 2017 sampling evenings were hot with minimum overnight temperatures between 20 and 25^{O}C. The moon in this period was first quarter to full. The May 2018 sampling evenings were cool to cold with minimum overnight temperatures between 5 and 15^{O}C. The moon in this period was first quarter. No rain fell during these survey periods. The March 2019 sampling evenings were hot and humid with minimum overnight temperatures between 25 and 30^{O}C typical of northern wet season. Some seasonal rain fell during this period. The moon was at first quarter. The September 2019 sampling evenings were warm and dry with minimum overnight temperatures between 10 and 15^{O}C. The moon was at third quarter.

Survey Team
Sites were chosen and detectors placed by Astron ecologists. Bob Bullen of Bat Call WA completed analysis of audio and echolocation recordings.

Sampling
The survey consisted of completing a total of forty overnight ultrasonic bat sound recordings in November 2017, thirty-seven in May 2018, twenty-four in March and twenty-two in September 2019, beginning at twilight, at twenty-seven locations within the survey area. A total of eleven acoustic survey nights were completed at two sites for Night Parrot in May 2018, twelve in March and eleven in September 2019. The recordings were “continuous” (Hyder *et al.* 2010) made using ultrasonic SM2BAT+ SongMeter and acoustic SM4A SongMeter (both by Wildlife Acoustics Inc., USA) detectors. The audio settings used followed the manufacturer’s recommendations contained in the user manuals.

For the ultrasonic recordings, once reformatted as .wav files, COOL EDIT 2000 (now available as AUDITION from Adobe Systems Inc.) was used to display each sequence for identification. Calls were identified manually. Only good quality call sequences were used. Details of calls analysed are provided in Table 2 as recommended by Australasian Bat Society (ABS 2006). Reference data for the species identified are available in Bullen and McKenzie 2002, McKenzie and Bullen 2003 and McKenzie and Bullen 2009.

For the acoustic recordings, each was reviewed both manually and using an automatic scan technique for Night Parrot calls. Candidate calls were compared with the author's confirmed reference calls from two Western Australian arid zone locations.

Survey Limitations

The sites surveyed were accessible on foot and the detectors, using omnidirectional microphones, were set on the ground with the microphone horizontal. Species are unlikely to be under-represented as a result.

Bat species density away from cave or adit entrances is impossible to estimate from echolocation records. Bat activity is therefore substituted as an approximate guide to the relative numbers of each species using the study area.

Results of bat fauna survey

An assemblage of twelve echolocating bat species was confirmed as present at the study sites including both the PLNb and PGb, table 4. Species activity levels were low to very high, which is expected for the study area habitat and the times of year.

PLNb detections

PLNb were detected at three widespread locations, two breakaway sites and a gorges site, table 4 and figure 3. Call numbers at all three were low with the maximum number of calls being eight at BAT 13 on the 22nd May 2018, figure 4. The temporal pattern of calls at all three sites, figure 4, is consistent with PLNb foraging away from their roost with timing gaps from civil twilight of approximately three hours and being widespread. This result is consistent with author's unpublished data that indicates that PLNb are only active across the study area in autumn. The closest confirmed permanent diurnal roosts are over 55 km to the north, west and south and over 80 km to the east (author's unpublished data). These distances suggest that the PLNb are possibly using temporary or satellite roosts in the district, as their usual foraging range is under 30 km (Bullen 2013). However, the pattern of the data, the three-hour time gap together with the low number of calls, is inadequate to indicate whether any potential satellite is within or outside the study area boundary. A more probable suggestion is that bats from existing permanent colonies take advantage of the benign conditions in autumn and spread across the country temporarily in search of additional foraging and roosting opportunities.

PGb detections

Ghost bats were detected ultrasonically at three, widely spaced sites, Bat 4 in November 2017, BAT 21 in May 2018 and BAT 25 in March 2019, table 4, figure 5. Additional observations were made by the field survey team, Table 5. Four caves ('4, '5, '7 and '9) containing PGb middens or scats were located and a foraging PGb was seen at an opportunistic site, Table 5. Also, a scat pile was observed under a highway bridge at site BAT 9. There were no category 1 or 2 caves identified. Two caves, Cave 1 and 5, were assessed as category 3 "occasional diurnal roosts" based on their size and depth (see Appendix 1), however no ultrasonic detections were recorded at these sites. The other caves and the highway bridge were assessed as category 4 nocturnal sites. These records are consistent with the PGB foraging in low numbers on both the Hope Down 2 and

Bedded Hilltops study area ridges year-round. This result is consistent with the known presence of the PGb across the central Pilbara in general and on the major ridges immediately to the north of the study area and west of the Hope Downs 1 mining area. No groupings of caves or sites with regular calls were identified suggesting a more heavily used "apartment block".

Common bat species detections
Five common species, *Austronomus australis*, *Chaerephon jobensis*, *Chalinolobus gouldii*, *Taphozous georgianus* and *Vespadelus finlaysoni* dominated bat presence in the area. Both *Taphozous* species were detected

Taxonomy presented herein is after Reardon *et al.* (2014) and Jackson and Groves (2015).

Results of Night Parrot survey.

No Night Parrot calls were detected.

Recommendations.

PLNb
The results of the survey are consistent with the author's existing data on the autumn dispersal of this species from its permanent roosts. No further specific targeted survey effort is indicated by these results.

PGb
The results of the survey are consistent with the use of the ridge lines within the north-central and western ends of the study area by foraging PGb on a year-round basis. Targeted survey effort for groupings of caves that are important for the persistence of PGb has been carried out at both the eastern and western ends of the study area, without locating significant diurnal roosting sites.

Executive Summary

Rio Tinto is evaluating the potential development of additional iron ore deposits at Hope Downs 2 in the Pilbara region of Western Australia. Astron Environmental Services was commissioned by Rio Tinto to assist with development and establishment of a Northern Quoll, *Dasyurus hallucatus* (Endangered) baseline monitoring program within the Hope Downs 2 Proposal area (the survey area, 10,817.7 ha) as part of the Environmental Management Plan. This was achieved through undertaking:

- desktop review and analysis of Northern Quoll monitoring programs and previous biological surveys relevant to the survey area
- field surveys including the deployment and retrieval of Northern Quoll long-term monitoring cameras at five monitoring localities - 35 cameras; Phase 1 (2,128 trap nights) between September and November 2020, Phase 2 (4,151 trap nights) between October 2021 and February 2022, and Phase 3 (2,221 trap nights) between July and October 2022.
- data analysis determining the presence and where possible, the abundance of Northern Quolls
- interpretation of results and reporting on the data capture from the long-term camera monitoring sites and comparable studies within the Pilbara region.

The overall distribution of records surrounding the survey area suggests that the Northern Quoll is likely to be patchily distributed at low density. Other targeted surveys for Northern Quoll in the surrounding locality and broader south-east Pilbara region reported low capture rates, variable capture rates, or the apparent absence of the species. Available data and occupancy modelling from regional studies suggest that Northern Quoll are largely absent or at very low density in the south-eastern portion of the Pilbara.

There are several Northern Quoll records documented in Detailed surveys and a Targeted survey within the Bedded Hilltop (BHT) area prior to the establishment of the monitoring program, with few records since. The records from Detailed surveys were initially considered to be of significance given that the survey area is at the edge of the species' regional distribution, and there has been a paucity of previous local and regional records. Since the Detailed (formerly Level 2) surveys (2017 to 2019) few records of Northern Quoll have been documented, including two motion-camera records from the Targeted survey (2020) prior to the monitoring program and one opportunistic scat record during Phase 1 (2020) of the program. No Northern Quolls have been recorded on the long-term cameras during the baseline monitoring program (8,500 camera trap nights in total), despite utilising a survey designed to target the species within suitable habitat.

Northern Quoll populations are highly variable in both temporal and spatial scales and experience natural fluctuations due to the species life history and other stochastic factors. Fluctuations may also be a function of additional (and linked) factors such as fire history, and predator and prey densities. Fire events in 2019 affected large areas of BHT and may have contributed to the lack of Northern Quoll records since 2019 by limiting resource availability during the earlier phases of monitoring. High Feral Cat (**Felis catus*) activity has also consistently been recorded since the establishment of the monitoring program in 2020.

Given the extensive survey effort now completed (8,500 camera trap nights), and the overall distribution pattern of records surrounding the HD2 area, it is concluded that currently, the Northern Quoll is patchily distributed and at a low density within the HD2 area and surrounding locality. It is not clear why the number of Northern Quoll records has decreased from 12 records in May 2018 to only

four records subsequently, but the presence of feral predators and recent fire may be explanatory variables.

1 Introduction

1.1 Project Background

Rio Tinto is evaluating the potential development of additional iron ore deposits at Hope Downs 2 (HD2) in the Pilbara region of Western Australia, approximately 68 km north-west of Newman (Figure 1). To support assessment of the HD2 Proposal under the Western Australian *Environmental Protection Act 1986* and the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act), an Environmental Management Plan (EMP) has been developed by Rio Tinto on behalf of Hamersley HMS Pty Limited (the Proponent). The EMP specifically addresses the following environmental factor associated with the HD2 Proposal:

- Terrestrial fauna – Matters of National Environmental Significance (MNES) fauna species and their high value habitat: Northern Quoll (*Dasyurus hallucatus*), Ghost Bat (*Macroderma gigas*), Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) and Pilbara Olive Python (*Liasis olivaceus barroni*).

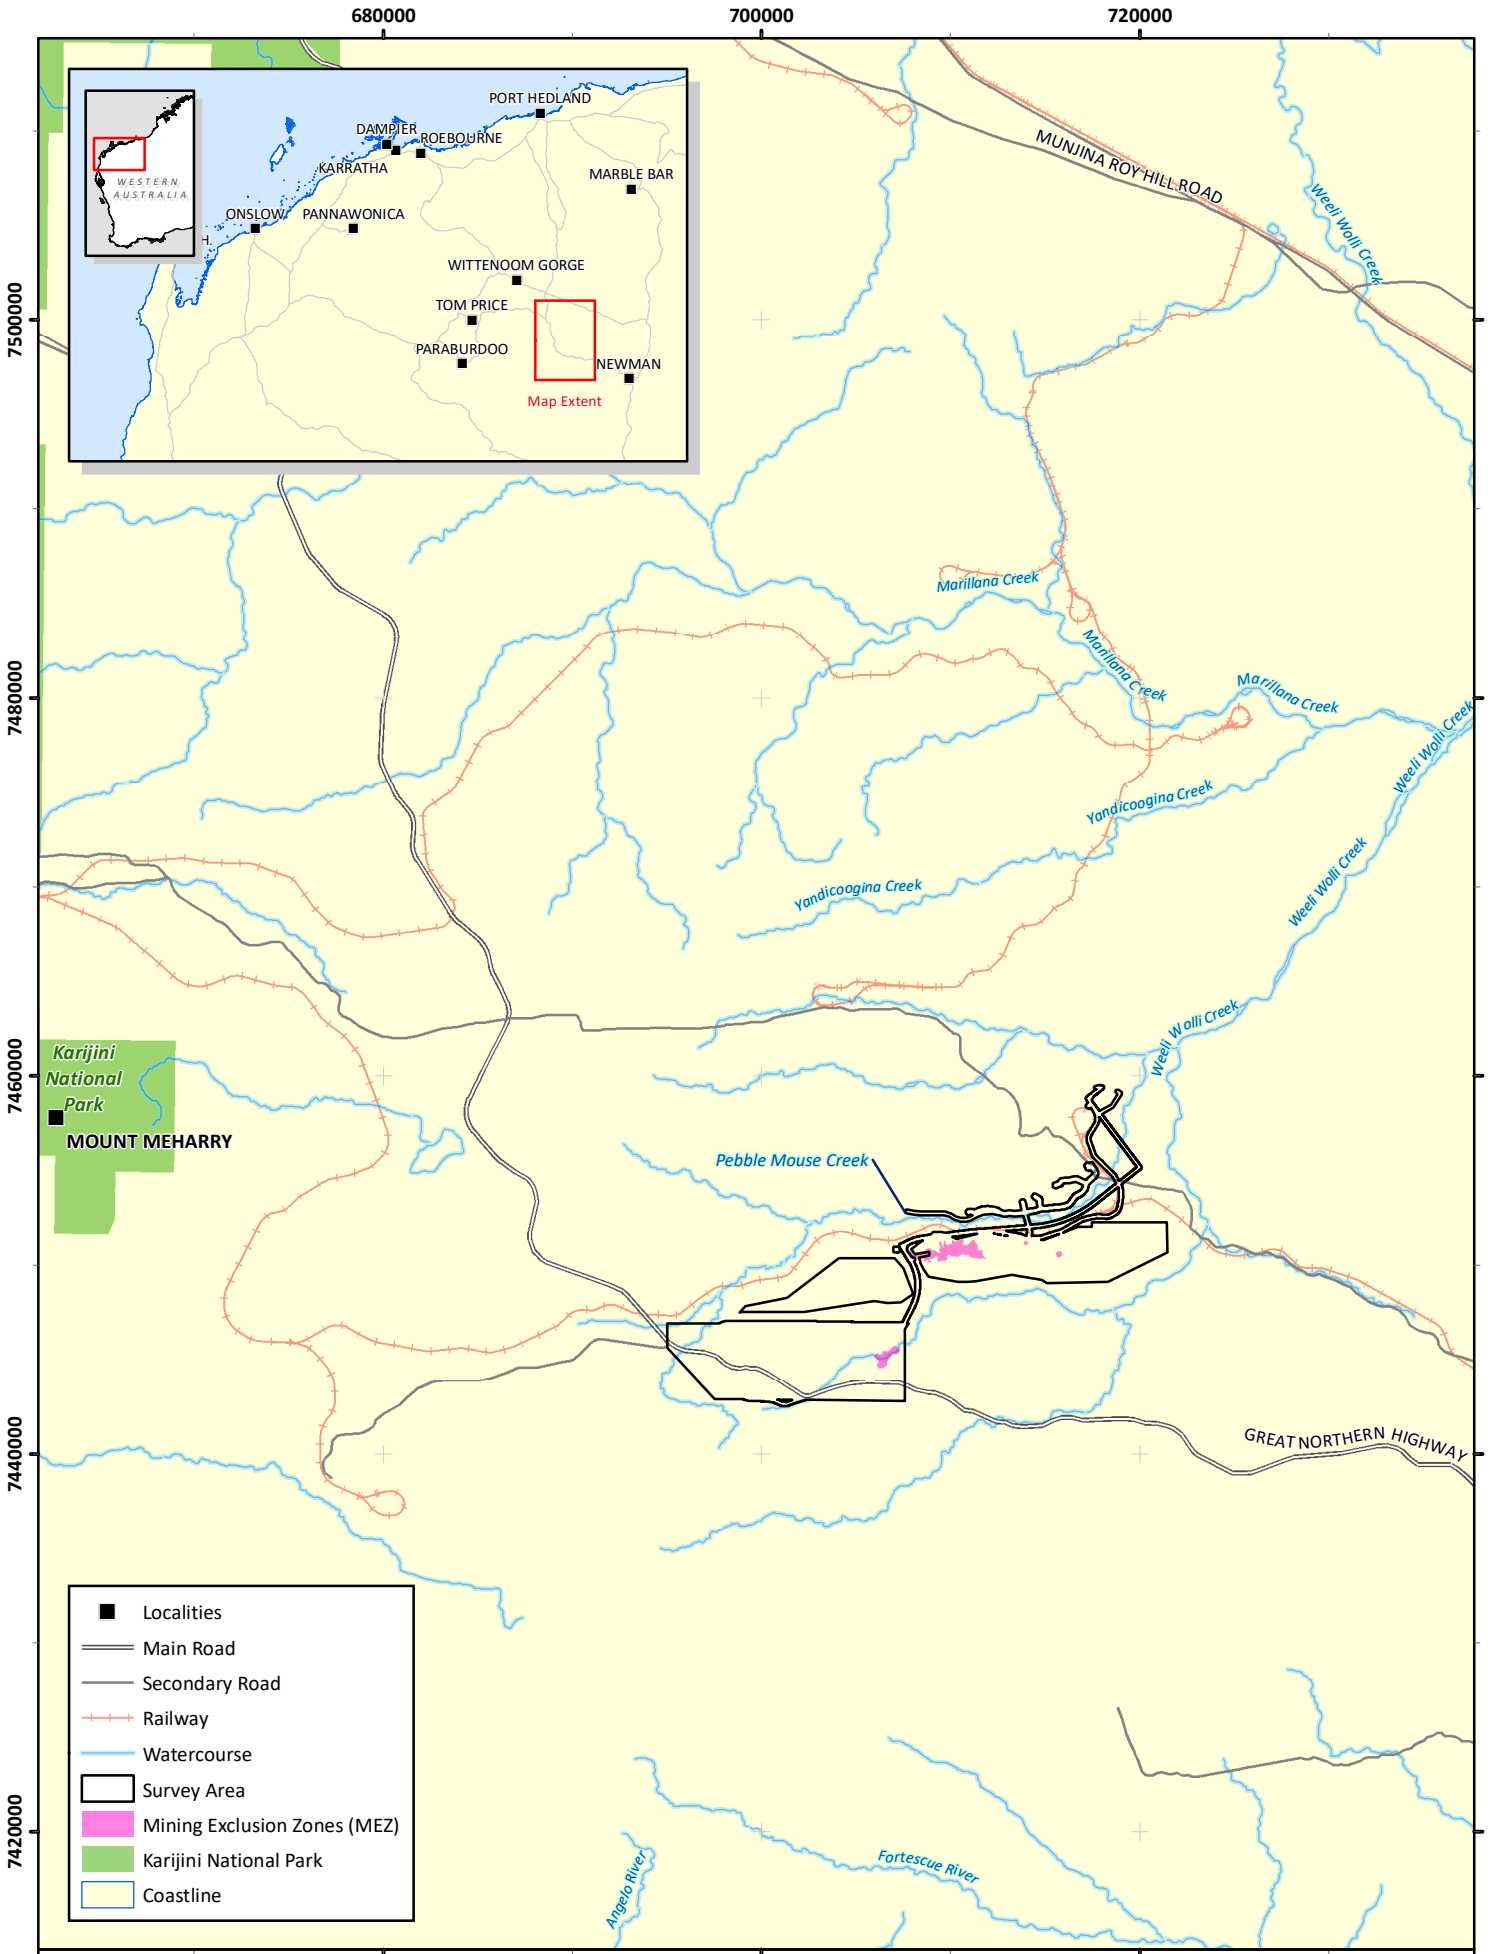
The overall management strategy for MNES fauna is to maintain the integrity of the high value habitat mapped within the HD2 Proposal area (the survey area), mainly comprising Gorge/Gully and Breakaway habitats. These habitats are known to contain core foraging, denning and roosting habitats for species of elevated conservation significance. Given the presence of Northern Quolls, albeit at low numbers, additional management-based provisions are proposed for this species.

This report considers aspects relating to the development and implementation of the Northern Quoll monitoring program by Astron Environmental Services (Astron) using long-term motion sensitive cameras. This program began with the establishment and monitoring of five sites between September and November 2020 (Phase 1; 2,128 trap nights) which were then re-monitored between October 2021 and February 2022 (Phase 2; 4,151 trap nights), and between July and October 2022 (Phase 3; 2,221 trap nights). The monitoring program aims to establish a baseline for species' presence and use of high value habitats to further inform management practices and procedures.

1.2 Scope and Objectives

Astron was commissioned by Rio Tinto to assist with development and establishment of a Northern Quoll baseline monitoring program within the survey area (Figure 1). The specific aspects considered in this report relate to the implementation of long-term camera trap monitoring for Northern Quolls and include:

- desktop review and data analysis of Northern Quoll monitoring programs and previous biological surveys relevant to the survey area
- field survey including:
    - re-deployment and retrieval of 35 cameras set across five existing monitoring sites (three impact and two reference sites)
- data analysis determining the presence and if possible, the abundance of Northern Quolls
- interpreting the results and reporting on the data capture from the long-term camera monitoring sites.



The resultant data have been incorporated to produce this report, which is intended to support and inform the environmental assessment and monitoring process in accordance with the requirements of the EPBC Act. Astron conducted the Northern Quoll monitoring survey in accordance with the regulatory guidance detailed in Table 1.

The scope and key limitations of the Northern Quoll monitoring survey are outlined in Table 1 and further detail is provided in Section 4.3 of this report.

Table 1: Summary of Astron's Northern Quoll desktop assessment and long-term monitoring program.

Level of survey	Survey area and size	Survey timing	Relevant regulatory and technical guidance documents	Compliance with survey guidelines	Key survey limitations
Northern Quoll desktop assessment and targeted monitoring	Hope Downs 2 (HD2) Proposal 10,817.7 ha (survey area)	Phase 1: September – November 2020 (Astron Environmental Services 2023a) Phase 2: October 2021 – February 2022 (Astron Environmental Services 2023b)	• EPBC Act referral guideline for the Endangered Northern Quoll *Dasyurus hallucatus* (Department of the Environment and Energy 2016) • Survey Guidelines for Australia's Threatened Mammals Technical Guidance - Sampling Methods for Terrestrial Fauna (Department of Sustainability Environment Water Population and Communities 2011) **Other supporting guidance documents:** • Environmental Factor Guideline – Terrestrial Fauna (Environmental Protection Authority 2016)	• Surveys conducted by suitably qualified and experienced zoologists. • Cameras were deployed for more than the minimum number of nights recommended.	• Rainfall in the three months preceding and during Phase 1 and 2 was below average but annual rainfall was on average, with good summer rainfall. In Phase 3, annual rainfall was below average but rainfall in the three months preceding was higher than average. • Historically high Feral Cat (**Felis catus*) activity in the area, prior to Phase 1, with records on 40% of deployed cameras. This is classified as a potential

Level of survey	Survey area and size	Survey timing	Relevant regulatory and technical guidance documents	Compliance with survey guidelines	Key survey limitations
		Phase 3: July – October 2022 (current survey)	• Technical Guidance - Terrestrial Fauna Surveys for Environmental Impact Assessment (Environmental Protection Authority 2020) • Pilbara Northern Quoll Project: Surveying and Monitoring *Dasyurus hallucatus* in the Pilbara, Western Australia (Dunlop et al. 2014 p. 2014).		explanatory variable for the low detection of Northern Quoll compared to previous records (14). • Deployment of camera traps without an attractant in Phase 1 due to ethics requirements. This was classified as a potential limitation for the low detection of Northern Quoll compared to previous records. However, Phases 2 and 3 were conducted with attractant. • Survey timing of Phase 1 and Phase 2 was suboptimal regarding Northern Quoll activity. This was classified as a potential limitation for the low detection of Northern Quoll compared to previous records. However, Phase 3 was conducted at an optimal time.

2 Environmental Context

2.1 Physical Environment

2.1.1 Climate

The climate of the Pilbara region of Western Australia is classified as arid tropical with two distinct seasons: a hot, wet summer (October – April) and a mild, dry winter (May – September) (Bureau of Meteorology 2022).

Based on long-term climatic data from the nearest Bureau of Meteorology (BoM) weather station at Newman Aero (Station 007176) (approximately 90 km south-east of the survey area) the mean annual rainfall since 1971 is 317 mm. The mean maximum daily temperatures since 1996 range between 23.1°C and 39.3°C, and range above 30°C for much of the year (Figure 2) (Bureau of Meteorology 2022).

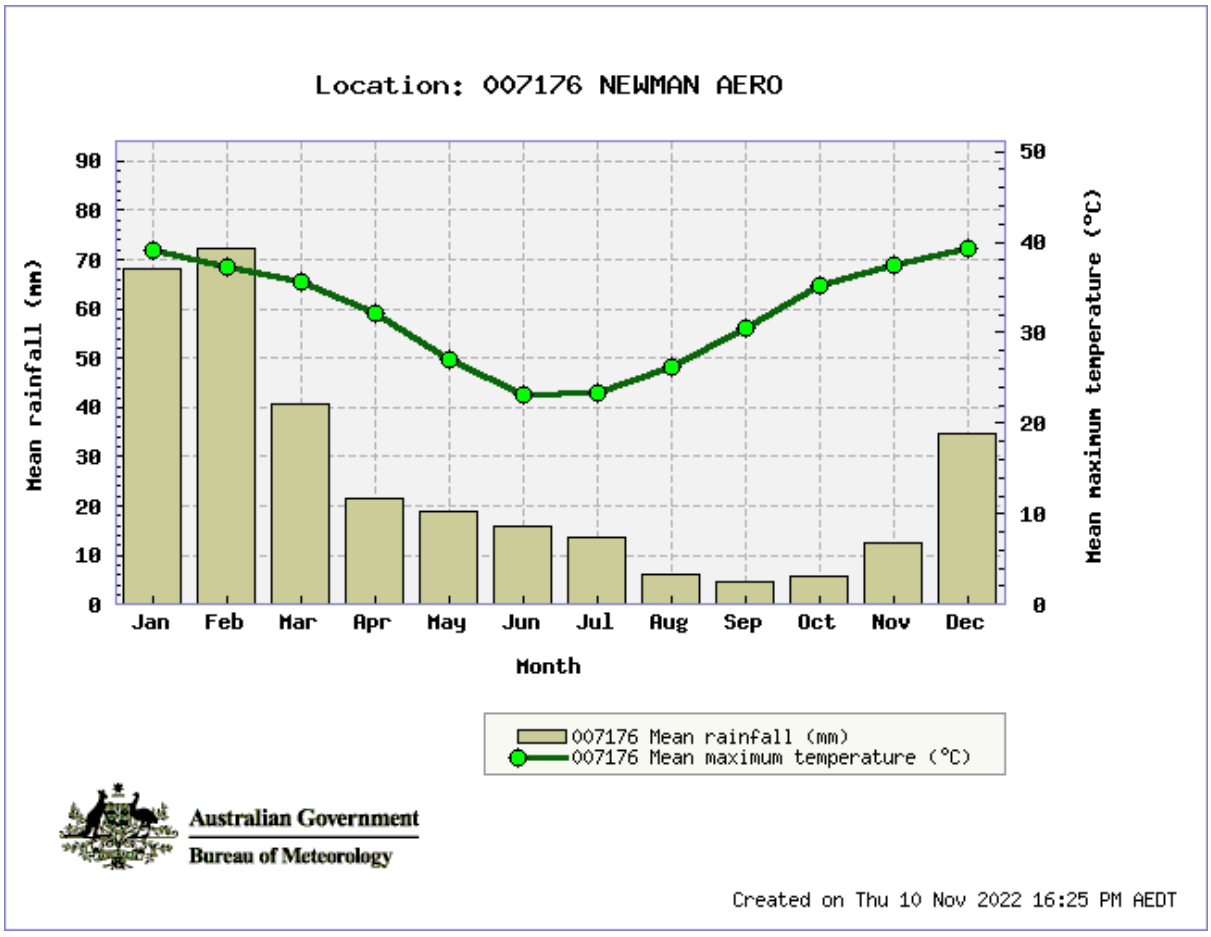

Figure 2: Climate data for Newman Aero Station (Station 007176). Mean annual rainfall data has been calculated from 1971 – 2022 and mean maximum temperature has been calculated from 1996 – 2022 (Bureau of Meteorology 2022).

2.1.2 Geology and Soils

The surface geology of the survey area is comprised of 10 units (Stewart et al. 2008), with Colluvium 3841 as the most dominant (Table 2). Geological mapping of the survey area and surrounds is presented in Figure A.1 (Appendix A).

Table 2: Geological units of the survey area (Stewart et al. 2008).

Geological name	Label	Area (ha)
Alluvium 38485: Channel and flood plain alluvium; gravel, sand, silt, clay, locally calcreted.	Qa	431.4
Brockman Iron Formation: banded iron-formation, chert, mudstone and siltstone.	Lchk	681.7
Calcrete 38497 - Pisolitic, nodular or massive calcrete; ferruginous inclusions; calcareous cementing of bedrock and transported materials; locally with intercalated chalcedony; as low mounds, in playa lakes, or as valley calcrete; locally dissected and karstified	Czk	18.1
Colluvium 38491: Colluvium, sheetwash, talus; gravel piedmonts and aprons over and around bedrock; clay-silt-sand with sheet and nodular kankar; alluvial and aeolian sand-silt-gravel in depressions and broad valleys in Canning Basin; local calcrete, reworked laterite.	Qrc	2,587.8
Fortescue Group: Metadolerite, dolerite, gabbro; medium to coarse grained, massive grey-green rock, usually foliated.	Adf	763.6
Jeerinah Formation: Shale, sandstone, siltstone, mudstone, dolomite, local microbanded chert, jaspilite, conglomerate; fine-grained massive rhyolite; mafic tuff with local accretionary lapilli and agglomerate; thin basalt/dolerite and andesitic basalt flows.	Awfj	1,443.9
Marra Mamba Iron Formation: Chert, ferruginous chert, jaspilite, banded iron-formation, minor shale, siltstone, mudstone.	Achm	2,328.3
Mount McRae Shale and Mount Sylvia Formation: Interbedded shale, chert, banded iron-formation.	Ashm	1,212.5
Weeli Wolli Formation: Banded iron-formation (commonly jaspilitic), mudstone, siltstone; common interlayered metadoleritic sills.	Lchw	1,036.1
Wittenoom Formation: Calcitic dolomite, interbedded chert and shale in upper and lower parts, volcaniclastic sandstone.	Alhw	314.3

2.1.3 Surface Water and Hydrology

No Wetlands of International Importance (i.e. Ramsar wetlands) or Nationally Important Wetlands occur within the survey area (Department of the Environment and Energy 2020). The nearest Nationally Important Wetland is Fortescue Marshes, located 40 km north of the survey area, which has been nominated as a proposed Ramsar site. One of the upper tributaries of Weeli Wolli Creek and Pebble Mouse Creek pass through the survey area.

2.2 Biological Environment

2.2.1 Interim Biogeographic Regionalisation of Australia

The Interim Biogeographic Regionalisation for Australia (IBRA version 7) divides the Australian continent into 89 bioregions and 419 subregions (Department of Agriculture, Water and the Environment 2020). The IBRA regions represent a landscape-based approach to classifying the land surface, including attributes of climate, geomorphology, landform, lithology, and characteristic flora and fauna. The survey area occurs in the Pilbara bioregion, of which 8.4% is represented in the national reserve system (Department of the Environment and Energy 2018).

The biodiversity of the 53 subregions recognised in Western Australia was documented as part of a national audit to provide priorities for conservation action (Department of Conservation and Land Management 2002). The survey area occurs within the Hamersley subregion of the Pilbara region and is described in the audit as:

- Hamersley PIL3 – dissected bold plateaux and ranges of flat lying, moderately folded sandstone and quartzite with vegetation described as Mulga low woodland over tussock grasses occurring on fine textured soils in valley floors, with scattered snappy gum (*Eucalyptus leucophloia*) over *Triodia brizoides* on skeletal soils of the ranges (Kendrick 2001).

2.2.2 Land Systems

Land systems of the Western Australian rangelands have been mapped and described by the Department of Primary Industries and Regional Development (formerly the Department of Agriculture and Food WA) outlining the distributions and providing comprehensive descriptions of biophysical resources, including soil and vegetation condition. A total of 102 land systems occur in the Pilbara bioregion covering 181,723 km^2. Nine land systems occur in the survey area (Table 3). The layout of these land systems within the survey area is shown in Figure A.2 (Appendix A).

Table 3: Distribution of land systems within the survey area.

Land system	Total area within bioregion (ha)	Total area (ha) (proportion of survey area (%))
Boolgeeda - stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands.	961,847	1,486.0 (13.7)
Calcrete - low calcrete platforms and plains supporting shrubby hard spinifex grasslands.	134,834	4.9 (<0.1)
Egerton - highly dissected plains and slopes with sparse mulga shrublands or shrubby hard spinifex grasslands.	66,849	1.4 (<0.1)
McKay - hills, ridges, plateaux remnants and breakaways of meta sedimentary and sedimentary rocks supporting hard spinifex grasslands with acacias and occasional eucalypts.	426,124	326.7 (3.0)
Newman - rugged jaspilite plateaux, ridges and mountains with hard spinifex.	1,994,339	4,647.2 (43.0)
Pindering - gravelly hardpan plains supporting groved mulga shrublands with hard and soft spinifex.	38,738	410.5 (3.8)
Platform - dissected slopes and raised plains supporting shrubby hard spinifex grasslands.	236,390	2,522.2 (23.3)
Rocklea - basalt hills, plateaux, lower slopes and minor stony plains supporting hard spinifex and occasionally soft spinifex grasslands with scattered shrubs.	2,880,288	1,314.2 (12.1)
Wannamunna - hardpan plains and internal drainage tracts supporting mulga shrublands and woodlands and occasionally eucalypt woodlands.	63,004	104.6 (1.0)

2.2.3 Pre-European Vegetation

Beard (1975) completed broad-scale (1:1,000,000) pre-European vegetation mapping at an association level. The Beard mapping was later used by the Department of Agriculture and Food WA (Shepherd et al. 2002) to compile vegetation units that assisted with identifying pre-European and current extents of vegetation throughout Western Australia.

Three pre-European vegetation units, 82, 18 and 29 (Shepherd et al. 2002), are associated with the survey area (Figure A.3, Appendix A). Table 4 summarises the current and pre-European extent of these three vegetation units in the Pilbara bioregion and the survey area.

Table 4: Extent of pre-European vegetation within the survey area (Department of Biodiversity, Conservation and Attractions 2018).

Vegetation association	Mapping unit (Beard 1975)	Description	Total area (ha) (proportion of survey area (%))	Pre-European extent (ha)	Current extent in bioregion (ha)	Proportion of pre-European extent remaining (%)	Pre-European extent with formal protection (%)
82	e16Lr t3Hi	Hummock grasslands, low tree steppe; snappy gum over *Triodia wiseana*	5,452.2 (50.4)	2,168,702	2,156,558	99.4	13.7
18	a1Li	Low woodland, open low woodland or sparse woodland; mulga (*Acacia aneura*)	5,339.0 (49.4)	580,512	576,389	99.3	29.6
29	a1Lp	Mulga (*Acacia aneura*) and associated species.	26.5 (0.2)	172,083	171,975	99.9	12.8

2.3 Commonwealth Conservation Categories and Management

The EPBC Act provides a legal framework to protect and manage MNES including listed flora, fauna and ecological communities. Listed flora, fauna and ecological communities are allocated a conservation category, which are outlined in Tables B.1 and B.2 (Appendix B).

2.4 Land Use and Tenure

The survey area is located within the Shire of East Pilbara. The local area is mainly used for mineral exploration and mining activity. Karijini National Park is the nearest conservation reserve, located approximately 35 km to the west of the survey area (Figure 1).

3 Background on the Northern Quoll

3.1 Distribution

The Northern Quoll occurs in a variety of habitats (Oakwood 2008) but is commonly found in open lowland savannah forest and rocky escarpments. Northern Quolls were once common across the majority of northern Australia but have suffered significant range contractions and population fragmentation since European settlement (Braithwaite and Griffiths 1994, Hill and Ward 2010).

Rocky areas are a particularly important habitat type for Northern Quolls in the Pilbara as these areas retain water and provide a diversity of microhabitats. Rocky areas also tend to have greater floristic diversity and productivity resulting in greater prey density compared to non-rocky areas. Importantly, these areas provide refuge from Feral Cats, fire and livestock (Hill and Ward 2010), and provide breeding potential and denning options (Department of the Environment and Energy 2016).

Northern Quolls are more common in the northern parts than the southern and south-eastern parts of the Pilbara region, particularly within 150 km of the coast (Cramer et al. 2016, Dunlop et al. 2019; Figure 3 and Figure 4).

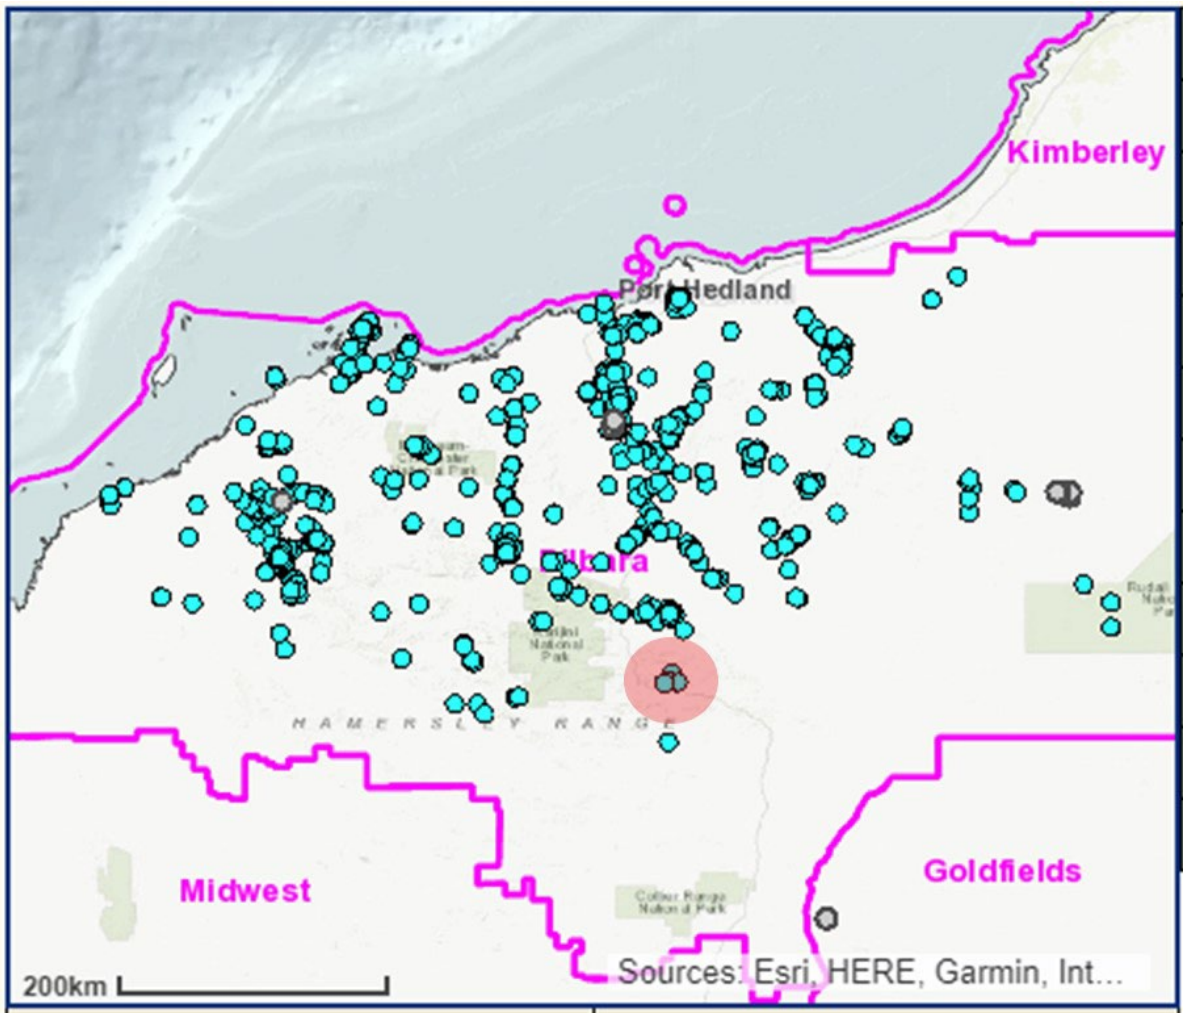

Figure 3: Northern Quoll records from the Pilbara region, available on NatureMap (Department of Biodiversity, Conservation and Attractions 2021). Current survey area with a 40 km buffer is indicated by the red circle.

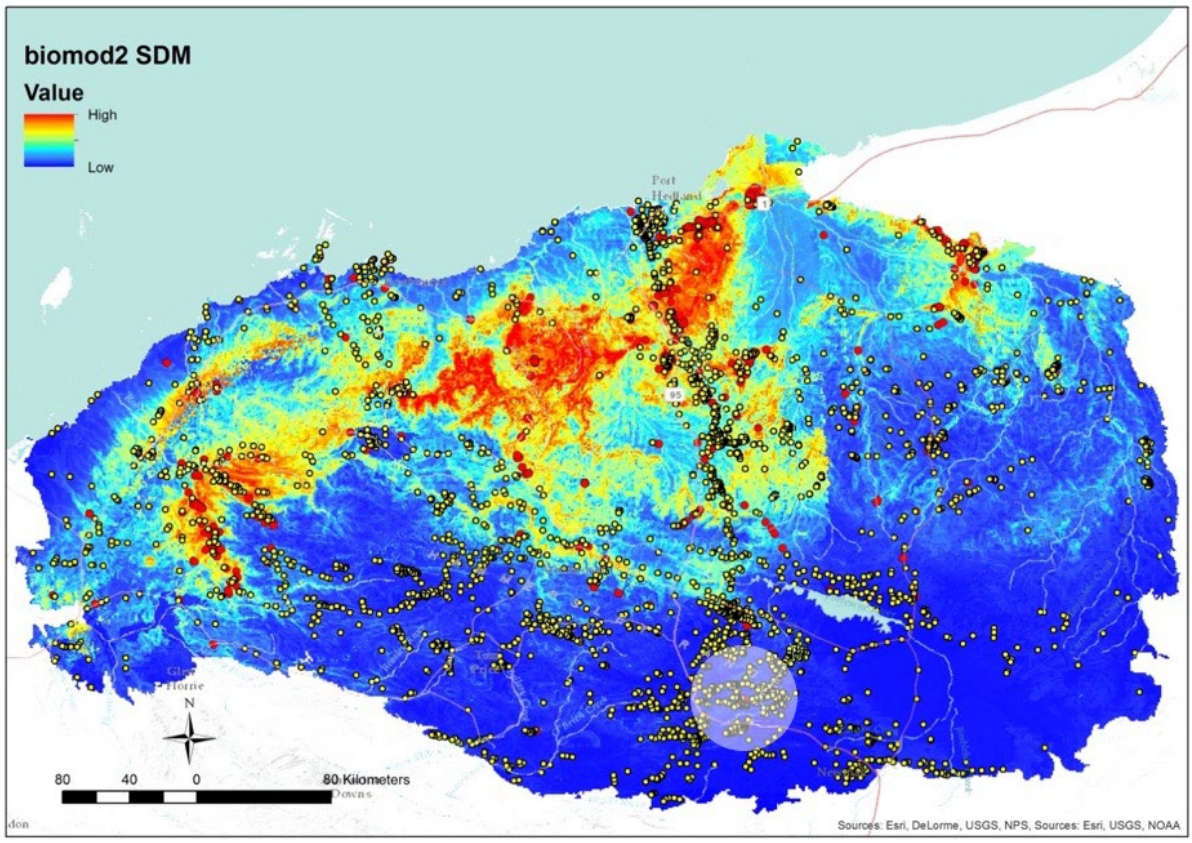

Figure 4: Likelihood of Northern Quoll presence in the Pilbara bioregion, ranging from red (highest likelihood) to blue (lowest likelihood) to a 1 km² resolution. The points indicate past fauna surveys that either detected (red) or did not detect (yellow) Northern Quolls. Current survey area with a 40 km buffer indicated by a white circle. Reproduced with permission from Molloy et al. (2017).

3.2 Biology

The Northern Quoll is a small (240 g to 1,120 g; Oakwood 2008), omnivorous dasyurid marsupial that is partially arboreal and mostly nocturnal (Dunlop et al. 2019 p. 2019). Northern Quolls are short-lived with both sexes maturing at 11 months and display a partly semelparous reproductive strategy, whereby many females and almost all males die following reproduction in their first year (Oakwood 2008, Fisher et al. 2013).

3.3 Conservation Status

The Northern Quoll is protected under both State and Federal legislation. The species is listed as Schedule 1 ('Endangered') under the Western Australian *Biodiversity Conservation Act 2016* (BC Act) and as 'Endangered' under the Federal EPBC Act.

Northern Quolls in the Pilbara have high conservation priority due to their separation from other northern populations, distinct genetics, occupancy of a unique habitat niche and exposure to different threatening processes (Dunlop et al. 2019).

3.4 Hope Downs 2 Northern Quoll Monitoring Program

Northern Quolls were recorded during baseline surveys at HD2 within Gorge/Gully and Breakaway habitats present on the Bedded Hilltop (BHT) deposit (Astron Environmental Services 2020a). Mining Exclusion Zones (MEZ) have been delineated on the western end of the BHT deposit to preserve this habitat within the survey area as part of the EMP (Figure 1). An additional monitoring program for Northern Quolls was proposed to employ a Before-After-Control-Impact survey design approach, including potential impact sites within the MEZ and on the BHT deposit, and reference sites on the range/s to the east of the development area for comparison. It was intended that the monitoring program would be implemented over two to three annual surveys prior to proposed activities at HD2 to account for any variability in the baseline data and satisfy the 'Before' element in planned monitoring. The field component of this survey involved the re-deployment of cameras at fixed sites (three impact sites and two reference sites) between July and October 2022 as part of this monitoring program (Phase 3 of 3).

The motion camera data captured is intended to be used to inform the data requirements under the EMP by establishing baselines for species' presence and use of high value habitats, and to further inform management practices and procedures. Data are to be specifically compared and contrasted against the Department of Biodiversity, Conservation and Attractions (DBCA) regional survey and monitoring work for the Northern Quoll for context (e.g. Dunlop et al. 2019; see Section 4.1.1).

4 Methods

4.1 Desktop Assessment

A desktop assessment including database searches and literature review with a specific focus on Northern Quolls was undertaken previously to assess records within the vicinity of the survey area (Astron Environmental Services 2023b, 2023a). The assessment provides context to the field results generated to date, the habitat requirements and presence of Northern Quolls within the survey area, and to place these results in a broader regional context.

Fauna surveys have been previously commissioned by Rio Tinto within the vicinity of the survey area (Figure 5) and the results supplied to Astron for the desktop assessment in the Phase 1 and Phase 2 monitoring reports (Astron Environmental Services 2023b, 2023a). No new survey reports or annual reports from the DBCA regional monitoring project were found since the initial desktop assessment.

4.1.1 Northern Quoll Regional Survey

In 2011 DBCA embarked on a 10 year Northern Quoll regional monitoring project within the Pilbara (Cook and Morris 2013) with the aim of improving understanding of Northern Quoll population distribution, ecology, abundance and demographics in the region. The project aims to provide contextual information to environmental regulators, consultants and resource development companies that will allow appropriate management to ensure the persistence of resident Northern Quoll populations in the Pilbara region.

The results provide a basis for comparison of abundance estimates between potential impact and reference sites for the current HD2 monitoring program. Following future monitoring surveys, temporal analyses can be conducted over the multiple phases of 'baseline' monitoring to determine inter-annual variability and compare this variability with regional trends. The latest publicly available report is the 2018 annual report (Dunlop et al. 2019).

4.2 Field Survey

4.2.1 Survey Timing and Personnel

Astron zoologists Brittany Osborn and Sean Smithies established 35 long-term monitoring cameras for Phase 1 between 8 and 14 September 2020. The 35 cameras were collected between 10 and 12 November 2020 by Astron zoologist Matthew Love.

Astron zoologists David Keirle and Brittany Osborn re-deployed 35 long-term monitoring cameras at the established monitoring sites for Phase 2 between 25 and 29 October 2021. The 35 cameras were collected between 22 and 24 February 2022 by Astron zoologists Kady Grosser and Sean Smithies.

Astron zoologists Lucy Dadour and Amelia Catterick-Stoll re-deployed 35 long-term monitoring cameras at established monitoring sites for Phase 3 between 28 July and 2 August 2022. The 35 cameras were collected between 3 and 6 October 2022 by Amelia Catterick-Stoll and Brett Jorgensen.

Opportunistic observations of fauna, including secondary signs (tracks and scats) were undertaken while traversing the survey area and during deployment and collection of cameras.

4.2.2 Weather

Daily weather observations recorded from Newman Aero (station 007176) were used to describe local rainfall and temperature preceding the surveys.

4.2.2.1 Phase 1

Rainfall in the 12 months preceding Phase 1 was 349 mm (8% more than the long-term mean of 324.3 mm). Rainfall in the 12 weeks preceding the commencement of the monitoring survey was 68% (25 mm) below the mean rainfall for the same period but followed an above average wet season with 43% (79 mm) more rainfall received between January and March than the long-term mean.

4.2.2.2 Phase 2

Rainfall in the 12 months preceding Phase 2 was 354 mm (10% more than the long-term mean of 317.8 mm). Rainfall in the 12 weeks preceding the commencement of the monitoring survey was 100% (8 mm) below the mean rainfall for the same period (no rainfall recorded in the 12 weeks prior to survey) but followed an above average wet season with 18% (12 mm) more rainfall received between January and March than the long-term mean.

4.2.2.3 Phase 3

The annual rainfall recorded preceding the Phase 3 survey (226.8 mm) was 28.0% below the long-term mean (315.2 mm) recorded at Newman (Figure 6). Rainfall in the three months preceding the field survey (86.4 mm) was 52.9% above the long-term mean (56.5 mm) (Figure 6). The maximum daily temperatures during the field survey ranged between 28.7°C and 38.2°C (Bureau of Meteorology 2022).

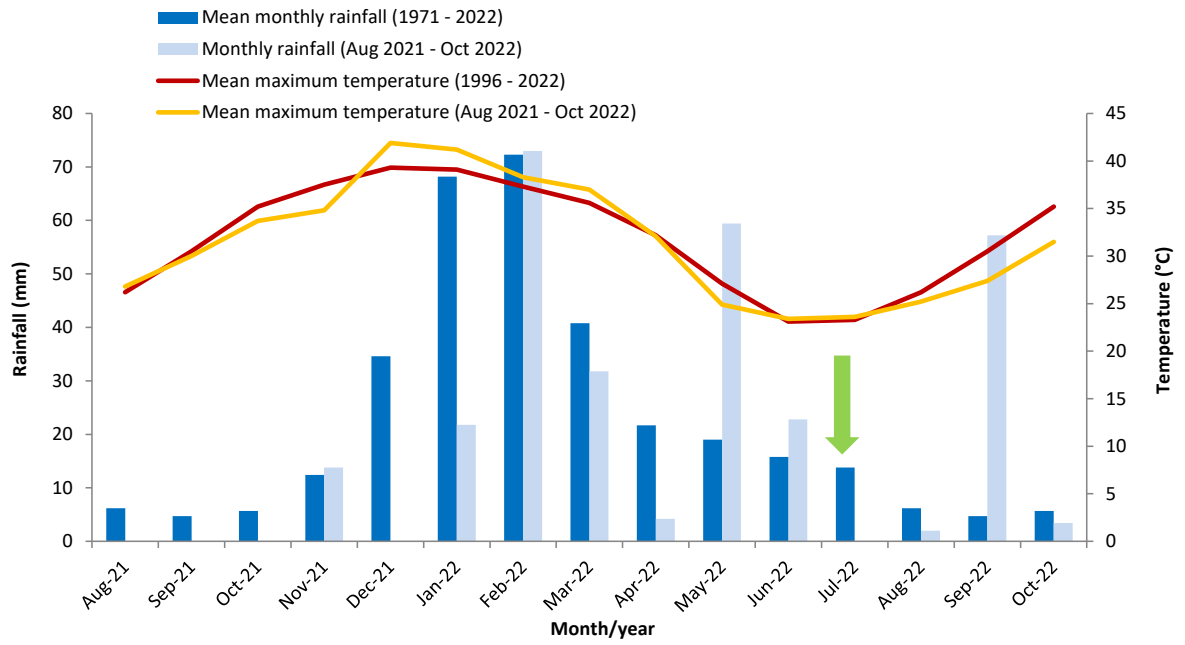

Figure 6: Newman Aero (station 007176) mean monthly rainfall (1971 - 2022), total recorded rainfall (August 2021 - October 2022), long-term mean monthly maximum temperatures (1996-2022) and mean monthly maximum temperatures (August 2021 - October 2022). The green arrow indicates the current Northern Quoll monitoring survey commencement (Phase 3).

4.2.3 Long-term Monitoring Motion Sensitive Cameras

The motion-sensitive cameras (Reconyx® HyperFire 2) set up in July/August 2022 (Phase 3) are part of a long-term monitoring program established in September 2020 (Table C.1 and Figure C.1, Appendix C).

The monitoring program consists of seven cameras set at five sites (35 cameras in total; sites NQ1-5) within Northern Quoll habitat; three sites within 'potential impact' areas (two within the MEZ, one on BHT) and two within 'reference' areas to the east of the MEZ, initially established in September 2020 (Phase 1). In October 2021 (Phase 2) the cameras were redeployed at four of the five previously established sites. One of the reference sites from Phase 1 was moved behind Hope Downs 1 (HD1) camp as the habitat is more suitable and was known to provide refuge to Northern Quolls based on the capture of an individual during the Hope Downs 2 Fauna survey in May 2018 (Astron Environmental Services 2023a). For the current survey (Phase 3), the cameras were re-deployed at the five sites, with minor adjustments to site NQ1. Five cameras within site NQ1 were moved from previous locations to avoid heritage sites and buffer boundaries. The new locations are still within moderate habitat suitability for Northern Quoll, which is in line with work undertaken in Phases 1 and 2.

Each of the five sites consist of five downward-facing cameras and two horizontally orientated cameras set approximately 50 m and 100 m apart. The cameras were fixed to star pickets using tie down straps or brackets and were set with non-reward scent lures inside bait cannisters that were secured to rocks. The downward-facing cameras (Figure 7) had a reduced focal length and were fixed approximately 1 m above the ground, whereas the horizontal cameras (Figure 8) had an opened focal range and the scent lure was placed 1 m in front of the camera. The downward-facing placement allows for Northern Quoll spot recognition to differentiate between individuals (e.g. Hohnen et al. 2013, Dunlop et al. 2019), whilst the horizontal placement with a wider field of view allows for the

capture of other animals of interest such as feral predators (Dunlop et al. 2019). All equipment was removed from site during the camera collection in October 2022, and the cameras were analysed following a combined trapping effort of 2,221 trap nights (Phase 3).

Plate 1: Downward-facing camera setup.

Plate 2: Horizontally orientated camera setup.

4.2.4 Data Analysis

Motion camera images were analysed by experienced Astron personnel to identify any Northern Quoll image captures, as well as any other conservation significant species or non-indigenous species. Field guides and accepted scientific peer reviewed references were used to assist with fauna identification. All false triggers (i.e. non-target photos, malfunctions etc) were eliminated from the data set.

The following minimum analyses (ongoing) are required to assess management targets for Northern Quoll as part of the monitoring program and were undertaken where possible:

- Determine presence – presence is deduced through camera monitoring, trap site recording and opportunistic identification of scats, tracks and traces during the camera trapping program.
- Calculate abundance from:
    - Camera images - where possible, individual quolls were identified through spot pattern recognition (Hohnen et al. 2013, Dunlop et al. 2019) and the number of individual Northern Quolls calculated. If not possible, an 'activity' index was instead calculated based on the proportion of records across all camera trap nights. An 'activity' index was also calculated for any feral species recorded on cameras in a similar manner.
    - Trapping records - abundance will be measured using the trap success rate (standardised by 100-trap nights) for the monitoring period. Trap success was used as a directly proportional indicator of population abundance to monitor fluctuations and impacts on the Northern Quoll population.
- Compare and contrast – comparison of abundance estimates between 'potential impact' and 'reference' sites, and comparison with regional survey work if results are available. In future monitoring surveys, temporal analyses are to be conducted over the multiple phases of 'baseline' monitoring to determine inter-annual variability and compare these changes regionally.

It was only possible to determine presence from the current survey. Abundance could not be calculated or compared between impact and reference sites and with the DBCA regional survey work due to the absence of Northern Quolls recorded on the cameras.

4.3 Limitations

Following completion of the desktop assessment and analysis of camera monitoring data, a review of any limitations that may affect a complete assessment of the data collected was conducted. The limitations listed in Table 5 are based on those suggested as considerations in Technical Guidance - Terrestrial Fauna Surveys for Environmental Impact Assessment (Environmental Protection Authority 2020) of relevance to this fauna monitoring program. Due to the number of fauna surveys conducted in the survey area, the populations of MNES are relatively well documented.

Table 5: Statement of limitations for the targeted vertebrate fauna assessment.

Potential limitation	Degree of limitation	Statement regarding potential limitations
(i) Competency/experience	No limitation	The senior and principal zoologists planning and conducting the monitoring have over 10 years' experience with fauna surveys and specifically, Northern Quoll surveys and monitoring in the Pilbara region.
(ii) Scope What faunal groups were sampled and were some sampling methods not able to be employed because of constraints such as weather conditions.	No limitation	The survey scope and the sampling method was targeted for the Northern Quoll. The survey was undertaken at optimal timing in this monitoring survey (previously part of Phase 1 and all of Phase 2 were at sub-optimal timing), given the survey: • aligned with breeding and increased animal movement (between September to October) • occurred before the male Northern Quoll post breeding die-off (October) • occurred before female denning (between November and February). The survey duration of over two months was considered adequate given that Dunlop et al (2019) found that Northern Quolls are highly detectable, with 95% confidence of detection after 12.6 camera-nights (5 cameras for 2.5 nights).
(iii) Proportion of fauna identified, recorded and/or collected	No limitation	A single, targeted survey technique was employed to detect Northern Quoll over multiple years. The current knowledge of the species, as well as the combined results of the current field survey and previous Northern Quoll assessments for Hope Downs and surrounds, suggests low detections are likely a function of low density rather than due to the survey technique.
(iv) Sources of information Previously available information (whether historic or recent) as distinct from new data.	No limitation	Adequate information was available from database searches and previous studies in the survey area and region.
(v) Proportion of task achieved. Further work which might be needed?	No limitation	The survey scope was able to be completed.
(vi) Timing/weather/season/cycle	Minor limitation	Rainfall in the 12 months preceding the survey was 28.0% below the long-term average (226.8 mm versus 315.2 mm). However, the rainfall three months preceding the field survey was 52.9% above the long-term mean (86.4 mm versus 56.5 mm). Rainfall for Phases 1 and 2 were below average for the three months preceding the field survey, but had received good to above average summer rainfall.

Potential limitation	Degree of limitation	Statement regarding potential limitations
(vii) Disturbances For example fire, flood, accidental human intervention which affected results of survey	Potential limitation. Possible explanatory variables.	Large areas of BHT have previously been affected by fires (2019) that may have limited resource availability and population numbers during the initial phases of monitoring. Feral Cat activity was documented in previous field surveys by Astron and during the current phase of monitoring within the survey area (see Section 5.2.4).
(viii) Intensity In retrospect, was the intensity adequate?	No limitation	The intensity was considered adequate for targeted Northern Quoll monitoring.
(xi) Completeness Was the relevant area fully surveyed?	No limitation	The survey targeted high value Northern Quoll habitat and areas of historical presence.
(x) Resources Degree of expertise available in animal identification to taxon level.	No limitation	Adequate resources were available to identify fauna species. All technical personnel involved in identification have extensive experience in conducting targeted fauna surveys in the Pilbara.
(xi) Remoteness and/or access problems	No limitation	No access constraints affected the survey outcomes.
(xii) Availability of contextual information For example biogeographic information on the region.	No limitation	Database searches and previous vertebrate fauna surveys in the vicinity of the survey area provided contextual information.

5 Results

5.1 Desktop Assessment

A Protected Matters and NatureMap database search previously revealed 17 Northern Quoll records within 40 km of the survey area, with records including multiple observations of the same individual (Astron Environmental Services 2023a). There were four additional known records within the survey area (Astron Environmental Services 2020a, 2023c, 2023b) not returned in database searches including one scat record from Phase 1 (Table 6).

A summary of literature review results of previous surveys undertaken in the vicinity of the survey area are presented in Table 7. Northern Quoll surveys conducted within the vicinity of the survey area have used a combination of Elliott traps, cage traps, motion sensitive cameras and opportunistic field observations at various times of the year and with variable survey effort. The total survey effort for the previous surveys is 9,530 camera nights, 3,727 combined cage and Elliott trap nights, 1,400 cage trap nights and 3,744 Elliott trap nights.

Table 7: Summary of literature review results from surveys conducted within the vicinity of the survey area. Only the survey effort that directly targeted or would reasonably be expected to record Northern Quoll within surveys has been included where possible.

Author (year)	Survey area; size (ha)	Survey level	Survey timing	Survey effort	Quoll records and targeted effort
Astron Environmental Services (2020a)	Hope Downs 2 survey area 10,817.7 ha	Level 2 (3 phases)	November 2017 May 2018 March 2019	Baseline fauna assessment of terrestrial vertebrate fauna and short range endemic (SRE) invertebrate fauna species within the survey area. Habitat assessments, 19 trapping sites, avifauna censuses at each trapping site, foot traverses, nocturnal searches, targeted searches for both vertebrates and SRE invertebrates, and the use of SM2 acoustic bat echolocation recorders and motion sensor cameras.	One male recorded from 1,265 combined cage and Elliott trap nights (<0.1 captures/100 trap nights). Ten records from 202 camera trap nights (4 captures/100 trap nights). Combined trap success of 0.2 captures/100 trap nights. Three scat records from targeted searches.
Astron Environmental Services (2023c)	Hope Downs 2 survey area 10,817.7 ha	Targeted (1 phase)	February to September 2020	Targeted Northern Quoll survey using long-term deployment of 12 motion sensitive cameras	Two records from 2,355 camera trap nights (<0.1 captures/100 trap nights).

Ecologia Environment (2014)	Greater West Angelas 17,565 ha	Level 2 (2 phases)	September – October 2012 March 2013	Habitat assessments, 12 trapping sites, avifauna censuses at each trapping site, foot traverses, nocturnal searches, targeted searches for both vertebrates and SRE invertebrates, and the use of SM2 acoustic bat echolocation recorders and motion sensor cameras.	Nil records from 2,016 combined cage and Elliott trap nights. Nil records from 48 camera trap nights.
Ninox Wildlife Consulting (2009a)	Hope Downs 4 Option 1 Infrastructure Corridor Size not stated	Level 2 (1 phase)	May 2008	Four trapping sites, Anabat ultrasonic call detector, avifauna census, SRE sampling and opportunistic searches.	Nil records from 288 combined cage and Elliott trap nights.
Ninox Wildlife Consulting (2009b)	Hope Downs 4 Option 6 Infrastructure Corridor Size not stated	Level 2 (2 phases)	September 2008 April 2009	Six trapping sites, Anabat ultrasonic call detector, avifauna census, SRE sampling and opportunistic searches.	Nil records from 864 combined cage and Elliott trap nights.
Phoenix Environmental Sciences (2014)	Wonmunna Size not stated	Level 2 (2 phases)	May and October 2011	Ten systematic survey sites and two targeted Northern Quoll sites	Nil records from 350 combined cage and Elliott trap nights. Nil records from 390 camera trap nights.

Results from the DBCA Pilbara Northern Quoll research program (PNQRP; see Section 4.1.1) are based on the deployment of a standardised annual monitoring regime for Pilbara populations, including searching in previously unsurveyed or poorly surveyed areas to better understand the distribution and habitat requirements. Results are presented from the most recent available 2018 data (Dunlop et al. 2019). Generally, lower numbers were reported throughout 2019 and only limited surveys were conducted in 2020 (Dr Judy Dunlop, Research Scientist DBCA pers. comm., December 2020; unpublished data in prep.).

Sites with Northern Quoll records that are nearest to the current survey area (Karijini National Park and Roy Hill Rail) show lower capture rates than more northerly and coastal sites, such as Dampier Archipelago, Indee Station and the combined survey averages (PNQRP all sites; Table 8).

Table 8: Trap nights and capture rates from DBCA Pilbara Northern Quoll research program (2014 – 2018) (Dunlop et al. 2019).

Site	Trap nights	Captures/100 traps	Individuals/100 traps
Karijini National Park	800	3.0	1.13
Roy Hill Rail	240	2.50	2.92
Dampier Archipelago	1,000	15.8	6.90
Indee Station	1,000	34.1	11.50
PNQRP all sites	8,080	8.97	3.61

5.2 Field Survey

5.2.1 Habitat Suitability for Northern Quolls

Approximately 107 ha (1%) of the survey area, comprising Gorge/Gully and some Breakaway habitats, is considered 'high value habitat' (Rio Tinto 2022) (or 'core habitat' as per the referral guidelines (Department of the Environment and Energy 2016)), based on proximity to known Northern Quoll records, microhabitat features and orientation aspect (Figure D.1, Appendix D).

Approximately 2,058 ha (19%) of the survey area is considered 'moderate habitat value' (Rio Tinto 2022), comprising some smaller Breakaway habitats, as well as Minor Drainage and Rocky Hill habitats in close association with the Gorge/Gully and Breakaway habitats as they provided microhabitats such as crevices and cracks for foraging (Figure D.1, Appendix D).

Approximately 7,821 ha (73%) of the survey area was considered 'low habitat value' (Rio Tinto 2022), consisting of Alluvial Plain, Low Hills and Slopes, Mulga Woodland and Stony Plain habitats (Figure D.1, Appendix D). The remaining 832 ha (7%) of the survey area was 'null habitat value' (Rio Tinto 2022), as these were Disturbed areas (Figure D.1, Appendix D).

5.2.2 Northern Quoll Field Records

No Northern Quoll were recorded on any of the long-term cameras during the current survey (Phase 3; 2,221 trap nights), nor previous phases of the monitoring program (8,500 total trap nights for all three phases). The only record for the monitoring program to date is one scat recorded near site NQ2 within Gorge/Gully habitat during Phase 1 in 2020.

5.2.3 Other Terrestrial Vertebrate Species

During Phase 1 of monitoring, 28 vertebrate fauna species were recorded on the cameras and opportunistically: six reptile species, 13 bird species and nine mammal species, including the Northern Quoll (scat record). Thirty-four vertebrate fauna species were recorded on the cameras and opportunistically during Phase 2, including nine reptile species, 19 bird species and six mammal species.

Thirty vertebrate fauna species were recorded on the cameras during the current phase (Phase 3), including 11 mammals, 12 birds and seven reptiles. The five most recorded species were Common Rock-rat *(Zyzomys argurus)*, Grey Shrike-thrush (*Colluricincla harmonica*), Torresian Crow (*Corvus orru*), Rothschild's Rock-wallaby (*Petrogale rothschildi*) and Western Bowerbird (*Chlamydera guttata*) representing 82 records (41.2% of total records).

5.2.4 Introduced Fauna

Two introduced species were recorded on motion cameras during Phase 1 of monitoring: Dog/Dingo (**Canis familiaris*) and Feral Cat (**Felis catus*). There was one record of the Dog/Dingo with one capture from 2,128 trap nights (0.05% trap success), and one record of the Feral Cat with one capture from 2,128 trap nights (0.05% trap success).

One introduced species was recorded on the motion cameras during Phase 2 of monitoring, the Feral Cat (**Felis catus*). There were 15 records of Feral Cats across 13 cameras from 4,151 trap nights (0.36% trap success). This result indicates cat activity on approximately 40% of deployed cameras (13 of 35 cameras).

Two introduced species were recorded on motion cameras during the current survey (Phase 3), including the Dingo (*Canis familiaris dingo*) and Feral Cat (*Felis catus*). Across the 2,221 trap nights there were two records of the Dingo (0.09% trap success), one at site NQ2 and one at site NQ3, and 12 Feral Cat records (0.54% trap success) recorded at sites NQ2, NQ3 and NQ5. Feral Cat activity was present across six cameras in total which indicates cat activity on approximately 20% of the deployed cameras (six out of 35 cameras), of which four cameras were set behind HD1 camp.

6 Discussion

6.1 Northern Quoll Habitat

The Gorge/Gully and Breakaway habitats identified in the survey area are considered potentially important high value habitat for Northern Quoll. This is due to the microhabitats and refugia they provide, such as caves and semi-permanent water pools, that are important for species foraging, breeding and sheltering requirements. These habitats are preferred by females for denning and are considered critical for the long-term survival of a particular subpopulation according to referral guidelines (Department of the Environment and Energy 2016).. These habitats were divided into 'high value habitat' (or core habitat), which comprised most of the Gorge/Gully habitat within the survey area and Breakaway habitats within the BHT area; and 'moderate value habitat', comprising the smaller Breakaway habitats, particularly within the HD2 area. These Gorge/Gully and Breakaway habitats are well represented outside of the survey area and are considered only of potential significance for the Northern Quoll within the HD2 survey area given the low density population demonstrated from survey effort to date.

Other habitats of 'moderate habitat value' included the Rocky Hill and Minor Drainage habitats. The Rocky Hill habitat within the survey area is widespread and common throughout the Pilbara bioregion and is not restricted to the Chichester and Hamersley Ranges. This habitat generally had low vegetation complexity and low diversity of microhabitats and had recently been impacted by fire; however, Northern Quoll are likely to traverse and forage within these habitats as part of their home range. The Minor Drainage habitats within the survey area were generally devoid of vegetation and impacted from pastoral activities, and are unlikely to provide significant refuge for species, but may provide dispersal and/or foraging habitat. Minor Drainage Line habitats, although not necessarily large in terms of area, are also common and well-represented habitats within the immediate vicinity of the survey area and the broader Pilbara region.

The Low Hills and Slopes, Alluvial Plain, Mulga Woodland and Stony Plain habitat in the survey area provide fewer microhabitat opportunities for Northern Quoll or other MNES fauna species and are also widespread in the immediate vicinity as well as the Hamersley subregion and wider bioregion.

Habitat suitability, however, is unlikely to be constant and the factors determining it are susceptible to change, particularly over time. Rockpiles, for example, are considered to provide potential denning and foraging habitat for Northern Quoll but would be unlikely to do so if a particular rockpile became inhabited by Feral Cats, or if the vegetation were recently impacted by wildfire. Similarly, the degree of landscape-scale connectivity is likely to be important whereby a rockpile with requisite geological and topographic features would not be considered critical habitat if it were sufficiently small or became isolated from another suitable habitat such that it was unable to retain a viable subpopulation. An ongoing assessment of habitat suitability should therefore be considered at the time of monitoring to help understand and interpret results accordingly.

6.2 Northern Quoll Records

The presence of a scat recorded in Phase 1 (2020) of this monitoring program, suitable habitat, and previous records (2017 to 2019) within the survey area suggested that the Northern Quoll were present at a low density within the survey area. Despite previous records, Northern Quoll have not been recorded on the cameras of the monitoring program and an individual has not been sighted since May 2020, despite extensive survey effort completed within the HD2 Proposal area. Recent Northern Quoll records (e.g. Astron Environmental Services (2020a)), particularly within the BHT area between November 2017 and March 2019 were initially of potential significance, given that the survey area is

at the edge of the species' regional distribution, and there has been a paucity of previous local and regional records with only four prior records documented within 40 km of the survey area, three of which were of the same individual. Since the Detailed (formerly Level 2) surveys (2017 to 2019) (Astron Environmental Services 2020a), targeted surveys have resulted in few or no records of Northern Quoll, with two motion camera records and one opportunistic scat record across four surveys between 2019 and 2022. The overall distributional pattern of records surrounding the survey area suggest that the Northern Quoll is likely to be patchily distributed at a low density in the surrounding locality.

Other targeted surveys for Northern Quoll in the surrounding locality and broader south-east Pilbara have also reported low capture rates or no captures. Biota (2014c) conducted a targeted survey at Juna Downs to the north-west of the survey area comprising 1,420 Elliott trap nights, 134 camera trap nights and targeted searches and recorded no evidence of presence. Biota (2009, 2014b) also conducted targeted Northern Quoll surveys to the north of the survey area at nearby Yandi and similarly recorded no evidence from 1,294 Elliott trap nights across multiple years. A single individual was captured near the survey area by Biota (2011) at Hope Downs from 500 Elliott trap nights (three records; 0.2 captures/100 trap nights) and additional records were documented from 100 camera trap nights (0.2 captures/100 trap nights), although it is not known whether these captures were the same or multiple individuals.

The results from other surveys indicate capture rates for Northern Quolls can be highly variable. Biota (2011b, 2012) conducted targeted surveys at Gudai-Darri to the north of the survey area with 3,890 Elliott trap nights and recorded no individuals despite subsequent monitoring in the same locality (e.g. Biota 2014d, 2014e) obtaining multiple records. The DBCA PNQRP also shows the amount of survey effort required to detect Northern Quoll is highly variable and site dependent (Dunlop et al. 2018; Table 7). Dunlop et al. (2018) found Northern Quoll were less readily detected at more southern and eastern sites within the Pilbara region than northern and coastal locations, most likely as a function of greater population density. The capture rates for the sites nearest to the current survey area were typically low with 3.0 captures/100 trap nights and 2.5 captures/100 trap nights for Karijini National Park and Roy Hill Rail, respectively. Recent capture rates within the survey area were generally much less than the nearby sites (<0.1 to 0.2 captures/100 trap nights).

Capture rate variability between sites and over time may be attributed to seasonality, fire history, and predator and prey densities. Seasonality may be a factor reflective of the boom and bust life cycle of the Northern Quoll, whereby they are capable of high reproductive rates and large dispersal distances when conditions are favourable (Cramer et al. 2016, Department of the Environment and Energy 2016). In 2019 large areas of BHT within the survey area were affected by fires which may have possibly limited resource availability in the area, particularly during the earlier phases of monitoring. Prior to the fires there were 12 Northern Quoll records in May 2018 and post-fire there have been a total of four records. In addition, high Feral Cat (**Felis catus*) activity has been consistently documented within the survey area. During cage trapping in September 2019 (Astron Environmental Services 2020b) three cats were caught at three different sites across the survey area, and cats have been captured on cameras during each phase of the monitoring program to date, with up to 40% of cameras during Phase 2 detecting cats.

Despite surveying across different times of year, with and without scent-lures, no Northern Quolls have been recorded on the cameras. The timing of past surveys (September to November 2020, and October 2021 to February 2022) and lack of a scent lure in Phase 1 were thought to be contributing to the lack of records. The surveys were conducted after male die-off and before recruitment of juveniles into the population (Oakwood 2000), as well as times when Northern Quolls are likely to be less active (denning females with pouch young) and therefore less detectable. The previous absence of a scent lure was necessitated by ethical constraints at the time. The use of non-reward scent lures

was adopted in the second and third phases, and this most recent survey was conducted during optimal timing, yet still no Northern Quolls were recorded.

Given the extensive survey effort now completed (8,500 camera nights), the most recent monitoring used attractants and was also conducted during the optimal survey period to maximise detection probability, and the overall distribution pattern of records surrounding the HD2 area, it is concluded that currently, the Northern Quoll is patchily distributed and at a low density within the HD2 area and surrounding locality. It is not clear why the number of Northern Quoll records has decreased from 12 records in May 2018 to four records since then, but the presence of feral predators and recent fire may be explanatory variables (rather than limitations of the monitoring program).

Appendix B: Conservation Categories

This page has been left blank intentionally.

Table B.1: Definitions and criteria for Threatened Ecological Communities (Department of Environment and Conservation 2013).

Three categories exist for listing Threatened Ecological Communities under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act). An ecological community may be categorised as:

Categories of ecological communities	
Critically endangered	If, at that time, it is facing an extremely high risk of extinction in the wild in the immediate future.
Endangered	If, at that time, it is not critically endangered and is facing a very high risk of extinction in the wild in the near future.
Vulnerable	If, at that time, it is not critically endangered or endangered, and is facing a high risk of extinction in the wild in the medium-term future.

Reference: Department of Environment and Conservation 2013, Definitions, Categories and Criteria for Threatened and Priority Ecological Communities DEC (Parks and Wildlife), <https://www.dpaw.wa.gov.au/images/plants-animals/threatened-species/definitions_categories_and_criteria_for_threatened_and_priority_ecological_communities.pdf.>

Table B.2: Categories and definitions for EPBC Act listed fauna species.

Conservation category	Definition
Extinct	Taxa with no reasonable doubt that the last member of the species has died.
Extinct in the wild	Taxa known to survive only in cultivation, in captivity or as a naturalized population well outside its past range; or it has not been recorded in its known and/or expected habitat, at appropriated seasons, anywhere in its past range, despite exhaustive surveys over a time frame appropriate to its life cycle and form.
Critically endangered (CR)	Taxa facing an extremely high risk of extinction in the wild in the immediate future, as determined in accordance with the prescribed criteria.
Endangered (EN)	Taxa are not critically endangered; and are facing a very high risk of extinction in the wild in the near future, as determined in accordance with the prescribed criteria.
Vulnerable (VU)	Taxa are not critically endangered or endangered; and are facing a high risk of extinction in the wild in the medium-term future, as determined in accordance with the prescribed criteria.
Conservation dependent (CD)	Taxa are the focus of a specific conservation program the cessation of which would result in the species becoming vulnerable, endangered or critically endangered; or the following subparagraphs are satisfied: i) the taxa is a species of fish; ii) the taxa is the focus of a management plan that provides management actions necessary to stop the decline of, and support the recovery of, the taxa so that its chances of long term survival in nature are maximized; iii) the management plan is in force under a law of the Commonwealth or of a State or Territory; iv) Cessation of the management plan would adversely affect the conservation status of the taxa Fish includes all taxa of bony fish, sharks, rays, crustaceans, molluscs and other marine organisms, but does not include marine mammals/reptiles.
Migratory (IA)	Taxa are considered migratory species on International Agreements; i) if they are native to Australia and are included in the appendices to the Bonn Convention (Convention on the Conservation of Migratory Species of Wild Animals Appendices I and II); ii) all migratory species included in annexes established under the Japan-Australia Migratory Bird Agreement (JAMBA) and the China-Australia Migratory Bird Agreement (CAMBA); and iii) Are native, migratory species identified in a list established under, or an instrument made under, an international agreement approved by the Minister, such as the Republic of Korea-Australia Migratory Bird Agreement (ROKAMBA).

Note: CD and IA are only related to conservation significant fauna

"IMPORTANT NOTE"

Apart from fair dealing for the purposes of private study, research, criticism, or review as permitted under the Copyright Act, no part of this report, its attachments or appendices may be reproduced by any process without the written consent of Biologic Environmental Survey Pty Ltd ("Biologic"). All enquiries should be directed to Biologic.

We have prepared this report for the sole purposes of Rio Tinto ("Client") for the specific purpose only for which it is supplied. This report is strictly limited to the Purpose and the facts and matters stated in it and does not apply directly or indirectly and will not be used for any other application, purpose, use or matter.

In preparing this report we have made certain assumptions. We have assumed that all information and documents provided to us by the Client or as a result of a specific request or enquiry were complete, accurate and up-to-date. Where we have obtained information from a government register or database, we have assumed that the information is accurate. Where an assumption has been made, we have not made any independent investigations with respect to the matters the subject of that assumption. We are not aware of any reason why any of the assumptions are incorrect.

This report is presented without the assumption of a duty of care to any other person (other than the Client) ("Third Party"). The report may not contain sufficient information for the purposes of a Third Party or for other uses. Without the prior written consent of Biologic:

a) This report may not be relied on by a Third Party; and

b) Biologic will not be liable to a Third Party for any loss, damage, liability or claim arising out of or incidental to a Third-Party publishing, using or relying on the facts, content, opinions or subject matter contained in this report.

If a Third Party uses or relies on the facts, content, opinions or subject matter contained in this report with or without the consent of Biologic, Biologic disclaims all risk and the Third Party assumes all risk and releases and indemnifies and agrees to keep indemnified Biologic from any loss, damage, claim or liability arising directly or indirectly from the use of or reliance on this report.

In this note, a reference to loss and damage includes past and prospective economic loss, loss of profits, damage to property, injury to any person (including death) costs and expenses incurred in taking measures to prevent, mitigate or rectify any harm, loss of opportunity, legal costs, compensation, interest and any other direct, indirect, consequential or financial or other loss.

1 INTRODUCTION

Rio Tinto Iron Ore (Rio Tinto) commissioned Biologic Environmental Survey (Biologic) to undertake a preliminary risk assessment for short-range endemic (SRE) invertebrate fauna identified from the Hope Downs 2 Project area (the Study Area/Development Envelope, Figure 1.1). These results will then be used to support the environmental impact assessment (EIA) for SRE invertebrate fauna which will in turn inform the environmental review document (ERD) for the development.

This memorandum report provides:

1. Consolidation of SRE species and habitat information from all surveys to date within the Development Envelope, including:
    a. Alignment of SRE fauna identifications from all previous surveys (as much as practicable based on available specimens, taxonomic frameworks, and genetic sequences);
    b. Updated taxonomic and ecological information relevant to assessment of species distributions relative to potential impact areas;
    c. Indicative linear ranges in the local or wider regional area for all SRE taxa, based on the best available data;
    d. Consolidation of fauna habitat mapping and occurrence of SRE taxa in habitat types mapped throughout the Development Envelope; and
    e. Occurrence of SRE taxa in relation to proposed impact areas.
2. Preliminary Risk Assessment of SRE species values and habitat values in relation to potential impacts of the project, as much as practicable within the constraints of available data.

Hope Downs 2 Preliminary SRE Risk Assessment

Figure 1.1: Project overview

2 DATA CONSOLIDATION AND ALIGNMENT

SRE species records were sourced from Rio Tinto's internal terrestrial invertebrate database (RTDB), Western Australian Museum databases (WAMDB) and external reports of surveys within the Development Envelope. These were:

- Astron Environmental Services (2020) Hope Downs 1 Development Envelope Fauna Habitat Mapping
- Astron Environmental Services (2019) Hope Downs 2 Proposal Fauna Survey.
- Astron Environmental Services (2018) Hope Downs 2, Bedded Hilltop and Wonmunna level 2 Fauna Survey
- Biota Environmental Sciences (2011) Hope Downs Project Life of Mine Targeted Fauna Survey
- Biota Environmental Sciences (2014) Hope Downs South West Marra Mamba Development Targeted Fauna Survey
- Ecologia Environment (2014) Greater West Angelas Terrestrial Fauna Assessment

Identifications at the species level were aligned as much as practicable based on the information available for morphological and molecular identification within existing taxonomic frameworks. Following alignment of taxonomic identifications between WAM database searches and external reports, the remaining indeterminate records were examined against potentially similar species from the same site or the same sampling event. The approach aimed to:

- Provide a single, consolidated list of species (morphological and molecular) occurring in the Development Envelope (DE);
- Inform the assessment of habitat associations and species occurrence relative to impact areas (proposed footprint) within the DE; and
- Facilitate the assessment of species distributions in the wider local and regional area beyond the DE.

2.1 Local and regional linear ranges

Preliminary linear ranges were calculated for all species based on collection records from the Development Envelope, WAM database records, and local and regional DNA databases, to the limit of available data.

3 SAMPLING ADEQUACY IN THE DEVELOPMENT ENVELOPE

3.1 Sample effort

The available habitat mapping was detailed throughout the entire DE and extended beyond the DE up to 5 km in most areas. This allowed for the extrapolation of habitat beyond the confines of the DE enabling us to determine whether significant habitat types or landscape features extended outside the DE. The mapping was adequately detailed for assessment of sample effort within each habitat type as well as to determine whether each habitat type was adequate sampled. This also enabled us to show the occurrence of habitat types mapped throughout the DE in relation to the potential impact areas from the Proposal. Figure 3.1 shows the habitat mapping within the DE and Table 3.1 details the sampling effort in each habitat type in relation to the percentage of the DE the habitat represents.

Table 3.1: Sample effort in each habitat type within the Hope Downs 2 Development Envelope.

RIO TINTO IRON ORE

Hope Downs 2 Preliminary SRE Risk Assessment

Figure 3.1: Previous SRE sampling sites and habitat mapping

3.2 Sampling adequacy

Widespread habitat

Widespread habitat includes the generally low-lying landscape units with greater extent and connectivity throughout and beyond the DE. From the Astron (2020) habitat mapping, this comprises the Alluvial Plain, Cleared, Low Hills and Slopes, Minor Drainage, and Stony Plain habitat units, all also considered of Low suitability for SRE fauna. Mulga Woodland, while considered of Moderate suitability for SRE fauna, is also widespread throughout and beyond the DE. Any SRE taxa recorded from these landscape units are likely to be at low risk from the Proposal and are considered adequately sampled.

Restricted habitat

Restricted habitat includes the largely elevated landscape units that are disconnected from other areas of similar habitat. From the Astron (2020) habitat mapping, this comprises the Rocky Hill habitat (of Moderate suitability for SRE fauna) and the Gorge/Gully and Breakaway habitat units (both considered of High suitability for SRE fauna).

The available habitat mapping, as well as local topographic and aerial mapping, indicate that the areas of restricted habitat within the central section of the DE, comprising Rocky Hill and associated Breakaway and Gorge/Gully, is highly isolated. This ridgeline lies almost entirely within the DE and is separated from other ridgelines by a large drainage system at the eastern end and a large expanse of low hills, plains, and woodland on the other three sides. In addition, the proposed footprint covers much of the ridgeline. Of the ca.15 separate mapped areas of Gorge/Gully along the ridge, only four have been actively sampled for SRE fauna, and unique fauna have been found at three of these sites (see Section 4). It could be considered that these restricted habitats could be considered inadequately sampled based on: a) the fauna that has already been found in this area; b) the extent of the area that will be impacted by the footprint; and c) the limited amount of sampling of the ridgeline outside of the proposed footprint.

4 SRE INVERTEBRATE FAUNA IN THE DEVELOPMENT ENVELOPE

In total, three Confirmed and 35 Potential SRE invertebrate taxa have been recorded within the DE (Table 4.1; Figures 4.1, 4.2 & 4.3). Of these, 19 Potential SRE taxa are known only from within the DE, ten of which are currently only known from within the proposed footprint (Table 4.1). Details regarding the 19 taxa restricted to the DE, as well as the three Confirmed SRE taxa, the habitats in which they occur, and the assessment of their taxonomic status and distribution are provided further below. Additional Potential SRE taxa that could not be identified to species or morphospecies that were recorded within the proposed footprint are summarised in Appendix A. All were collected in multiple or widespread habitats and are not considered further in this analysis.

4.1 Araneae

Araneomorph and mygalomorph spiders were well-represented in the fauna collected from the DE. In addition to widespread species, two Confirmed and ten Potential SRE taxa were identified from within the DE (Figure 4.1, Table 4.1). Three of these Potential SRE taxa are only known from the DE, two of which were recorded from within the proposed footprint.

Karaops banyjima – Confirmed SRE

Many named *Karaops* species in the Pilbara are Confirmed SRE, having limited ranges due to their habitat specialization within the cracks and crevices of rocky outcrops (Crews, 2013; Crews & Harvey, 2011). *Karaops banyjima* is a Confirmed SRE and the type locality is 19.2 km north of the centre of the study area (Crews, 2013). *Karaops banyjima* was sampled from Gorge/Gully sites SRE18, SRE19 and SRE21. This could indicate that it is locally widespread within the DE, however, population fragmentation is a potential risk to this limited range species.

Teyl heuretes – Confirmed SRE

Confirmed SRE *Teyl heuretes* was collected from Mulga Woodlands from within and beyond the DE. It is found in a widespread habitat (Mulga Woodlands) and hence is likely to be locally prevalent.

Aurecocrypta `HD1` - Potential SRE

This taxon was represented by a single female specimen from site SRE17. While DNA sequences were obtained from this specimen, no matches could be found. This singleton record was collected in a deep gorge at the edge of a central ridgeline which is within the footprint of the DE.

Synothele `MYG055` - Potential SRE

This specimen was collected from a single site in Mulga Woodland habitat. Based on habitat values it is not considered likely to be restricted to the footprint or the DE.

Aname `R6` - Potential SRE

This specimen was collected at a single site from the Rhodes Ridge Study Area in Stony Plain habitat. No further information is available for this taxon; however, it occurs in habitat that is widespread and is unlikely to be restricted to the DE.

Table 4.1: Consolidated list of SRE invertebrate fauna recorded within the Development Envelope.

NB: Taxa in red are only known from within the proposed footprint.

Taxon	Source	ID Level	SRE category	Recorded within footprint	Recorded outside footprint	Linear range	Identification and distribution comments
ARANEAE							
Actinopidae							
Missulena `MYG045`	Biota 2011	med: morpho	Potential SRE	Yes	Yes	~83 km	WAM morphospecies. Recorded from widespread habitat (Mulga Woodland) and from beyond the DE.
Anamidae							
Aname `R6`	Astron 2019	med: morpho	Potential SRE	No	Yes	single site	Unknown morphospecies. Recorded from within DE but outside proposed footprint. Likely Widespread based on habitat (Stony Plain).
Kwonkan `MYG339`	Biota 2011	med: morpho	Potential SRE	Yes	Yes	~22 km	WAM morphospecies. Recorded from widespread habitat (Mulga Woodland) and from beyond the DE.
Teyl heuretes	Biota 2011	med: morpho	Confirmed SRE	Yes	Yes	~22 km	Known species. Recorded from widespread habitat (Mulga Woodland) and from beyond the DE.
Barychelidae							
Aurecocrypta `HD1`	Astron 2019	high: genetic	Potential SRE	Yes	No	single site	Molecular ID could not match this specimen to any other known taxon. Potentially restricted range based on collection in Gorge/Gully habitat.
Aurecocrypta `MYG315`	Astron 2019	high: genetic	Potential SRE	Yes	Yes	~57 km	Molecular ID confirmed WAM morphospecies. Recorded from widespread habitat (Stony Plain) and from beyond the DE.
Synothele `MYG055`	Biota 2011	med: morpho	Potential SRE	Yes	No	single site	WAM morphospecies. Only known from within proposed footprint but collected from widespread habitat (Mulga Woodland).
Synothele `MYG309`	Astron 2019	high: genetic	Potential SRE	Yes	Yes	~47 km	Molecular ID confirmed WAM morphospecies. Recorded from widespread habitat (Mulga Woodland) and from beyond the DE.
Synothele `MYG311`	Astron 2019	high: genetic	Potential SRE	Yes	Yes	~75 km	Molecular ID confirmed WAM morphospecies. Recorded from widespread habitat (Mulga Woodland) and from beyond the DE.
Halonoproctidae							
Conothele `MYG002`	Biota 2011	med: morpho	Potential SRE	Yes	Yes	~68 km	WAM morphospecies. Recorded from widespread habitat (Mulga Woodland) and from beyond the DE.
Selenopidae							
Karaops banyjima	Astron 2019	high: genetic	Confirmed SRE	Yes	Yes	~20 km	Molecular ID confirmed as known species. Restricted to rocky habitats but known from beyond the DE.

Taxon	Source	ID Level	SRE category	Recorded within footprint	Recorded outside footprint	Linear range	Identification and distribution comments
Karaops `ARA001`	Astron 2019	high: genetic	Potential SRE	Yes	Yes	~30 km	Molecular ID matched to other specimens. Restricted to rocky habitats but known from beyond the DE.
PSEUDOSCORPIONES							
Chthoniidae							
Austrochthonius `PSE135, pilbara`	Biota 2012	med: morpho	Potential SRE	Yes	Yes	~46 km	WAM morphospecies. Recorded from widespread habitat (Mulga Woodland) and from beyond the DE.
Tyrannochthonius `HD2`	Astron 2018 & 2019, Alacran 2019, Biota 2012	high: genetic	Potential SRE	Yes	No	single site	Molecular ID could not match this specimen to any other known taxon. Only known from with proposed footrpint. Potentially restricted range based on collection in Gorge/Gully habitat.
Olpiidae							
Austrohorus `HD5`	Astron 2019	high: genetic	Potential SRE	No	Yes	single site	Molecular ID could not match this specimen to any other known taxon. Recorded from restricted habitat (Gorge/Gully) on the edge of the proposed footprint,
Euryolpium `HD6`	Astron 2018 & 2019	high: genetic	Potential SRE	No	Yes	single site	Molecular ID could not match this specimen to any other known taxon. Recorded from within DE but outside proposed footprint. Collected from widespread habitat (Mulga Woodland).
Euryolpium `HD7`	Astron 2018 & 2019	high: genetic	Potential SRE	No	Yes	single site	Molecular ID could not match this specimen to any other known taxon. Recorded from potentially restricted habitat (Breakaway) but outside proposed footprint.
Olpiidae `Genus 7/4` `PSE118`	Astron 2018 & 2019, Alacran 2019, Biota 2012	high: genetic	Potential SRE	No	Yes	~26 km	Molecular ID confirmed WAM morphospecies. Recorded from potentially restricted habitat (Gorge/Gully) but outside proposed footprint and known from beyond the DE.
Olpiidae `PSEAAA` `HD4`	Astron 2019	high: genetic	Potential SRE	Yes	No	single site	Molecular ID could not match this specimen to any other known taxon. Only known from within proposed footprint but collected from widespread habitat (Mulga Woodland).
SCORPIONES							
Buthidae							
Lychas `bituberculatus complex`	Astron 2018 & 2019	med: morpho	Potential SRE	No	Yes	uncertain	Species complex. Recorded from within DE but outside proposed footprint.
Lychas `hairy tail complex`	Astron 2019	med: morpho	Potential SRE	No	Yes	uncertain	Species complex. Recorded from within DE but outside proposed footprint.
Lychas `multipunctatus complex`	Astron 2019	med: morpho	Potential SRE	No	Yes	uncertain	Species complex. Recorded from within DE but outside proposed footprint.
Urodacidae							

Taxon	Source	ID Level	SRE category	Recorded within footprint	Recorded outside footprint	Linear range	Identification and distribution comments
Urodacus `HD1`	Astron 2019	high: genetic	Potential SRE	No	Yes	single site	Molecular ID could not match this specimen to any other known taxon. Recorded from within DE but outside proposed footprint. Likely Widespread based on habitat (Stony Plain).
GEOPHILOMORPHA							
Chilenophilidae							
Sepedonophilus `HD1`	Astron 2019	high: genetic	Potential SRE	No	Yes	~17 km	Molecular ID could not match this specimen to any other known taxon. Recorded from within DE but outside proposed footprint. Likely Widespread based on collection in various habitats.
Sepedonophilus `HD2`	Astron 2019	high: genetic	Potential SRE	Yes	No	single site	Molecular ID could not match this specimen to any other known taxon. Only known from within proposed footprint but collected from widespread habitat (Mulga Woodland).
Mecistocephalidae							
Mecistocephalus `HD1`	Astron 2019	high: genetic	Potential SRE	No	Yes	~4 km	Molecular ID could not match this specimen to any other known taxon. Recorded from within DE but outside proposed footprint. Likely Widespread based on habitat (Mulga Woodland).
Mecistocephalus `HD2`	Astron 2019	high: genetic	Potential SRE	Yes	No	single site	Molecular ID could not match this specimen to any other known taxon. Only known from within proposed footprint but collected from widespread habitat (Mulga Woodland).
Mecistocephalus `HD3`	Astron 2019	high: genetic	Potential SRE	Yes	No	single site	Molecular ID could not match this specimen to any other known taxon. Only known from within proposed footprint but collected from widespread habitat (Mulga Woodland).
Oryidae							
Orphnaeus `HD1`	Astron 2019	high: genetic	Potential SRE	Yes	No	single site	Molecular ID could not match this specimen to any other known taxon. Only known from within proposed footprint but collected from widespread habitat (Mulga Woodland).
SCOLOPENDROMORPHA							
Cryptopidae							
Cryptops `HD1`	Astron 2019	high: genetic	Potential SRE	Yes	No	single site	Molecular ID could not match this specimen to any other known taxon. Only known from within proposed footprint but collected from widespread habitat (Stony Plain).
POLYDESMIDA							
Paradoxosomatidae							

Taxon	Source	ID Level	SRE category	Recorded within footprint	Recorded outside footprint	Linear range	Identification and distribution comments
Antichiropus `wonmunna, DIP163`	Astron 2019	high: genetic	Confirmed SRE	Yes	Yes	~10 km	Molecular ID confirmed WAM morphospecies. Recorded from widespread habitat (Mulga Woodland) and from beyond the DE.
SPIROBOLIDA							
Trigoniulidae							
Austrostrophus `clade A`	Astron 2019	high: genetic	Potential SRE	No	Yes	~33 km	Molecular ID confirmed WAM morphospecies. Recorded from within DE but outside proposed footprint and from beyond the DE.
Austrostrophus `clade E`	Astron 2019	high: genetic	Potential SRE	Yes	Yes	~40 km	Molecular ID confirmed WAM morphospecies. Recorded from widespread habitat (Mulga Woodland) and from beyond the DE.
ISOPODA							
Armadillidae							
Buddelundia `10ma`	Astron 2018 & 2019	med: morpho	Potential SRE	Yes	Yes	~1.5 km	Morphological ID. Part of Widespread species complex Buddelundia `10` but morphologically distinct. DNA sequencing required to confirm whether it is a distinct species. Only recorded from within the DE, inside and outside of proposed footprint, though likely Widespread due to collection in a various habitat.
Buddelundia `10ts`	WAM Records	med: morpho	Potential SRE	No	Yes	~47 km	Morphological ID. Part of Widespread species complex Buddelundia `10` but morphologically distinct. DNA sequencing required to confirm whether it is a distinct species. Recorded from within DE but outside proposed footprint, and from beyond the DE. Likely Widespread based on collection in various habitats.
Buddelundia `77`	Astron 2019	med: morpho	Potential SRE	Yes	Yes	~23 km	Morphological ID. Recorded from various habitats and from beyond the DE.
Pseudodiploexochus `C75046`	Astron 2019	med: morpho	Potential SRE	Yes	No	single site	Morphological ID. Only identified to genus but only second record of this genus from the Pilbara, the previous specimen being troglobitic. Only known from with proposed footprint. Highly likely to be range restricted based on collection in Gorge/Gully habitat and known ecology of the genus (see text).

Hope Downs 2 Preliminary SRE Risk Assessment

Figure 4.1: SRE fauna recorded in the Development Envelope (Araneae)

4.2 Pseudoscorpiones

Six pseudoscorpion taxa have been recorded from the DE, primarily identified by molecular analysis (Astron, 2019) (Figure 4.2). Of these, five are only known from the DE, two of which were collected from within the proposed footprint.

Tyrannochthonius `HD2` - Potential SRE

This specimen was initially identified as the widespread species, *Tyrannochthonius aridus,* however, molecular sequencing later revealed that this specimen did not match other sequences in the genus and it was determined to be a separate taxon. *Tyrannochthonius* `HD2` was collected in Gorge/Gully habitat which is disconnected in the landscape and can be highly significant for SRE invertebrate species, it is possible this taxon has a restricted distribution. It was collected from within the proposed footprint.

Olpiidae (five taxa) – Potential SRE

Olpiidae taxonomy is poorly developed, with identification even to genus considered challenging by taxonomic experts. Molecular analyses of the family indicate significant cryptic diversity and many taxa that appear to have restricted ranges. Four of the five pseudoscorpion taxa were collected from single sites from within the DE. *Euryolpium* `HD6` and Olpiidae `PSEAAA` `HD4` were collected from single sites in widespread Mulga Woodland habitat within the DE. *Austrohorus* `HD5` was collected from a single Gorge/Gully site and *Euryolpium* `HD7` was collected from a single site Breakaway habitat both of which are restricted and significant habitat types. Only Olpiidae `PSEAAA` `HD4` was collected from within the proposed footprint (in widespread habitat) however, *Austrohorus* `HD5` was collected at a restricted habitat site on the edge of the proposed footprint and may be subjected to impacts from the development.

4.3 Myriapoda

Geophilomorpha and Scolopendromorpha – Potential SRE

Geophilomorpha taxonomy in Australia is very poorly developed. Most genera and species are undescribed, and species designation is primarily via molecular analysis, which has found many species that appear to have restricted ranges. Eight taxa were morphologically identified from the DE, six of which were successfully sequenced (Figure 4.3). Four taxa (*Sepedonophilus* `HD2`, *Mecistocephalus* `HD1`, *Mecistocephalus* `HD3` and *Orphnaeus* `HD1`) are only known from within the proposed footprint, however all were collected in widespread Mulga Woodland habitat. The scolopendromorph *Cryptops* `HD1` is also only know from the proposed footprint but was also collected in widespread habitat (Stony Plain).

Polydesmida – Confirmed SRE

One Confirmed SRE polydesmid myriapod belonging to the genus *Antichiropus* was collected at two sites in the DE. The specimen was collected in Mulga Woodland habitat and was molecularly confirmed as belonging to *Antichiropus* `wonmunna, DIP163`. *Antichiropus* 'wonmunna' has been collected from

sites within 10 km of the DE and though it was collected in widespread habitat, these millipedes have been known to aestivate in rocky habitats and hence may be associated with the more restricted habitat type.

4.4 Isopoda

Four armadillid isopod taxa have been recorded from the DE (Figure 4.3). These were morphologically identified by Dr Simon Judd. Two were collected in multiple habitats spread throughout and beyond the DE. *Buddelundia* `10ma` has only been recorded within the DE but was collected in multiple widespread habitats. One taxon, *Pseudodiploexochus* `C75046`, was collected from restricted habitat (Gorge/Gully) within the proposed footprint.

Pseudodiploexochus `C75046` - Potential SRE

This unusual specimen was collected in a Gorge/Gully site (SRE17) from within the proposed footprint of the DE. Communication with Dr Simon Judd regarding this specimen was as follows:

"The specimen that you mention in your email was determined by me in May 2019 and collected on 11/03/2019 by Erich Volschenk. It was hand collected by litter sifting and lodged at WAM under registration C75046 (AES190304).

The other record I have for the genus in the Pilbara is in the Greater West Angelas Area collected by Ecologia. This specimen is definitely troglobitic and was collected in a troglofauna trap. It is certainly not the same species as C75046.

This epigean Pseudodiploexochus is one of three Armadillidae genera in the Pilbara that are known only from a single specimen at a single location. There are undoubtedly more species there, but they are just impossible to collect. C75046 is almost certainly an SRE and probably only occurs in the gorge where it was collected.

Pseudodiploexochus are Gondwanic isopods occurring in relictual habits. They are found all over WA from the Pilbara southwards but are uncommon. Most species are very small around 2mm in length (maximum). Even in the Warren IBRA subregion, which is relatively wet and forested, there are obvious SRE species. They are primitive armadillids without pleopodal lungs and as such, are more moisture dependant than Buddelundia (for example). They also lack uropod exopodites and have distinctive interlocking structures on the first two pereonites. In my opinion (outside of south-west WA), they are all almost certainly SRE species. Their ranges are more likely to be in the order of square metres rather than square kilometres."

RIO TINTO IRON ORE

Hope Downs 2 Preliminary SRE Risk Assessment

Figure 4.3: SRE fauna recorded in the Development Envelope (Isopoda and Myriapoda)

5 PRELIMINARY RISK ASSESSMENT

The level of impact to significant habitat or populations of SRE taxa from mining activities in a particular area can be varied and difficult to assess adequately. However, the taxa recorded for an area and the level to which significant habitats have been surveyed can indicate whether or not a level of risk of impact can be estimated. Here, we provide a preliminary level of risk from impact based on what we know of a particular taxon's range, the habitat that it occurs in and the amount of that habitat that will be impacted by mining activities, i.e the proposed footprint (Table 5.1). This is of particular relevance to taxa that, to date, have been collected from single sites within the DE.

Table 5.1: Definition of level of risk for SRE invertebrate fauna and habitats

Category	Description
High	Taxonomic factors indicate that a species is **likely to be** restricted in range based on what is known of the genus or species, it has been collected from a **restricted** habitat type and a significant proportion of the known or likely habitat that it occurs in will be removed by mining activities (inside proposed footprint).
Medium	Taxonomic factors indicate that a species is **possibly** restricted in range based on what is known of the genus or species, it has been collected from a **restricted** habitat type and a significant proportion of the known or likely habitat that it occurs in will be removed by mining activities (inside proposed footprint).
Low	Taxonomic factors indicate that a species is **possibly** restricted in range based on what is known of the genus or species, it has been collected from a **widespread** habitat type.

Of the 38 taxa recorded within the DE, 27 were collected from outside the proposed footprint, most in widespread or varied habitats, and many also from beyond the DE (see Table 4.1). These 27 taxa are considered not at risk from the Proposal as it is currently mapped. This includes the three Confirmed SRE species, two of which were found in widespread habitat. Only the *Karaops banyjima* was collected in a restricted habitat type, however it has been collected at more than one site within and beyond the DE. Additionally, none of the indeterminate taxa (Appendix A) are currently at risk from the Proposal, as all were recorded in widespread habitat. This leaves 11 taxa for which the Proposal carries some form of risk (Table 5.2).

Table 5.2: SRE fauna considered at risk from the currently proposed footprint.

Taxon	Taxonomic factors affecting risk	Distribution and habitat factors affecting risk	Risk level
Aurecocrypta `HD1`	Genus infrequently collected and needs review. No described species from the Pilbara. Specimen did not match any of the seven WAM sequences from the Pilbara. Several other Pilbara morphospecies seem to have restricted ranges.	Both were collected from a single site (SRE17) in restricted habitat (Gorge/Gully) within the footprint.	High
Pseudodiploexochus `C75046`	Genus has only been collected twice in the Pilbara. This is the first terrestrial collection. Genus		

Taxon	Taxonomic factors affecting risk	Distribution and habitat factors affecting risk	Risk level
	has no arid adaptations and is almost certainly restricted to areas that retain moisture all year round.		
Tyrannochthonius `HD2`	Could not be matched to any known sequences. Genus contains widespread and restricted taxa.	Collected from a single site in restricted habitat (Gorge/Gully).	Medium
Austrohorus `HD5`	Olpiidae taxonomy very limited and needs review. Molecular analysis seems to show many species with restricted ranges. Could not be matched to any other sequences.	Collected from a single site in restricted habitat (Gorge/Gully), on the edge of the proposed footprint, in area likely to be indirectly impacted.	
Synothele `MYG055`	Could not be matched to any known sequences. Genus contains widespread and restricted taxa.	Collected from a single site in widespread habitat (Mulga Woodland).	Low
Olpiidae `PSEAAA` `HD4`	Olpiidae taxonomy very limited and needs review. Molecular analysis seems to show many species with restricted ranges. Could not be matched to any other sequences.		
Sepedonophilus `HD2`	Taxonomic framework for geophilomorph centipedes severely lacking. Molecular analysis seems to show many species with restricted ranges.		
Mecistocephalus `HD2`			
Mecistocephalus `HD3`			
Orphnaeus `HD1`			
Cryptops 'HD1'	Could not be matched to any known sequences. Genus contains predominantly restricted taxa.	Collected from a single site in widespread habitat (Stony Plain).

Dear Sally,

Re: Hope Downs 2 Proposal – Long-term Motion Cameras, February to September 2020

1 Introduction

Astron Environmental Services (Astron) (2020a) first recorded the Northern Quoll (*Dasyurus hallucatus*) (EN; EN) on 14 occasions, including records at Bedded Hilltop (BHT), in the form of motion camera recordings and scat recordings at separate locations during the baseline fauna assessment. Based on these findings, Astron provided a recommendations letter and proposal to undertake further Northern Quoll work within the Hope Downs 2 (HD2) Proposal survey area, specifically a GPS tracking study (Astron Environmental Services 2019). However, given the low numbers of Northern Quoll captures recorded during the targeted Matters of National Environmental Significance (MNES) survey in September 2019 (Astron Environmental Services 2020b), the chances of capturing enough individuals to conduct a successful tracking study is low. Instead, Rio Tinto aimed to increase their knowledge of the presence/absence of this species in this area and commissioned Astron to deploy long-term motion sensitive cameras at BHT.

2 Methods

Astron zoologists Matthew Love and Lucy Dadour deployed 12 long-term cameras (supplied by Rio Tinto) between 27 and 29 February 2020. Twelve Hyperfire Reconyx were set in highly prospective locations across BHT (Figure A.1 and TableA.1, Attachment A) and 'baited' with scent lures to increase the chance of recording this species. The cameras were positioned horizontally with a wide field of view to capture all species that investigate the lure. Astron zoologists Brittany Osborn and Sean Smithies retrieved the 12 cameras between 11 and 13 September 2020.

3 Results

A total of 2,355 total camera nights were recorded on 12 long-term motion cameras (ranging from 195 to 199 camera trap nights) deployed within the survey area. A total of 142 species day-records were made from the long-term motion cameras. A day-record represents a different species being recorded on a camera from each individual date.

3.1 Northern Quoll

The Northern Quoll was recorded twice at two separate locations on 1 May (CAM2) and 4 May 2020 (CAM8). CAM2 was placed at the western end of BHT within a Breakaway fauna habitat type and CAM8 was placed in a Gorge/Gully fauna habitat type in the eastern end of BHT; these cameras were spaced 8.2 km apart. Both Breakaway and Gorge/Gully fauna habitat types represent core habitat as per the referral guidelines (Department of the Environment and Energy 2016). The Gorge/Gully and Breakaway habitats contain rocky environments of high relief that are particularly important for this species as they provide denning sites for breeding and shelter and diverse microhabitats for foraging. Comparison of individual spot markings was difficult as the photos captured from separate cameras recorded opposite sides of the individuals and/so individual status could not be deduced.

Plate 1. Northern Quoll Recorded at CAM2 (1 May 2020). Plate 2. Northern Quoll Recorded at CAM8 (4 May 2020).

3.2 Other Terrestrial Species

Twenty species were recorded: two reptile species, 11 bird species and seven mammal species (including the Northern Quoll) (Table 1).

Table 1: Summary of terrestrial vertebrate fauna species recorded on the long term motion cameras deployed within the Hope Downs 2 Proposal survey area.

Group	Number of species	Conservation significant species	Introduced species
Reptiles	2	0	0
Birds	11	0	0
Mammals	7	1	2
Total	**20**	**1**	**2**

The most commonly recorded species on the motion cameras were large mammals and birds, with the Rothschild Rock-wallaby (*Petrogale rothschildi*), Dog/Dingo (**Canis familiaris*) and Grey-headed Honeyeater (*Ptilotula keartlandi*) representing 42, 20, and 15 day-records, respectively (Attachment B).

3.3 Introduced Fauna

A total of two introduced species were recorded on motion cameras: Dog/Dingo and Feral Cat (**Felis catus*). There were 20 day-records of the Dog/Dingo from six of the 12 cameras (50% of deployed cameras), and six day-records of the Feral Cat from five of the 12 cameras (40% of deployed cameras). While staying at Hope Downs 1 (HD1), the September field team witnessed cats on two separate occasions moving about the camp. During the targeted MNES survey in September 2019 (Astron Environmental Services 2020b) three individual cats were captured at different cage trapping sites

across the BHT survey area. Also, an individual cat was observed on a motion sensitive camera within the HD2 area and the field team observed cat sightings in and around both the HD1 and Hope Downs 4 villages during the survey (Matthew Love, pers. obs.). These previous records of Feral Cats and the records made during this assessment indicate a potentially high level of cat activity within the survey area at the time of both surveys.

4 Conclusions

Since the initial 14 records made during the baseline assessment from November 2017 to March 2019 (Astron Environmental Services 2020a), the number of Northern Quoll records made during this long-term motion camera assessment and the targeted MNES survey conducted in September 2019 (Astron Environmental Services 2020b) have been low and sporadic. Since the baseline assessment, seasonal conditions have been poor (i.e. dry) and a seemingly high level of cat activity has been observed. Given the recent camera records were made in May at the onset of the mating season, the records are suggestive of a male expanding their home range looking for breeding opportunities. Home ranges of male Northern Quolls are similar to female home ranges before the mating season (10 ha to 35 ha), but expand during the mating season to > 100 ha to overlap extensively with several female home ranges (Oakwood 2002). However as individual status could not be deduced for certain for the two records generated, it is unclear whether this represents one or potentially two individuals. The recent findings suggest the habitat within BHT perhaps does not currently support breeding females, however only through capture can the sex of individuals and therefore breeding condition be accurately assessed. The records made at BHT during this long-term camera assessment have contributed to the understanding of this species' usage of habitats found at BHT, but further investigations will help to deduce whether the species is resident or transient, as well as seasonal usage patterns within BHT. An additional 35 long-term motion sensitive cameras were recently deployed within BHT and surrounds in September 2020.

This letter was prepared by Environmental Scientist Brittany Osborn and Senior Environmental Scientist Matthew Love, and was technically reviewed by Principal Environmental Scientist Dr Jessica Johnston. If you would like to discuss this further, please feel free to contact me on 9421 9600.

Yours sincerely

Executive Summary

Rio Tinto is evaluating the potential development of additional iron ore deposits at Hope Downs 2 (HD2), approximately 80 km northwest of Newman, in the Pilbara region of Western Australia. The HD2 Proposal includes two above water table (AWT) deposits: Bedded Hilltop (BHT) and HD2, including supporting infrastructure with transport of ore to existing processing plant at Hope Downs 1 (HD1).

Stantec was commissioned to undertake a level 2 troglofauna survey (the Study) for the HD2 Proposal which includes a 10,818 hectare (Ha) Development Envelope. This report presents the findings of the Study for the HD2 Proposal.

The main objective of the Study was to define the troglofauna values present for each of the deposits in order to enhance and contextualise the level of knowledge at the locality scale. The findings of the Study will inform an environmental impact assessment (EIA) as part of the regulatory approvals process for the HD2 Proposal.

Troglofauna sample effort:

- **BHT**: A total of 134 litter trap samples and 65 scrape samples were collected from 71 sites (**Table ES-1**).
  - 2015 — 38 trap samples and three scrape samples from 13 sites were collected by Biota in the early dry season from April 8 to May 21, 2015.
  - 2018 — 41 trap samples and 38 scrape samples from 38 sites were collected in the late dry season from October 26, 2018 to January 16, 2019.
  - 2019 — 55 trap samples and 37 scrape samples from 49 sites were collected in the late wet season from March 28 to May 30, 2019.
- **HD2**: A total of 75 litter trap samples and 50 scrape samples were collected from 38 sites (**Table ES-1**).
  - 2018 — 38 trap samples and 25 scrape samples from 38 sites were collected in the late dry season from October 26, 2018 to January 16, 2019.
  - 2019 — 37 trap samples and 25 scrape samples from 36 sites were collected in the late wet season from March 28 to May 30, 2019.

Table ES-1: Troglofauna sample effort.

Deposit	Litter Traps (n)	Net Scrapes (n)	TOTAL	Sites (n)
Bedded Hilltop	134	65	199	71
Hope Downs 2	75	50	125	38

Troglofauna Results

A total of 109 troglofauna specimens, representing at least 15 species from 8 higher level taxonomic groups were recorded from the 2018 and 2019 surveys for the HD2 Proposal. The summary of results are:

- Eleven species were collected from BHT;
- Eight species from HD2;
- Four species shared between the BHT and HD2 deposits; and
- Three species, *Dodecastyla* `sp. Biologic-ZYGE001`, Lophoproctidae `sp. Biologic-POLX001`, and *Nisia* `sp. Biologic-HEMI001` belonged to relatively widespread troglophillic species, with linear distributions extending for over 140 km, 300 km, and 175 km, respectively.

An additional species, *Lagynochthonius* `sp. WAMPSE096`, had been collected from BHT in 2015, bringing the total number of identified species from BHT to 12.

The nocticolid cockroaches were the most abundant group, with genetic analysis revealing four *Nocticola* species to occur. *Nocticola* `SP. BIOLOGIC-BLAT003` was the most abundant and widespread species, with 47 specimens collected from BHT and HD2 within mapped Brockman BIF, colluvial, and Mount McRae Shale surface geologies from modelled prospective habitat profiles ranging from deep, particularly at HD2, to more commonly relatively shallow.

The troglobitic schizomid, *Draculoides* SCH068, was also relatively abundant with eight specimens collected from the BHT deposit area. *Draculoides* SCH068 was also collected in 2015 from Baby Hope deposit and BHT. The species has been recorded from both mapped Brockman and Marra Mamba BIF, as well as Mount McRae Shale mapped surface geologies, from modelled prospective habitat profiles ranging from shallow to deep.

Species Richness Estimates and Survey Adequacy

The species richness predicted to occur across the Development Envelope ranged from 18 to 24 species. Sampling completed in this Study is estimated to have recorded between 63% to 85% of the total species predicted to occur in the Development Envelope. The species accumulation curves for five of the richness estimators were still trending upwards to varying degrees, with two estimators trending strongly downwards. The extrapolation to a 100 % increase in survey effort (from 282 to 564 samples) estimates an additional four troglofauna species to be recorded.

The sampling effort conducted to date within the Development Envelope (BHT — 199 (including Biota 2015 sample effort of 41 samples); HD2 — 125), has exceeded the recommended minimum requirements for a Level 2 troglofauna survey. The total number of troglofauna samples collected is therefore considered sufficient to provide a reliable characterisation of the troglofauna values present within the Development Envelope and to properly inform an environmental impact assessment (EIA).

Conclusion

The Study has shown that the BHT and HD2 deposits do host a relatively diverse troglofauna assemblage with prospective modelled habitat present within the mineralised Brockman and Marra Mamba BIF, as well as within the associated alluvial, colluvial and fractured, weathered rock units.

1. Introduction

Rio Tinto is evaluating the potential development of additional iron ore deposits at Hope Downs 2 (HD2), approximately 80 km northwest of Newman, in the Pilbara region of Western Australia (**Figure 1-1**). The HD2 Proposal includes two above water table (AWT) deposits: Bedded Hilltop (BHT) and HD2, including supporting infrastructure with transport of ore to existing processing plant at Hope Downs 1 (HD1).

Stantec was commissioned to undertake a level 2 troglofauna survey (the Study) for the HD2 Proposal which includes a 10,818 hectare (Ha) Development Envelope. This report presents the findings of the Study for the HD2 Proposal.

The main objective of the Study was to define the troglofauna values present for each of the deposits in order to enhance and contextualise the level of knowledge at the locality scale. The findings of the Study will inform an environmental impact assessment (EIA) as part of the regulatory approvals process for the HD2 Proposal.

1.1 Scope and Objectives

The main objective of this Study was to define the troglofauna values present within the Development Envelope by means of a desktop study and Level 2 comprehensive surveys (dry and wet seasons) to enhance and contextualise the level of knowledge at the local scale. The findings of the study will inform environmental impact assessment (EIA) as part of the regulatory approvals process for the HD2 Proposal.

To achieve the above the following were completed:

- Desktop assessment including database searches, literature review including reports of previous completed surveys, habitat evaluation and characterisation at the local and regional scale from geological and hydrogeological data, and assessment of the likelihood of the occurrence of identified conservation listed species and/or communities in the Development Envelope.
- Two field survey phases for troglofauna; and
- Documentation and mapping of the diversity and distribution of troglofauna species recorded from current and past surveys;

The objectives and survey methods were aligned with relevant regulatory guidelines. These included:

- Environmental Protection Authority (EPA) (2016a) Technical Guidance Sampling Methods for Subterranean Fauna Survey (equivalent to EPA 2007 Guidance Statement No. 54A Sampling Methods and Survey Considerations for Subterranean Fauna in Western Australia); and
- EPA (2016b) Technical Guidance Subterranean Fauna Survey (equivalent to EPA 2013 EAG 12 Environmental Assessment Guideline for Consideration of subterranean fauna in environmental impact assessment in Western Australia).

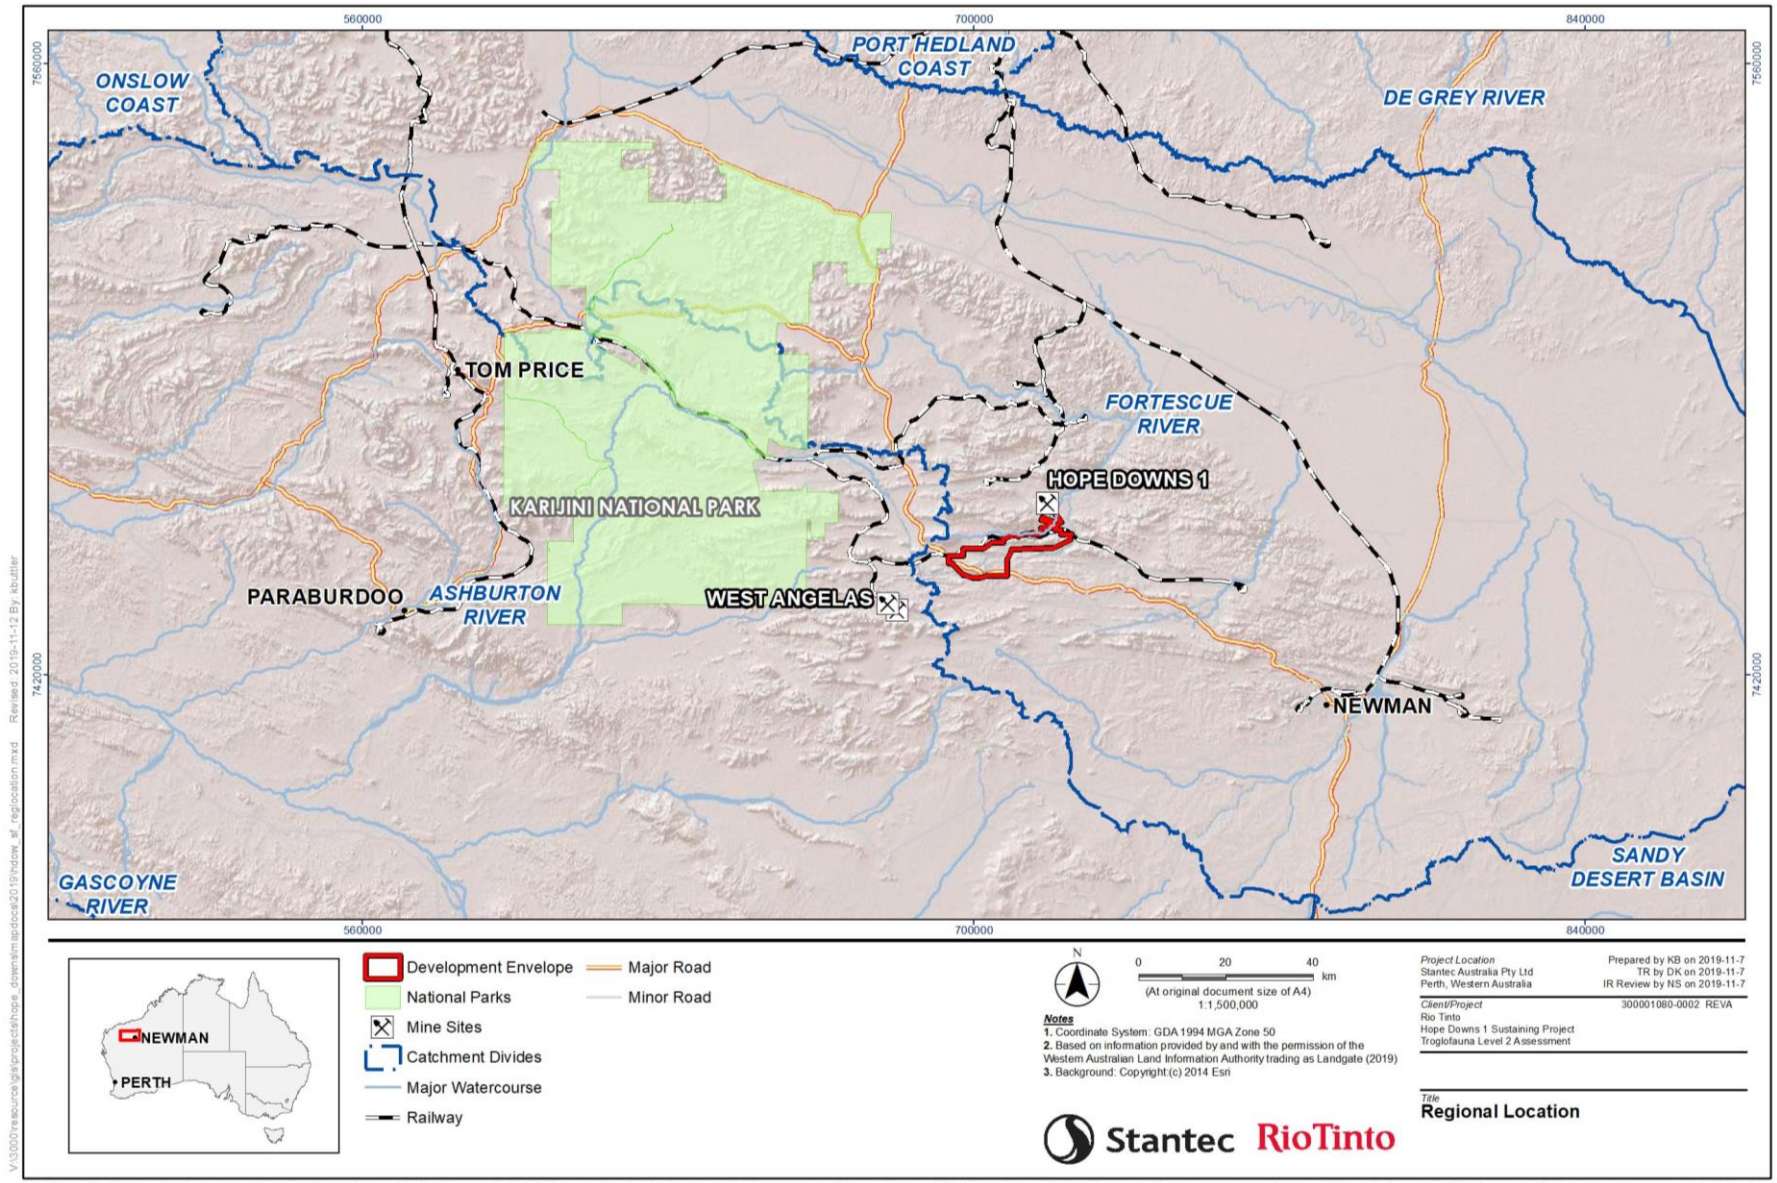

Figure 1-1: Regional location of the Hope Downs 2 Proposal

2. Existing Environment

2.1 Biogeographic Region

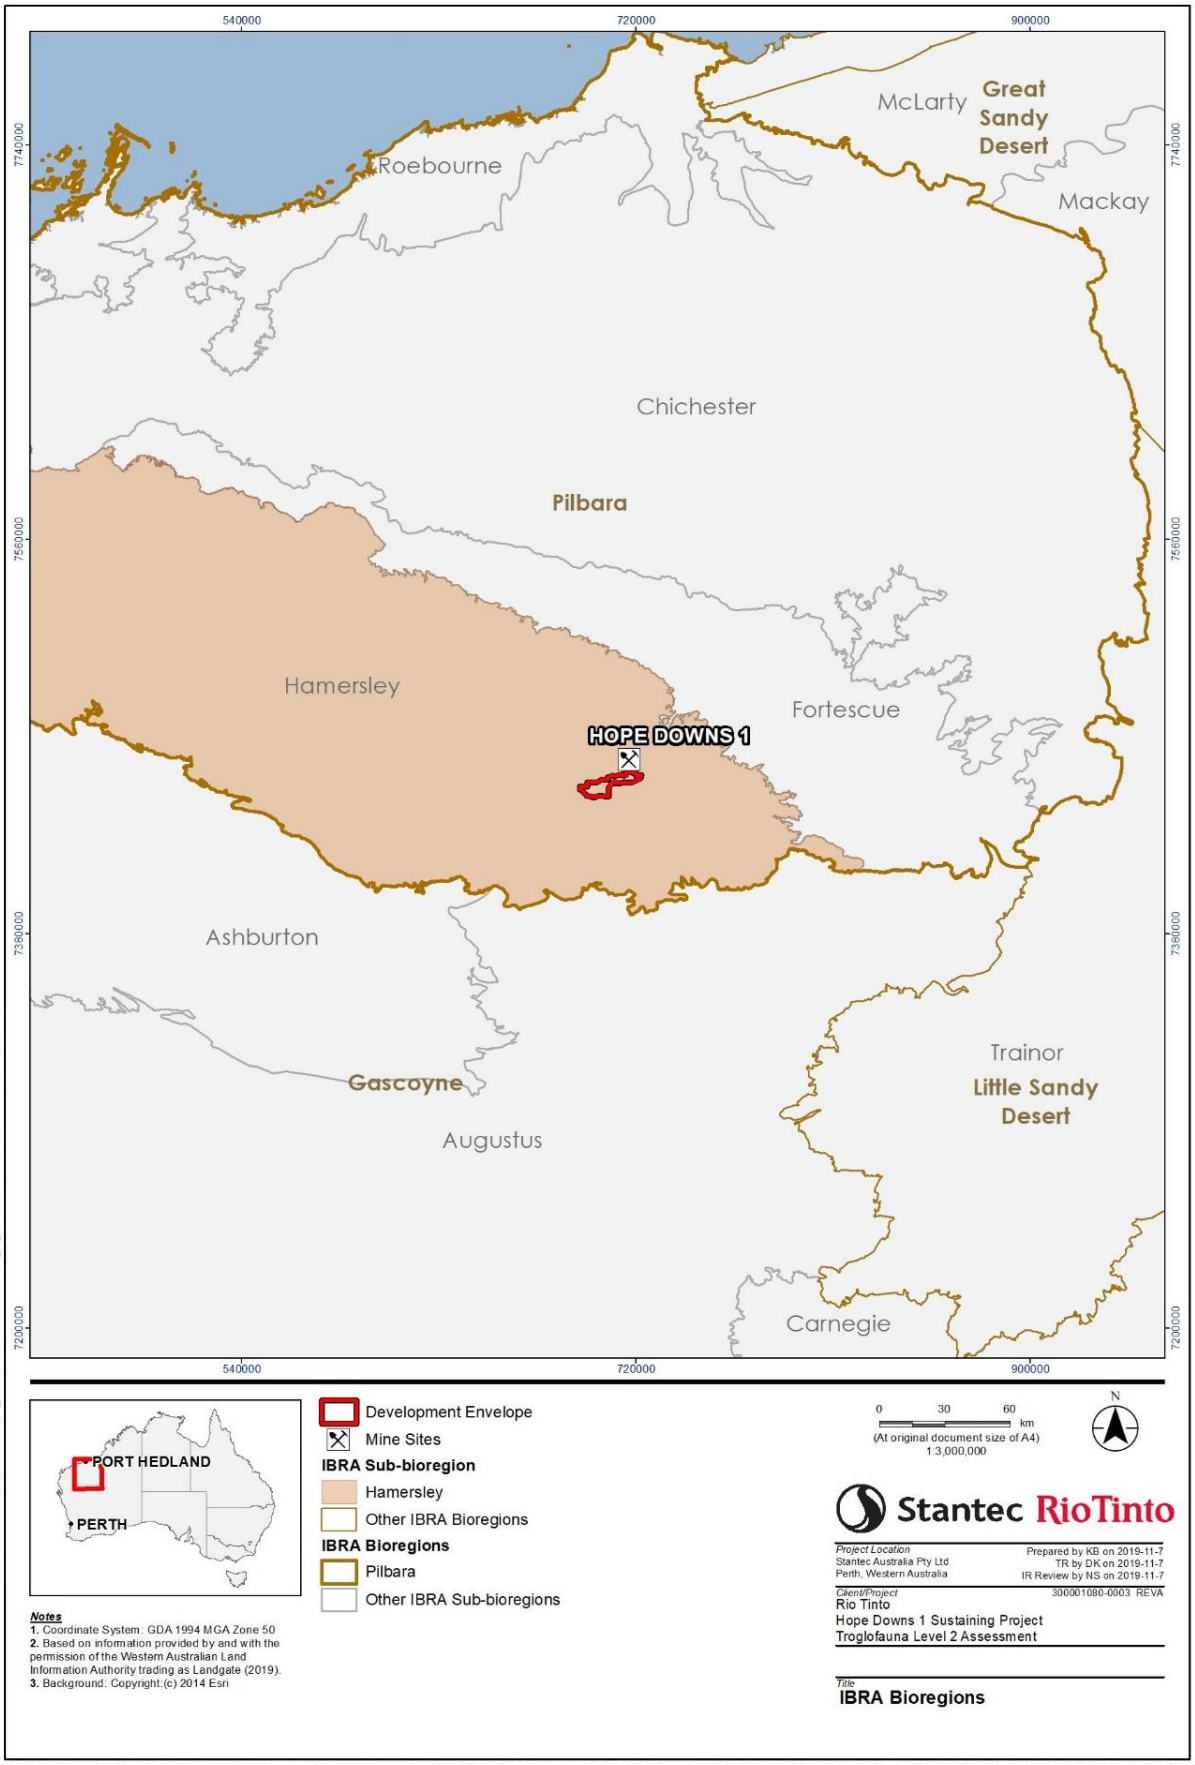
The HD2 Proposal is in the Hamersley subregion (PIL03) within the southern section of the Pilbara bioregion (**Figure 2-1**). The Hamersley subregion is 5,634,727 ha in size and classified as a Desert and Xeric Shrubland ecoregion, characterised as a mountainous area of Proterozoic sedimentary ranges and plateaux that are extensively dissected by gorges. The vegetation mainly consists of low mulga woodland over grasses on fine textured soils in valley floors, with *Eucalyptus leucophloia* over *Triodia brizoides* on skeletal soils of the ranges (Department of the Environment and Energy 2019; Kendrick 2001).

The Hamersley subregion hosts the headwaters of three of the main drainage systems in the Pilbara: the northern portion drains into the Fortescue catchment; the southern portion drains into the Ashburton catchment; and the western portion drains into the Robe catchment (Kendrick 2001)(**Figure 1-1**).

The subterranean fauna values for the subregion are known to be high with calcrete aquifer systems and banded iron formations (BIF) hosting diverse stygofauna and troglofauna assemblages (Halse *et al.* 2014; Kendrick 2001). Diverse subterranean fauna assemblages are known to inhabit many groundwater calcrete systems across the Pilbara and Murchison regions (Cooper et al. 2002, Humphreys 2008, Outback Ecology 2008, 2011b, 2012b, c, d, Subterranean Ecology 2011a).

2.2 Land Use

The tenure of the Pilbara bioregion is mostly comprised of Aboriginal land, pastoral and industry leasehold, with conservation reserves and areas managed by the Crown. The majority of the Pilbara falls under pastoral leasehold, with eight per cent of lands allocated to the conservation estate, including both the Karijini and Millstream Chichester National Parks (Pilbara Corridors 2019). Land within the Hamersley subregion is mainly used for native pasture grazing, with smaller areas classified as unallocated Crown land (UCL), Crown and Aboriginal reserves, as well as mining and small urban centres (Kendrick 2001). In the region neighbouring the HD2 Proposal previous mining exploration activities, and active mining, associated with Hope Downs 1 mine have occurred.



2.3 Climate

The climate of the Hamersley subregion is classed as semi-desert tropical, receiving the majority of the average 300mm rainfall during the wet season from cyclonic or tropical low thunderstorm events (Kendrick 2001). Winter rainfall (early to mid-dry season) also occurs but to a lesser extent (**Figure 2-2**). The nearest Bureau of Meteorology (BOM) weather stations to the HD2 Proposal, with reliable long-term and recent climatic data, are Marillana (station number 5009) and Newman Aero (station number 7176). Marillana station, located approximately 55 km northeast of the HD2 Proposal, provided long term rainfall trends. Newman Aero station, located approximately 85 km south-east of the HD2 Proposal provided long term temperature trends.

The mean long-term annual rainfall (1936 to 2019) recorded at Marillana is 328 mm with the majority falling during the warmer months from January to March (Bureau of Meteorology 2019) (**Figure 2-2**). The annual rainfall in 2018 was below average with 281 mm received. However, February and June received above-average rainfall with more than four times the monthly average falling in June with 83 mm compared to the average of 20 mm. Much drier than average conditions prevailed from July. The annual rainfall in 2019 was well below average with only 150 mm received.

The minimum and maximum temperatures recorded in both 2018 and 2019 were largely consistent with the mean temperatures recorded since 1997 at Newman Aero station, although the maximum and minimum temperatures were higher over the March to early May periods (Bureau of Meteorology 2019).

Dry conditions persisted throughout the 2018 phase of subterranean fauna sampling that began in November 2018 during the late dry season, and finished in mid-January 2019 in the early dry season (**Figure 2-3**). The 2019 sample phase extended from the late wet season, to the early dry season.

3. Subterranean Fauna

3.1 Habitat

The prospective habitat for subterranean fauna (stygofauna and troglofauna) is dependent on the presence of voids of suitable size and connectivity to satisfy biological requirements. Subterranean fauna were previously believed to be mostly restricted to karst landscapes that provide a relatively high degree of secondary porosity, but in more recent times have been found to occur in various types of non-karstic geologies and aquifer systems that exhibit suitable voids for colonisation (Humphreys 2008). Stygofauna are now known to occur in non-karstic aquifers in coarse alluvial sediments, fractured rock, pisolites and thin rocky regoliths (Halse *et al.* 2014; Humphreys 2006;2008; MWH 2016b; Outback Ecology 2014). Likewise, recent surveys have identified troglofauna from non-karstic geologies such as vuggy pisolite ore beds, and fractured and weathered rock formations in the Pilbara and Yilgarn regions (Barranco and Harvey 2008; Bennelongia 2009; Halse *et al.* 2002; MWH 2015; Outback Ecology 2011b; Subterranean Ecology 2008d).

The extent of subterranean fauna habitat is dependent on the interconnection of sub-surface crevices, fractures and voids, within suitable geological and hydrogeological units and aquifer systems. In addition to allowing for the movement of subterranean fauna, adequate interconnected void spaces and associated high permeability can provide pathways for infiltration (vertical or lateral) of resources such as oxygen and nutrients, key factors influencing subterranean fauna persistence and distribution (Humphreys 2008; Strayer 1994). Geological, hydrological, and hydrogeological studies can give an indication of the extent of subterranean fauna habitat present by providing information on the geological units and structures present, as well as recharge zones, groundwater flow and aquifer characteristics.

3.2 Troglofauna

Troglofauna (air-breathing subterranean fauna) are often relictual forms related to surface dwelling (epigean) groups and can be distinguished by characteristics associated with a below-ground existence (Humphreys 2000b). Troglofauna can be divided into:

- troglophiles, which carry out most of their lifecycle underground but are able to survive in epigean habitats;
- trogloxenes, which can enter subsurface habitats passively or incidentally; and
- troglobites (the focus of this assessment), which are obligate or permanent subterranean inhabitants (Thurgate *et al.* 2001) that generally lack pigmentation, are blind (or have reduced eyes), have elongated limbs and may possess enhanced non-visual sensory adaptations (Culver and Sket 2000).

Troglofauna are found worldwide and historically had been generally classified as cave organisms (Culver and Sket 2000). However, the discovery of diverse troglofauna communities inhabiting sub-surface rock fractures in non-karst areas in Europe in the 1980s prompted broader consideration of potential habitat (Juberthie 2000). The most common environments in which troglofauna occur are those that support suitably sized and extensively connected crevices, small cavities or vugs associated with secondary porosity from erosion, fractures and shears zones, that remain relatively humid, an important condition considered to be a key requirement for troglofauna existence (Environmental Protection Authority 2016b). Troglobites are restricted to their subterranean environment and often have locally-restricted distributions. As a consequence, most species are considered to be short range endemics (SRE's) that are more vulnerable to extinction because of their limited distribution range (Harvey *et al.* 2011; Harvey 2002). An SRE categorisation system was developed by the Western Australian Museum (WAM) and is used for the assignment of SRE status for terrestrial and subterranean fauna in Western Australia (**Table 3-1**).

The most researched areas for troglofauna in Western Australia are the Cape Range and Barrow Island karst cave systems where large, diverse communities have been discovered(Hamilton-Smith and Eberhard 2000; Humphreys 1991;2000a). Diverse troglofauna assemblages have also been commonly collected from groundwater associated calcrete (i.e. non-pedogenic calcrete) and alluvial/colluvial geologies within palaeodrainage channels of the arid and semi-arid zones, particularly in the Pilbara and Yilgarn regions (Harrison *et al.* 2014; MWH 2015; Outback Ecology 2011b;2012a;b; Platnick 2008), but less so in the more arid interior of Australia (Outback Ecology 2011c). Less diverse troglofauna assemblages have also been recorded from weathered fractured rock (Outback Ecology 2011a;2014) and metamorphic mafic rock systems (Bennelongia 2009). Continued studies are likely to increase the understanding of prospective troglofauna habitat in Western Australia. It is only recently that troglofauna have become a focus of

environmental assessment in Western Australia, and there is still relatively little information on their distribution compared to stygofauna (Eberhard *et al.* 2007; Environmental Protection Authority 2016a).

Table 3-1: SRE categorisation used by Western Australian Museum (WAM)

<table>
<tr><th>Distribution Range</th><th>Taxonomic certainty</th><th>Taxonomic uncertainty</th></tr>
<tr><td>< 10,000 km²</td><td>Confirmed SRE
A known distribution of <10,000 km2;

This category considers the expert knowledge held within the WAM.</td></tr>
</table>

3.3 Risks and Relevant Legislation

Development and operation of mines in Western Australia pose a number of risks to subterranean fauna and their habitat, including:

- direct removal of, or disturbance to, habitats through mining excavation;
- lowering the groundwater table through groundwater abstraction for pit dewatering and supply; and
- altering water quality parameters, to levels which may exceed species tolerance limits.

Subterranean fauna are protected under State and Federal legislation, governed by three Acts:

- *Biodiversity Conservation Act 2016* (WA) (BC Act);
- *Environmental Protection Act 1986* (WA) (EP Act); and
- *Environment Protection and Biodiversity Conservation Act 1999* (Cth) (EPBC Act).

With this legislation in mind, the EPA developed the technical Guidance (EPA 2016a, b) guidance documents. which outline considerations and sampling methods for subterranean fauna in Western Australia. These documents provide advice to proponents and the public on the requirements for environmental impact assessment (EIA) and management of subterranean fauna. The assessment reported here was designed in accordance with both the EPA (2016a, b) guidance documents.

Mining proposals that will potentially impact on groundwater, or hypogean habitats that support subterranean fauna, require a risk assessment to ensure mining operations do not threaten the viability of important species or communities. Proponents must demonstrate that any species existing within potential mine-related impact zones also occur outside this area. For taxa restricted to impact zones, a suitable management plan must be developed, which includes ongoing monitoring of subterranean fauna to ensure the persistence of the species.

3.4 Regulatory Survey Adequacy Guidelines

The EPA (2016a) stipulates that the appropriate level of survey depends on the likely presence of subterranean fauna, the degree of impact proposed, and adequacy to reliably inform decisions as part of the EIA process as to whether a proposal meets the EPA's objective and is tailored to the circumstances of the proposal.

For Level 1 low intensity (pilot) surveys the recommended survey intensity considered to provide a reliable indication of the habitat present hosting subterranean fauna is:

- Troglofauna — 10 to 15 samples; and
- Stygofauna — 6 to 10 samples.

If the findings from a desktop assessment and pilot survey indicate that an area is not prospective for subterranean fauna then no further survey would be required. If a pilot survey does collect stygofauna and / or troglofauna species, thereby demonstrating that subterranean fauna are a potential environmental factor, then a Level 2 (baseline or comprehensive) survey would be required.

For Level 2 (baseline) troglofauna surveys in areas that are likely to host 'significant troglofaunal values', a minimum of 60 litter trap samples deployed over two rounds for a minimum of six weeks each are recommended (EPA 2016b). The definition of 'significant values' is not specified or quantified but has been interpreted to relate to the presence of a relatively diverse troglofauna assemblage in or associated with the proposed development area.

4. Methods

4.1 Database Searches and Lists

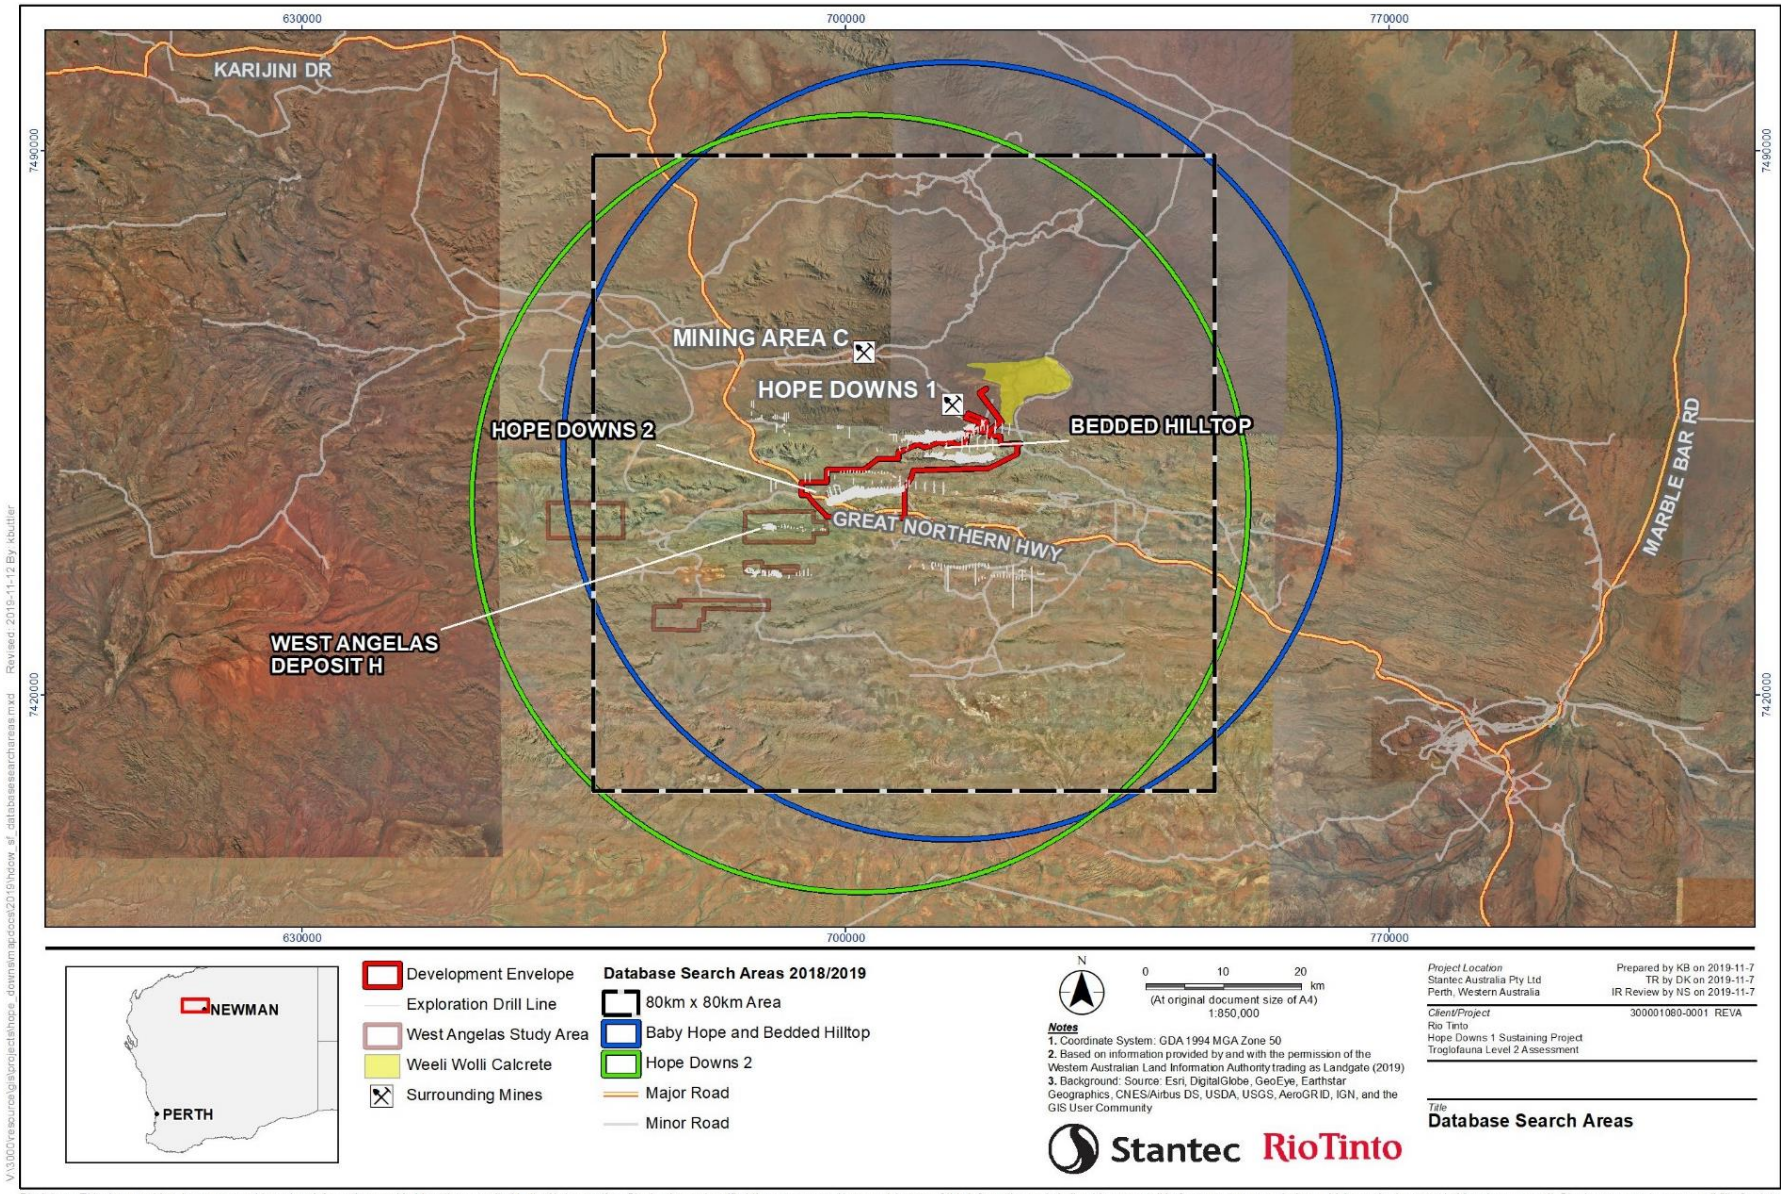
Searches of both Commonwealth and WA State databases were undertaken as part of the desktop review to reveal if any troglofauna taxa had been previously recorded from within or near the Development Envelope, and to identify if any threatened or priority ecological communities (TEC's and PEC's) were in the vicinity. Search areas were either from a central point in the Development Envelope or a designated rectangular search area (**Figure 4-1**, **Table 4-1**). Database and internet information sources included:

- Department of Biodiversity, Conservation and Attractions (DBCA) TEC/PEC database was searched for TEC's and PEC's occurring within a 50 km radius of the Development Envelope;
- Western Australian Museum's (WAM) arachnid, crustacean, myriapod and oligochaete collection databases were searched for subterranean fauna;
- Atlas of Living Australia (ALA); and
- Nature Map of Western Australia.

The following Federal and State government lists were also checked against the database results, to identify any threatened or priority subterranean fauna that may occur within the search area:

- BC Act Specially Protected Species List;
- EPBC Act TEC List; and
- EPBC Act Threatened Fauna List.

Table 4-1: Defined search parameters of database and internet sources



Data Source	Search Area	Co-ordinates
DBCA TEC/PEC	50 km radius	Central point @ 23.060597 S, 119.038855°E
Nature Map		
Literature Review		
WAM Collections	80 km square	NW corner @ 22.694628°S, 118.630309 E SE corner @ 23.422667 S, 119.422871 E
ALA		

4.2 Literature Review

A literature review was conducted to gather existing information on troglofauna from within the vicinity of the Development Envelope. The review included technical reports, scientific journal articles and government publications. The areas of focus for the literature review were drainage and palaeochannel systems associated with and/or near to the HD2 Proposal, as well as BIF ridge systems within approximately 40 km of the Development Envelope.

4.3 Field Personnel and Licences

The field survey methods and sampling effort completed followed both the EPA (2016a, b) technical documents. A Regulation 17 licence to collect fauna for scientific purposes was obtained from the DBCA prior to survey (Licence Number: 08-003053-1). Personnel involved in the field sampling were Dr Nicholas Stevens and Emma Dobinson.

Figure 4-1: HD2 Proposal database search areas

4.4 Troglofauna Survey

Troglofauna samples were taken from exploration drill holes, referred to hence forth as sites, using litter traps and net haul scrapes. The details of sites sampled are presented in **Appendix A.**

4.4.1 Litter Traps

Troglofauna were sampled using litter traps as follows:

- litter traps were packed with sterilised organic material and sealed to maintain moist, sterile conditions prior to field deployment;
- traps were then moistened with water prior to deployment in sites;
- once installed in the sites, traps were left in place for eight weeks to allow adequate time for colonisation by troglofauna; and
- on retrieval, traps were sealed in zip lock bags, labelled, and couriered to the Stantec laboratory in Perth for sorting and identification.

In the laboratory, troglofauna specimens were extracted from the litter using Tullgren funnels. Litter was placed into funnels, and light and low heat was applied from overhead lamps to create a temperature gradient of approximately 14°C in the litter. This method was applied to encourage any troglofauna, which are light sensitive and prefer humid conditions, to migrate down through the litter as it dried. Troglofauna specimens then fell through a mesh layer into collection vials at the base of the funnels, containing 100% ethanol. After collection of troglofauna in the vials, the litter was removed from the funnels and manually searched under magnification for any troglofauna specimens that may remain (**Figure 4-2**).

Figure 4-2: Troglofauna collection and extraction methods: A) Litter trap; B) Tullgren funnels.

4.4.2 Net Haul Scraping

Net haul scraping has been found to be an efficient method for sampling for troglofauna that compliments troglofauna trapping (Halse and Pearson 2014; Outback Ecology 2011b; Subterranean Ecology 2008c). Net haul scraping involves the following:

- Lowering a stygofauna haul net to the bottom of a dry site or at least 1 m below the standing water level if groundwater is present.
- Scraping the net up along the uncased wall surface of the site on retrieval, with the aim of dislodging and collecting any invertebrates that may be present.
- This process is repeated four times per site, with each scrape sampling a different side of the wall surface of the site.

Scraping for troglofauna can also be conducted simultaneously when sampling uncased bores with water present for stygofauna so that the stygofauna sample also counts as a troglofauna scrape sample. The only difference is the sample effort is greater with six net hauls taken per sample rather than four. Stygofauna sampling of fully-cased bores is not regarded as net haul scrape samples, regardless of whether potential troglofauna taxa may have been collected.

All haul samples were preserved in 100% ethanol prior to shipment back to the Stantec laboratory in Perth for processing. To enhance preservation of specimens and their DNA, samples were kept cool onsite in eskies with ice bricks then refrigerated at the end of each survey day. All samples were then shipped back to Perth in eskies with ice bricks then placed in freezers (at minus 20 Celsius) to preserve DNA.

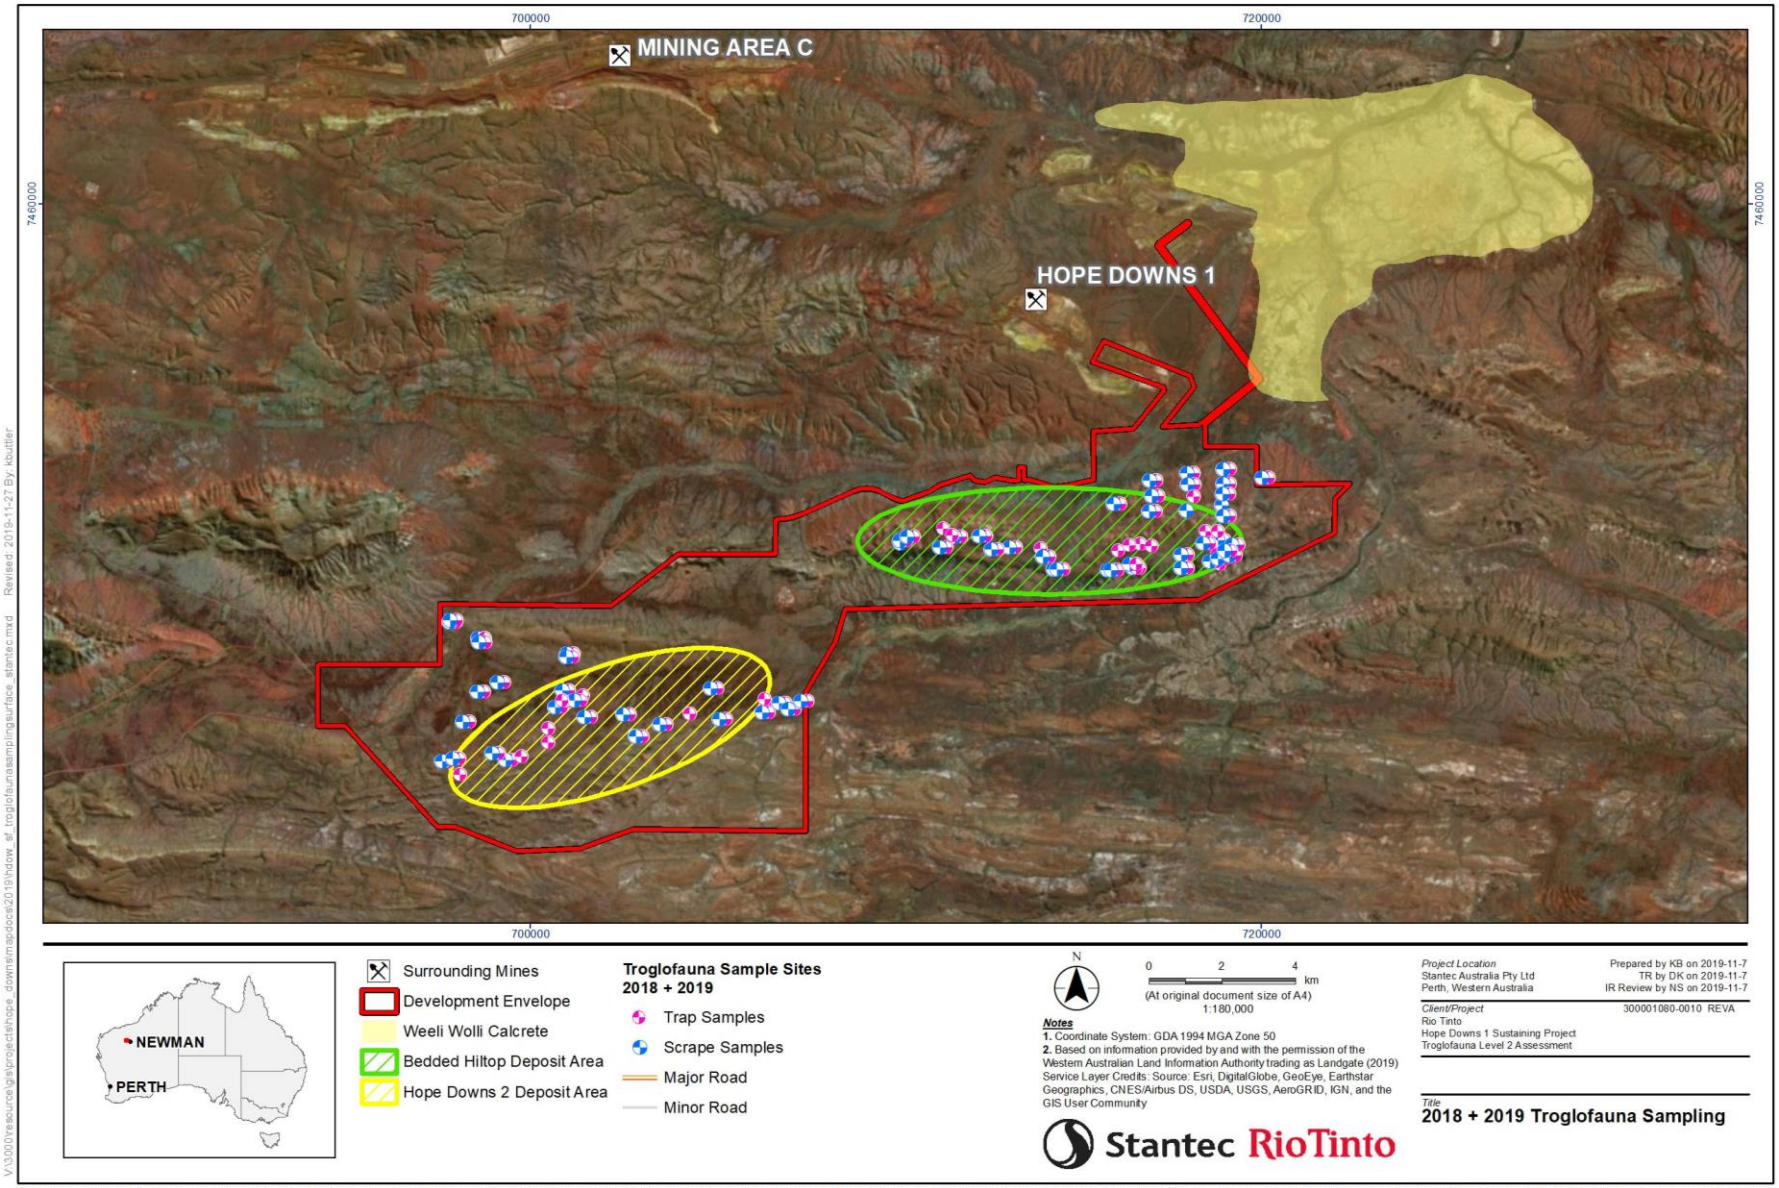
4.4.3 Troglofauna Survey Effort

4.4.3.1 Bedded Hilltop

The total sample effort that has been completed for BHT includes 134 litter trap samples and 65 scrape samples from 71 sites (**Table 4-2**). In the 2018 and 2019 survey phases completed by Stantec, a total of 96 litter trap samples and 75 scrape samples were collected from 58 sites (**Figure 4-3, Figure 4-4, Figure 4-5, Appendix A**).

- The 2018 survey phase included 41 trap samples and 38 scrape samples from 38 sites collected in the late dry season from October 26, 2018 to January 16, 2019.
- The 2019 survey phase included 55 trap samples and 37 scrape samples from 49 sites collected in the late wet season from March 28 to May 30, 2019.

An earlier survey phase of BHT was completed in 2015 (Biota 2015b). The 2015 survey phase included 38 trap samples and three scrape samples from 13 sites collected in the early dry season from April 8 to May 21, 2015 (Biota 2015b).



4.4.3.2 Hope Downs 2

A total of 75 litter trap samples and 50 scrape samples were collected from 38 sites over the 2018 and 2019 survey phases (**Figure 4-3**, **Figure 4-4**, **Figure 4-5, Table 4-2**, **Appendix A**).

- The 2018 survey phase included 38 trap samples and 25 scrape samples from 38 sites collected in the late dry season from October 26, 2018 to January 16, 2019.
- The 2019 survey phase included 37 trap samples and 25 scrape samples from 36 sites collected in the late wet season from March 28 to May 30, 2019.

Table 4-2: Troglofauna sample effort, including Biota (2015b)

Deposit	Litter Traps (n)	Net Scrapes (n)	TOTAL	Sites (n)
Bedded Hilltop	134	65	199	71
Hope Downs 2	75	50	125	38

Figure 4-3: Troglofauna sampling in 2018 and 2019

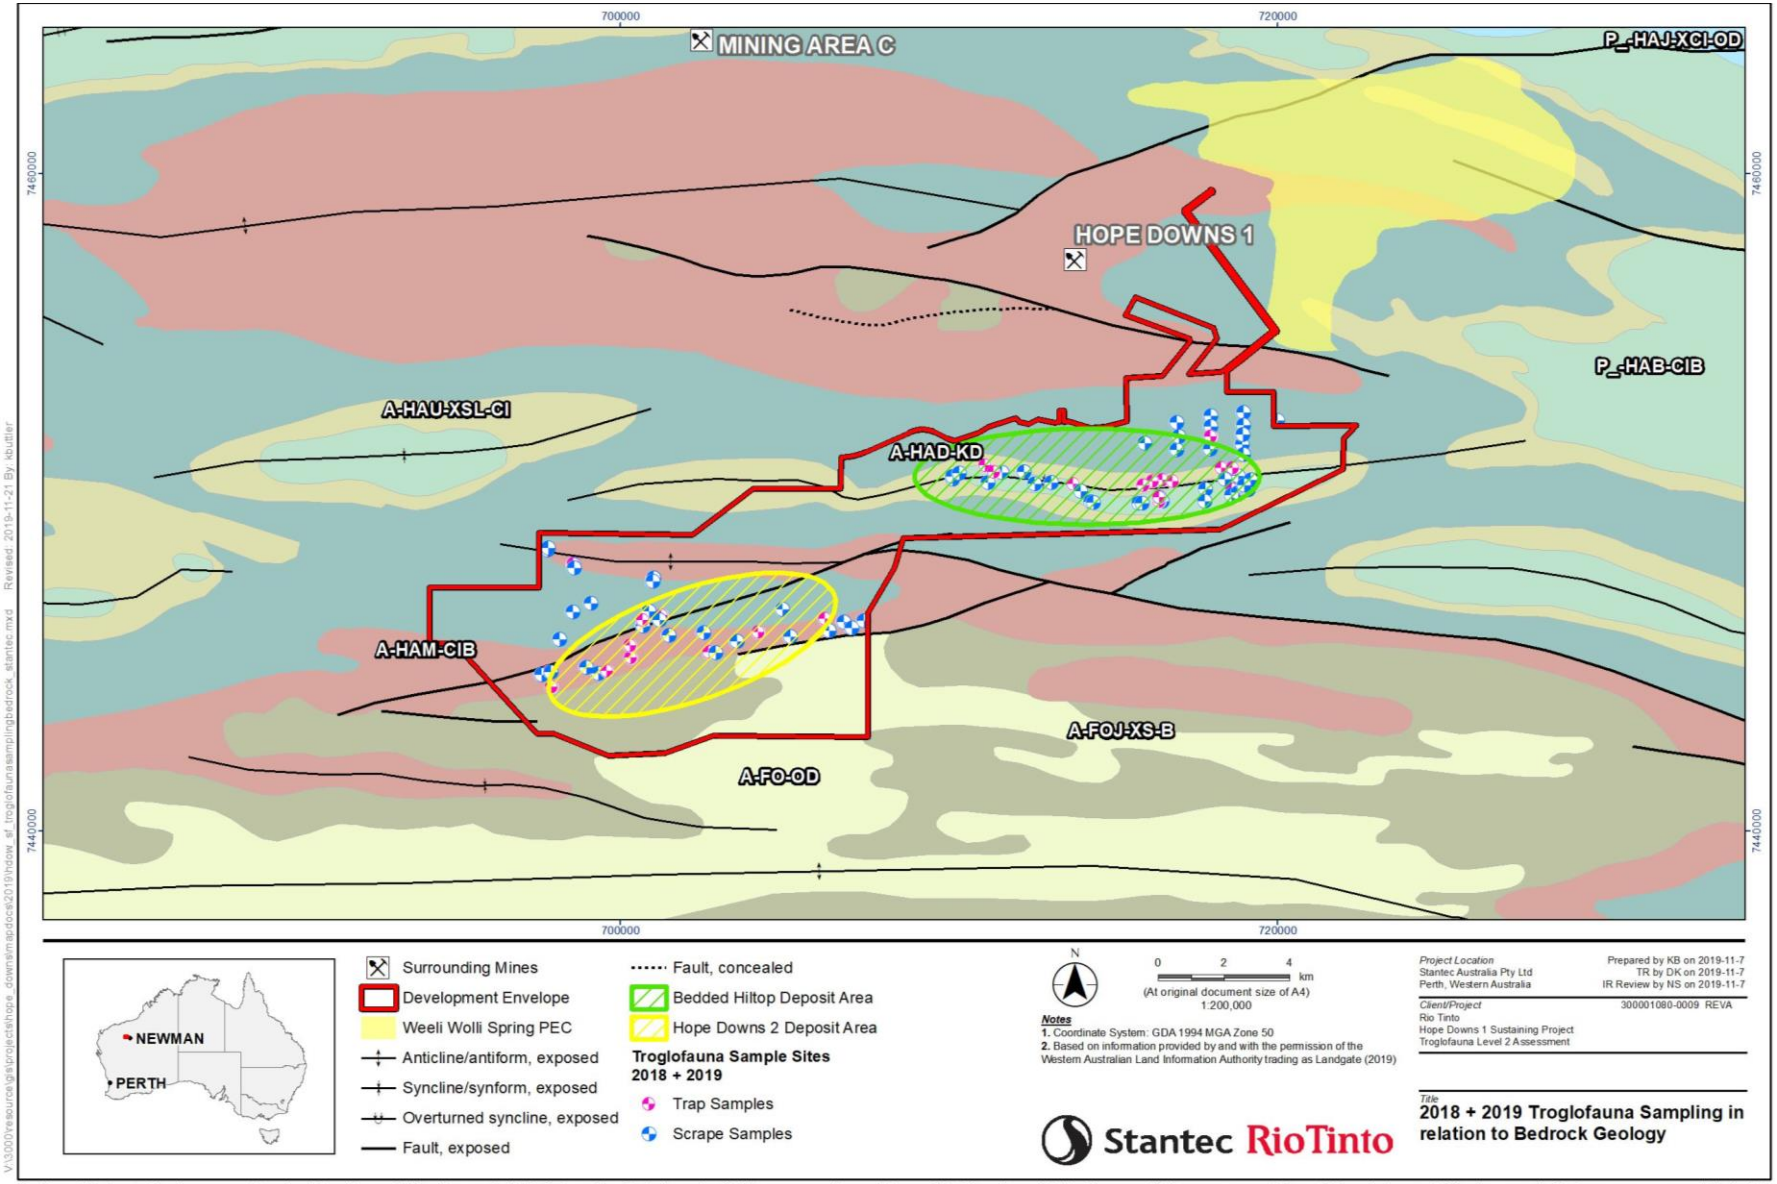

Figure 4-4: Troglofauna sampling in 2018 and 2019 in relation to bedrock geology (refer **Table 4-3** for descriptions of relevant geological codes)

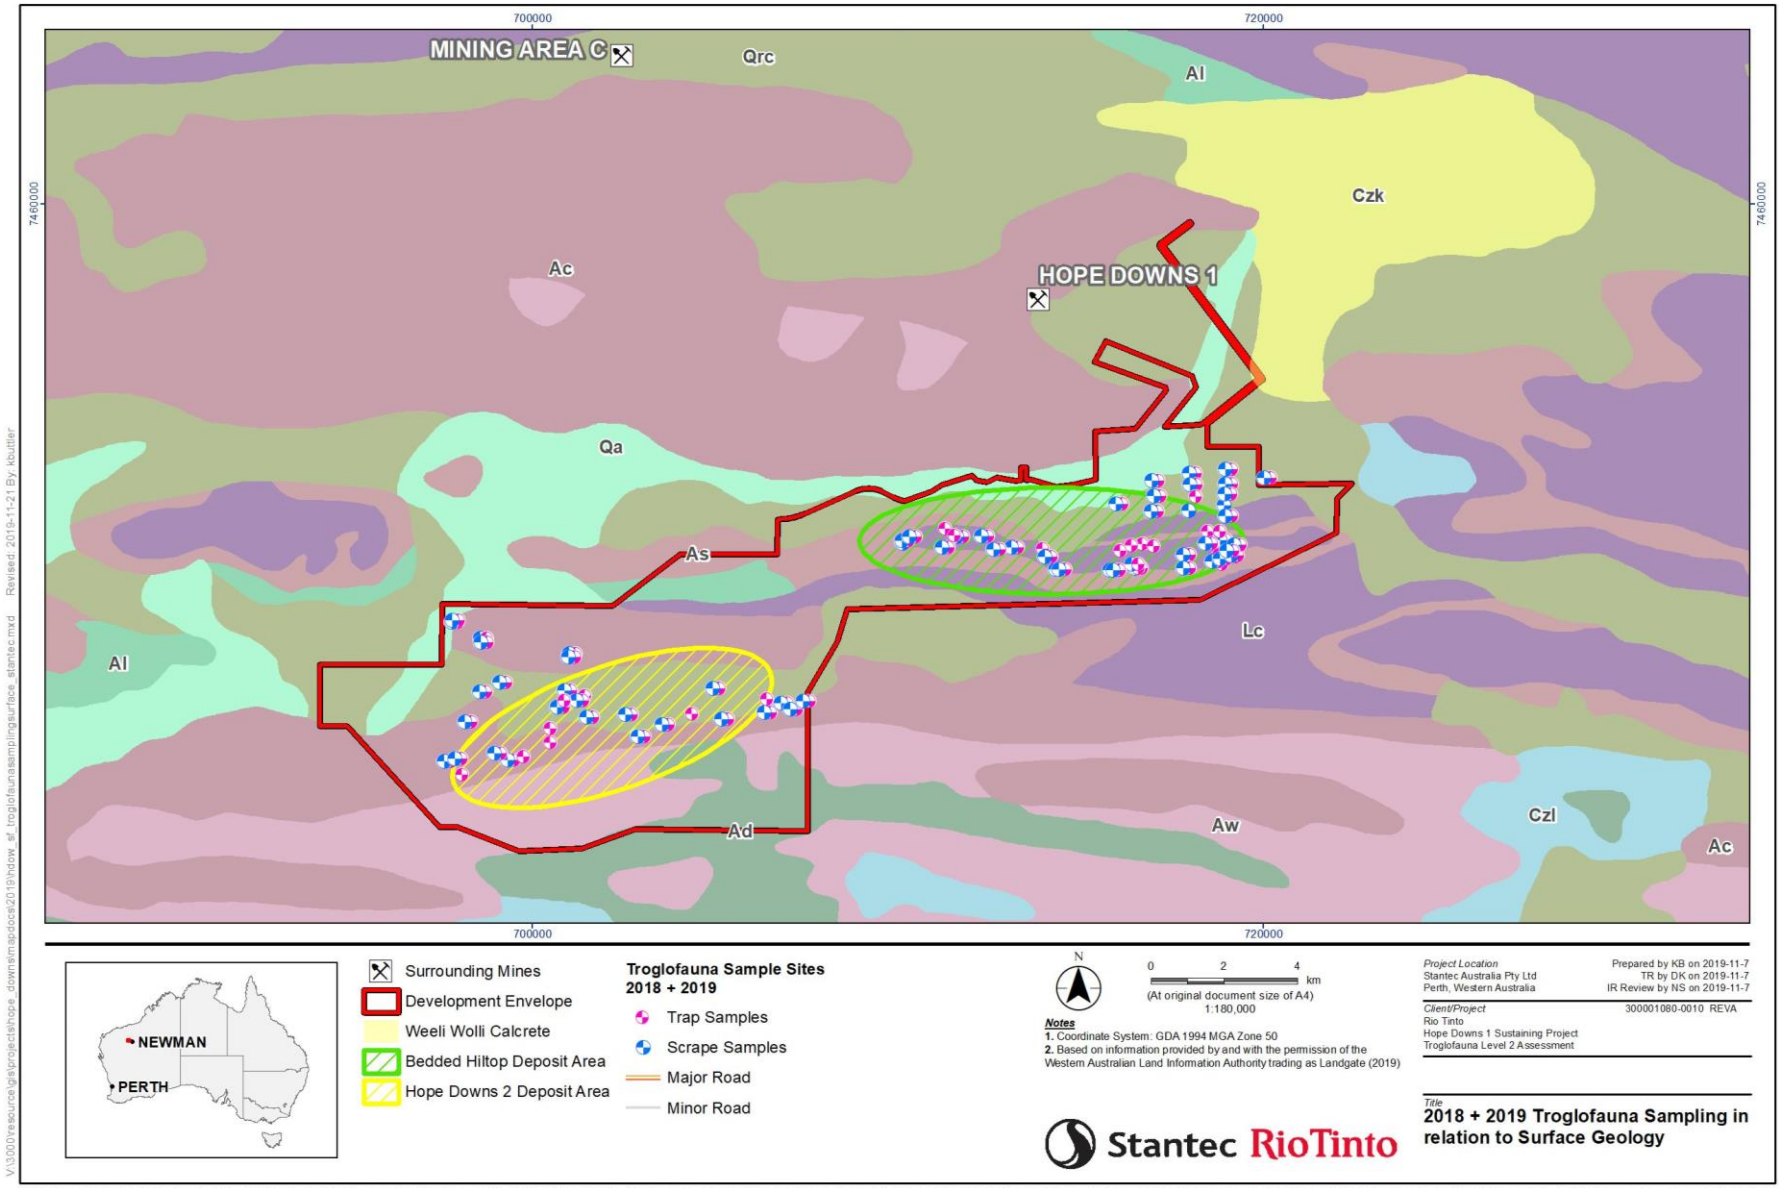

Figure 4-5: Troglofauna sampling in 2018 and 2019 in relation to surface geology (refer **Table 4-3** for descriptions of relevant geological codes)

Table 4-3: Description of bedrock and surface geological codes relevant to the HD2 Proposal

Geology	Code	Bedrock Unit Name	Description
Bedrock	A-FOj-xs-b	Jeerinah Formation	Siliciclastic sedimentary rocks, mafic volcanic rocks and minor felsic volcanic rocks; local carbonate rocks, chert, and dolerite sills
	A-FO-od	Fortescue Group	Dolerite dyke or sill
	A-HAd-kd	Wittenoom Formation	Thinly bedded dolomite and dolomitic shale, with minor black chert, shale, banded iron formation and sandstone
	A-HAm-cib	Marra Mamba Iron Formation	Chert, banded iron-formation, mudstone, and siltstone; minor carbonate; metamorphosed
	A-HAm-cib	Marra Mamba Iron Formation	Chert, banded iron-formation, mudstone, and siltstone; minor carbonate; metamorphosed
	A-HAu-xsl-ci	Mount McRae Shale and Mount Sylvia Formation	Mudstone, siltstone, chert, banded iron-formation, and dolomite; metamorphosed
	P_-HAb-cib	Brockman Iron Formation	Banded iron-formation, chert, mudstone, and siltstone; metamorphosed
Surface	Achm	Marra Mamba Iron Formation	Chert, ferruginous chert, jaspilite, banded iron-formation, minor shale, siltstone, mudstone.
	Ad	Fortescue Group - mafic intrusions	Metadolerite, dolerite, gabbro; medium to coarse grained, massive grey-green rock, usually foliated.
	Al	Wittenoom Formation	Calcitic dolomite, interbedded chert and shale in upper and lower parts, volcaniclastic sandstone
	As	Mount McRae Shale and Mount Sylvia Formation	Interbedded shale, chert, banded iron-formation.
	Aw	Jeerinah Formation	Shale, sandstone, siltstone, mudstone, dolomite, local microbanded chert, jaspilite, conglomerate; fine-grained massive rhyolite; mafic tuff with local accretionary lapilli and agglomerate; thin basalt/dolerite and andesitic basalt flows.
	Czk	Calcrete	Pisolitic, nodular or massive calcrete; ferruginous inclusions; calcareous cementing of bedrock and transported materials; locally with intercalated chalcedony; as low mounds, in playa lakes, or as valley calcrete; locally dissected and karstified.
	Lc	Brockman Iron Formation	Banded iron-formation, chert, mudstone and siltstone.
	Qa	Alluvium	Channel and flood plain alluvium; gravel, sand, silt, clay, locally calcreted.
	Qrc	Colluvium	Colluvium, sheetwash, talus; gravel piedmonts and aprons over and around bedrock; clay-silt-sand with sheet and nodular kankar; alluvial and aeolian sand-silt-gravel in depressions and broad valleys in Canning Basin; local calcrete, reworked laterite.

4.5 Sorting and Identification of Specimens

Preserved samples were sorted manually using Leica MZ6, MZ7.5, M80 and M205C stereomicroscopes within the Stantec laboratories by Emma Dobinson, Jake Daviot and Thomas de Silva. Once sorted, any potential subterranean fauna specimens found were preserved in 100% ethanol and stored at minus 20°C to allow future DNA analysis (if required). Taxa were identified by Dr Nicholas Stevens of Stantec, using published and unpublished keys and taxon descriptions. Undescribed taxa were assigned morphospecies names based on morphological features.

4.6 DNA Sequencing

Material from 44 specimens were sent to Biologic for genetic analysis (**Appendix B**). The main aim of the molecular analysis was to test the robustness of identifications based on morphological characters, including juvenile specimens, and align morphospecies with any described and/or previously sequenced taxa.

4.7 Diversity Analysis

The EstimateS software package (Colwell (2013) Version 9.1.0) was used to assess the survey adequacy by investigating the species richness recorded in the Development Envelope. The species richness was analysed using species accumulation rarefaction and extrapolation curves, and various species richness estimators (using incidence and abundance data).

The species richness analysis provided a statistical evaluation of the proportion of the stygofauna assemblage detected. A range in the number of species predicted to form the assemblage was developed using seven species richness estimators (ACE, Bootstrap, Chao1, Chao2, ICE, Jack 1 and Jack 2). Statistically, it is more robust to show the results of several estimators to provide a range in predicted richness rather than present only one prediction (Hortal *et al.* 2006).

4.8 Limitations of the Assessment

The availability of suitable sites for sampling from non-resource areas was limited with few sites present beyond the BIF. The seemingly restricted distributions of subterranean fauna species to within a specific resource target habitat type can largely be an artefact of the disproportionate sampling effort conducted between likely impact areas and reference areas.

Specimens were identified to the lowest taxonomic level possible. However, specimens may not always be identified to the level of species or morphospecies due to:

- loss or damage of important taxonomic features during collection and/or sorting of specimens;
- lack of adult specimens; or
- limitation in taxonomy, in that the current state of taxonomy for a particular group is insufficiently advanced, and/or relevant taxonomic keys and descriptions are lacking.

While every effort has been made to assess the taxonomy, distribution and conservation significance of the subterranean fauna collected, using in-house data collections, publications, publicly available reports, and information provided by specialist taxonomists, some accounts may be limited if specialist information was unavailable.

4.9 Habitat Assessment

The extent, thickness, and connectivity of local geological habitats above and below water table was assessed by Rio Tinto by creating a three-dimensional habitat model based on drill-hole logging data in the program Leapfrog® Geo v4.3.1. Drilling log data from reverse circulation and diamond core drill holes throughout the Development Envelope was compiled into a database in Microsoft Excel®. The drill log data was codified to indicate commonly encountered stratigraphic units (strands), as well as mineralisation and geomorphology (tags), using consistent codes/ terminology across all drilling campaigns undertaken throughout the Development Envelope. All strand/ tag code combinations were collaboratively assessed by a team of Rio Tinto personnel experienced with geology, hydrogeology, and subterranean fauna surveys/ ecology, to determine the most likely categorisation for each geological unit (combination of strand and tag) in relation to its general suitability for subterranean fauna. Where strand/ tag combinations or their descriptions in the database were unclear, further advice was sought from Rio

Tinto geologists and hydrogeologists experienced in the local geological setting. The habitat suitability assessment used the following categorisation system:

- **High certain**: strand/ tag indicates a geological unit that is known to frequently support subterranean fauna (AWT/BWT), including rich assemblages, in similar geological contexts in the Hamersley Ranges/ Pilbara region;
- **Medium certain**: strand/ tag indicates a geological unit that is known to sometimes support subterranean fauna (AWT/BWT), or may support less rich assemblages in similar geological contexts in the Hamersley Ranges/ Pilbara region;
- **Medium uncertain**: strand/ tag indicates a geological unit that is poorly sampled or not often associated with subterranean fauna assemblages (AWT/BWT), but may have potential to support subterranean fauna, based on known characteristics. This category was also used for geology/ geomorphology combinations that were difficult to categorise as high certain, medium, or low certain because of a lack of information, knowledge, personal experience, or regional context; and
- **Low certain**: strand/ tag indicates a geological unit that is known to very rarely support subterranean fauna in similar geological contexts in the Hamersley Ranges/ Pilbara region, or typically lacks the physical characteristics required for supporting subterranean fauna (i.e. sufficient void spaces or porosity).

The assessment of suitability (of the strand/ tag combinations) for subterranean fauna was based upon the following criteria:

- Presence or likelihood of subterranean voids, cavities, fractures, faults, vugs, or other geomorphological characteristics that typically form habitat for subterranean fauna;
- Permeability and/or likelihood of secondary weathering (including mineralisation by supergene enrichment, secondary weathering, and hydrated mineralisation);
- Geological formation/ stratigraphic unit, and the typical processes occurring within each unit that create and influence subterranean fauna habitat, within the local context of the Development Envelope; and
- Personal experience with subterranean fauna surveys and habitat assessment, and results from previous studies in similar geological contexts throughout the Hamersley Ranges/ Pilbara region.

Three-dimensional modelling of the extent of high certain and medium certain habitats was undertaken by spatially linking the occurrence of high certain and medium certain strands/tags within drill holes mapped in three-dimensional space throughout the Development Envelope, using Leapfrog® software.

The resulting 3D volumes were then exported as 2D thickness grids of high certain and medium certain habitats. These 2D grids were used to display the modelled thickness, spatial extent, and connectivity of high certain and medium certain habitats throughout the drilled area of the Development Envelope. Low certain and medium uncertain habitat units were not modelled or mapped as these were not considered significant habitat for subterranean fauna. ArcGIS® v10.6 was used for mapping. Pre-mining topography, bore/ drill hole locations, locations of sampling, and locations of key subterranean fauna species were added as separate layers for spatial reference.

Not all areas of the Development Envelope have been drilled, and the modelling is limited to the area within and immediately surrounding the locations of bores and drill holes; therefore, a 300 m buffer was used as a stopping point around the maximum extent of drilling, to provide a spatial indication of the area of confidence in the habitat modelling. Within this 300 m confidence boundary, the 3D habitat modelling is expected to be reasonably consistent with the data obtained from the drilling logs, while there is less confidence in habitat interpretations beyond this distance. Nevertheless, it is not suggested that suitable habitat ceases to occur beyond the 300 m confidence boundary; its occurrence is simply not supported by the same level of information.

5. Results

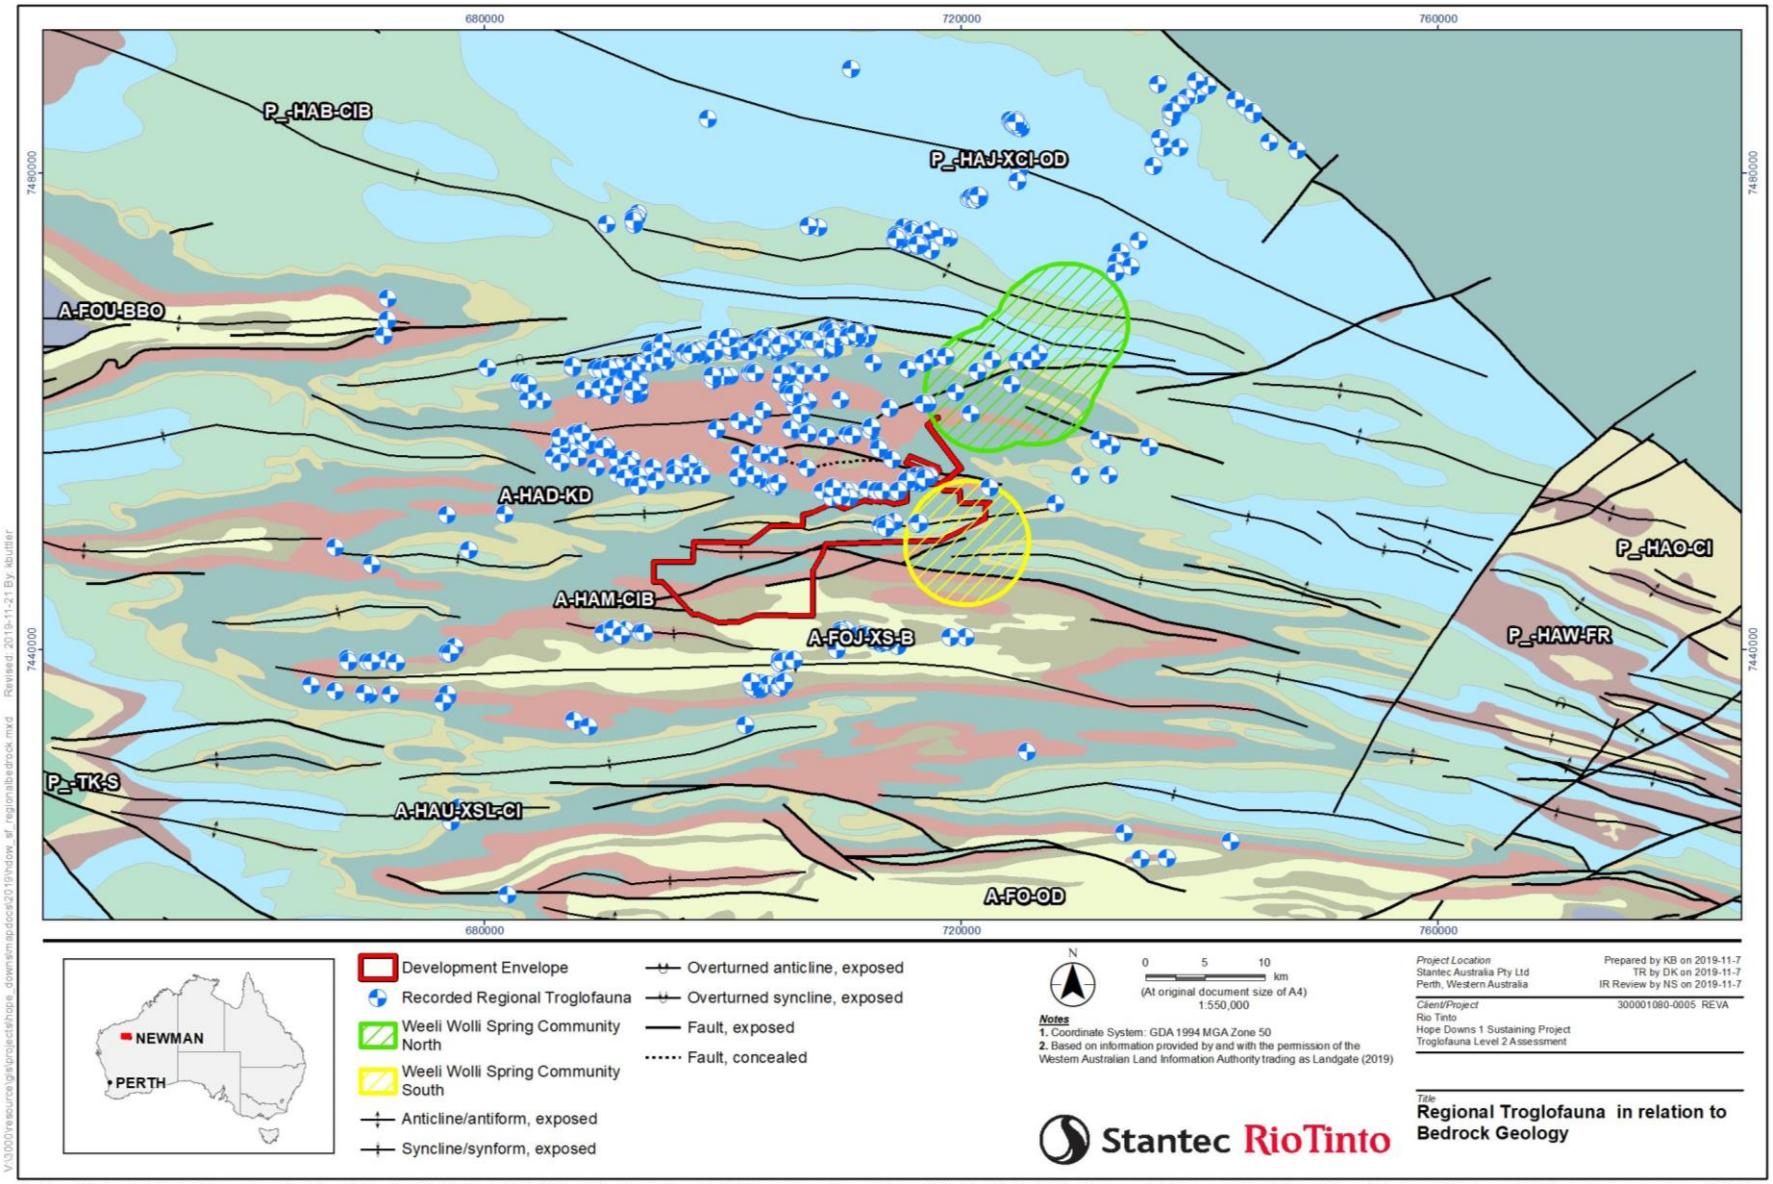
5.1 Database Searches

There have been no previous reports of threatened or priority subterranean fauna species in the Development Envelope or surrounds, based on a search of the DBCA's threatened and priority fauna database (DBCA 2019b).

A search of the DBCA's threatened and ecological communities database did identify two priority ecological groundwater communities (PEC's) within a 50 km radius of the Development Envelope: the Weeli Wolli Spring Community North, and Weeli Wolli Spring Community South PEC's (**Figure 5-1**, **Figure 5-2**) (DBCA 2019b). The large Weeli Wolli calcrete system, and associated wetlands, spring and creeklines are noted for their unique riparian floristic values as well as hosting diverse stygofauna assemblage/s (DBCA 2019a). Both PEC's are classified as priority 1 due to the 'poorly known ecological communities' that are 'known from very few occurrences with a very restricted distribution' (DBCA 2019a). The 5 km buffer zone associated with the Weeli Wolli Spring Community South PEC overlaps with the eastern portion of the proposed development envelope and the BHT deposit area.

A search of the WAM Arachnida, Crustacea, Insecta and Myriapoda databases identified 581 troglofauna records within a 50 km radius of the Development Envelope (**Figure 5-1**, **Figure 5-2, Appendix C**). The majority of records were from subterranean fauna environmental baseline studies for the regulatory assessment of iron ore resource development projects; e.g., Greater West Angelas, Hope Downs 1, Mining Area C, and South Flank (**Appendix C**). Therefore, many records are from BIF ridges within the Hamersley Ranges (**Figure 5-1**). However, there are also many records from alluvial/colluvial habitats, particularly in association with the Weeli Wolli Creek system (**Figure 5-2**).

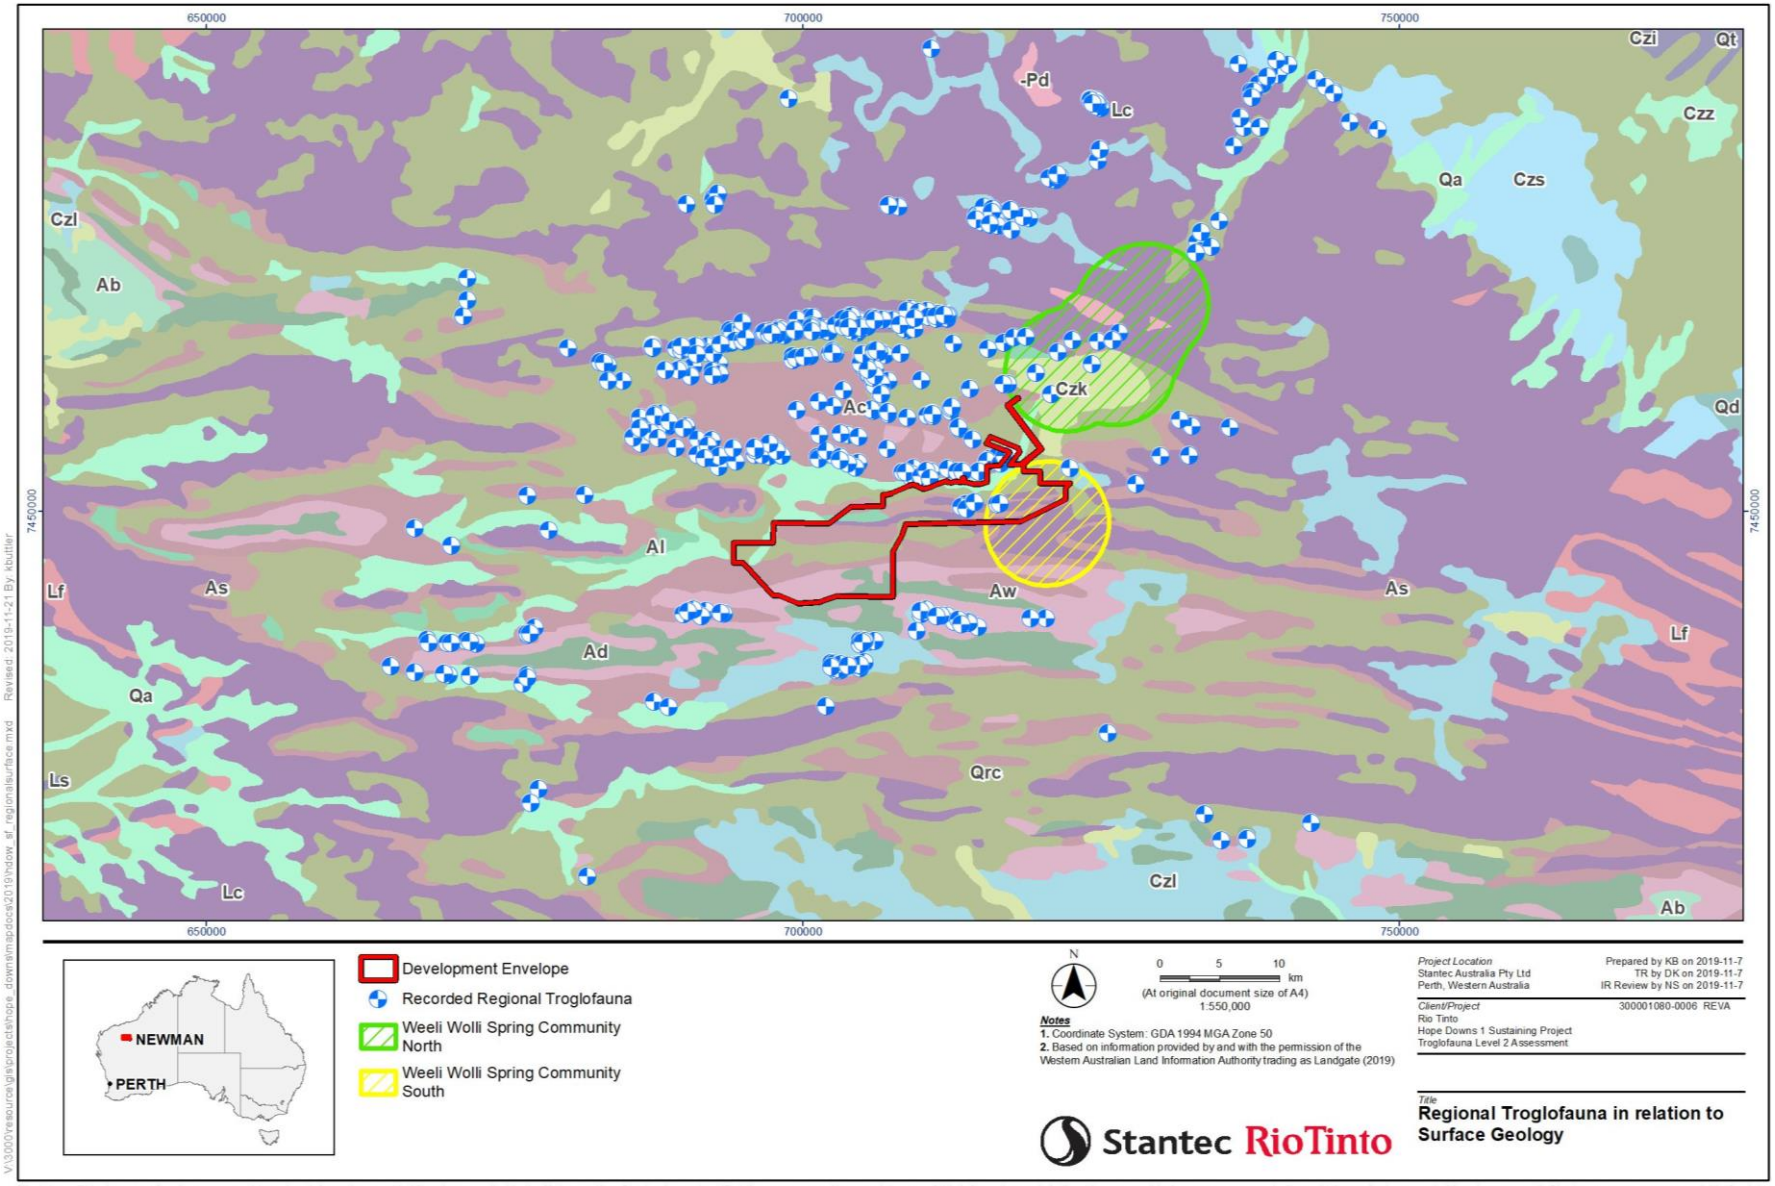
A search of the DBCA's NatureMap database, and Atlas of Living Australia (ALA) for the Development Envelope did not return any additional listings of troglofauna records.



5.2 Literature Review

Studies undertaken in the immediate surrounds of the Development Envelope as part of the HD1 and Baby Hope (BH) subterranean fauna assessments have recorded troglofauna from the alluvial, colluvial, BIF (Brockman and Marra Mamba), and calcrete mapped geology (**Figure 5-4**, **Figure 5-5**, **Figure 5-6**, **Appendix D**) (Biota 2011;2014a;2015a;b). Many other studies in the Hamersley Ranges and the broader region have consistently demonstrated that relatively diverse troglofauna assemblages do commonly occur in such habitats in the Pilbara (Bennelongia 2014;2015a;c;2016; Biota 2009;2014b; ecologia Environment 2013; Halse and Pearson 2014; Subterranean Ecology 2008b).

A genetic study of material of the troglobitic schizomid genus, *Draculoides*, collected from in and near to the Development Envelope revealed that the BHT and BH deposits do not represent completely isolated subterranean systems (Abrams *et al.* 2019), in contrast to what has been shown for the Robe Valley pisolitic mesas that have each been shown represent distinct 'subterranean islands' (Burger *et al.* 2012; Harvey *et al.* 2008b; Humphreys *et al.* 2006). The distributions of two *Draculoides* species recorded from BH were found to extend beyond the deposit (**Figure 5-3**, **Figure 5-4**) (Abrams *et al.* 2019):



- *Draculoides SCH068* — distribution extended linearly from the BH deposit for 5.8 km to the northeast to just south of the HD1 mine within Marra Mamba BIF, and for 7.5 km to the southeast to two sites high up on the BHT ridge landform within Brockman BIF; and
- *D. SCH067* — distribution extended linearly from the Marra Mamba BIF within BH deposit for 13.5 km to the northeast to the Weeli Wolli calcrete system, north of the HD1 mine.

The *Draculoides* genetic results indicate that the subterranean habitats associated with the landforms that host the BH and BHT deposits are more broadly interconnected with the surrounding landscape and not strictly confined to each ridge system (**Figure 5-5**, **Figure 5-6**). Prospective troglofauna habitat modelling overlain mapped surface geology indicates that suitable troglofauna habitat is not confined to the BIF units of the BH and BHT deposits, but also exists within the alluvial (Qrc), colluvial (Qa), and weathered profile of the Mount McRae Shale and Mount Sylvia Formations (As) (**Figure 5-6**). It therefore appears that these geological units associated with the BIF deposits can host troglofauna and provide conduits for geneflow among the populations of species present.

Figure 5-6: Troglofauna taxa collected pre-2018 from in and near to the Development Envelope relevant to surface geology and modelled habitat (refer **Table 4-3** for descriptions of relevant geological codes)

5.3 Subterranean Habitats

The modelled extent of prospective troglofauna habitat in and near the Development Envelope has been shown to be associated with the mapped alluvial, colluvial and weathered BIF units, as well as within the weathered and fractured outcrop formations of the Mount McRae Shale and Mount Sylvia Formations (**Figure 5-1**, **Figure 5-2**, **Figure 5-6**, **Figure 5-11**).

5.3.1 Bedded Hilltop

The BHT deposit occurs within the mineralised Dales Gorge Member of the Brockman Iron Formation and forms part of a distinct ridge landform system (**Figure 5-7**). The deposit dips to the north beneath the colluvial and alluvial detritals within of the Pebble Mouse Creek valley, south of the BH deposit.

Suitable troglofauna habitat has been found in secondarily weathered and fractured zones of Brockman Iron Formation atop BHT. The topography of BHT is highly undulating and exposed, causing high amounts of weathering in the hilltop surface strata. The BHT landform is also ringed by a highly fractured, outcropping Mt Sylvia formation. The limited encroachment of habitat modelling on the Mt Sylvia formation does indicate that prospective troglofauna habitat can exist (**Figure 5-6**). However, the subsurface habitat properties of this geological unit have not been investigated across a broader extent outside of the deposit exploration program.

Surrounding the BHT landform is a ring of colluvial and alluvial sheet wash. This geology provides connection through the Pebble Mouse Creek valley with nearby habitats at BH (**Figure 5-6**). BH is located outside of the Development Envelope, in predominately Marra Mamba Formation. Extensive habitat is present at BH and the surrounding range.

Habitat modelling indicates that the prospective troglofauna habitat hosted at BHT is largely connected throughout the modelled area of the landform via varying thicknesses. The thickest sections of high and medium suitability troglofauna habitat (~107 m) occurs in the eastern section of the landform, in the Brockman Iron Formation (**Figure 5-6**).

Further suitable habitat is highly likely to occur outside of the area of high confidence 3D modelling. The most prospective areas and geologies are the Mt Sylvia formation, the colluvial and alluvial sheetwash units surrounding the landform, and the far western and eastern parts of the BHT landform. All of these geologies appear prospective at the surface but would require subsurface information prior to inclusion into the area of high confidence modelling.

5.3.2 Hope Downs 2

The HD2 deposit occurs within the Marra Mamba Formation and the overlying detrital deposits and does not represent a distinct ridge landform system (**Figure 5-8**). The low rolling hills of the HD2 deposit provides a less distinctive landform compared to the BHT range. A small amount of outcropping Marra Mamba rock exists, dissected by an upstream tributary of Pebble Mouse Creek in the west, and Weeli Wolli Creek in the east. Troglofauna habitat in the area is predominately within the Marra Mamba Formation, overlain by detrital cover with canga deposits in the southwest (**Figure 5-11**). The groundwater table in the HD2 area is located within both the Marra Mamba and abutting Wittenoom Formations and is generally below the base of the detrital deposits. Colluvium and alluvial sheet wash surround these small outcrops.

Habitat modelling indicates troglofauna habitat is connected throughout the modelled area of HD2 via varying thicknesses (**Figure 5-13**). The thickest sections of high and medium suitability troglofauna habitat (~112 m) occurs in the western section of the deposit, in the deepest area of detritals with some Marra Mamba Formation.

High confidence 3D modelling does not currently exist between the HD2 and BHT deposits, however, mapped surface geology indicates habitat connectivity may be present through valley floor colluvium and alluvium (**Figure 5-11**).

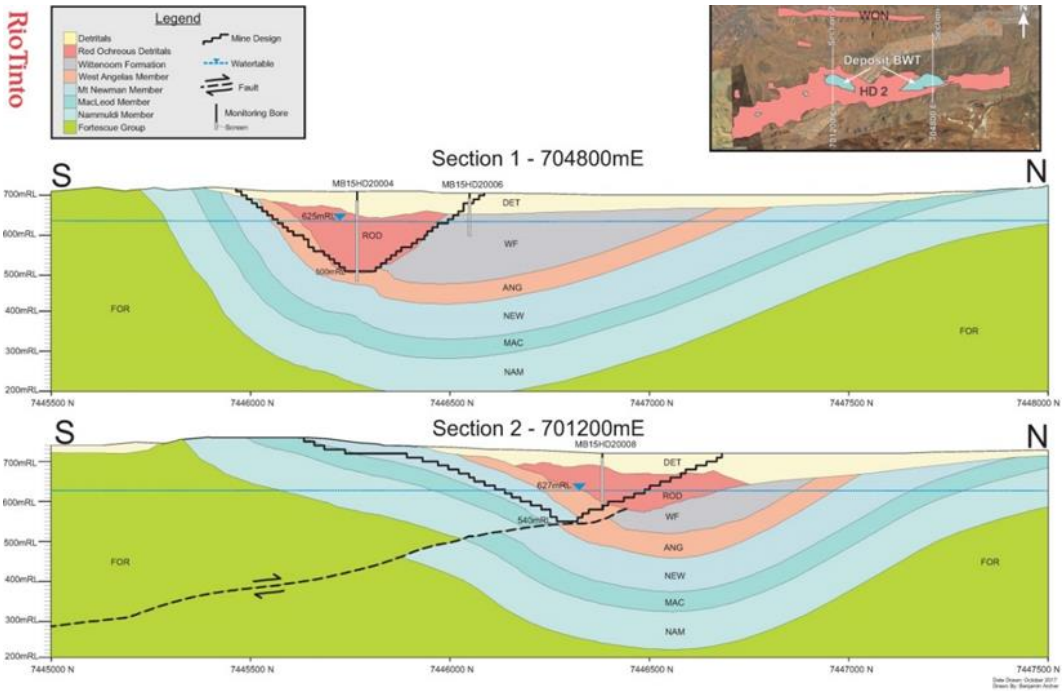

Figure 5-8: Hydrogeological cross sections of the HD2 deposit (Supplied by RTIO).

5.4 Troglofauna Findings

A total of 109 potential troglofauna specimens, representing at least 15 species from 8 higher level taxonomic groups (Blattodea, Scolopendromorpha, Diplura, Hemiptera, Palpigradi, Pseudoscorpiones, Schizomida, and Zygentoma) were recorded from the 2018 and 2019 surveys of BHT and HD2 deposits (**Table 5-1**, **Appendix E**). BHT was found to host a more diverse troglofauna assemblage than HD2 with 11 species collected compared to eight species from HD2 (**Figure 5-9**). An additional species, *Lagynochthonius* `sp. WAMPSE096`, was collected from BHT in 2015 (Biota 2015), meaning 12 species have been recorded from BHT in total (**Table 5-1**). Four taxa, *Eukoenenia* `sp. Biologic-PALP001`, Lophoproctidae `sp. Biologic-POLX001`, *Nocticola* `sp. Biologic-BLAT003`, and Pauropda sp. Indet., were found to occur in both deposits. The troglobitic species, *Draculoides* `sp. SCH068`, recorded from BHT had previously been collected from BH deposit.

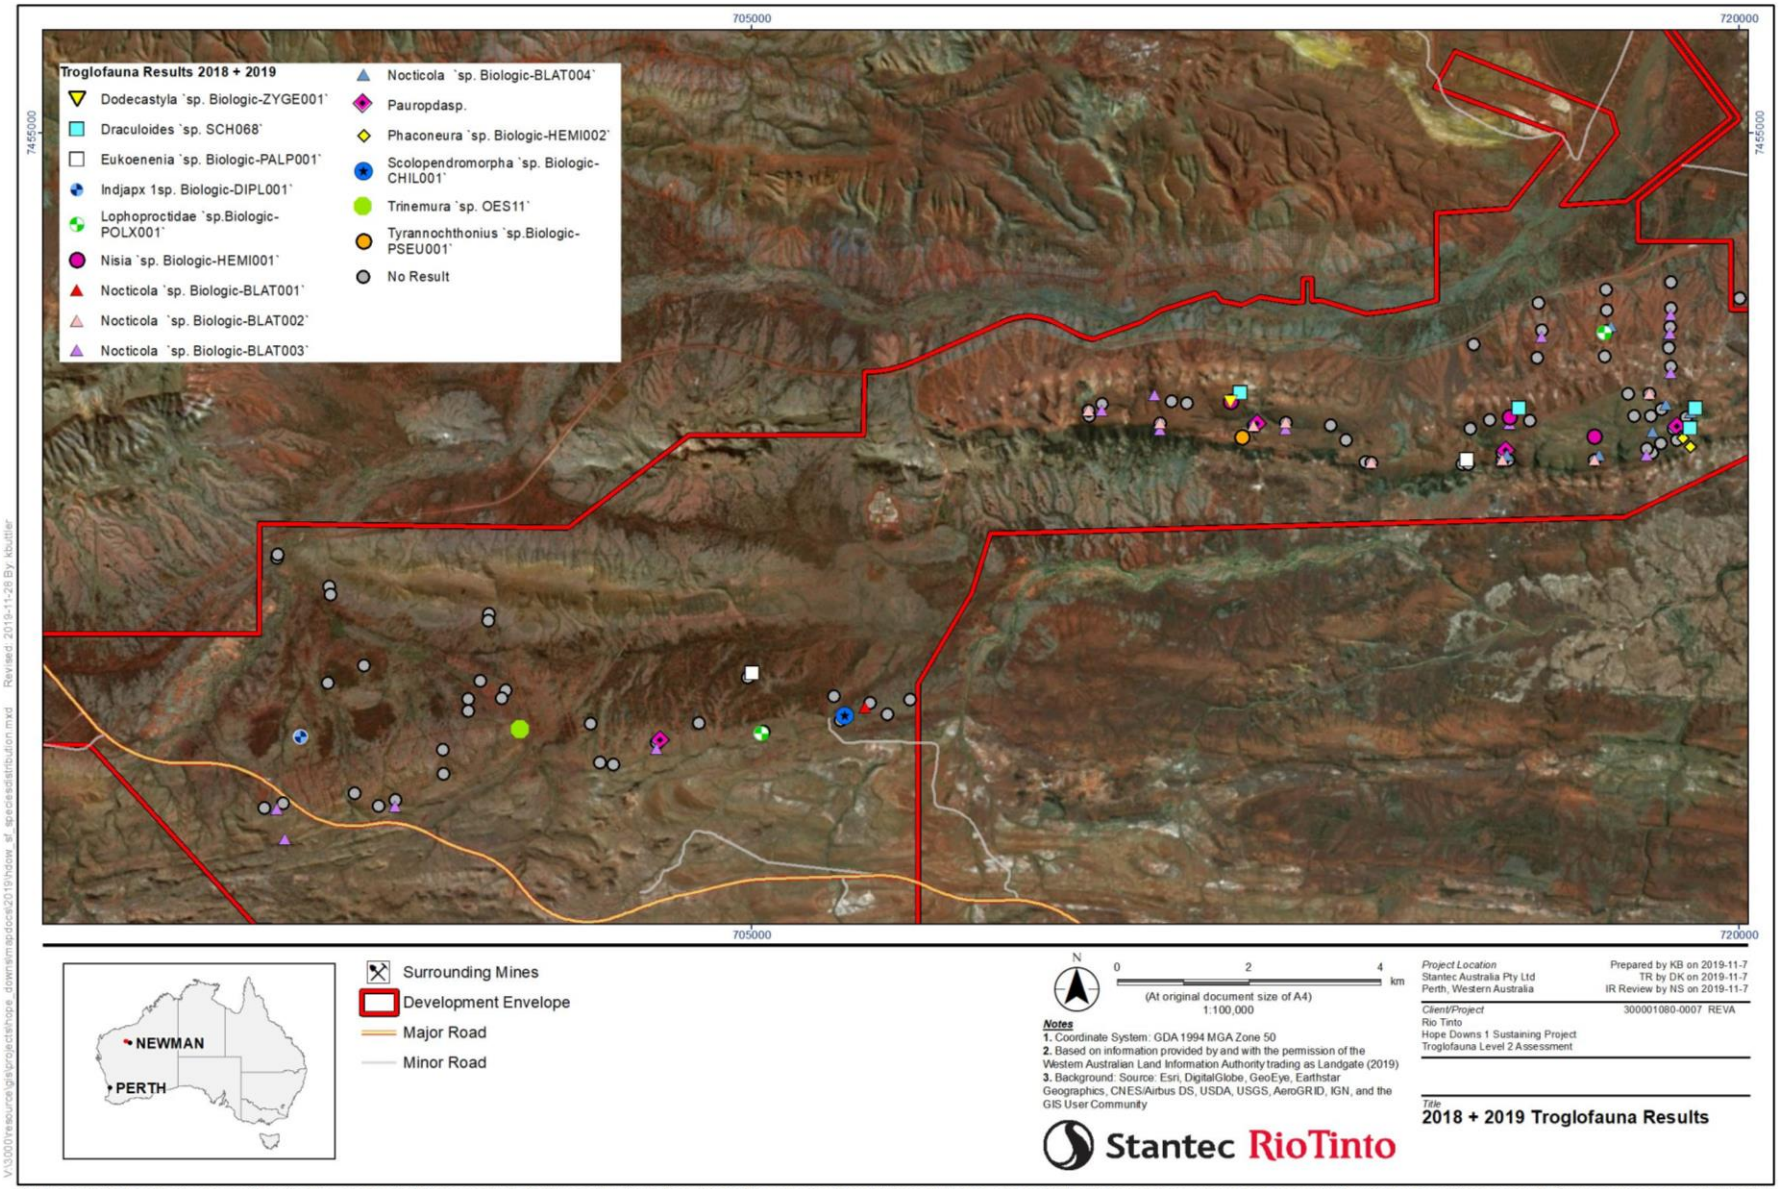
Within BHT, troglofauna were recorded from 27 (50%) of the 54 sites sampled, and 36 (23%) of the 158 samples collected in 2018 and 2019. Within the HD2, troglofauna were not collected as commonly as at BHT, with material recorded from 10 (29%) of the 38 sites sampled, and 13 (10%) of the 124 samples collected.

The nocticolid cockroaches were the most abundant and species rich group, with genetic analysis revealing four *Nocticola* species to occur (**Appendix B**). *Nocticola* `sp. Biologic-BLAT003` was the most abundant and widespread species, with 47 specimens collected from BHT and HD2 (**Figure 5-9**, **Figure 5-10**). The 14 sites from which *Nocticola* `sp. Biologic-BLAT003` was recorded occurred within mapped Brockman BIF, colluvial, and Mount McRae Shale surface geologies (**Figure 5-10**) from modelled prospective habitat profiles ranging from deep, particularly at HD2, to more commonly relatively shallow (**Figure 5-11**, **Figure 5-12**, **Figure 5-13**, **Table 5-1**).

The troglobitic schizomid, *Draculoides* `sp. SCH068`, was also relatively abundant with 13 specimens collected in total from the BH and BHT deposits from within mapped Brockman and Marra Mamba BIF, and Mount McRae Shale surface geological units (**Figure 5-4**, **Figure 5-6**, **Figure 5-10**, **Table 5-1**) from modelled prospective habitat profiles that ranged in thickness from 14 to 53 m (**Figure 5-11**, **Figure 5-12**).

Of the 16 identified species recorded to date from BHT and HD2, seven species (*Dodecastyla* `sp. Biologic-ZYGE001`, *Indjapx* `sp. Biologic-DIPL001`, *Lagynochthonius* `sp. WAMPSE096`, *Nocticola* `sp. Biologic-BLAT001`, Scolopendromorpha `sp. Biologic-CHIL001`, *Trinemura* `sp. OES11`, and *Tyrannochthonius* `sp. Biologic-PSEU001`), were recorded as singletons or from a single site only (**Table 5-1**). There is the possibility that at least two of the singleton species, *Indjapx* `sp. Biologic-DIPL001` and *Nocticola* `sp. Biologic-BLAT001`, could be represented in material collected previously as part of the HD1 and BH troglofauna assessments that was not identified to species by morphological examination or molecular analysis (Biota 2011;2014a;2015a;b) (**Appendix D**). The early collected specimens of Blattodea and Japygidae have not yet been compared morphologically or genetically to the 2018 and 2019 material. Most of the Blattodea material collected in 2018 and 2019 was represented by juvenile specimens so morphological comparison would not be a valid method of investigating taxonomic alignment. Morphological examination of the japygid material could achieve a level of taxonomic alignment, however, this would not be as robust as genetic analysis.

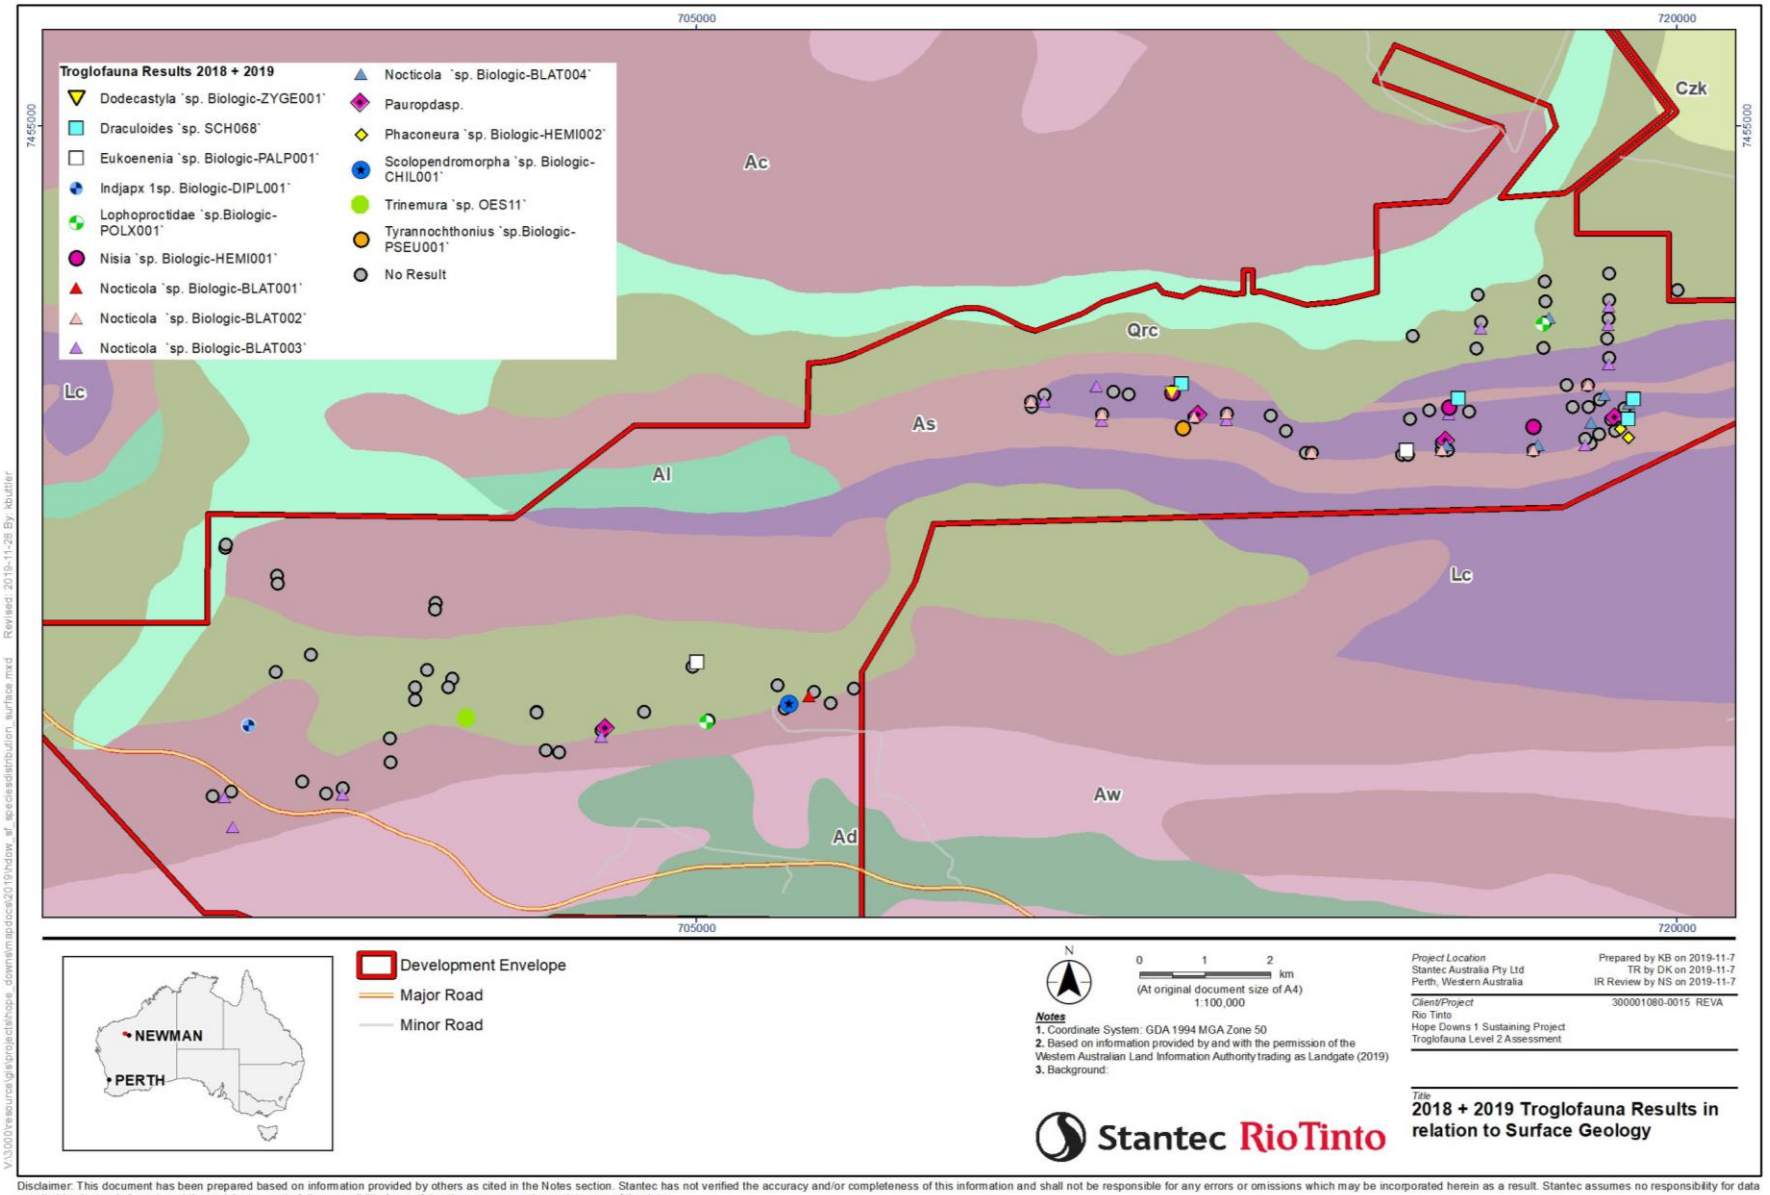
The genetic analysis of 2018 and 2019 material, with other available sequences of Pilbara material included, did find that three species, the singleton *Dodecastyla* `sp. Biologic-ZYGE001`, Lophoproctidae `sp. Biologic-POLX001`, and *Nisia* `sp. Biologic-HEMI001` belonged to relatively widespread troglophillic species, with linear distributions extending for over 140 km, 300 km, and 175 km, respectively (**Appendix B**, **Table 5-2**).



The majority of the species recorded from BHT and HD2 are considered to be troglophiles for reasons outlined in **Table 5-2**. Four species are considered to be troglobitic: *Eukoenenia* `sp. Biologic-PALP001`, *Tyrannochthonius* `sp. Biologic-PSE001`, *Lagynochthonius* `sp. WAMPSE096` and *Draculoides* `sp. SCH068` (**Table 5-2**). All the troglobitic species have been recorded from BHT, with only one troglobite recorded from HD2, *Eukoenenia* `sp. Biologic-PALP001`, that was also shared with BHT. There are three species, Scolopendromorpha `sp. Biologic-CHIL001`, *Indjapx* OES7, and *Trinemura* OES11, all recorded as singletons from HD2, that are likely to be troglophiles but this status remains uncertain.

Additional details of the taxonomic groups recorded are provided in **Table 5-2**.

Table 5-1: Troglofauna results



Taxon	ID Method	Abun-dance	Deposit	Number of Sites	Linear Range (km)	Sample Method	Sample Depth (m bgl)	Mapped Geological Unit	Modelled Habitat Profile Thickness (m)	SRE Category (subcategory)	Troglofauna Status

Figure 5-14: Troglofauna taxa collected pre-2018 as well as 2018 and 2019 relevant to surface geology and modelled habitat.

Table 5-2: Details of troglofauna taxa recorded

Palpigradi
• Are de-pigmented, blind invertebrate-predators prone to desiccation so rarely seen on the surface, usually found in humid conditons in the soil, under rocks, or subterranean habitats in caves and karstic/ vuggy geology (Harvey 2003). • Taxonomic framework not well established, with few described species known globally and from Australia (Harvey et al. 2006). • Many of the described epigean species may display widespread distributions as a result of anthropogenic aided dispersal (Harvey et al. 2006). • There are known troglobitic species (Souza and Ferreira 2016;2019), including *Eukoenenia guzikae*, the first formally described Australian native species, recorded from the Sturt Meadows calcrete system in the Yilgarn region of Western Australia (Barranco and Harvey 2008). • Undescribed troglobitic species have been recorded from other Yilgarn calcrete habitats (Subterranean Ecology 2011b) as well as karstic, banded iron formation and alluvial/colluvial habitats in the Pilbara region, including areas near to the BHT and HD2 deposit sites (Bennelongia 2015b; Biota 2015b; Outback Ecology 2009)(Appendix C).
Eukoenenia `sp. Biologic-PALP001`
• Linear range of distribution displayed exceeds 11 km. The species distribution is considered likely to range further considering the contiguous habitat present that extends more broadly in and around each of the deposits. • DNA analysis — Only the HD2 specimen successfully sequenced (CO1). The lineage was found to be >55% divergent from the nearest lineage included in analysis. The BHT specimen failed to sequence, so conspecific status with HD2 is based on morphological examination only.
Pseudoscorpiones
• The pseudoscorpion genera *Lagynochthonius* and *Tyrannochthonius* were once considered to be two separate but closely related genera based on distinctive morphological characteristics differentiating the two groups (Edward and Harvey 2008). However, genetic data has demonstrated that the morphologically distinct groupings do actually form a single genus (Harrison *et al.* 2014). The group is composed of epigean (surface) species (possess eyes) and troglobitic species (no eye development and elongated appendages). • All species are considered to be SRE's (Edward and Harvey 2008; Harrison *et al.* 2014). • Troglobitic *Lagynochthonius* and *Tyrannochthonius* species are relatively commonly recorded in subterranean fauna surveys, often with numerous species recorded in a limited geographic area, but in low abundances, often as singletons (Bennelongia 2015b;2016; MWH 2015; Outback Ecology 2011b;2012b; Subterranean Ecology 2011a)(**Appendix C**). • Where multiple specimens of a species have been genetically analysed, linear distributions have been shown to range for a least 5 km or 12 km (MWH 2015; Outback Ecology 2011b;2012b; Harrison *et al.* 2014).
Tyrannochthonius `sp. Biologic-PSEU001`
• Collected as a singleton so not able to empirically determine distribution. However, based on results from better documented *Tyrannochthonius* and *Lagynochthonius* species, it is considered likely that this species has a broader distribution than currently known that is likely to extend along much of the BHT landform. • DNA analysis — The CO1 sequence was >19% divergent from the nearest lineage included in analysis.
Lagynochthonius `sp. WAMPSE096`
• Collected as a singleton so not able to empirically determine distribution. However, based on results from better documented *Tyrannochthonius* and *Lagynochthonius* species, it is considered likely that this species has a broader distribution than currently known that is likely to extend along much of the BHT landform. • Identified morphologically only, no DNA sequence obtained.
Schizomida
• Troglobitic schizomids in Western Australia have been relatively well studied with unpublished (e.g., Rio Tinto Robe Valley studies) and published (Abrams and Harvey 2015; Abrams *et al.* 2019; Harvey *et al.* 2008b) genetic studies confirming the SRE status of *Draculoides* species.
Draculoides `sp. SCH068`
• Distribution considered likely to extend throughout much of BHT and BH, and further west along the landform hosting BH deposit. Considered not to occur at HD2. • DNA analysis — The eight specimens sequenced were found to fall into the same clade as previously sequenced material (Abrams *et al.* 2019).

Scolopendromorpha
• A troglobitic scolopendromorph species with distinctly elongated appendages was described from the Nullarbor Plains of Western Australia (Edgecombe 2005), however, the troglomorphic status of centipedes collected in subterranean surveys is difficult to determine as many known epigean species are generally pale and eyeless. • Commonly collected as singletons (Bennelongia 2015b; MWH 2016a; Subterranean Ecology 2008b).
Scolopendromorpha `sp. Biologic-CHIL001`
• Singleton recorded from colluvial habitat within the HD2 deposit area. The species distribution is considered likely to range further considering the contiguous habitat present that extends more broadly in and around the deposit. • Did not display distinctly elongate appendages and considered more likely to be a troglophile. • DNA analysis — The specimen successfully sequenced for CO1. Was found to be >21% divergent from the nearest lineage included in analysis.
Polyxenida
• Genetic studies of troglomorphic polyxenida material have indicated that many polyxenid species are not short range endemics as they can have extensive distributions ranging across hundreds of kilometres from the northern Goldfields region of Western Australia to the Pilbara (MWH 2014b; Outback Ecology 2011b;2013; Stantec 2017b).
Lophoproctidae `sp. Biologic-POLX001`
• Recorded from BHT and HD2 within mapped colluvial and Mount McRae Shale surface geologies. • Distribution is considered likely to be relatively widespread within the colluvial and detritals in and around the Development Envelope. • DNA analysis — One specimen successfully sequenced for CO1 that was found to belong to a widespread species sequenced from other project areas (Greater Brockman, Robe Headwaters, West Turner Syncline, Mesa G, and Paraburdoo), displaying a linear distance of more than 300 km. Previously collected polyxenid material from BH and HD1 was not sequenced so has not been compared with BHT and HD2 material.
Diplura
• All dipluran species have evolved to be largely unpigmented with no eye development and rely on highly specialised antennae for sensing their environment. • Most species are known to be soil dwelling (edaphofauna), particularly in more mesic environments (Naumann 1991). • Dipluran taxa are often recorded in subterranean fauna assessments from cavernous subterranean habitats (Subterranean Ecology 2010) as well as alluvial soil profiles (Outback Ecology 2011b). • Not enough is known about the group to conclusively determine if specimens collected are true troglobites or if they are edaphofauna, particularly as all species are pale and blind. • A dipluran taxonomist has considered that most diplurans collected in Western Australia are likely to be soil dwelling species (A. Sendra pers. comm. in Subterranean Ecology 2011b).
Indjapx `sp. Biologic-DIPL001`
• The single specimen recorded from HD2 has not be compared morphologically or genetically to earlier collected Japygidae from BH and HD1. Morphological examination of the japygid material could achieve a level of taxonomic alignment, however, this would not be as robust as genetic analysis. • Distribution is considered to be relatively widespread, extending along the contiguous habitat present in and around the Development Envelope. • DNA analysis — The specimen successfully sequenced for CO1. Was found to be >16% divergent from the nearest lineage included in analysis.
Blattodea: Nocticola
• *Nocticola* species are relatively commonly found from many locations throughout the Pilbara and often represent the most abundant troglofauna group recorded (Ecologia Environment 2011; Stantec 2017b; Subterranean Ecology 2007;2008a;c;2012) (**Appendix C**). • Unpublished genetic data has shown a Pilbara *Nocticola* species to possess a linear distribution of over 125 km suggesting some species may not be SRE. • Many *Nocticola* species do appear to be SRE but with less confined distributions compared to troglobitic SRE: e.g. arachnids, diplopods (Ecologia Environment 2011; MWH 2014a; Subterranean Ecology 2012). • *Nocticola* material collected in the 2018 and 2019 surveys was mostly juvenile so morphological comparisons with previously collected material from HD1, BH and BHT would not be valid as adult material, particularly male, is required. Sequencing of previously collected material would be required to properly investigate relationships present and achieve taxonomic aligments.
Nocticola `sp. Biologic-BLAT001`

• Singleton collected from HD2 deposit area, from mapped colluvial surface geology within medium modelled habitat profile depth. • The distribution of this species appears likely to extend further to the west of HD2 and the Development Envelope, and likely not at BHT. • DNA analysis — The CO1 sequence was 7% divergent from *N*. BLAT002, 11% divergent from *N*. BLAT004 and >21% from *N*. BLAT003.
Nocticola `sp. Biologic-BLAT002`
• Collected from across much of the BHT ridge system within BIF and fractured rock surface geology within shallow to medium modelled habitat profile depths. • Not recorded from beyond the BHT landform, but is considered likely that does occur more broadly. • DNA analysis — The CO1 intra-specific divergence shown was 1%. The interspecific divergence shown was: 7% from *N*. BLAT001; >9% from *N*. BLAT004; and >21% from *N*. BLAT003.
Nocticola `sp. Biologic-BLAT003`
• The most abundant and widespread species recorded from both BHT and HD2, found within broad range of surface geologies from BIF, colluvial and fractured rock, from within shallow to deep modelled habitat profile depths. • The linear range of 22.5 km that extended from low lying areas, including the low HD2 landform, to along the BHT ridge system, indicates that this species would occur more broadly beyond the Development Envelope. • DNA analysis — The CO1 maximum intra-specific divergence shown was 3%. The interspecific divergence shown was >19% from all other *Nocticola* material sequenced from Development Envelope.
Nocticola `sp. Biologic-BLAT004`
• Collected from BHT within mapped Brockman BIF and colluvial surface geologies, from within shallow to deep modelled habitat profile depths. • Linear range extent 2.5 km, extending from low lying colluvial geology to north of BHT, to along eastern portion of BHT ridge system. • DNA analysis — The CO1 intra-specific divergence shown was 1%. The interspecific divergence shown was: 9% from *N*. BLAT002; >11% from *N*. BLAT001; and >20%from *N*. BLAT003.
Hemiptera: Meenoplidae
• Published and unpublished genetic studies have indicated that some Meenoplidae species collected in subterranean fauna surveys are relatively widely distributed and not likely SRE (Subterranean Ecology 2008c). • *Nisia* material can be relatively abundantly collected in subterranean fauna surveys, represented mostly by early and late juvenile stages, but less commonly by fully winged adults with full eye development (Stantec 2017b); therefore, as with cicadas, the blind juveniles are troglophilic confined to the hypogean environment feeding on plant roots with the adults representing the epigean dispersal stage. • Adult *Phaconeura* material collected has also displayed full wing development but with significantly reduced eyes such that are unlikely to be functional other than for detecting differences in light and dark. Due to the reduced eye development found, it is suspected that the dispersal capacity of *Phaconeura* species may be limited compared to *Nisia* species (Stantec 2017b). • No adult meenoplid material was collected in the 2018 and 2019 surveys.
Nisia `sp. Biologic-HEMI001`
• Distribution within the Development Envelope shown to extend along much of the BHT ridge system, from a limited number of sites (3) only. • DNA analysis — The CO1 sequence data found that BHT material belonged to a widespread species sequenced from another project area, Greater Brockman, displaying a linear distance of more than 175 km.
Phaconeura `sp. Biologic-HEMI002`
• Only known from two neighbouring sites located on the south eastern margin of BHT. However, based on knowledge of other Phaconeara species that also have a non-troglophillic adult dispersal stage, the distribution of this species is considered to occur more broadly beyond the Development Envelope. • DNA analysis — One specimen successfully sequenced for CO1 and was found to be >11% divergent from the nearest lineage included in analysis.

Zygentoma: Atelurinae
• Atelurinae species are more commonly regarded as inquilines within termite or ant nests, however, are also found within soil and cave environments independent of a host nest (Smith and McRae 2014). Recent species described from the Pilbara were considered to be troglophillic (Smith and McRae 2014).
Dodecastyla `sp. Biologic-ZYGE001`
• Collected from a single site within BHT ridge system. • Species considered troglophillic • DNA analysis — The 12S sequence was found to belong to a relatively widespread species sequenced from other project areas (West Angelas and Paraburdoo), displaying a linear distance of more than 140 km.
Zygentoma: Nicoletiinae
• Troglobitic *Trinemura* species have been described from the Pilbara, that displayed larger body size and elongated appendages (e.g., longer antennal length versus head width) compared to other Pilbara species commonly collected in subterranean fauna surveys that were considered to be hypogean (Smith 1998; Smith *et al.* 2012).
Trinemura `sp. OES11`
• Singleton recorded from colluvial geology at HD2. • Distribution is considered likely to be relatively widespread, extending along the contiguous habitat present in and around the HD2 deposit. • The specimen was missing all appendages so not able to assess morphologically for troglobitic features such as elongated appendages. However, condition of head and body sufficient for generic determination. Specimen not sent for DNA analysis.
Pauropoda
• All species are blind and pale known as soil and organic litter inhabitants. • Pauropods are relatively well documented from wetter regions in Australia, particularly Tasmania and the southwest of Western Australia, compared to the more arid regions of the continent where they are less common (Greenslade 2008; Scheller 2013). • Taxonomy of group not well known. • *Decapauropus tenuis*, known to occur in the Pilbara from Hope Downs, is considered to be a widespread species across the tropical, sub-tropical regions of the world (Scheller 2010).
Pauropoda sp. indet.
• Four specimens recorded from BHT and HD2 from mapped Brockman BIF and colluvial geology. • Specimens were not unable to be confirmed as the same species morphologically due to the lack of species level defining characters available for this group. • All specimens were submitted for genetic analysis but no DNA sequences were successfully obtained.

5.5 Troglofauna Species Richness Estimates and Survey Adequacy

Based on the 2018 and 2019 survey data only, the various species richness estimators indicated the total species richness within the Development Envelopment to range from 17.7 to 24 species (**Figure 5-15**, **Table 5-3**). The 15 taxa collected in 2018 and 2019 represent an estimated 63 % to 85 % of the total species predicted to occur in the Development Envelope. The species accumulation curves for five of the richness estimators were still trending upwards to varying degrees, with two estimators, Chao 1 and Chao 2 strongly trending downwards. The Bootstrap mean most closely resembled the rarefaction curve of the observed (S(est)). The species accumulation curves for other subterranean fauna surveys in Australia (e.g. Eberhard *et al.* 2009, Stantec 2017a) and overseas (Pipan and Culver 2007), can continue to trend upwards despite many years of intensive survey effort. The extrapolation of the observed species accumulation curve (S(ext)) indicates that increasing the survey effort by more than 100 % (i.e. from 283 to 566 samples) will likely record an additional four troglofauna species.

The sampling effort conducted to date across each of the deposit areas (BHT — 199 (including Biota 2015 sample effort of 41 samples); HD2 — 125), has exceeded the recommended minimum requirements of 60 impact samples for a Level 2 troglofauna survey (EPA 2016a, b). The total number of troglofauna samples collected is considered sufficient to provide a reliable characterisation of the troglofauna values present for the BHT and HD2 deposits within the Development Envelope to properly inform an EIA.

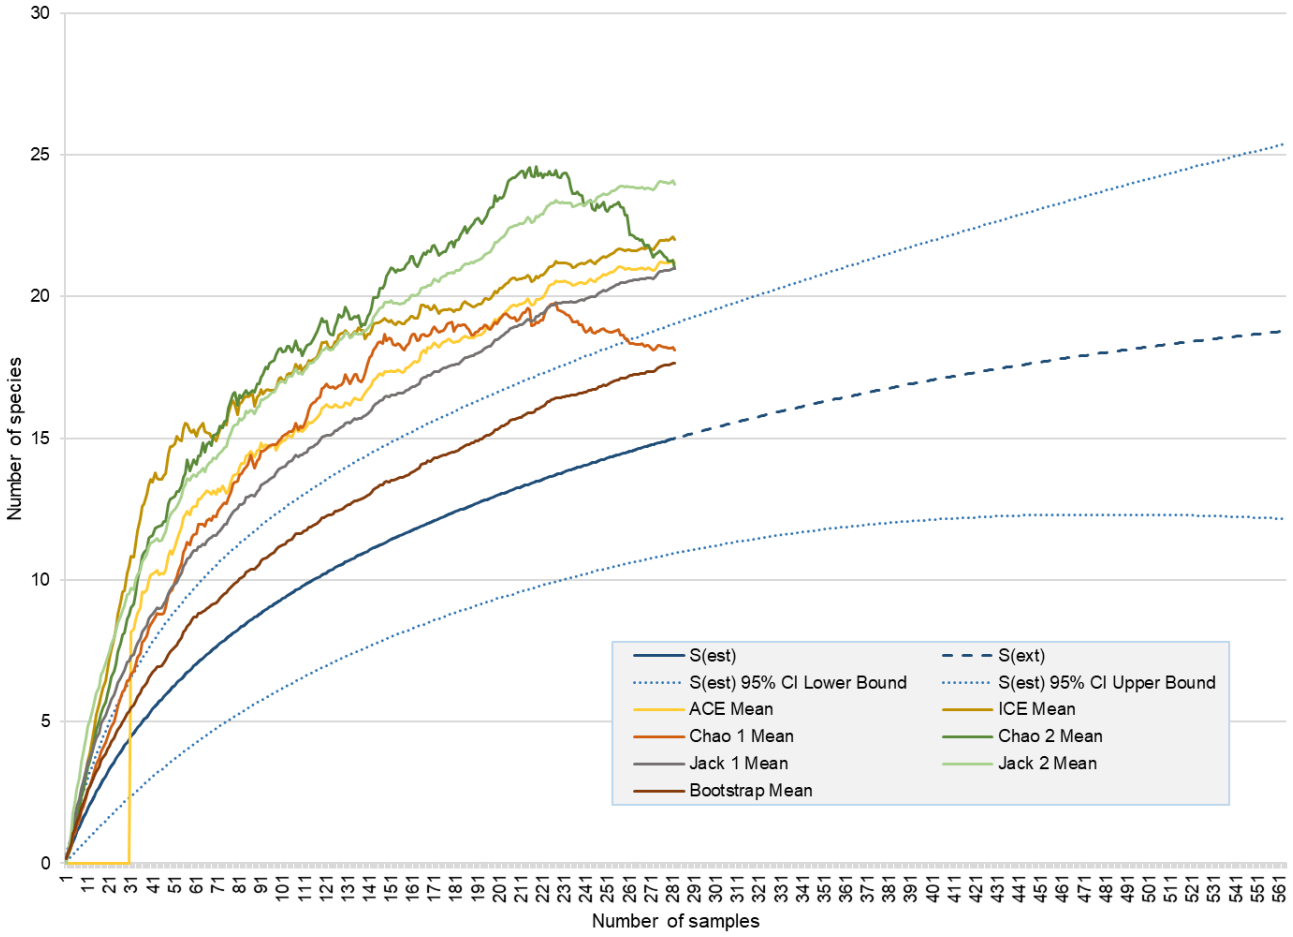

Figure 5-15: Troglofauna species accumulation curves for various diversity estimators and rarefaction curves for observed (S(est)) and extrapolated (S(ext) for the 2018 and 2019 results

Table 5-3: Observed 2018 and 2019 troglofauna species diversity for the Development Envelope compared to estimated diversity using EstimateS (Colwell 2013) diversity estimators

	Observed vs Estimated	Obs. & Pred. spp richness	% Predicted collected
Obs.	Sobs	15	
	Extrapolated (566 samples)	18.78	79.9%
Diversity estimators	Bootstrap Mean	17.7	84.9%
	Chao 1 Mean	18.1	82.9%
	Chao 2 Mean	21.0	71.5%
	Jack 1 Mean	21.0	71.5%
	ACE Mean	21.2	70.8%
	ICE Mean	22.0	68.1%
	Jack 2 Mean	24.0	62.6%
	Range	17.7 — 24	62.6 — 84.9%

6. Discussion

It is known in the Pilbara that the distribution of troglofauna can strongly depend on the continuity of the landforms in which they are found. A well documented example concerns the Robe Valley pisolitic mesas that have been shown to each host distinct troglofauna assemblages, with resident troglobitic species confined in distribution to a particular discrete landform (Burger *et al.* 2012; Harvey *et al.* 2008a; Humphreys *et al.* 2006). The genetic analysis of the Robe Valley schizomid fauna clearly demonstrated that six Mesa landforms each hosted an endemic schizomid species (Harvey *et al.* 2008a). This trend was also shown by other troglobitic arachnid and diplopod species (Burger *et al.* 2012). By contrast, the troglofauna distributions within HD2 Proposal Development Envelope indicate that the landforms present are not as isolated from the surrounding landscape as the Robe Valley Mesa's. The genetic analysis of the troglobitic schizomid material from in and around the Development Envelope demonstrated that both *Draculoides* `sp. SCH067`and *D*. `sp. SCH068`were not restricted to a single landform (**Figure 5-14**) (Abrams *et al.* 2019). The distribution of *D.* SCH067 was found to extend from the mapped BIF surface geology from within the BH deposit, north-eastwards to the Weeli Wolli calcrete system. *Draculoides* SCH068 was shown to extend in a southerly direction from near HD1, through BH to atop the BHT ridge system. *Eukoenenia* `sp. Biologic-PALP001` was also found to have a distribution that was not confined to a single landform, with specimens collected from both BHT and HD2 deposits (**Figure 5-14**).

The distribution range of *Draculoides* SCH068 within BH to BHT deposits correlated with the high confidence 3D modelled extent of prospective troglofauna habitat in and near the Development Envelope. The modelled habitat profiles showed that shallow to medium depth habitable profiles extend between both BH and BHT landforms, with deeper profiles occurring to varying depths along each landform. Within the high confidence modelled extent, shallow to medium habitat profiles were shown to occur within the mapped surface alluvial, colluvial and weathered and fractured outcrop formations of the Mount McRae Shale and Mount Sylvia Formations geological units. The deeper habitable profiles coincided more with the mapped BIF surface geological units present.

Seven of the troglofauna species recorded are known from a single specimen or site only. It is not possible to reliably assess the distribution range or habitat preferences of troglofauna species known from only a single location. The seemingly restricted distribution is considered more likely to be an artefact of that species occurring at a low population density and/or possessing an irregular distribution in response to varying habitat factors, biological interactions and availability of energy resources, rather than the actual distribution being confined to one limited area that was intercepted by a single drill hole.

Biological and physical surrogates can assist in determining likely species distributions and addressing the artefact of sampling difficulties associated with subterranean fauna, as recommended by the EPA (2016b). Considering the expanse of neighbouring geological habitat (physical surrogate) as well as reviewing records of closely related species, or species collected sympatrically (biological surrogates), can provide further insight into the potential distribution patterns of species that are known from limit records. The distribution of the troglobite and confirmed SRE, *D.* SCH068, along with the broader occurrence of the modelled habitat, support the notion that the species recorded to date from a single location are likely to possess a broader distribution within and around each landform.

7. Conclusion

The subterranean fauna assessment reported here has shown that the BHT and HD2 deposits do host a relatively diverse troglofauna assemblage with prospective modelled habitat present within the mineralised Brockman and Marra Mamba BIF, as well as within the associated alluvial, colluvial and fractured, weathered rock units.

8. Glossary

alluvium – sediment deposited by a stream or river

aquatic – relating to water

aquifer – a body of permeable rock or sediment capable of storing groundwater

arid – a region characterised by a severe lack of available water, to the extent that the growth and development of biota is hindered or prevented

bedrock – consolidated rock attached to the earth's crust

biodiversity – the diversity of biota in a particular environment or region

calcrete – carbonate deposits that form in arid environments, as a result of groundwater evaporation

cave – a subsurface cavity of sufficient size that a human could enter

dissolved oxygen – a measure of the amount of gaseous oxygen dissolved in a solution; oxic = > 3 mg/L; dysoxic = 0.3 to 3.0 mg/L; suboxic = < 0.3 mg/L levels

distribution range – the overall geographic area that a species is known to occur in

divergence – degree of separation from a common ancestor

diversity – a combination of species richness and abundance

drawdown – the lowering of the adjacent water table or piezometric surface as a result of groundwater extraction

ecotone – zone of transition among different ecosystems

electrical conductivity – an estimate of the total dissolved salts in a solution, or salinity

endemic – having a distribution restricted to a particular geographic region

epigean – pertaining to the surface zone

fractured rock – a rock formation characterized by separation or discontinuity, usually as a result of geological stress (e.g. faulting)

geological ages (e.g. Cainozoic) – distinct time periods within the geological history of the earth

groundwater – water occurring below the ground surface

habitat – an ecological or environmental area that is inhabited by a particular animal or plant species

hypogean – pertaining to the subterranean zone

hyporheic zone – spatially fluctuating ecotone within the bed of a river or stream between surface and groundwater. Considered important component of groundwater ecosystems and involved in the 'interstitial highway', forming hyporheic corridor linking associated aquifers.

invertebrates – animals lacking vertebrae

karst – a region of limestone or other soluble rock, characterized by distinctive features such as caves, caverns, sinkholes, underground streams and springs

lineage – a group of organisms related by descent from a common ancestor

molecular – pertaining to the genetic characteristics of an organism or group

morphology – the specific form and structure of an organism or taxon

morphospecies – a general grouping of organisms that share similar morphological traits, but is not necessarily defined by a formal taxonomic rank

palaeoriver, palaeochannel, palaeodrainage – a remnant of a stream or river channel cut in older rock and filled by the sediments of younger overlying rock

pH – a measure of the hydrogen ion concentration of a soil or solution (values below pH of 6.5 are 'acidic', and those above pH 7.5 are 'alkaline')

relictual – having survived as a remnant

salinity – the concentration of all dissolved salts in a solution. The salinity level classification *sensu* Hammer (1986): freshwater = salinity less than 5 mS/cm (3 ppt); hyposaline = salinity ranging from 5–30 mS/cm (3–20 ppt); mesosaline = salinity ranging from 30–70 mS/cm (20–50 ppt); hypersaline = salinity equal to or greater than 70 mS/cm (50 ppt)

semi-arid – a climatic region that receives low annual rainfall (250 – 500 mm)

species – a formal taxonomic unit defining a group or population of organisms that share distinctive characters or traits, are reproductively viable and/or are otherwise identifiable as a related group

species richness – the number of species present in a particular habitat, ecosystem or region

species accumulation curve – a model used to estimate species diversity or richness

standing water level (SWL) – the depth to groundwater from a particular reference point (e.g. in a monitoring bore)

stygal – pertaining to groundwater habitat or biota

stygobite – an obligate aquatic species of groundwater habitats

stygobiont – another term used to describe obligate inhabitants of groundwater systems

stygofauna – a general term for aquatic groundwater fauna

stygophile – an aquatic species that temporarily or permanently inhabits groundwater habitats

stygoxene – an aquatic species that has no fixed affinity with groundwater habitats, but may nonetheless occur in groundwater habitats

sympatry / sympatric – two or more species that are considered to exist in the same or overlapping geographic area and may regularly interact with, or encounter, each another (without interbreeding)

taxon (singular), taxa (plural) – an identifiable group of organisms, usually based on a known or inferred relationship or a shared set of distinctive characteristics

troglobite – an obligate terrestrial species of subterranean habitats

troglofauna – a general term for terrestrial subterranean fauna

troglomorphic features – morphological characteristics resulting from an adaptation to subterranean habitats (e.g. a reduction in pigment)

troglophile – a terrestrial species that temporarily or permanently inhabits subterranean habitats

trogloxene – a terrestrial species that has no fixed affinity with subterranean habitats, but may nonetheless occur in subterranean habitats

void – a pore space in the rock or stratum

Yilgarn – pertaining to the Yilgarn Craton, a 65,000 km2 body of the earth's crust in south-western Australia that dates back to the Archaean period, 2.6 to 3.7 million years ago

Appendix B Molecular Analyses

Hope Downs 1
Subterranean Fauna
Molecular Systematics Analysis

Biologic Environmental Survey

Report to Stantec Pty Ltd

November 2019

1 INTRODUCTION

Stantec Pty Ltd (Stantec) commissioned Biologic Environmental Survey (Biologic) to undertake a molecular systematics analysis (DNA barcoding) of 44 subterranean fauna (stygofauna and troglofauna) specimens collected from Rio Tinto's Hope Downs 1 (HDOW1) Project (the Study Area).

1.1 Aims and objectives

The aims and objectives of the molecular systematics analysis were to:

- Undertake DNA sequencing of 44 subterranean fauna specimens to obtain barcoding sequences of the mitochondrial gene Cytochrome Oxidase I (COI; Hebert *et al.* 2003), and the nuclear gene 12S for Zygentoma specimens;
- Investigate the interspecific and intraspecific relationships between sequences of each higher taxonomic group (i.e. use the results of the DNA analysis to indicate how many different species/ OTUs are likely to occur within each genus or relevant higher taxon, based on published species-thresholds); and
- Investigate the relationships between sequences from the HDOW1 specimens and relevant previous sequences from the wider Pilbara region, using available DNA databases (i.e. compare the results of the current analysis with accessible DNA databases to assess whether any of the species/ OTUs from the Study Area have been collected previously or more widely beyond the Study Area).

This document reports the methods and results of the molecular systematics analysis. Any remaining specimen material has been returned to Stantec, and sequence data has been incorporated within the Rio Tinto (RTIO) molecular sequence database and uploaded to GenBank as per Rio Tinto requirements.

2 METHODS

2.1 Sub-sample preparation

A total of 44 subterranean fauna specimens collected from the HDOW1 Study Area by Stantec, were sent to Biologic for molecular systematics analysis. The specimens belonged to seven different classes comprising 11 orders, nine families, and eight genera, based on morphological identifications conducted by Stantec.

Where whole specimens were submitted, Biologic undertook tissue preparation by removing a leg, briefly drying off the ethanol, and placing the tissue in ATL buffer. Where tissue was submitted, these were briefly dried and placed in ATL buffer at Biologic's laboratories. In all instances, greatest care was taken to decontaminate all tools and equipment between samples, using bleach and repeated rinsing in deionised water. Table 2.1 provides morphological identification details for each specimen included in the analysis.

Table 2.1: Specimens and tissue samples included in the analysis (ordered by taxon and lot number).

2.2 DNA extraction, amplification and sequencing

DNA extraction and sequencing methods followed Cullen and Harvey (2017, 2018), as follows:

Subsampled tissue was placed directly into ATL buffer for extraction using the *QIAGEN DN-easy* extraction kit. 20µl of proteinase K was added and incubated overnight at 56°C, immediately prior to extraction. DNA samples were amplified by Polymerase Chain Reaction (PCR) using Folmer PCR primers (LCO1490, HCO2198; Folmer *et al.* 1994) to assess the variability of COI for taxa other than Zygentoma. Zygentoma samples were amplified using 12S primers (12Sai, 12Sbi; Simon *et al.* 1994).

Resulting PCR product was sequenced by the Australian Genomic Research Facility (AGRF) Perth node. Specimen records, extraction data, PCR results, and DNA sequence data were managed using GENEIOUS v 10.1.2 (Kearse *et al.* 2012) with the Biocode plugin (http://www.mooreabiocode.org).

2.3 Analysis of sequence alignments/ divergence

Raw sequence data were edited and assembled in GENEIOUS. Consensus sequences were BLASTed against GenBank to determine nearest matches within the target higher taxonomic group. The consensus sequences were then aligned using MAFFT (Multiple Alignment using Fast Fourier Transform) algorithm (Katoh *et al.* 2002). Trees were constructed on resulting alignments using the Geneious Tree Builder using Tamura-nei Genetic Distance Model and Neighbour-joining as the Tree Build Method. Sequence data obtained using the 12S primers were edited, aligned and resulting consensus sequences BLASTed against GenBank. Regional sequences were obtained from RTIO's molecular sequence database as well as genetic data from accessible previous reports (Helix Molecular Solutions) and were included in the tree building analyses.

Lineages determined in this study were defined using molecular data with reference to morphological identifications undertaken by Stantec. These designations were specific to each higher taxon and the level of taxonomic certainty involved. Fauna-specific thresholds for determining species-level divergence were used wherever possible, based on published literature and available previous reports.

Where fauna-specific thresholds from literature or reports were not available, the assessment used average divergence thresholds for related groups or higher taxa developed by broad-level studies (e.g. Hebert *et al.* 2003).

Based on the number of specimens within each taxonomic level, DNA comparisons were typically conducted at the order level as follows:

- Amphipoda (2 specimens, plus regional comparisons);
- Blattodea (20 specimens, plus regional comparisons);
- Chilopoda (1 specimen, plus regional comparisons);
- Diplura (1 specimen, plus regional comparisons);
- Hemiptera (6 specimens, plus regional comparisons);
- Palpigradi (2 specimens, plus regional comparisons);
- Pauropoda (1 specimen, plus regional comparisons);
- Polyxenida (1 specimen, plus regional comparisons);
- Pseudoscorpiones (1 specimen, plus regional comparisons);
- Schizomida (8 specimens, plus regional comparisons); and
- Zygentoma (1 specimen, plus regional comparisons).

2.4 Constraints and Limitations

The analysis was constrained by the breadth of data available to undertake comparisons, the accessibility of pre-existing regional sequences, and the success rate of genetic sequencing, which can be affected by specimen collection, preservation, and storage methods, as well as contamination. Our understanding is that best practises were followed during specimen collection, preservation, and storage, prior to specimens arriving at Biologic. All care was taken to ensure that the risks of laboratory contamination, data handling issues, and specimen management issues were minimised within Biologic's laboratories throughout the subsampling, processing and genetic analysis. This was largely reflected in the results, with a low rate of sequence failure (5/44 sequences, or 11%) and no contaminated samples detected.

The databases used for regional comparisons were limited to Genbank, the RTIO molecular sequence database, and available data from previous genetic reports conducted for RTIO (by Helix Molecular Solutions). While these sequence databases, in combination, comprise a large portion of the subterranean fauna genetic work that has been undertaken for RTIO in the Pilbara region, it is acknowledged that there may be many other relevant sequences from third party project areas nearby or elsewhere in the region that were not available for comparison at the time of the study.

DNA barcoding using the mitochondrial gene COI, while useful for explaining genetic differences between closely-related or moderately-related species, is limited in its ability to resolve deeper phylogenies/ relationships between taxa at higher taxonomic levels (e.g. genus, family, order). In the current study, phylogenetic relationships between species/ OTUs at >25% COI divergence are treated with caution. If further resolution of deeper phylogeny is important for project goals, this could be investigated using a multiple gene approach.

3 RESULTS AND DISCUSSION

3.1 Amphipoda

Two specimens of Amphipoda (LN35584 and LN35145) were successfully sequenced from Baby Hope, from bores MB16SW0006 and MB16HD1SW0006 respectively. The two sequences showed a negligible level of divergence within their lineage (`Biologic-AMPH001`), indicating a single OTU (<0.1% COI). Stantec's morphological identifications of one of these specimens revealed a paramelitid amphipod, *Pilbarus* OES12 (nr *millsi*). The genetic results indicate that both specimens can be considered to belong to this taxon. Figure 3.1 shows a neighbour joining tree based on a comparison of 38 Amphipoda sequences from the available regional databases while Appendix 1 shows pairwise comparisons of sequences from the Study Area vs the sequence databases.

The sequences from the Study Area were not closely aligned (26%-45% COI) with any of the sequences included in these comparisons, suggesting that *Pilbarus* OES12 (nr millsi) has not been sequenced from elsewhere in the region (Figure 3.1, Appendix 1). There was a relatively high level of divergence (27%-29% COI) from previous specimens in the same taxonomic group, including *Pilbarus* and *Yilgarus* sequences from Paraburdoo/ Turee Creek, and Paramelitidae sequences from Yandi and Weeli Wolli. However, the average divergence compared to other Amphipoda taxa was the same or even higher; 29%-35% divergence from Bogidiellidae at Paraburdoo and Robe Valley, 39%-40% from *Nedsia* and Eriopsidae from Paraburdoo and Robe Valley, and 45% from Niphargidae at Tods Bore (Appendix 1).

Further genetic and morphological work may be required to validate the phylogenetic relationships of the current sequences with *Pilbarus* OES12 (nr millsi). Nevertheless, based on current results, Lineage `Biologic-AMPH001`/ *Pilbarus* OES12 (nr millsi) appears to represent a new/ unique OTU currently known only from the Study Area.

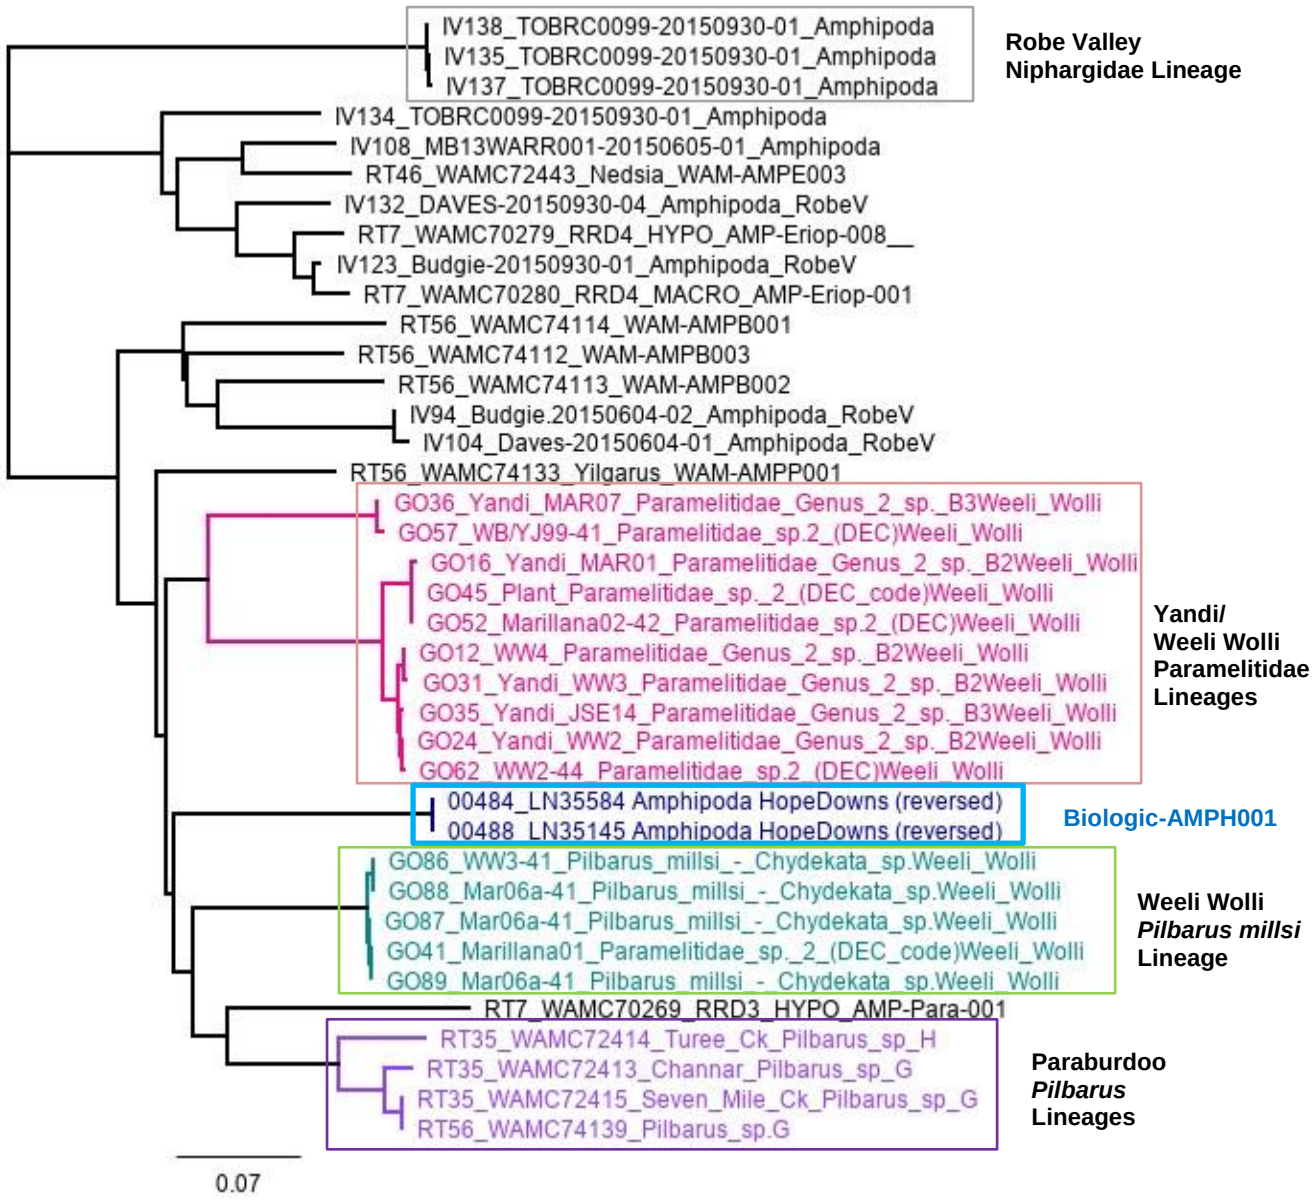

Figure 3.1. Neighbour Joining tree of Amphipoda haplotypes included in the analysis. Lineages from the Study Area are indicated by blue text.

3.2 Blattodea

All 20 specimens of Blattodea from Bedded Hill Top and Hope Downs 2 were successfully sequenced. Local comparisons revealed four lineages (intraspecific variability <3% COI), representing three to four potential OTUs (Table 3.1, Figure 3.2):

- *Nocticola* `Biologic-BLAT001` (LN34133, Hope Downs 2);
- *Nocticola* `Biologic-BLAT002` (LN33372, LN33532, LN34509, LN36536, and LN37718, Bedded Hill Top);
- *Nocticola* `Biologic-BLAT003` (LN33514, LN33574, LN35535, LN36514, LN36582, LN37412, and LN39408, Hope Downs 2 and Bedded Hill Top); and
- *Nocticola* `Biologic-BLAT004` (LN33391, LN35427, LN37424, LN37717, LN38726, LN34142, and LN38585, Bedded Hill Top).

Three of the four lineages (Biologic-BLAT002, BLAT003, and BLAT004) were well supported at COI divergences >8% (Appendix 2), indicating distinct species/ OTUs (based on average divergence thresholds Hebert *et al.* 2003). Lineage BLAT001 was only 7% different to BLAT002, indicating a borderline population/ species-level divergence, which may reflect geographical separation between Biologic-BLAT001 occurring in HD2 and BLAT002 in BHT. Nevertheless, based on a recent molecular study by Trotter *et al.* 2017 showing 3%-4% divergences between *Nocticola* species/ OTUs, 7% could be considered to indicate species-level divergence in *Nocticola*.

Table 3.1. Genetic results of *Nocticola* specimens from the Study Area (lineages represented by highlighted colours).

Area	Site Name	Morphological ID	No. of Individuals	Lot No. (LN)	BMR Code	Biologic-BLAT Lineage

BHT	RC16BHT0291	*Nocticola* OES13	tissue	LN38585	BMR00485	004

The genetic results did not match the morphological identifications, which determined only two OTUs (*N*. OES12 and *N*. OES13). While the morphological identifications within Lineages BLAT001, BLAT002, and BLAT003 were consistent (within each respective lineage), the high COI divergence (36%-39%) between Lineages BLAT002 and BLAT003 (both morphologically identified as *N*. OES13) suggested cryptic morphology or further taxonomic work may be required (Appendix 2).

In addition, BLAT004 contained specimens morphologically identified as both *N*. OES12 and *N*. OES13 (Table 3.1), despite intraspecific variability <1.1% (COI). Lineage BLAT003 showed slight intraspecific variability (2%-3% COI), although this was not consistent between specimens from the two different sampling areas; therefore, it is uncertain whether there could be separated populations within this lineage (Appendix 2).

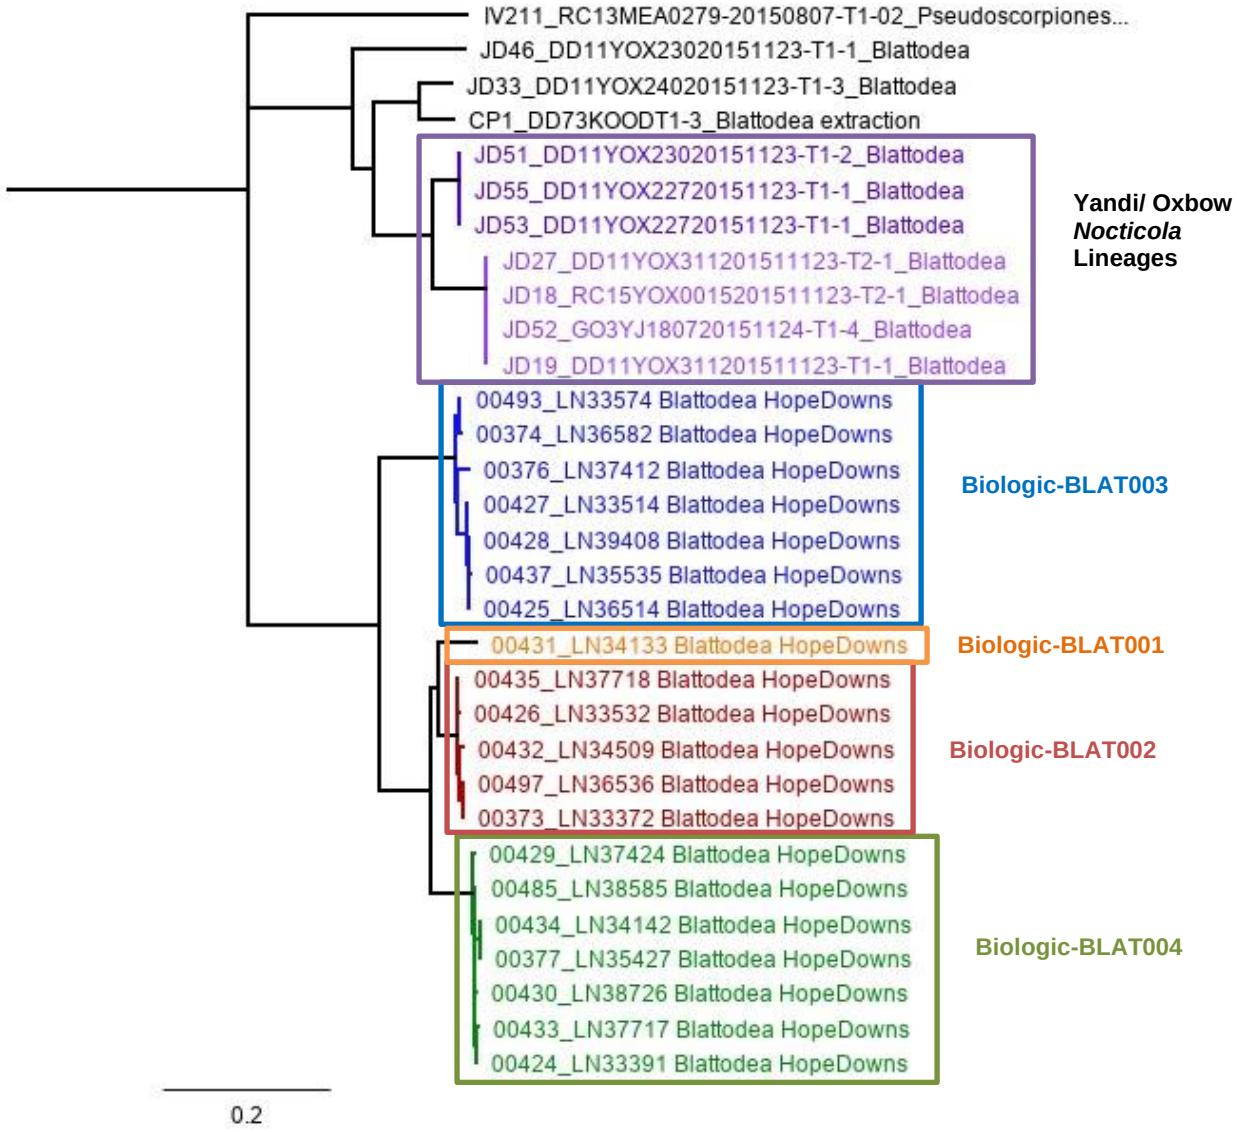

Figure 3.2. Neighbour Joining tree of Blattodea haplotypes (COI) included in the analysis. Lineages are indicated by coloured text.

In terms of sampling areas, Biologic-BLAT001, BLAT002, and BLAT004 were consistently collected from a single sampling area per lineage, while BLAT003 was collected in both Bedded Hill Top and Hope Downs 2. This suggests the potential for complicated evolutionary patterns such as allopatric and sympatric speciation, or multiple colonisations of subterranean habitats amongst the different OTUs of *Nocticola* from the Study Area.

Regional comparisons (Figure 3.2, Appendix 2) revealed that all sequences from the Study Area showed a high level of divergence (minimum 43% COI) from previous material based on a comparison of 11 regional sequences from the available databases. At this level of divergence all four lineages/ OTUs from the Study Area would be considered regionally unique (based on available sequences although further genetic (and potentially further morphological work) may be required to verify the deeper phylogenetic relationships.

3.3 Chilopoda

One specimen of Chilopoda (Scolopendromorpha sp.) (LN37426) was successfully sequenced at the COI gene (Biologic-CHIL001).

Regional comparisons (Figure 3.3) with previous sequences revealed a high COI divergence (min 21%) indicating that the lineage from the Study Area is not represented in the available sequence databases. This result was based on a comparison of 16 available subterranean Chilopoda sequences from the Pilbara region, and used the epigean species *Scolopendra mortisans* as an outgroup (Appendix 3).

Divergences were generally high between most lineages/ OTUs within the Chilopoda, excluding sequences likely representative of intraspecific variability (i.e. COI divergences below 3%) (Appendix 3). In this broader context the high divergences between Biologic-CHIL001 from the Study Area and other regional sequences was not considered out of trend with the rest of the group.

Based on comparisons with available databases, the Scolopendromorpha sp. `Biologic-CHIL001` collected from the Study Area appears to represent a new/ unique OTU that has not been sequenced elsewhere in the region.

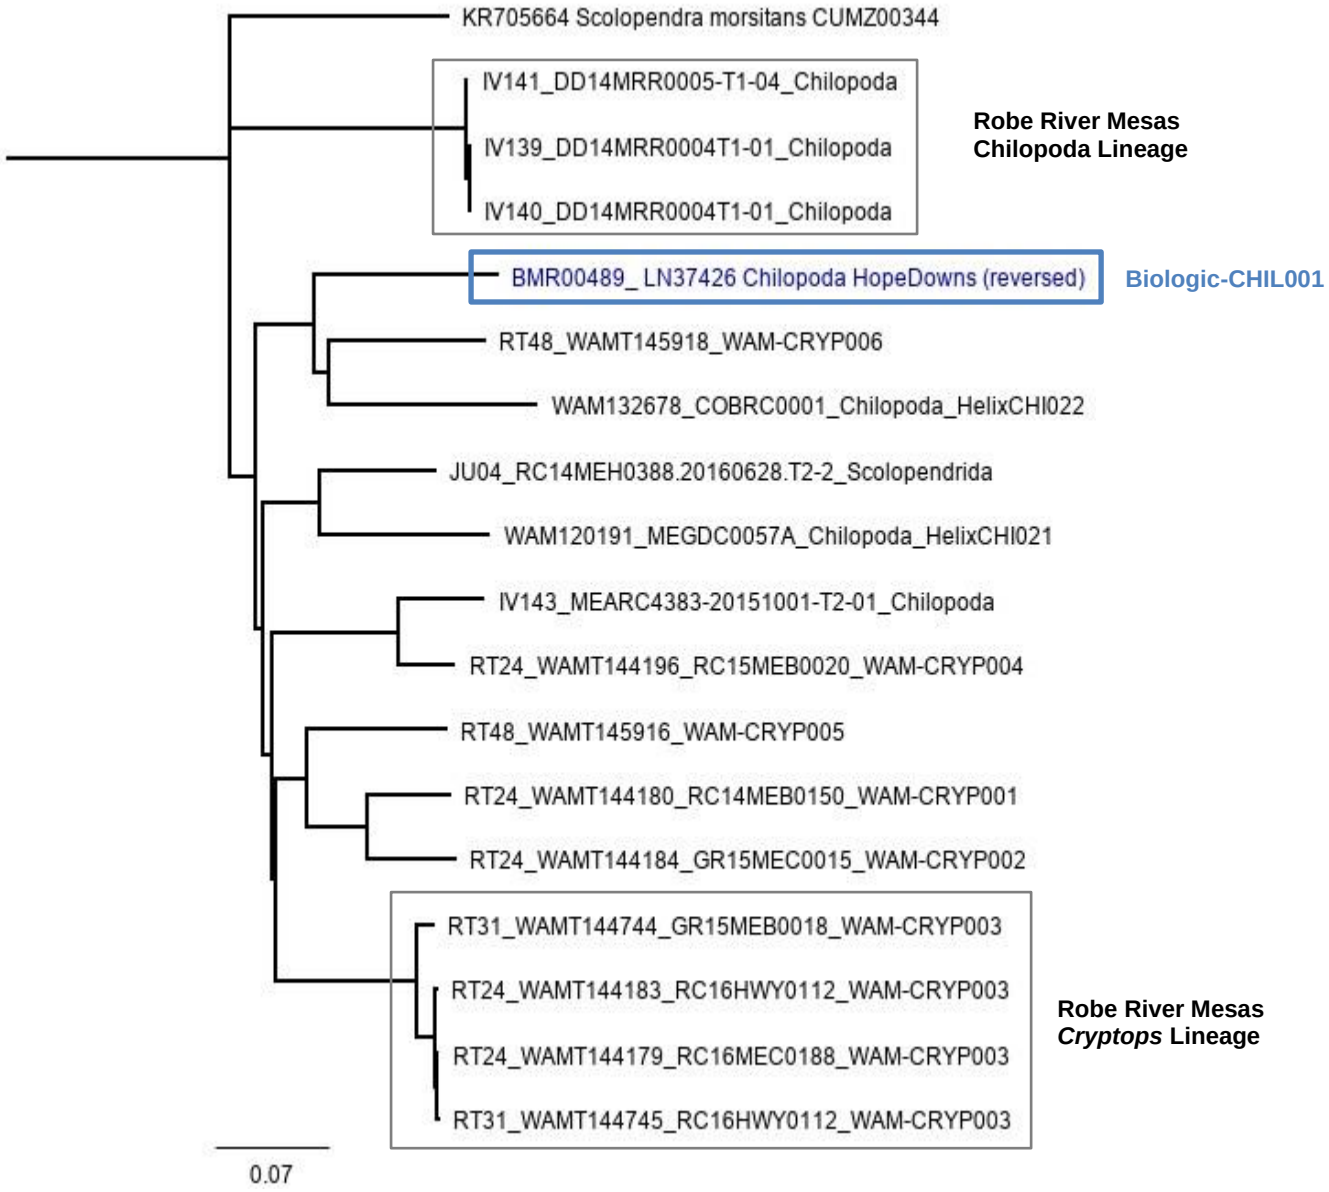

Figure 3.3. Neighbour Joining tree of Chilopoda haplotypes included in the analysis. Lineages from the Study Area are indicated by coloured text.

3.4 Diplura

One specimen of Diplura (LN33785; identified as *Indjapyx* OES7) was successfully sequenced (COI).

Regional comparisons (Figure 3.4) with previous sequences in Genbank and the RTIO databases revealed a high level of divergence (min 16% COI), indicating that Lineage DIPL001 from the Study Area is not represented elsewhere in the available sequence databases. This result was based on a comparison of 32 available Diplura sequences from the Pilbara region within the available sequence databases, and a Ptiliidae beetle was used as an outgroup (Figure 3.4, Appendix 4).

The dipluran sequenced from the Study Area (Lineage DIPL001) was closest to other diplurans identified as Japygidae, but at the high levels of divergence recorded (16%-19% COI), and due the lack of genus level identifications for most of the other sequences, further genetic or morphological information would be required to validate the phylogeny shown in Figure 3.4.

Indjapyx OES7 (Biologic-DIPL001) appears to represent a new/ unique OTU based on current comparisons with the available genetic databases.

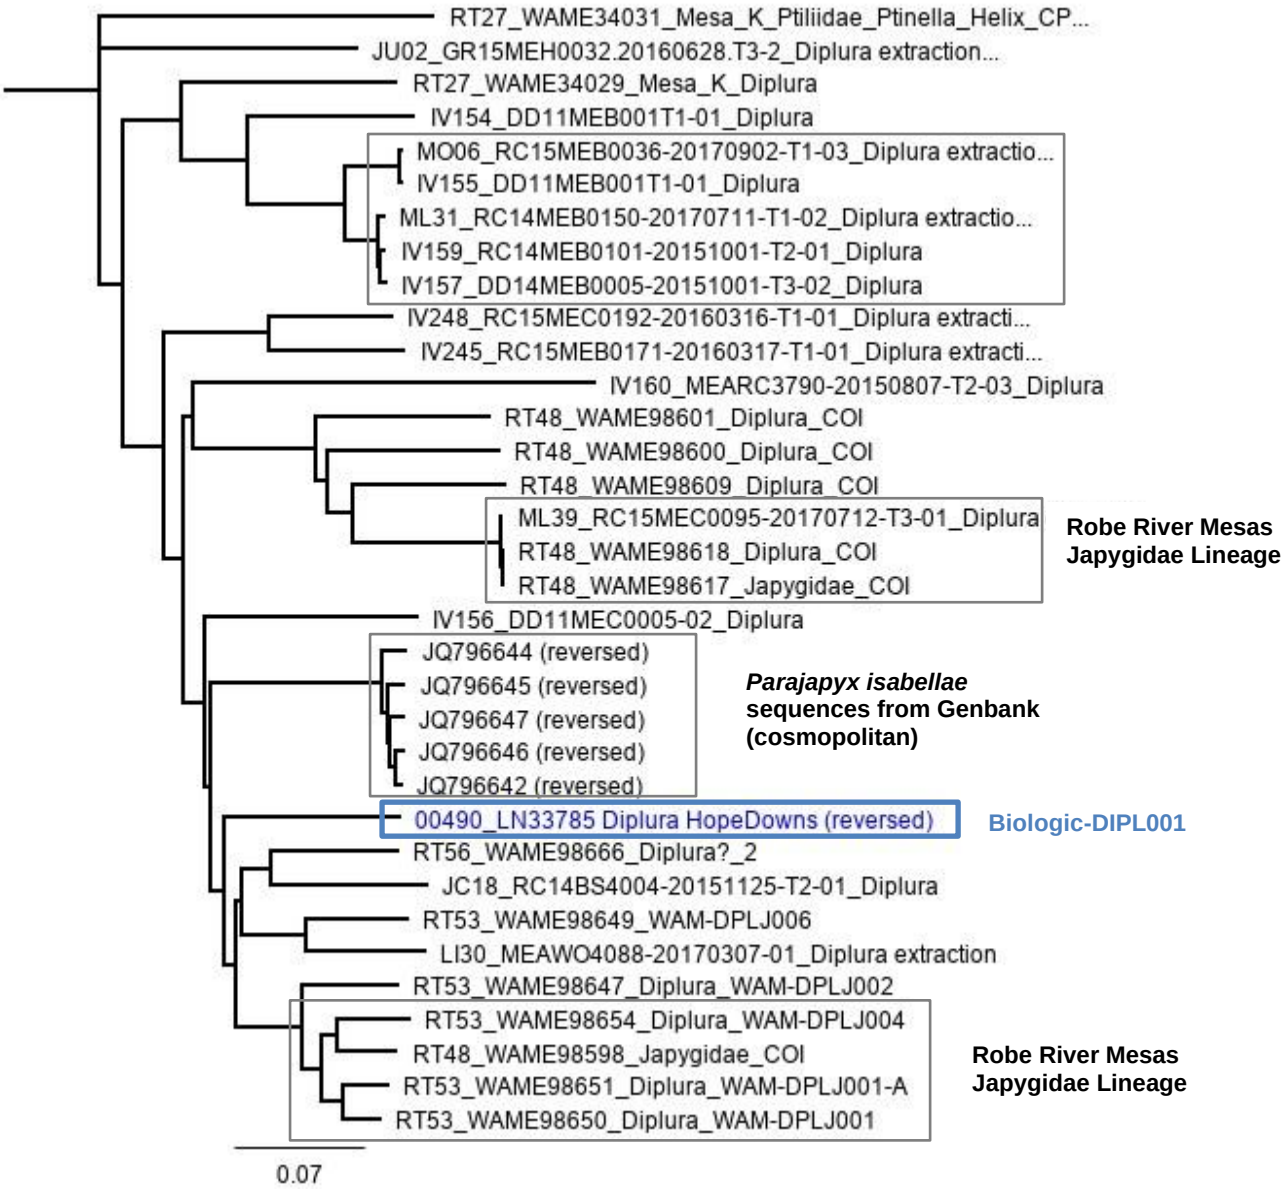

Figure 3.4. Neighbour Joining tree of Diplura haplotypes included in the analysis. Lineages from the Study Area are indicated by coloured text.

3.5 Hemiptera

Four of a total six specimens of Hemiptera from the Study Area were successfully sequenced (COI). Local comparisons revealed three well-supported lineages (intraspecific variability <1%), representing three distinct OTUs (Table 3.2, Figure 3.5):

- *Nisia* OES16 (HEMI001) (LN36535, 33789, Bedded Hill Top);
- *Phaconeura* HEMI002 (LN33774, Bedded Hill Top); and
- *Phaconeura* HEMI003 (LN35120, Bedded Hill Top);

These lineages each varied between 18% and 34% COI divergence (Appendix 5), indicating three highly divergent OTUs. Although morphological identifications (at Stantec) suggested that LN33774 and LN35120 belonged to the same morphospecies (*Phaconeura* OES15), the current genetic results revealed 18% (COI) divergence of Biologic-HEMI002 and HEMI003, indicating cryptic morphology or additional taxonomic work may be required.

Table 3.2. Genetic results of Hemiptera specimens (lineages represented by highlighted colours).

Area	Site Name	Morphospecies ID	No. of Individuals	Lot No. (LN)	BMR Code	HEMI Lineage
BHT	RC15BHT0267	*Nisia* OES16	1	LN36535	BMR00436	001
BHT	RC16BHT0222	*Nisia* OES16	1	LN33789	BMR00487	001
BHT	RC16HD10193	*Phaconeura* OES15	1	LN33774	BMR00486	002
BBH	RC14HD10072	*Phaconeura* OES15	1	LN35120	BMR00553	003

Regional comparisons (Figure 3.5 Appendix 5) revealed that each of the three lineages showed a high level of divergence (minimum 13-26% COI) from previously sequenced Hemiptera specimens. Specimens identified by Stantec as *Phaconeura* were clustered with other *Phaconeura* lineages, including one widespread OTU sampled at both Paraburdoo and West Angelas (P. WAM-PHAC001). However, at 13-14% COI divergence, *Phaconeura* sp. `Biologic-HEMI003` is regarded as a different OTU to *P*. `sp. WAM-PHAC001`, while *Phaconeura* `sp. Biologic-HEMI002` is regarded as different to another Paraburdoo taxon, P. `sp. WAM-PHAC002` (11-15% COI) (Appendix 5).

Nisia sp. Biologic-HEMI001 was highly divergent from all the available Meenoplidae sequences in the analysis (25-28% COI), although owing to the lack of genus level identifications for most of these sequences, further genetic (and/ or morphological work) may be required to validate these phylogenetic relationships.

Based on current results, the three Hemiptera OTUs from the Study Area do not appear to be represented elsewhere in the available databases.

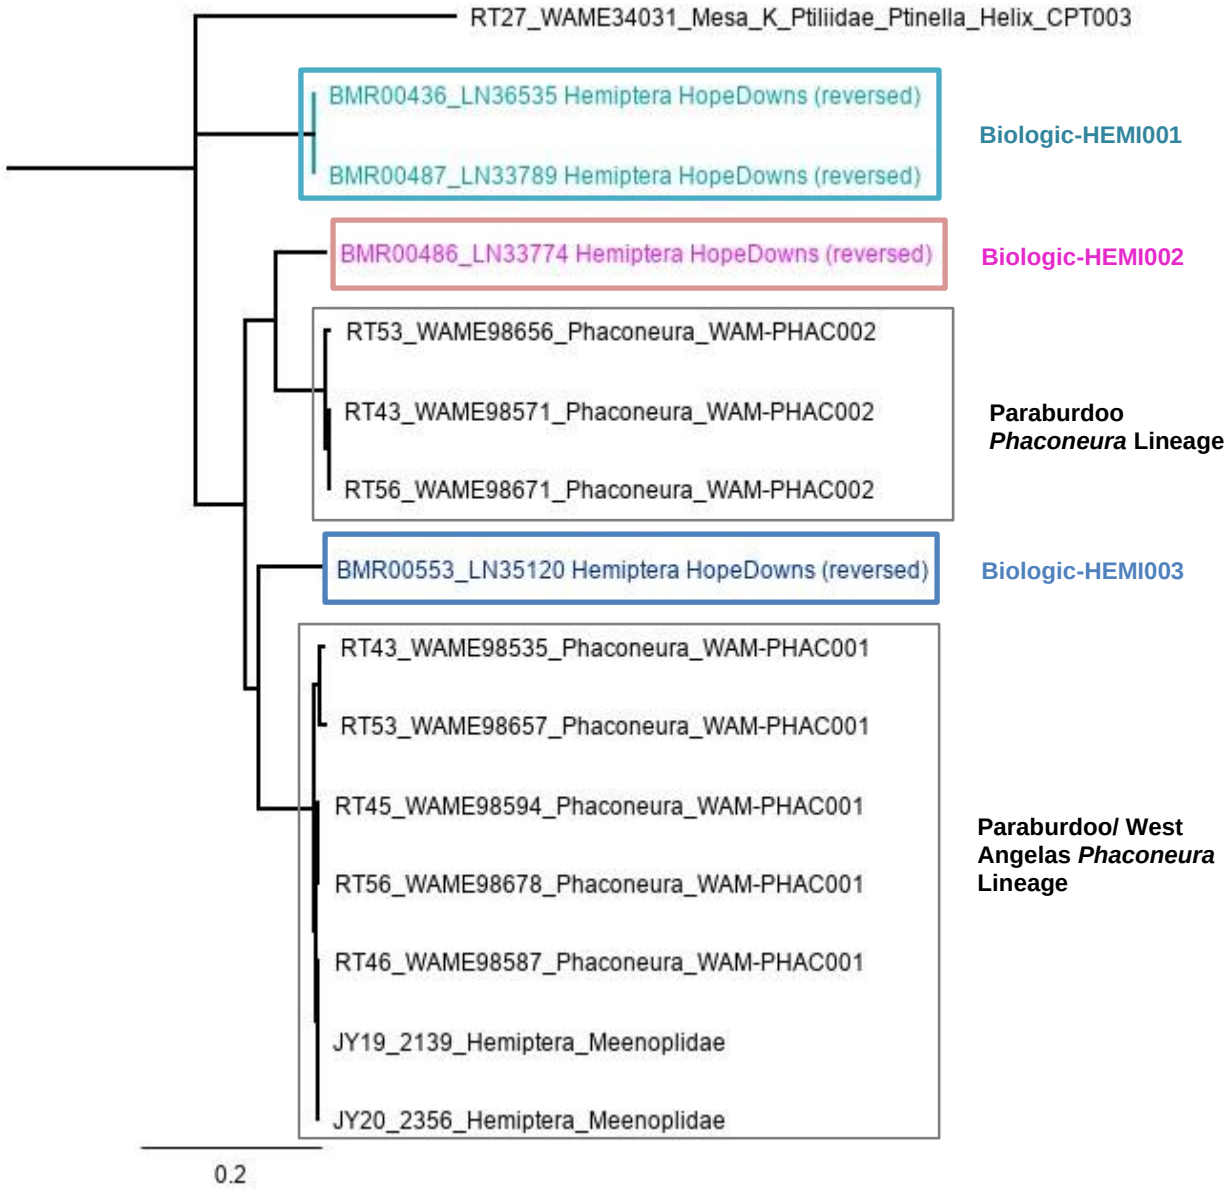

Figure 3.5. Neighbour Joining tree of Hemiptera haplotypes included in the analysis. Lineages from the Study Area are indicated by coloured text.

3.6 Palpigradi

One of the two specimens of Palpigradi (LN39264, identified as *Eukoenenia* OES2) was successfully sequenced (Lineage PALP001).

Regional sequences for this taxonomic group were very limited within the available databases, but the lineage from the Study Area was found to be 55-63% divergent (COI) from two other subterranean Palpigradi lineages collected at Paraburdoo (Figure 3.6, Appendix 6). A subterranean spider and an epigean spider sequence were used as outgroups in the analysis. At the high levels of divergence shown in this analysis, further genetic work (and potentially additional specimens/ sequences) would be required to verify the relationships between subterranean Palpigradi lineages from the region.

Based on the limited information currently available, *Eukoenenia* OES2 (Biologic-PAL001) does not appear to have been collected elsewhere to date.

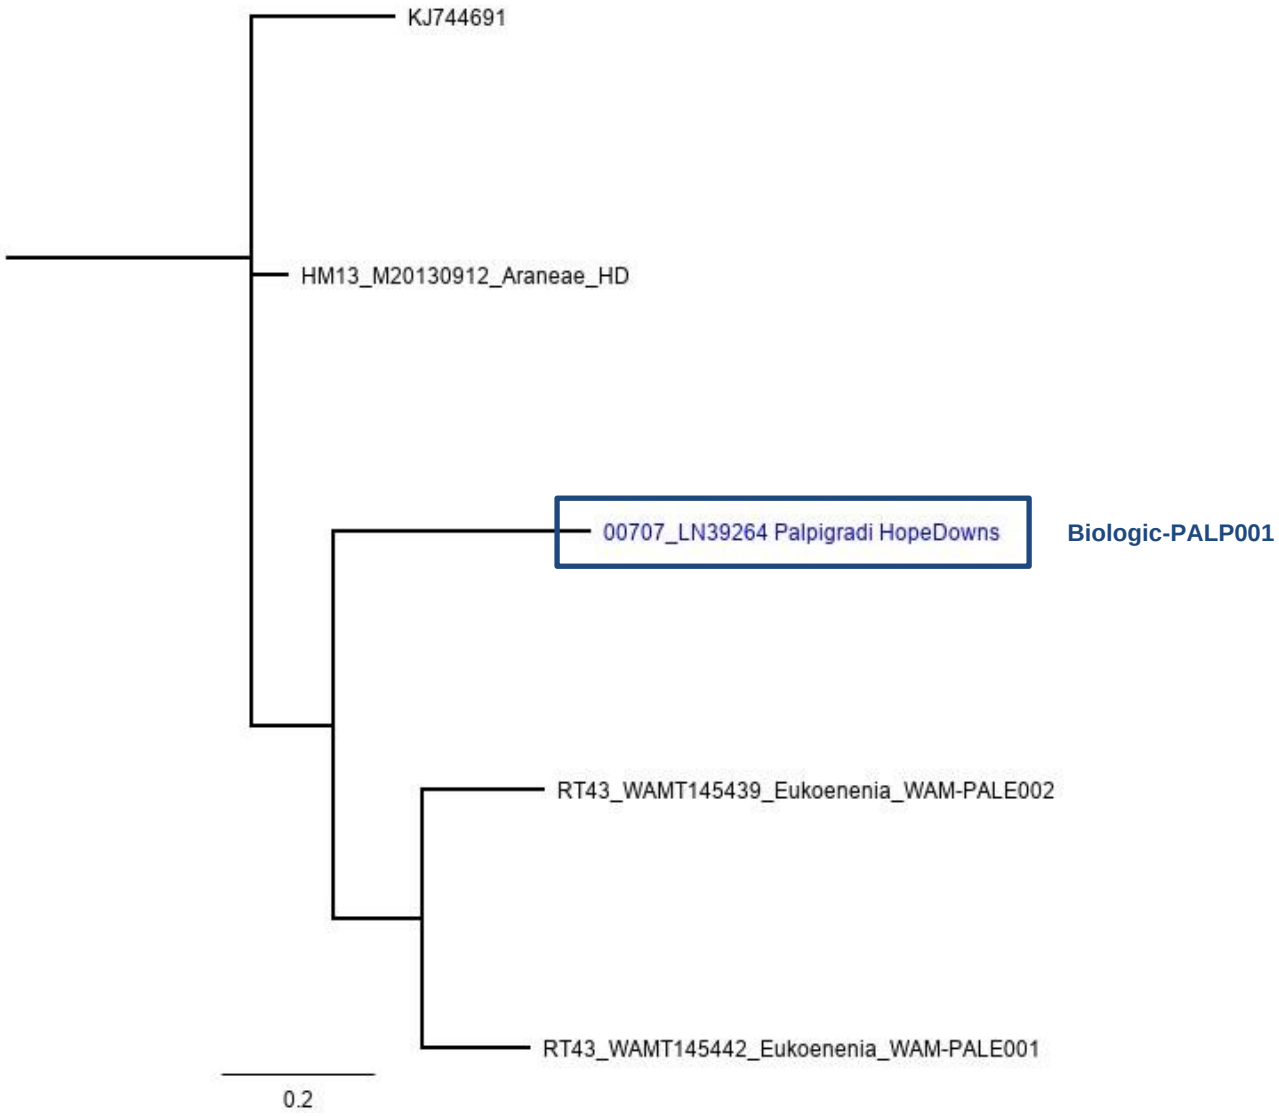

Figure 3.6. Neighbour Joining tree of Palpigradi haplotypes included in the analysis. Lineages from the Study Area are indicated by coloured text.

3.7 Pauropoda

One specimen of Pauropoda (LN35790) failed to sequence (COI). No further work was undertaken on this specimen.

3.8 Polyxenida

One specimen of Polyxenida (LN33785; Lophoproctidae sp.) was successfully sequenced (COI). Regional comparisons (Figure 3.7) were based on 25 available subterranean Polyxenida sequences from the Pilbara region (Appendix 7).

The analysis revealed a moderate level of divergence (9%-13% COI) with Polyxenida specimens collected at Robe Headwaters (S45), Cabbage Gum Bore (S12 and S31), Silvergrass (P3 and P1), and Western Range (P51 and P52). Based on average COI divergence thresholds of 8% (Hebert et al 2003), the sequence from the Study Area would still be considered to represent a distinct OTU (Biologic-POLYX001).

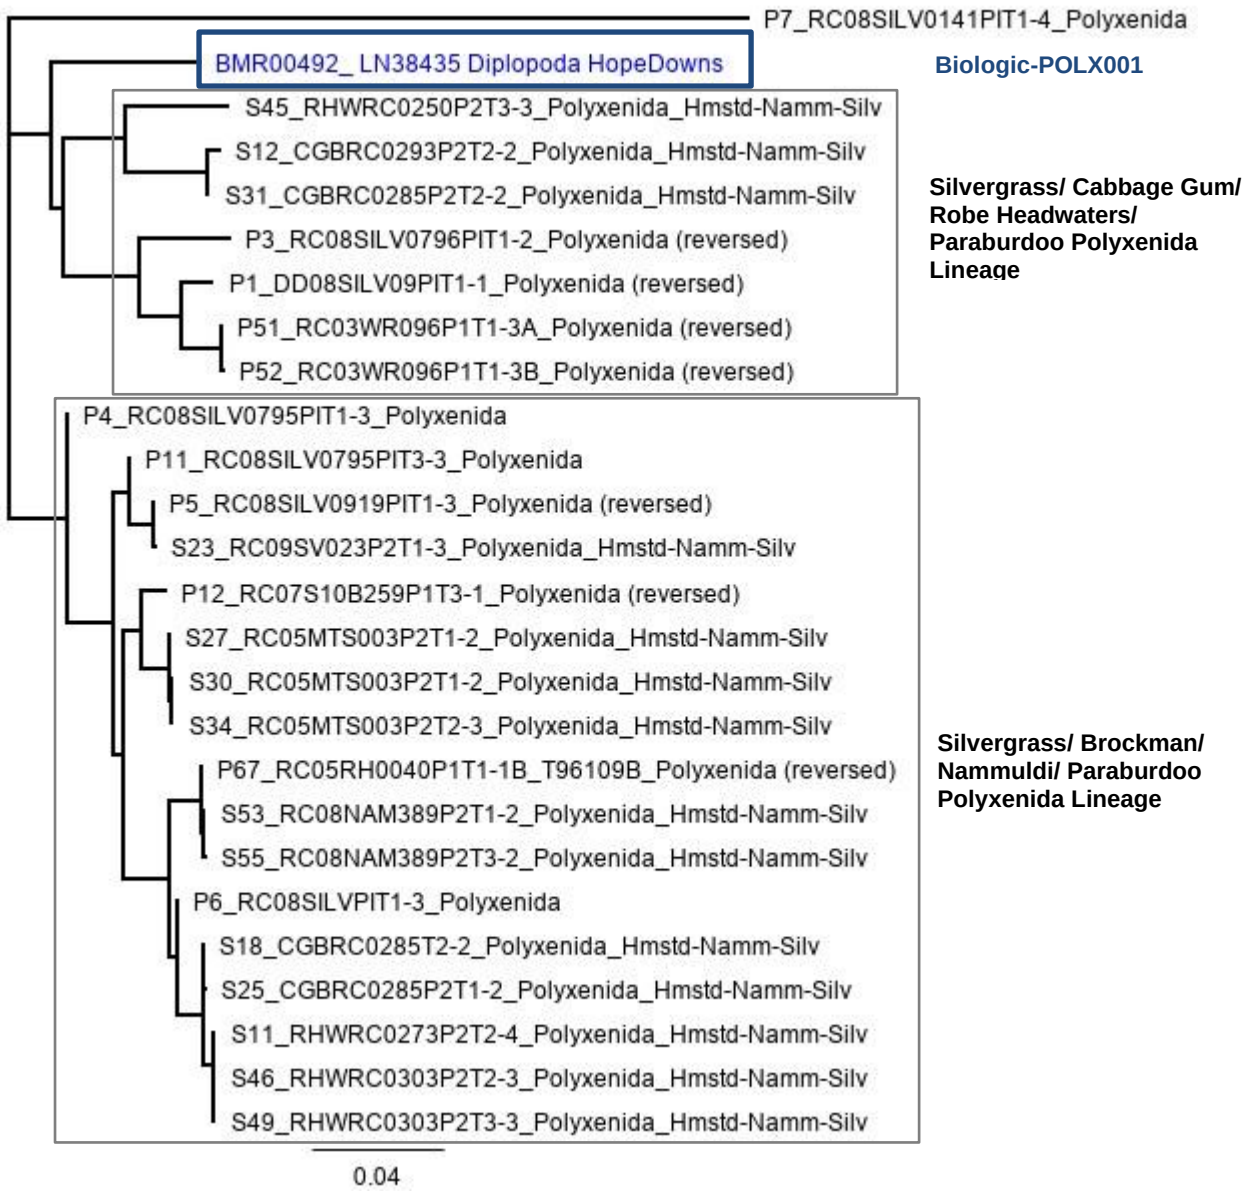

Figure 3.7. Neighbour Joining tree of Polyxenida haplotypes included in the analysis. Lineages from the Study Area are indicated by coloured text.

Although regionally widespread Lophoproctidae species are known to occur throughout the Pilbara region (i.e. the cosmopolitan species *Lophoturus madecassus,* which can be found in epigean and subterranean habitats), due to the lack of resolution in the accompanying morphological identifications, it is uncertain whether sequence material for this widespread species has been included in the current comparisons. However, it does appear that the most closely related lineages to the one collected at the Study Area have been recorded widely throughout the region.

Based on the currently available sequence information in the accessible databases, Lophoproctidae sp. (Biologic-POLYX001) does not appear to have been collected beyond the Study Area.

3.9 Pseudoscorpiones

One of the two specimens of Pseudoscorpiones (LN35130, identified as *Tyrannochthonius* OES20) was successfully sequenced at COI (Biologic-PSEU001). Figure 3.8 shows regional comparisons with 17 regional Chthoniidae sequences, and an *Aname* spider used as an outgroup.

Based on these regional comparisons, the Lineage PSEU001 from the Study Area was found to be highly divergent (19%-25% COI) from other sequences from Robe Valley (RT53 and RT48), and Paraburdoo (RT46) (Figure 3.8, Appendix 8). A subterranean spider and a subterranean Olpiidae sequence were used as outgroups in the analysis. Sequence data from the pseudoscorpion *Lagynochthonius* `sp. WAM-PSE096` previously collected from Baby Hope Downs were not available for genetic comparisons.

While the overall level of divergence between the sequence from the Study Area and other regional sequences in the same family was high, this was not considerably different from the range of divergences between *Tyrannochthonius* OTUs within the available databases (ranging from 12% to 24% COI, Appendix 8). In this broader context the high divergences between the lineage from the Study Area (Biologic-PSEU001) and other regional sequences was not considered out of trend with the range of divergences between other lineages in the genus.

Based on currently available information, *Tyrannochthonius* OES20/ Biologic-PSEU001 does not appear to have been collected elsewhere to date.

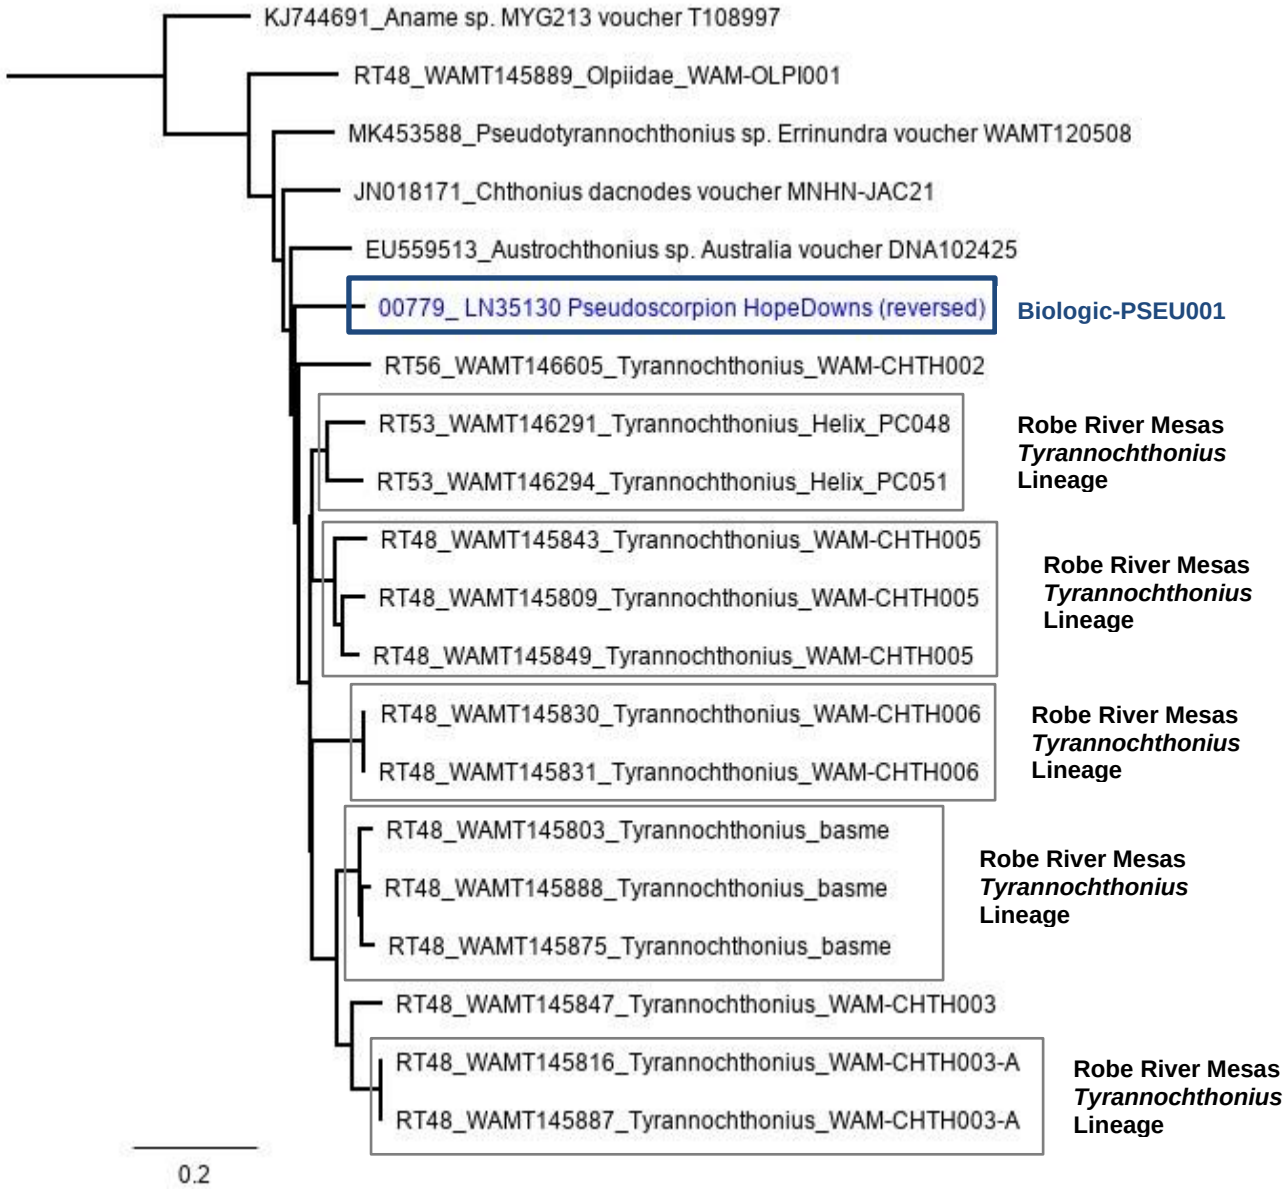

Figure 3.8. Neighbour Joining tree of Pseudoscorpiones haplotypes included in the analysis. Lineages from the Study Area are indicated by coloured text.

3.10 Schizomida

Eight specimens of Schizomida specimens were successfully sequenced at COI. Local comparisons revealed two potential lineages (intraspecific variability <1% COI, Appendix 9):

- Lineage A: LN35581, LN38567, LN33570, LN33590, and LN35572 from Bedded Hill Top; and
- Lineage B: LN37569, LN38573, and LN36580, also from Bedded Hill Top.

COI divergence between these lineages was only 6%- 7% (Appendix 9) and based on average COI divergence thresholds of 8% (Hebert et al 2003), these would be considered to represent a single OTU.

When compared to the sequences from specimens previously collected in the Hope Downs 1 South West area and Baby Hope Downs (Figure 3.9, Appendix 9), the two lineages are nested with the intraspecies variability within *Draculoides* sp. SCH068, as recently described by Abrams *et al.* (2019). Within the published sequences of *Draculoides* sp. SCH068, the current analysis showed variability between 3%-7% COI (Appendix 9). Current sequences within Lineage A varied from *D*. sp. SCH068 by 6%-9%, while sequences within Lineage B varied from *D*. sp. SCH068 by 2%-7% (Appendix 9). As stated above, Lineages A and B varied from each other by 6% - 7%.

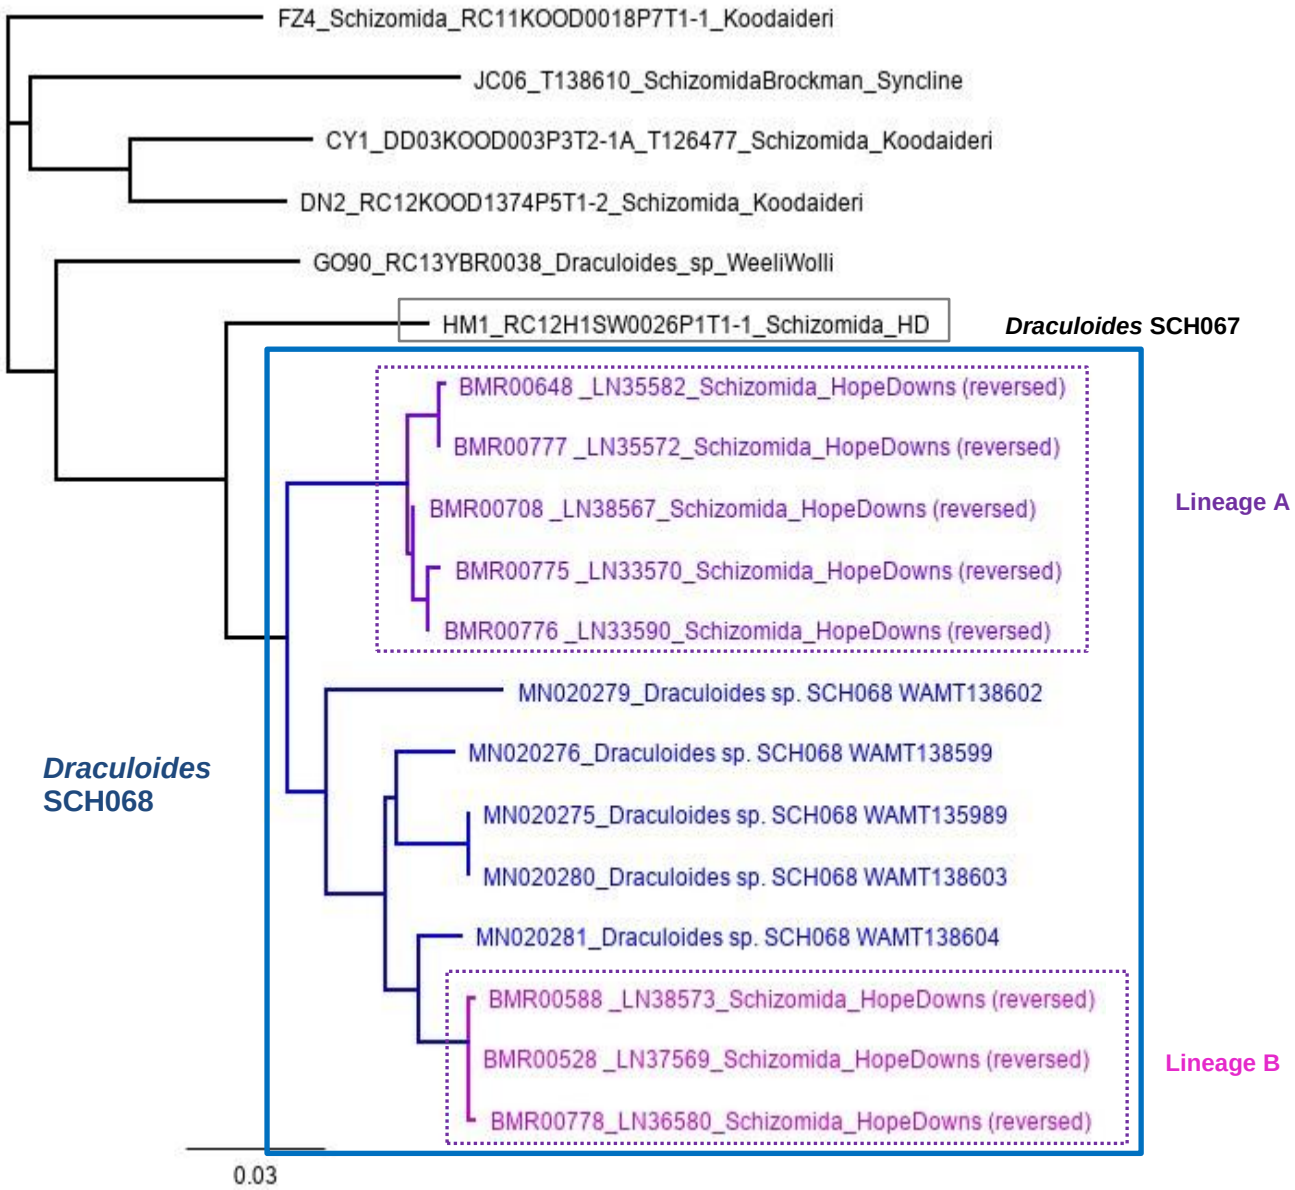

Figure 3.9. Neighbour Joining tree of Schizomida haplotypes included in the analysis. Lineages are indicated by coloured text.

The current analysis also suggests that Lineage A is also closely related to another OTU from Hope Downs 1 South West, *Draculoides* sp. SCH067 (Abrams *et al.* 2019). The average pairwise divergences of specimens in Lineage A vs SCH068 were 7% (SD 0.009), whereas Lineage A vs SCH067 was 8% (SD 0.004) (Table 3.3). This very marginal difference suggests that, even though both OTUs are quite similar to Lineage A, based on current sequences, Lineage A is closer to *Draculoides* sp. SCH068 (as in Figure 3.9).

Table 3.3: Average and standard deviation of COI divergences between lineages of Schizomida collected from the Hope Downs area, in the current analysis

	Lineage A (5)	Lineage B (3)	SCH068 (5)	SCH067 (1)
Lineage A (5)	1% (intra)	SD 0.003	SD 0.009	SD 0.004
Lineage B (3)	Ave 7%	0% (intra)	SD 0.017	SD <0.001
SCH068 (5)	Ave 7%	Ave 4%	4% (intra)	SD 0.004
SCH067 (1)	Ave 8%	Ave 10%	Ave 10%	n/a

Meanwhile, Lineage B was much more similar to *Draculoides* sp. SCH068 (COI divergence mean 4%, SD 0.017), which was within the same mean intraspecific variability as SCH068 itself (Table 3.3). Lineages A and B were also quite similar (COI divergence mean 7%, SD 0.003), indeed, the same average level of divergence as Lineage A vs SCH068, suggesting that Lineages A, B, and SCH068 can be regarded as the same OTU, albeit one with a relatively high level of intraspecific variability (mean 5%, range 0%-9%).

Based on the current results, all of the new sequences of Schizomida collected from the Study Area appear to align to the previously known OTU, *Draculoides* sp. SCH068. However, some of the divergences between the current lineages and the available sequence material for *Draculoides* sp. SCH068 and *Draculoides* sp. SCH067 were gradational/ marginal, therefore further genetic work using a multi-gene approach, potentially combined with morphological work as in Abrams *et al.* (2019) may be useful to validate the species-level phylogenetic relationships between these specimens.

3.11 Zygentoma

One specimen of Zygentoma (Atelurinae sp., LN39280) failed to sequence at COI, therefore analysis was conducted at 12S, following Smith *et al.* (2012). The specimen was successfully sequenced using 12S (Biologic-ZYGE001).

Based on comparisons with 20 regional Zygentoma sequences within the available databases, the lineage from the Study Area was found to be moderately divergent (8%-10% 12S) from a *Dodecastyla* OTU collected at Paraburdoo (*Dodecastyla* WAM-ZYGA001), and more highly divergent (19%-48% 12S) from other subterranean Zygentoma, several of which were morphologically identified as

Trinemura (Figure 3.10, Appendix 9). Smith *et al.* (2012) regarded sequences of *Dodecastyla* at 6.2% - 6.5% divergence (12S) as different species, therefore the lineage from Study Area would be considered distinct from *Dodecastyla* WAM-ZYGA001.

The current genetic results appear to confirm the morphological assessment, that the Zygentoma from the Study Area (ZYGE001) likely belongs to the Atelurinae (e.g. *Dodecastyla* sp.). This taxonomic group is commonly regarded as soil-dwelling (including inhabitants of termite nests), rather than troglobitic (Smith *et al.* 2012). While Biologic-ZYGE001 is closely related to *Dodecastyla* WAMZYGA001 sequenced at Paraburdoo, based on currently available information in the accessible databases, does not appear to have been collected elsewhere beyond the Study Area to date.

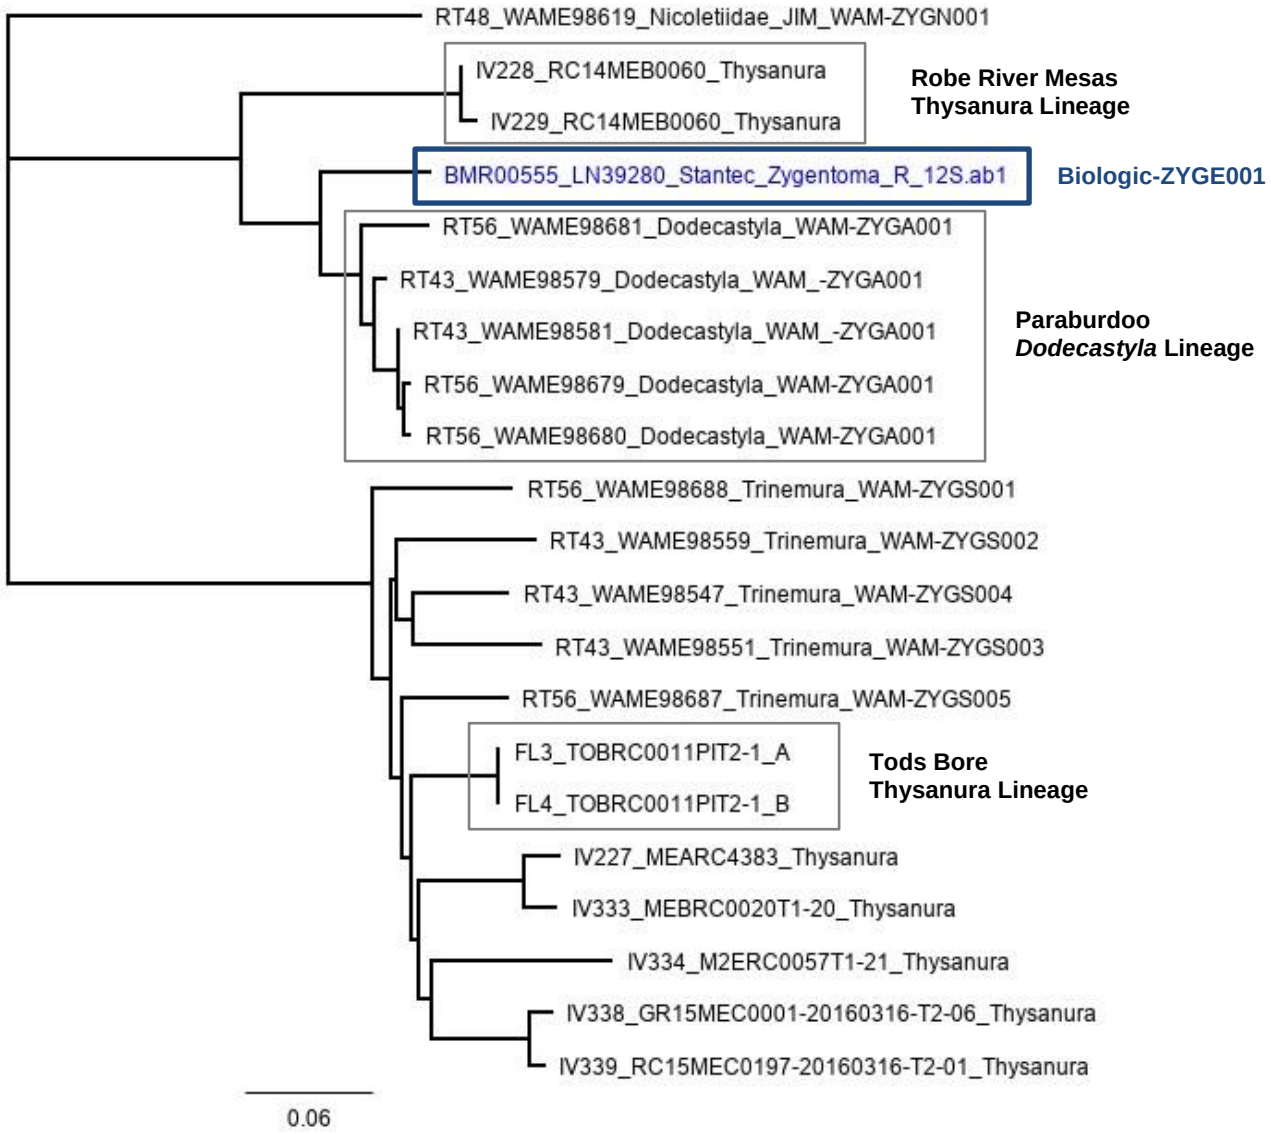

Figure 3.10. Neighbour Joining tree of Zygentoma haplotypes included in the analysis. Lineages from the Study Area are indicated by coloured text.

4 KEY FINDINGS

The molecular analysis of subterranean fauna from the HDOW1 Study Area resulted in the following key findings at the species/ OTU level:

- Amphipoda (CO1): 1 OTU, Biologic-AMPH001 (*Pilbarus* nr *millsi* OES12), regionally unique;
- Blattodea (CO1): 4 OTUs (formerly *Nocticola* sp. OES12 and OES13), Biologic-BLAT001, Biologic-BLAT002, Biologic-BLAT003, and Biologic-BLAT004, all regionally unique;
- Chilopoda (CO1): 1 OTU, Biologic-CHIL001 (Scolopendromorpha sp.), regionally unique;
- Diplura (CO1); 1 OTU, Biologic-DIPL001 (*Indjapyx* OES7), regionally unique;
- Hemiptera (CO1): 3 OTUs, Biologic-HEMI001 (*Nisia* OES16), Biologic-HEMI002 and Biologic-HEMI003 (the latter both formerly *Phaconeura* OES15), all regionally unique.
    - Two other specimens failed to sequence;
- Palpigradi (CO1): 1 OTU, Biologic-PALP001 (*Eukoenenia* OES2), regionally unique.
    - A second specimen failed to sequence;
- Pauropoda (CO1): failed to sequence;
- Polyxenida (CO1): 1 OTU, Biologic-POLX001 (Lophoproctidae sp.), regionally unique;
- Pseudoscorpiones (CO1): 1 OTU, Biologic-PSEU001 (*Tyrannochthonius* OES20).
- Schizomida (CO1): 1 OTU (*Draculoides* sp. SCH068),
    - Previously recorded OTU *Draculoides* sp. SCH068 encompasses Lineage A, Lineage B, and morphospecies *Draculoides* ?BH4/BH5;
- Zygentoma (12S): 1 OTU, Biologic-ZYGE001 (Ateluridae sp.), regionally unique.

Thank you for giving Biologic the opportunity to undertake this work. Please contact us if you have any further questions.
