Yandicoogina Iron Ore Project – Revised Proposal

Public Environmental Review

November 2015

State Assessment Number: Assessment No. 2017

Prepared for Rio Tinto by Eco Logical Australia

Invitation to make a submission

The Environmental Protection Authority (EPA) invites people to make a submission on this proposal. The environmental impact assessment process is designed to be transparent and accountable, and includes specific points for public involvement, including opportunities for public review of environmental review documents. In releasing this document for public comment, the EPA advises that no decisions have been made to allow this proposal to be implemented.

Hamersley Iron – Yandi Pty Limited proposes to construct and operate a new mine pit, waste dumps and associated infrastructure at Pocket and Billiard South, located in the central Pilbara region of Western Australia. In accordance with the Environmental Protection Act 1986, a Public Environmental Review (PER) document has been prepared which describes this proposal and its likely effects on the environment. The PER document is available for a public review period of six weeks from **2nd November 2015** closing on **14th December 2015**.

Comments from government agencies and the public will assist the EPA to prepare an assessment report in which it will make recommendations to government.

Printed and CD copies of this document may be obtained from Ms Melinda Brand at Rio Tinto Iron Ore, 152-158 St Georges Terrace, Perth or +61 8 6211 6991. Hard copies of the document cost of $10 (including postage); CDs will be provided free of charge.

The PER may also be accessed through the proponent's website at: http://www.riotinto.com/ironore/documents-9622.aspx.

Why write a submission?

A submission is a way to provide information, express your opinion and put forward your suggested course of action – including any alternative approaches. It is useful if you indicate any suggestions you have to improve the proposal.

All submissions received by the EPA will be acknowledged with electronic submissions being acknowledged electronically. The proponent will be required to provide adequate responses to points raised in submissions. In preparing its assessment report for the Minister for Environment, the EPA will consider the information in submissions, the proponent's responses and other relevant information. Submissions will be treated as public documents unless provided and received in confidence, subject to the requirements of the Freedom of Information Act 1992, and may be quoted in full or in part in the report.

Why not join a group?

If you prefer not to write your own comments, it may be worthwhile joining a group or other groups interested in making a submission on similar issues. Joint submissions may help to reduce the workload for an individual or group, as well as increase the pool of ideas and information. If you form a small

group (up to 10 people) please indicate all the names of the participants. If your group is larger, please indicate how many people your submission represents.

Developing a submission

You may agree or disagree with, or comment on, the general issues discussed in the PER document or on specific elements. It helps if you give reasons for your conclusions, supported by relevant data. You may make an important contribution by suggesting ways to make the proposal more environmentally acceptable.

When making comments on specific elements of the PER:

- clearly state your point of view;
- indicate the source of your information or argument if this is applicable; and
- suggest recommendations, safeguards or alternatives.

Points to keep in mind

By keeping the following points in mind, you will make it easier for your submission to be analysed:

- attempt to list points so that issues raised are clear. A summary of your submission is helpful;
- refer each point to the appropriate section, chapter or recommendation in the PER document;
- if you discuss different sections of the PER document, keep them distinct and separate, so there is no confusion as to which section you are considering; and
- attach any factual information you may wish to provide and give details of the source. Make sure your information is accurate.

Remember to include:

- your name;
- address;
- date; and
- whether you want your submission to be confidential.

The closing date for submissions is: **14th December 2015**

The EPA prefers submissions to be made at:
https://consultation.epa.wa.gov.au.

Alternatively, submissions can be

- posted to: Chairman, Environmental Protection Authority, Locked Bag 10, EAST PERTH WA 6892; or
- delivered to the Environmental Protection Authority, Level 8, The Atrium, 168 St Georges Terrace, Perth.

If you have any questions on how to make a submission, please ring the Office of the Environmental Protection Authority on 6145 0800.

Executive summary

INTRODUCTION

This Public Environmental Review (PER) has been prepared to assess the potential environmental impacts of the proposed 'Yandicoogina Pocket and Billiard South Iron Ore Development' (the Proposal).

The Proposal is located in the central Pilbara region of WA approximately 90 km north west of Newman and 300 km south east of Dampier (**Figure ES1**). The Proposal deposits are centred on a substantial channel iron deposit (CID), located immediately east of the existing Yandicoogina Operations (Yandi Operations: Junction Central (JC) and Junction South East (JSE) deposits; and the more recently approved Junction South West (JSW-A & C) and Oxbow deposits; **Figure ES2**). The Proposal is a revision to the existing Yandi Operations as approved under Ministerial Statement No. 914 (MS 914) in 2012 and involves construction and operation of a new mine pit, waste dumps and associated infrastructure. The purpose of the proposal is to enable sustained production from the existing Yandi Operations by providing replacement tonnages as the existing approved resources are depleted. The Proposal contemplates saleable ore production up to 31 Million tonnes per annum (Mtpa) with an expected operational mine life of approximately 16 years. The Proponent for the Proposal is Hamersley Iron – Yandi Pty Limited (herein 'the Proponent'), a wholly owned member of the Rio Tinto Group.

EXISTING YANDI OPERATIONS

The existing Yandi Operations is subject to the *Iron Ore (Yandicoogina) Agreement Act 1996*, and comprise a number of individual pits located within a continuous CID formation, which also forms a major aquifer in the area. The existing Yandi Operations, as approved, currently consists of:

- five open cut pits within the CID: JC, JSE and JSW-C (currently operating); and JSW-A and Oxbow (approved but not yet operating);
- a 90 km rail line to Juna Downs;
- mine infrastructure (e.g. product stockpiles, waste dumps, topsoil, low grade stockpiles, waste fines storage facilities and haul roads);
- associated infrastructure (e.g. overland conveyors, mine access roads, offices, warehouses, accommodation, bore fields, fuel storage facilities and utilities);
- abstraction of 53 gigalitres per year (GL/y);
- a water management system including on-site reuse of water abstracted from pit dewatering, and discharge of surplus volumes into creek systems;
- dry and wet processing plants;
- flood protection structures; and
- power and communications infrastructure.

Geospatial Information and Mapping

DESCRIPTION OF THE PROPOSAL

The Proposal will minimise the disturbance footprint by optimising the use of existing infrastructure already installed at the existing Yandi Operations. Key additional components of the Proposal are:

- **A new below water table open cut iron ore pit** to the east of the existing Yandi Operations within the CID.
- **Temporary surface waste dumps**, including mineral waste dumps, sub-grade dumps, low grade ore dumps and topsoil and subsoil stockpiles.
- **Major infrastructure, including:**
  - **A flood protection levee** along the western margin of the pit.
  - **A diversion drain** along the eastern margin of the new pit.
  - **A culvert-floodway** creekline crossing structure.
- **Supporting mine infrastructure** – haul roads and ramps, mine access and internal road network, dewatering pumps and associated pipelines, discharge outlet(s), power and communications.

In addition, a number of the Yandi Operation's existing facilities and processes will be upgraded or integrated as part of the Proposal including:

- **Trucking ore** back to the existing Yandi Plant.
- **Yandi plant** including JC and JSE processing plants (including a wet plant), and associated conveyors, stackers, reclaimers, train load-out and other materials handling infrastructure.
- **A water management system** including on-site reuse of water abstracted from pit dewatering, and discharge of surplus volumes into creek systems. Discharge infrastructure servicing the existing Yandi Operations will be used where possible.
- **Mine support facilities** (e.g. power supply infrastructure, communications infrastructure, offices, explosives storage, waste water treatment plants etc.).

The Proposal is scheduled to be commissioned with first ore production from the first half of 2019, however project schedules may change, depending on business priorities.

Rio Tinto's existing rail network will be used to transport mined and processed ore from the Proposal to existing port operations at Cape Lambert.

A summary of the existing Yandi Operations and the Proposal key characteristics, which together would comprise the Yandicoogina Iron Ore Project – Revised Proposal (hereafter Revised Proposal), are outlined in **Table ES1**.

Table ES1: Summary of the existing Yandi Operations, the Proposal and the Revised Proposal Key Characteristics

Characteristic	Yandi Operations (existing)	The Proposal (additional proposed)	Yandi Operations (Revised Proposal)
Short description	The proposal is to develop Iron Ore deposits Junction Central, Junction South East, Junction South West and Oxbow, located in the central Pilbara region of Western Australia, on mining lease 274SA. Key aspects of the proposal include: • Ore transport and storage infrastructure (including rail link) – car dumpers, conveyors, stockyards, ore stackers and ore reclaimers, and storage infrastructure, rail loops; • Rail corridor allowing for rail lines and associated infrastructure; • Construction and operations support infrastructure; • 220kV power network, including switchyard and powerlines; • A diesel-fired power station and transmission lines; • Dry and wet processing plants (including in pit waste fines storage facilities); • Flood protection structures; • Accommodation camps; • Access roads; and • An airstrip.	The proposal is to develop a below water table open cut Iron Ore mine at Pocket and Billiard South, located in the central Pilbara region of Western Australia, on mining lease 274SA. Key aspects of the proposal include: • Temporary surface waste dumps; • Major infrastructure including a flood protection levee, a diversion drain and Weeli Wolli Creek crossing; and • Supporting mine infrastructure including power spur, haul roads and ramps, mine access and internal road network, and dewatering infrastructure (dewatering pipeline, bores and outlets).	The proposal is to develop Iron Ore deposits Junction Central, Junction South East, Junction South West, Oxbow and Yandi PBS, located in the central Pilbara region of Western Australia, on mining lease 274SA. Key aspects of the proposal include: • Ore transport and storage infrastructure (including rail link) – overland conveyors, stockyards, ore stackers and ore reclaimers, and storage infrastructure, rail loops. • Rail corridor allowing for rail lines and associated infrastructure. • Construction and operations support infrastructure. • 220kv power network including switchyard, back-up diesel power and transmission lines. • Dry and wet processing plants (including in pit waste fines storage facilities). • Flood protection structures and creek crossings. • Accommodation camps. • Access roads.
Physical elements			
Mine and associated infrastructure	Vegetation clearing up to 5,600 ha within Restricted Clearing Area 1; and Vegetation clearing up to 60 ha within Restricted Clearing Area 2	Vegetation clearing up to 1,300 ha for mining and waste dumps Vegetation clearing up to 500 ha for infrastructure	Vegetation clearing up to 7,400 ha within Revised Proposal Development Envelope. Vegetation clearing up to 129 ha within proposed Restricted Clearing Area.

Characteristic	Yandi Operations (existing)	The Proposal (additional proposed)	Yandi Operations (Revised Proposal)
Railway and associated infrastructure	90 km rail line	No additional rail required	No additional rail required.
Operational elements			
Dewatering	No more than 35 GL/year from Junction South East and Junction Central operations. No more than 18 GL/year from Junction South West A, Junction South West C and Oxbow operations.	Approximately 50 GL/year for the Proposal	No more than 83 GL/year for the entire Revised Proposal.
Surface water discharge	Up to 16 GL/year from Junction South West A, Junction South West C and Oxbow operations.	Approximately 50 GL/year for the Proposal	Up to 78 GL/year for the entire Revised Proposal. No water flow or pooling further than 17 km downstream from the Marillana Creek and Weeli Wolli Creek system confluence.

The key characteristics of the Revised Proposal, as per EAG 1 *Defining the Key Characteristics of a Proposal* (EPA 2012a), are also listed in **Table ES2**.

Table ES2: Key Proposal Characteristics

Summary of the Proposal		
Proposal title	Yandicoogina Iron Ore Project – Revised Proposal	
Proponent name	Hamersley Iron – Yandi Pty Limited	
Short description	The proposal is to develop Iron Ore deposits Junction Central, Junction South East, Junction South West, Oxbow and Pocket and Billiard South, located in the central Pilbara region of Western Australia, on mining lease 274SA. Key aspects of the proposal include: • Ore transport and storage infrastructure (including rail link) –overland conveyors, stockyards, ore stackers and ore reclaimers, and storage infrastructure, rail loops. • Rail corridor allowing for rail lines and associated infrastructure. • Construction and operations support infrastructure. • 220kv power network including switchyard, back-up diesel power and transmission lines. • Dry and wet processing plants (including in pit waste fines storage facilities). • Flood protection structures and creek crossings. • Accommodation camps. • Access roads.	
Physical elements	**Location**	**Proposed Extent**
1. Mine and associated infrastructure	Figure 4 and Figure 79	Vegetation clearing up to 7,400 ha within Revised Proposal Development Envelope. Vegetation clearing up to 129 ha within proposed Restricted Clearing Area.
Operational elements	**Location**	**Proposed Extent**
1. Dewatering	Figure 34	No more than 83 GL/year for entire Revised Proposal.
2. Surface water discharge	Figure 34	Up to 78 GL/year for entire Revised Proposal. No water flow or pooling further than 17 km downstream from the Marillana Creek and Weeli Wolli Creek system confluence.

ASSESSMENT PROCESS

The Proposal was referred to the Western Australian (WA) Environmental Protection Authority (EPA) under Section 38 of the *Environmental Protection Act 1986* (EP Act) on 4 July 2014. The EPA determined that the Proposal required environmental assessment at the level of PER (with a six week public review period), whereby the Proponent must fulfil the requirements of Section 10.2 of the *Environmental Impact Assessment (Part IV Division 1) Administrative Procedures 2012* for environmental assessment prescribed under the EP Act.

The EPA issued an Environmental Scoping Document (ESD) for the Proposal on 31 December 2014. The ESD provides an outline of the key environmental factors, a description of the scope of the assessment of the Proposal and an indicative timeline for the assessment process.

Subsequent to a six week public review period of the PER document, the Proponent will respond to any public submissions received and then the EPA will assess the Proposal and submit its assessment report to the Minister for the Environment. The Minister will publish the EPA report and subsequent to the determination of appeals (if any) received on the findings or recommendations of the EPA's assessment report, the Minister will then decide whether or not the Proposal should be implemented and if so, under what conditions.

The Proposal was also referred to the Commonwealth Department of the Environment (DoE) under the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) on 26 September 2014. DoE determined that the Proposal was 'not a controlled action' on 25 October 2014 (Decision notice 2014-7343), and therefore does not require assessment and approval under the EPBC Act.

The ESD was prepared with input from other WA decision making authorities and the Proponent. The EPA identified seven preliminary key environmental factors relevant to the Proposal that require detailed consideration by the Proponent. These preliminary key environmental factors were:

- Flora and Vegetation;
- Terrestrial Fauna;
- Subterranean Fauna;
- Hydrological Processes;
- Inland Waters Environmental Quality;
- Rehabilitation and Closure (integrating factor); and
- Offsets (integrating factor).

The EPA identified air quality, amenity and (indigenous) heritage as 'other environmental factors' that it considers relevant to the Proposal. Other environmental factors are also addressed in this PER to demonstrate how the Proposal will meet the relevant EPA objectives and principles.

ENVIRONMENTAL IMPACTS AND MANAGEMENT

Assessment of the key environmental factors and other environmental factors is provided below.

HYDROLOGICAL PROCESSES AND INLAND WATERS ENVIRONMENTAL QUALITY

The Proposal Area is located within the Weeli Wolli Creek surface water catchment, with Weeli Wolli Creek flowing through and adjacent to the Proposal Area from south of the Proposal ore deposits. Weeli Wolli Creek is part of an ephemeral system characterised by a generally singular, meandering low-flow channel set within a broader floodplain. The high flow channel comprises a gravel-bed stream, with large gravel bars present within the channel and more active anabranches. These numerous anabranches of the Weeli Wolli Creek that cross the Proposal Area convey flows towards the creek as a result of episodic high rainfall events.

Weeli Wolli Creek drains parallel to the Proposal ore deposits in a predominantly north easterly direction, receiving flows from Marillana Creek (its major tributary), and terminates as an alluvial fan at the Fortescue Marsh, outside of the Revised Proposal Development Envelope.

The Proposal will operate within a modified and managed hydrological system. The existing approved mining operations within the Weeli Wolli Creek catchment undertake dewatering and discharge activities as part of their mining operations and have modified the natural hydrological conditions of Marillana and Weeli Wolli Creeks since the mid 1990's and mid 2000's, respectively. The BHP and Rio Tinto mining operations that occur within the CID (Rio Tinto's existing Yandi Operations, BHP's Marillana Creek [Yandi]), are within the same hydrological and hydrogeological setting as the Proposal, with the dewatering and discharge activities undertaken to manage the productive aquifers of the CID. Hamersley HMS's Hope Downs 1 upstream operation occurs in a different local hydrogeological setting; however discharges into the same catchment (into Weeli Wolli Creek), which ultimately recharges the aquifers in the vicinity of the Revised Proposal (adjacent to Junction South East and the Proposal Area).

The groundwater levels in the aquifers underlying Weeli Wolli Creek have increased in recent history, as a consequence of surplus water discharge from upstream mining operations. In some locations along Weeli Wolli Creek, the groundwater table has risen such that it is now only a few metres from the surface. Dewatering associated with the Proposal will lower the artificially elevated groundwater table. After mining, however, the aquifers beneath Weeli Wolli Creek are projected to return to within approximately 10% of their natural (pre-mining) levels, which will enable Weeli Wolli Creek to return to the ephemeral system that existed prior to continuous surplus water discharge from mining activities in the area.

Development of the Proposal will modify local topography and intercept a portion of surface water flows. The Proposal mine pit will marginally encroach into the Weeli Wolli Creek floodplain, requiring a flood protection levee to be installed to prevent floodwaters from Weeli Wolli Creek flowing into the mine pit. Additionally, as the Proposal ore deposit is entirely located on the east side of Weeli Wolli Creek, a creek crossing via a culvert-floodway structure and an upgrade to the existing road crossing to an engineered floodway will be required to access facilities at the existing Yandi Operations. The

changes associated with surface hydrology are confined to specific sections of Weeli Wolli Creek and are considered unlikely to affect the wider catchment flows.

Due to the nature of the orebody being located below the water table, dewatering will be required to allow for mining. Peak cumulative abstraction volumes from the existing Yandi Operations and the Proposal of up to 83 gigalitres per year (GL/y) are modelled to occur within the first 6 years of mining. Local maximum drawdown during this period would be most pronounced along the CID aquifer and is predicted to be in the order of 75 to 85 m below ground level (bgl).

The Proposal will contribute at its peak up to 50 GL/y of the total 83 GL/y abstraction from the Revised Proposal. Of the 50 GL/y, up to approximately 70% is estimated to be associated with surplus water discharge from the upstream Hope Downs 1 project that has infiltrated into the downstream Weeli Wolli Creek floodplain and CID aquifers. Groundwater abstracted through the dewatering network will be integrated with the existing and proposed site water demand, with surface water of up to 78 GL/y discharged to Marillana and Weeli Wolli Creeks. The remaining 5 GL/y (to a maximum of 11 GL/y for the Revised Proposal) is expected to be used for on-site operations purposes across the Revised Proposal.

Surplus water will be discharged and constrained to a well defined low-flow channel, with the modelled wetting extent within the existing MS 914 approved footprint of 17 km beyond the Marillana – Weeli Wolli Creek confluence. Given the wetting front is expected to remain within existing approved limits, it is considered that there will be minimal additional effects on the downstream hydrological system of Weeli Wolli Creek and negligible impacts are expected on Fortescue Marsh.

FLORA AND VEGETATION

The Proposal Area lies within the within the Hamersley and Fortescue subregions of the Pilbara bioregion. The majority of the landscape within the Proposal Area is considered to be typical of the Hamersley subregion, while the creek systems have affinities with the Fortescue subregion. Twenty-three vegetation units have been mapped and described in the Proposal Area, grouped according to the following major landforms with which they are associated:

- Vegetation of Major Creeklines and Tributaries.
- Vegetation of Minor Creeklines, Floodplains and Valleys.
- Vegetation of Hills, Ridges and Breakaways.
- Vegetation of Plains.

Further refined mapping within the riparian zones in Marillana and Weeli Wolli Creeks was also undertaken, differentiating 13 riparian sub-associations throughout the greater Yandicoogina area.

None of the vegetation types recorded in the Proposal Area represent Threatened Ecological Communities or Priority Ecological Communities. Some of the vegetation units recorded are considered to have elevated local conservation significance, specifically those that support riparian vegetation species *Melaleuca argentea*, *Eucalyptus camaldulensis and Eucalyptus victrix.*

Vegetation clearing will be required to enable development of the mine pit and associated infrastructure. The Proposal Area covers approximately 4,486 ha of which a maximum of 1,800 ha (including 69 ha of riparian zone vegetation) is proposed to be cleared for the Proposal. The majority of vegetation proposed to be cleared was assessed to be in Good condition (46% of all mapped vegetation) and has been historically impacted by grazing and trampling by domestic and feral animals, weed invasion, frequent fire, and mining and exploration activities.

Riparian vegetation in the vicinity of the Proposal Area has been subject to the effects of groundwater drawdown and discharge of surplus groundwater by existing approved mining activities within the catchments of Marillana Creek since the mid 1990s and Weeli Wolli Creek since the mid 2000s. Dewatering associated with the Proposal will lower the water table by approximately 75 to 85 m bgl over two to three years, with the water table in the vicinity of the mine pit remaining at that depth for the duration of mining. Approximately 50 GL/y of surplus water is proposed to be discharged from a new discharge outlet, adjacent to the existing discharge outlet (DO9) as a result of developing the Proposal, with the total peak discharge from the Revised Proposal being approximately 78 GL/y. Surface water modelling indicates Weeli Wolli Creek could accommodate the maximum discharge rate without exceeding MS 914 condition 6-3, which limits the perennial surface water wetting front to 17 km downstream of the Marillana and Weeli Wolli Creek confluence. Local impacts around the discharge outlet and immediate vicinity are likely to be associated with waterlogging, which may result in declining health of some species.

One flora species, *Lepidium catapycnon* (Hamersley Lepidium), listed under the *Wildlife Conservation Act 1950* as Threatened (Declared Rare) Flora and under the EPBC Act as Vulnerable, has been recorded in the Proposal Area. *L. catapycnon* was recorded in areas that were originally designated for waste dumps in earlier versions of the conceptual design; however, the Proponent re-configured the waste dumps to avoid known and recorded populations of *L. catapycnon*. Further, all recorded populations of *L. catapycnon* have currently been designated as 'areas of special protection from ground disturbance' and therefore will not be cleared.

Four records (37 individuals) of *Goodenia nuda* (Priority 4) will be impacted by the Proposal. Rio Tinto records show that *Goodenia nuda* has been recorded at least 551 locations across the Pilbara surveys, including 5,862 individual plants. The loss of the individuals recorded from the Proposal Area is therefore considered negligible and would not affect the species' conservation status.

Vegetation clearing will be minimised as much as practicable and restricted to the extent approved by clearly delineating areas and adhering to internal ground disturbance procedures for areas to be cleared. Disturbed areas will be rehabilitated following completion of mining, in accordance with the Yandicoogina Closure Plan.

TERRESTRIAL FAUNA

Terrestrial Vertebrate Fauna

Five fauna habitat types have been mapped in the Proposal Area: Alluvial Plain (Flood Plain), Mulga woodland, Hilltops and Slopes, Pediment Slope and Major Drainage Line. These habitats are considered to be common and widespread in the Hamersley and

Fortescue subregions of the Pilbara bioregion, and are therefore not restricted to the Proposal Area.

Five conservation listed terrestrial vertebrate species have been recorded in the Proposal Area, including four species listed under the EPBC Act and/or the *Wildlife Conservation Act 1950* (WC Act), and one species listed in the Parks and Wildlife Priority Fauna List, as follows:

- Pilbara Olive Python, *Liasis olivaceus barroni* (Vulnerable, Schedule 1);
- Fork-tailed Swift, *Apus pacificus* (Migratory, Schedule 3);
- Eastern Great Egret, *Ardea modesta* (Migratory, Schedule 3);
- Rainbow Bee-eater, *Merops ornatus* (Migratory, Schedule 3); and
- Western Pebble-mound Mouse, *Pseudomys chapmani* (Priority 4).

An additional species, the Chocolate Wattled Bat (*Chalinolobus morio*), while currently not listed under Commonwealth or State legislation, is also considered to be of regional significance as the population appears to be geographically restricted, with records existing only at Weeli Wolli Spring and extending along Weeli Wolli Creek and Marillana Creek.

Clearing of terrestrial fauna habitat is required to facilitate construction of the mine and associated infrastructure. Clearing will include up to 69 ha of riparian zone vegetation. Approximately 87 ha of core habitat, which includes riparian zone vegetation, will be lost within the Proposal Area for the conservation listed Pilbara Olive Python. Aside from one record of a Rainbow Bee-eater, the records of the Western Pebble-mound Mouse are the only conservation listed species recorded within the proposed mine pit and waste dump locations.

Vegetation clearing is not anticipated to cause any significant fragmentation of habitat or disruptions to ecological linkages. The Proposal Area contains fauna habitats that are consistent with the surrounding landscape. Based on the distribution of land systems, fauna habitats occurring in the Proposal Area are well represented in the surrounding area, and connectivity will remain with the intact habitats outside the Proposal Area.

Short Range Endemic Fauna

Twenty potential short range endemic (SRE) invertebrate specimens were recorded from within the Proposal Area, with genetic analysis determining six putative species. Of these species, four mygalomorph spider species are considered to represent potential SREs: Idiopidae sp. I1, Idiopidae sp. I9, Nemesiidae sp. N42 and Nemesiidae sp. N44. All species have been previously observed outside the Proposal Area. These species have been recorded in multiple land systems and substrate types, suggesting they are not restrained to a specific landscape-scale habitat unit. Therefore the probability that these mygalomorph spiders possess a narrow spatial distribution is lower, and thus it is less likely that the removal of potential SRE habitat within the Proposal Area will adversely affect these species.

Aquatic Fauna

The most recent aquatic fauna surveys completed in 2013 and 2014 recorded 283 invertebrate fauna taxa in the Proposal Area. Several undescribed hyporheic taxa were considered to be new species, including species *Cephalodella* n. sp. and *Lecane* 'bulloid' n. sp. Five stygobitic amphipod/isopod species were considered to be potential SREs, of these, two (*Maarrka weeliwolli* and *Pygolabis weeliwolli*) appear to be restricted to Marillana Creek and Weeli Wolli Creek. Three fish species were observed, none of which are conservation listed. Limited aquatic fauna habitat will be lost or fragmented as a result of the Proposal, as the low-flow channel will remain in situ and larger rainfall events will continue to provide natural flood flows in Weeli Wolli Creek, which sustains connection upstream to Weeli Wolli Spring and downstream to Fortescue Marsh. In addition, surplus water discharge has increased the range extent due to increased water availability.

SUBTERRANEAN FAUNA

Stygofauna

A total of 13 phases of stygofauna sampling have been conducted in and around the Revised Proposal Development Envelope since 2003. A total of 2,761 specimens from 62 taxa have been found in the Proposal Area to date, 39 of which occur within the proposed mine pit boundary. Of the 39 taxa recorded within the proposed pit boundary, three species are not known from any other records outside this area: *Notobathynella* sp., *Billibathynella* sp. B02 and *Brevisomabathynella* cf. *pilbaraensis*. These species are not currently conservation listed.

Excavation of the mine pit would result in direct loss of individuals and habitat, and alteration of habitat would also occur as a result of groundwater abstraction and discharge.

The taxa that are present in the proposed pit footprint and the drawdown cone of depression are most at risk from the Proposal. However, the habitat in which the stygofauna occur extends beyond the predicted area of impact from pit excavation and groundwater drawdown. Almost half of the stygofauna assemblage recorded from the Revised Proposal Development Envelope is known from the wider region and the frequency of wider ranging taxa indicates there is unlikely to be geographically restricted taxa. It is considered likely that the three taxa recorded only from the proposed pit would occur throughout the broader alluvials, colluvium calcrete and CID units and therefore would not be significantly impacted by the Proposal. The paucity of records of these taxa may be an artefact of sampling, rather than an indication of an extremely restricted distribution. Due to the large abundance of stygofauna throughout the Proposal Area and the broader Weeli Wolli Creek and Marillana Creek catchments, it is considered unlikely that there will be a substantial regional impact on stygofauna.

Troglofauna

Two phases of troglobitic fauna surveys were undertaken across the Proposal Area and additional troglofauna were opportunistically collected during stygofauna sampling. Six potential troglobitic fauna specimens have been recorded in the Revised Proposal Development Envelope, three of which have been recorded within the Proposal Area: *Myrmopopaea* sp. nov (confirmed troglobite), *Draculoides* sp. indet (confirmed troglobite) and Pauropoda sp. indet (unconfirmed troglobite). *Myrmopopaea* sp. nov. is the only

taxon recorded from within the proposed pit boundary and it is not currently known from any other locations.

The excavation of the mine pit will result in the direct removal of the habitat for troglobitic fauna. However, the low number of specimens recorded within the Proposal Area indicates it is unlikely that troglobitic fauna inhabit the ore deposit in high densities.

The confirmed troglobite *Myrmopopaea* sp. nov. was recorded from interconnected calcrete and alluvium formations within the proposed pit area. These largely interconnected geological formations are located adjacent to, and extend parallel to Weeli Wolli Creek and contain sufficient interstitial spaces and cavities to allow movement of troglobitic fauna. This habitat continuity outside the Proposal Area suggests that all three troglofauna taxa are likely to occur outside the proposed pit.

REHABILITATION AND CLOSURE

The proposed closure strategy, described within the Yandicoogina Closure Plan, has been developed to create a safe, stable, non-polluting landform that supports a native ecosystem. The available overburden and waste materials will be utilised to stabilise the pit walls adjacent to the floodplain and to create a spillway that will facilitate flood water ingress into the final mine void during the peak of large flood events.

The volume of overburden and waste material generated by implementing the Proposal is relatively low compared to the volume of ore extracted. As a consequence, there is insufficient overburden and waste material available to backfill into the pit to cover the groundwater table on closure. Proximity to Weeli Wolli Creek is also an important consideration in development of the closure strategy. Removal of the flood protection levee of closure will reduce the stressors on the riparian floodplain vegetation, but will also enable flood water to interact with the final mine void.

Pit lakes are expected to develop either side of the flood ingress area. The groundwater aquifers, dewatered by implementing the Proposal, will recover to natural (pre-disturbance) levels and provide the base flow for the pit lakes. Flood water entering the mine void will result in rapid increases in the pit lake water levels, creating a dynamic wetland environment on the fringe of the Weeli Wolli Creek floodplain.

Research and trials are required to develop an appropriate revegetation strategy for the wetland areas that will be developed inside the final mine void. Outside of the final void area, rehabilitation will be completed using standard practice techniques, as successfully implemented across Rio Tinto's Pilbara mining operations.

The following closure objectives have been established for the Yandi Operation and will be applied to the Revised Proposal:

- Rehabilitated landforms are stable and designed to manage floodwater appropriately.
- The environmental and cultural heritage values associated with creek flows and function are maintained post-closure.
- Environmental values of Fortescue Marsh are not compromised.

- Water quality within pit lakes support natural ecosystems and are compatible with post-mining land use.
- Alluvial groundwater systems support remnant phreatophytic vegetation.
- Final landforms are rehabilitated to be compatible with post-mining land use.
- Public safety hazards have been addressed.

Completion criteria to measure closure implementation success against these closure objectives have been recommended within the Yandicoogina Closure Plan. The completion criteria will be refined based on information developed during implementation of the Proposal, from baseline studies and rehabilitation trials, then finalised with stakeholders as the Proposal approaches closure.

During the life of the Proposal, investigations will be undertaken and an adaptive management approach will be used to ensure that risks to closure are identified and addressed so as to meet the EPA's objective for rehabilitation and closure.

The key anticipated long term outcomes are as follows:

- Pit walls of the final mine void that are adjacent to Weeli Wolli Creek are stabilised in a way that prevents the creek from collapsing into the mine voids post-closure ensuring continued function of Weeli Wolli Creek.
- All areas disturbed for mining (with the exception of pit walls) and infrastructure that are not required by the State (under conditions of applicable State Agreements) are rehabilitated to a condition compatible with the post-mining land use following decommissioning.
- Creation of two pit lakes and associated dynamic wetland environment within the mine void with water levels that will rise and fall in accordance with flooding of the creek systems.
- Regional hydrogeological impacts are minimised and adequately managed.
- Outside of the mining disturbance areas and more than 2 km from the Proposal mine voids, water levels are largely predicted to return to pre-disturbance levels.
- No impacts to the hydrological regime of the Fortescue Marsh as a result of closure of the site.

OTHER FACTORS

Aboriginal Heritage

Aboriginal archaeological and ethnographic surveys have been completed across the proposed footprint and for the majority of the Proposal Area, with numerous Aboriginal archaeological sites recorded, ranging from low to high in archaeological and cultural significance. The major risks to Aboriginal heritage are related to the disturbance of archaeological or ethnographic sites and impacts on the heritage values of sites and places. Aboriginal heritage sites could potentially be disturbed by proposed activities such as clearing, dewatering, excavation and surface water discharge, although it is Rio Tinto's policy to avoid heritage sites, wherever practicable.

A heritage zone is currently delineated around Weeli Wolli Creek, due to the association of this site with camping activities, ceremonial activities and other cultural activities.

However, it is noted that part of the proposed mining activities occur within this zone. Any long term alteration to the regional water regime will be undertaken in consultation with local traditional owner groups.

The Proposal is expected to have some effect on the ethnographic cultural values of Weeli Wolli Creek, however any disturbance within the Weeli Wolli Creek heritage zone or of other archaeological/ethnographic sites will be in accordance with the provisions of the *Aboriginal Heritage Act 1972* (WA) and will have the consent of the relevant Traditional Owners. Rio Tinto will maintain ongoing consultation with Aboriginal stakeholders over the life of the Proposal, in accordance with processes established for the existing Yandi Operations.

Air Quality

Dust will be generated by construction and mining activities such as vegetation clearing, earthworks and mining (including blasting), vehicle movements and dry ore processing, stockpiling, reclaiming and transport.

As the majority of the Iron Ore at the Proposal is below watertable ore, the moisture content of the ore will reduce the likelihood of dust-related impacts from materials handling. Additionally, the Proposal is remote from sensitive air quality receptors, with other mining operations being the nearest premise.

Amenity

Temporary visual effects in the immediate region around the mine pit will occur from the development of the waste dumps and infrastructure/facilities. The extent and condition of riparian vegetation is also expected to be reduced in the long term as the creeks are ultimately returned to the pre-mining ephemeral system.

During mine closure, the maintenance of aesthetic values for cultural and amenity purposes are an important consideration. Rehabilitation is expected to return the visual amenity as much as possible to the original pre-disturbance landscape. Two pit lakes will be created within the Proposal Area and while changing components of the pre-mining amenity, they are expected to create new ecosystems.

OFFSETS

The Proponent has considered measures to avoid, minimise and rehabilitate impacts to environmental values throughout the design of the Proposal. Taking into account these measures, the following significant residual impact arising from the Proposal has been identified:

- Clearing of up to 1,731 ha of native vegetation in Good to Excellent condition within the Proposal Area, including fauna habitat (excluding riparian zone vegetation[1]).
- Clearing of up to 69 ha of native riparian zone vegetation[1] within the Proposal Area, including fauna habitat.

The EPA has established a strategic conservation initiative to coordinate offsets in the Pilbara. Consistent with the WA Environmental Offsets Guidelines, it is considered that

[1] For the purposes of the offset calculation, riparian zone vegetation is classified as vegetation units within the riparian zone comprising C-coded and F2 coded vegetation located within the RCA.

the residual impact of disturbance of vegetation in Good to Excellent condition or riparian zone vegetation is significant and will therefore require compensation via an offset. A standard offset approach has been developed by the EPA in regard to this residual impact and it has been applied consistently to projects in the Pilbara. As such, the Proponent is proposing to contribute funding of $1,500 (excluding GST) per hectare of native vegetation, and funding of $3,000 (excluding GST) per hectare of riparian zone vegetation cleared to a government-established conservation offset fund or an alternative offset arrangement providing an equivalent outcome as determined by the Minister.

ENVIRONMENTAL MANAGEMENT

The Proponent is a member of the Rio Tinto Group, which has extensive experience in managing the development, operation and environmental compliance of Iron Ore mining projects similar to the Proposal. This experience, along with stakeholder consultation, has been used to define the potential environmental impacts from the Proposal, and the proposed mitigation and management measures. The Proponent aims to conduct its business in an efficient and environmentally responsible manner that is compatible with the expectations of stakeholders. A systematic process of environmental management has been adopted, which improves the likelihood that significant environmental impacts have been identified, investigated and mitigated, as far as practicable. As a result, there is greater certainty in achieving desirable environmental outcomes.

Environmental Management System

Rio Tinto requires its operations to implement and maintain an EMS that provides a model for continuous improvement, the key elements of which include assessing environmental risk and legal requirements, developing objectives and targets for improvement, training, operational control, communication, emergency response, corrective actions, audits and reviews.

Environmental Management Plans

The following key Yandi Operations site specific management documents will be implemented to manage potential impacts associated with the Proposal:

- Yandicoogina Monitoring and Management Plan, which includes:
    - Yandicoogina Vegetation and Groundwater Dependant Ecosystems Monitoring and Management Plan; and
    - Yandicoogina Surface Water Discharge Monitoring and Management Plan;
- Yandicoogina Weed Action Plan:
- Proponent's Pilbara-wide Significant Species Management Plan, including Yandi Operations site specific addendum; and
- Yandicoogina Closure Plan.

Environmental Values Statement

As part of the approval for the existing Yandi Operations, an Environmental Values Statement (EVS) was developed for Weeli Wolli Creek. The current EVS for the Weeli Wolli Creek catchment, included in the revision to the Yandicoogina Monitoring and Management Plan, identifies three high level values; Fortescue Marsh, Flora and

Vegetation and Stygofauna. Other recognised values include fauna, heritage and social aspects.

Environmental Control Instruments and Proposed Environmental Conditions

There are a number of existing regulatory controls that will ensure that environmental values are protected during implementation of the Proposal including requirements under the EP Act regarding discharges and emissions and the Rights in Water and Irrigation Act regarding dewatering. Another of these controls includes environmental conditions in a Ministerial Statement that may be issued by the Minister for Environment allowing the Proposal to be implemented as approved.

The Proponent has proposed environmental conditions for consideration by the Minister for Environment. These conditions are based on those outlined in MS 914 for the existing Yandi Operations, which would be superseded by a new Ministerial Statement, subject to approval of the Revised Proposal.

OUTCOMES

In summary, the key outcomes of the assessment for the Proposal, relating specifically back to the ESD include:

Hydrological processes and Inland waters environmental quality

- Natural surface water systems and flows – potential impacts likely to be minor due to the main creekline surface water flowpaths being maintained and can be managed through typical stormwater management measures such as levees around the pit, diversion drains around waste dumps, and culverts under roads.
- Surface water resources – discharge wetting front will be within existing approved limits, and therefore there will be negligible additional impacts on the downstream hydrological system of Weeli Wolli Creek.
- Altered flow regime to the Fortescue Marsh – surface water wetting front associated with the additional discharge from the Proposal is predicted to remain within existing approved limits of MS 914.
- Potential contamination of surface water and groundwater – acid rock drainage risk at the Revised Proposal Development Envelope has been assessed as low. Site drainage will be designed to minimise or eliminate surface runoff into areas where activities with a potential risk of hydrocarbon contamination occur. Management of waste dumps will ensure that risks of contamination of surface and groundwater are minimised. Groundwater discharged at the surface is fresh and is currently monitored and managed following ANZACC guidelines for freshwater ecosystems.

Flora and vegetation

- Clearing of up to 1,800 ha of vegetation (including 69 ha riparian vegetation).
- Stress and loss of some riparian vegetation associated with dewatering activities (drawdown), particularly more groundwater dependant vegetation and younger recruitment/augmented areas of riparian vegetation sustained by pre-existing

discharge, with the vegetation expected to return to a more 'natural' state (i.e. pre-mining).

- Loss of some riparian vegetation associated with surplus water discharge, particularly waterlogging affects and the establishment of waterlogging tolerant species including sedges and rushes, though overall impacts will be limited to the currently approved footprint limit within MS 914 (17 km downstream from confluence of Marillana and Weeli Wolli Creeks).
- No loss of known and recorded individuals of *Lepidium catapycnon* (Hamersley Lepidium); redesign of the waste dumps has avoided recorded individuals.
- Other vegetation communities within the Proposal Area are largely typical of that occurring in similar habitats elsewhere in the region, or are considered relatively widespread in the Pilbara beyond the Proposal Area.
- Removal of some individuals of Priority 4 flora species (*Goodenia nuda*), which will not affect the species' conservation status.
- Rehabilitation using native vegetation of areas disturbed by the Proposal, consistent with the Yandicoogina Closure Plan.

Terrestrial fauna

Terrestrial vertebrate fauna

- Clearing of up to 1,800 ha of terrestrial fauna habitat over the life of the project and habitat degradation due to the altered groundwater regime (some tree deaths within the riparian zone), which may lead to local reductions in current fauna populations in the Proposal Area.
- The habitat types present in the Proposal Area are considered to be well represented in the local and regional area. It is considered likely that terrestrial fauna will continue to persist in the remaining habitats within and adjacent to the Proposal Area during operations.
- Clearing will result in the direct removal of up to 1,800 ha of potential SRE habitat within Proposal Area; this habitat is considered widespread locally and regionally.
- Limited aquatic habitat will be lost or fragmented as a result of the Proposal.
- Vegetation clearing within the Proposal Area is not anticipated to cause any significant fragmentation of habitat or disruptions to ecological linkages.
- Progressive rehabilitation, with consideration given to restoring pre-mining fauna habitat values where practicable.

Short range endemic fauna

- Four mygalomorph spider species are considered to represent potential SREs: Idiopidae sp. I1, Idiopidae sp. I9, Nemesiidae sp. N42 and Nemesiidae sp. N44.
- All species have been previously recorded outside the Proposal Area.
- Potential SRE habitat within the Proposal area is considered widespread locally and regionally.

Aquatic fauna

- The most recent aquatic fauna surveys in 2013 and 2014 recorded 283 invertebrate fauna taxa in the Proposal Area.
- Some undescribed hyporheic taxa are potential new species.
- Five stygobitic amphipod/isopod species were considered to be potential SREs.
- Three fish species were observed, none of which are conservation listed.
- Limited aquatic fauna habitat will be lost or fragmented as a result of the Proposal, as the low-flow channel will remain in situ and larger rainfall events will continue to provide natural flood flows in Weeli Wolli Creek, which sustains connection upstream to Weeli Wolli Spring and downstream to Fortescue Marsh.

Subterranean fauna

- Thirteen phases of stygofauna sampling have been conducted in and around the Revised Proposal Development Envelope since 2003.
- A total of 2,761 specimens from 62 taxa have been recorded in the Proposal Area to date, 39 of which occur within the proposed mine pit boundary.
- Of the 39 taxa recorded within the proposed pit boundary, three species are not known from any other records outside this area: *Notobathynella* sp., *Billibathynella* sp. B02 and *Brevisomabathynella* cf. *pilbaraensis*. These species are not currently conservation listed and current distribution is considered likely to be an artefact of sampling.
- Direct mortality and reduction in available subterranean habitat will occur as a result of pit excavation and groundwater drawdown.
- Potential impacts will be localised to the proposed pit area and the groundwater drawdown zone during mining operations. However, it is not expected to significantly impact subterranean assemblages and species persistence.
- The continuous nature of the alluvium, colluvium and calcrete units in which the subterranean fauna were predominately recorded indicates that geology is not a limiting factor in the distribution of the taxa currently known from the proposed pit area and the groundwater drawdown zone within the Proposal Area.
- The risk of pollutants being transported into the subterranean habitats is likely to be low and restricted to localised areas.

Rehabilitation and closure

- Pit walls of the final mine void that are adjacent to Weeli Wolli Creek are stabilised in a way that prevents the creek from collapsing into the mine voids post-closure, ensuring continued function of Weeli Wolli Creek.
- All areas disturbed for mining (with the exception of pit walls) and infrastructure that are not required by the State (under conditions of applicable State Agreements) are rehabilitated to a condition compatible with the post-mining land use following decommissioning.

- Creation of a dynamic wetland environment within the mine void, including two pit lakes and associated lake fringe, with water levels that will rise and fall in accordance with flooding of the creek systems.

- Regional hydrogeological impacts are minimised and adequately managed.

- Outside of the mining disturbance areas and more than 2 km from the Proposal mine voids, water levels are largely predicted to return to pre-disturbance levels.

- No impacts to the hydrological regime of the Fortescue Marsh as a result of closure of the site.

Other Factors

Aboriginal heritage

- Aboriginal heritage sites could potentially be disturbed by proposed activities such as clearing, dewatering, excavation and surface water discharge; however it is Rio Tinto's policy to avoid heritage sites, wherever practicable.

- Any disturbance to archaeological/ethnographic sites will be in accordance with the provisions of the *Aboriginal Heritage Act 1972* (WA) and will have the consent of the relevant Traditional Owners.

Air quality

- The proposal will generate dust during construction and mining activities such as vegetation clearing, earthworks and mining (including blasting), vehicle movements and dry ore processing, stockpiling, reclaiming and transport.

- Existing Rio Tinto procedures and practices used at the existing Yandi Operations to effectively prevent significant dust emissions will be applied to the Proposal.

Amenity

- Temporary visual effects in the immediate region around the mine pit with the use of waste dumps and infrastructure/facilities.

- Extent and condition of riparian vegetation is expected to be reduced in the long term as the creeks (that are currently receiving discharge water from mining operations) are ultimately returned to an ephemeral system.

- Rehabilitation is expected to return the visual amenity as much as possible to the original pre-disturbance landscape. Two pit lakes will be created within the Proposal Area; while changing components of the pre-mining amenity, they are expected to create new ecosystems.

- The management measures outlined in the Yandicoogina Closure Plan are expected to maintain the key amenity values after mine closure.

Offsets

Taking into account measures to avoid, minimise and rehabilitate impacts, the following significant residual impact arising from the Proposal has been identified:

- Clearing of up to 1,731 ha of native vegetation in Good to Excellent condition within the Proposal Area, including fauna habitat (excluding riparian zone vegetation[2]).

- Clearing of up to 69 ha of native riparian zone vegetation[2] within the Proposal Area, including fauna habitat.

[2] For the purposes of the offset calculation, riparian vegetation is classified as vegetation units within the riparian zone comprising C-coded and F2 coded vegetation located within the RCA.

Part 1 – Introduction

This part introduces and broadly outlines the Proposal and the purpose and scope of this document. This part also outlines development alternatives considered and describes the stakeholder engagement process undertaken for the Proposal.

1. Introduction

1.1 Overview

Hamersley Iron – Yandi Pty Limited is seeking to develop a new brownfields iron ore mine pit to sustain its existing Yandicoogina Operations (Yandi Operations). This Proposal is referred to as the 'Yandicoogina Pocket and Billiard South Iron Ore Development' (the Proposal) and will involve construction and operation of a new mine pit, waste dumps and associated infrastructure to enable sustained production from the existing Yandi Operations. Collectively, the Proposal and the existing Yandi Operations are referred to as the 'Revised Proposal'.

The Proposal is expected to have a total throughput of up to 31 million tonnes per annum (Mtpa), as the existing Yandi Operations are depleted, and is expected to have an operational mine life of approximately 16 years.

1.2 Proponent

The Proponent for the Proposal is Hamersley Iron – Yandi Pty Limited ('the Proponent'). The Proponent is a wholly owned member of the Rio Tinto Group and forms part of Rio Tinto's global Iron Ore business. This includes several wholly owned subsidiaries and joint venture initiatives in the Pilbara region of north west Western Australia (WA).

The Proponent contact person in relation to the environmental approvals process for the Proposal is:

Ms Melinda Brand
Rio Tinto Iron Ore
152-158 St Georges Terrace, Perth
GPO Box A42
Perth WA 6837
Telephone: +61 8 6211 6991
Facsimile: +61 8 9327 2696
Email: melinda.brand@riotinto.com

1.3 Location of the Proposal and Proposal elements

The Proposal (the Proposal) is located in the central Pilbara region of WA approximately 90 kilometres (km) north west of Newman and 300 km south east of Dampier (

Figure 1). The Proposal deposits are located immediately east of the existing Yandi Operations Junction Central (JC) and Junction South East (JSE) deposits and the more recently approved Junction South West (JSW) and Oxbow deposits (**Figure 2**).

Plan No: PDE0133270v2
Proj: MGA94 Zone50

Geospatial Information and Mapping

The Proposal is centred on a substantial CID immediately to the east of the existing Yandi Operations. The Proposal is a revision to the existing Yandi Operations as approved under Ministerial Statement No. 914 (MS 914) in 2012, and includes the following key additions:

- A new below water table open cut pit and associated infrastructure (ore and waste dumps and haul roads).
- Supporting infrastructure (light vehicle roads, creek crossing, flood protection levees, diversion drains, dewatering infrastructure, power and telecommunications).
- Additional dewatering of the CID aquifer, including discharge to local creeks.

The Proposal will utilise processing and materials handling infrastructure already installed at the existing Yandi Operations.

1.4 Proposal context

1.4.1 Existing Yandi Operations

The existing Yandi Operations are currently centred over three mining areas: JC, JSE and JSW (A & C); with a replacement orebody Oxbow due to come online in 2017.

The mine pits are all contained within a continuous CID orebody, which also forms a major aquifer in the area. Approximately 80% of the orebody is situated below the pre-mining water table and as a consequence, dewatering is a key requirement of mining activities for the existing Yandi Operations.

The existing Yandi Operations, as approved, currently consists of:

- Five open cut pits within the CID: JC, JSE and JSW-C (currently operating); and JSW-A and Oxbow (approved but not yet operating).
- A 90 km rail line to Juna Downs.
- Mine infrastructure (e.g. product stockpiles, waste dumps, topsoil, low grade stockpiles, waste fines storage facilities and haul roads).
- Associated infrastructure (e.g. overland conveyors, mine access roads, offices, warehouses, accommodation, bore fields, fuel storage facilities and utilities).
- Abstraction of up to 53 gigalitres per year (GL/y).
- A water management system including on-site reuse of water abstracted from pit dewatering, and discharge of surplus volumes into creek systems.
- Dry and wet processing plants.
- Flood protection structures.
- Power and communications infrastructure.

The key characteristics of the existing Yandi Operations, as described in Schedule 1 of MS 914, and the Proposal key characteristics, which together comprise the Yandicoogina Iron Ore Project – Revised Proposal, are outlined in **Table 1**.

Table 1: Summary of Revised Proposal key characteristics

Characteristic	Revised Proposal		
	Yandi Operations (existing)	**The Proposal (additional proposed)**	**Yandi Operations (Revised Proposal)**
Short description	The proposal is to develop Iron Ore deposits Junction Central, Junction South East, Junction South West and Oxbow, located in the central Pilbara region of Western Australia, on mining lease 274SA. Key aspects of the proposal include: • Ore transport and storage infrastructure (including rail link) – car dumpers, conveyors, stockyards, ore stackers and ore reclaimers, and storage infrastructure, rail loops. • Rail corridor allowing for rail lines and associated infrastructure. • Construction and operations support infrastructure. • A diesel-fired power station and transmission lines. • Dry and wet processing plants (including in pit waste fines storage facilities). • Flood protection structures. • Accommodation camps. • Access roads. • An airstrip.	The proposal is to develop a below water table open cut Iron Ore mine at Pocket and Billiard South, located in the central Pilbara region of Western Australia, on mining lease 274SA. Key aspects of the proposal include: • Temporary surface waste dumps; • Major infrastructure including a flood protection levee, a diversion drain and Weeli Wolli Creek crossing; and • Supporting mine infrastructure including power spur, haul roads and ramps, mine access and internal road network, and dewatering infrastructure (dewatering pipeline, bores and outlets).	The proposal is to develop Iron Ore deposits Junction Central, Junction South East, Junction South West, Oxbow and Yandi PBS, located in the central Pilbara region of Western Australia, on mining lease 274SA. Key aspects of the proposal include: • Ore transport and storage infrastructure (including rail link) – overland conveyors, stockyards, ore stackers and ore reclaimers, and storage infrastructure, rail loops. • Rail corridor allowing for rail lines and associated infrastructure. • Construction and operations support infrastructure. • 220kv power network including switchyard, back-up diesel power and transmission lines. • Dry and wet processing plants (including in pit waste fines storage facilities). • Flood protection structures and creek crossings. • Accommodation camps. • Access roads.
Physical elements			
Mine and associated infrastructure	Vegetation clearing up to 5,600 ha within Restricted Clearing Area 1; and Vegetation clearing up to 60 ha within Restricted Clearing Area 2	Vegetation clearing up to 1,300 ha for mining and waste dumps Vegetation clearing up to 500 ha for infrastructure	Vegetation clearing up to 7400 ha within Revised Proposal Development Envelope. Vegetation clearing up to 129 ha within the proposed Restricted Clearing Area.
Railway and associated infrastructure	90 km rail line	No additional rail required	No additional rail required.

Characteristic	Revised Proposal		
	Yandi Operations (existing)	**The Proposal (additional proposed)**	**Yandi Operations (Revised Proposal)**
Operational elements			
Dewatering	No more than 35 GL/year from Junction South East and Junction Central operations. No more than 18 GL/year from Junction South West A, Junction South West C and Oxbow operations.	Approximately 50 GL/year for the Proposal	No more than 83 GL/year for the entire Revised Proposal.
Surface water discharge	Up to 16 GL/year from Junction South West A, Junction South West C and Oxbow operations.	Approximately 50 GL/year for the Proposal	Up to 78 GL/year for the entire Revised Proposal. No water flow or pooling further than 17 km downstream from the Marillana Creek and Weeli Wolli Creek system confluence.

1.4.2 Approvals history of the existing Yandi Operations

Iron Ore mining at the existing Yandi Operations is subject to the *Iron Ore (Yandicoogina) Agreement Act 1996*, which came into effect on 22 October 1996. Mining at JC received approval from the Minister for the Environment on 24 May 1996 (MS 417) and was subsequently amended on 1 October 1999 (MS 523). Mining at JSE received approval from the Minister for the Environment on 22 October 2005 (MS 695), with mining activities commencing at JC and JSE in 1998 and 2006 respectively.

The most recent approval (MS 914, issued on 18 October 2012) amalgamated the existing JC and JSE Ministerial Statements to a single set of contemporary conditions via s46B of the WA *Environmental Protection Act 1986* (EP Act), and included the incorporation of three new mine pits at JSW-A & C and Oxbow. The JSW and Oxbow approval was also subject to Commonwealth approval under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) via Decision notice 2011/5815.

1.5 Purpose and scope of this document

This Public Environmental Review (PER) document is required for the formal assessment of the Proposal under Part IV of the EP Act, administered by the WA Environmental Protection Authority (EPA). The Proposal was referred to the WA EPA on 4 July 2014 and the EPA determined that the Proposal required assessment at the level of PER.

The purpose of the PER is to present an environmental review of the principal components of the Proposal, including a detailed impact assessment and description of proposed environmental management measures for key environmental factors in accordance with the Environmental Scoping Document (ESD) prepared by the EPA (**Appendix 1**).

The preliminary key environmental factors relevant to the Proposal are (as outlined in the ESD):

- Flora and vegetation.
- Terrestrial fauna.
- Subterranean fauna.
- Hydrological processes and inland waters environmental quality.
- Rehabilitation and closure (integrating factor).
- Offsets (integrating factor).

During the assessment of proposals, other factors or matters may be identified as relevant to the proposal, but are not of significance to warrant further assessment by the EPA, or are impacts that can be regulated by other statutory processes to meet the EPA's objectives. However in some circumstances, other factors, while not being considered as preliminary key environmental factors or integrating factors, may require greater emphasis in the PER document. The preliminary other environmental factors relevant to the Proposal are (as outlined in the ESD):

- Aboriginal heritage.
- Air quality.
- Amenity.

The State environmental assessment process and the identification of key environmental factors for the Proposal are further described in Section 8 and Section 9 respectively.

The PER addresses all phases of the Proposal (construction, commissioning, operations and closure) and is structured as follows:

- **Part 1 Introduction**: A discussion of the purpose and scope of this document, the background to and development of the Proposal, the development alternatives considered, and details of the stakeholder engagement process undertaken.
- **Part 2 Description of Proposal**: A detailed description of the Proposal.
- **Part 3 Overview of Existing Environment**: An overview of the relevant features of the existing environment of the Revised Proposal Development Envelope and surrounding area.
- **Part 4 Approach to environmental factors**: A description of the State and Commonwealth environmental assessment processes, the applicable legislative and policy context and the approach taken for considering the potential environmental impacts of the Proposal.
- **Part 5 Assessment of environmental factors**: An assessment of key potential environmental impacts of the Proposal on the identified key environmental factors and the environmental management measures and predicted outcomes.
- **Part 6 Summary of cumulative impacts**: A summary of the cumulative impacts associated with the Proposal and nearby projects.
- **Part 7 Proposed environmental management program and environmental commitments**: A description of the environmental management framework and measures to offset any significant residual impacts that may arise from implementation of the Proposal, and proposed conditions of approval.

2. Development justification and alternatives considered

2.1 Proposal rationale and benefits

The Proposal is in close proximity to the existing Yandi Operations including ore processing plants and rail load-out facilities at JC, and will sustain mining as the existing deposits become depleted.

The Proposal will optimise Rio Tinto's existing infrastructure where possible, including railway, power, communications and road networks. This will reduce the extent of new infrastructure typically required for greenfield developments and result in a smaller disturbance footprint than would otherwise be required for a project of this scale.

These aspects make the Proposal a highly desirable option to contribute to the continued success of the WA Iron Ore industry, with consequent benefits for the wider economy.

New employment will be created during the mine construction phase of the Proposal. Further, the operating life of existing mine and rail transportation infrastructure will be extended resulting in the operational workforce being maintained beyond the lifespan of the existing Yandi Operations.

The Proposal will result in the continuation of economic benefits for WA and Australia through:

- contribution to the value of mineral exports;
- royalties and taxation payments;
- capital investment;
- increasing direct and indirect employment opportunities in the region;
- increasing demand for goods and services supporting the regional economy; and
- assisting to sustain the Pilbara Iron Ore industry.

The Banjima, Nyiyaparli and Yinhawangka people (the Traditional Owners) will also benefit under the terms of the Yandicoogina Land Use Agreement (YLUA). The YLUA was the first major land use agreement to be signed in Australia, and provides the basis for delivering social and economic benefits to Aboriginal stakeholders.

The ongoing activities of the Proponent, and more broadly Rio Tinto, in the Pilbara region will continue to support social and economic development projects, including:

- increasing the potential education, training, employment and business options for local Aboriginal people; and
- funding a range of organisations in the region, including sporting and cultural groups.

In connection with its existing and planned mining activities in the Pilbara, Rio Tinto also contributes to a range of research activities addressing regionally relevant environmental impacts. Examples of these projects include research into:

- Plant-water relationships in Pilbara vegetation, including:
  - the occurrence and nature of groundwater dependence in different tree species;
  - developing methods for measuring the effects of groundwater drawdown on vegetation; and
  - water use physiology of Mulga vegetation and strategies for maintaining surface flow regimes for Mulga conservation.
- The distribution and taxonomy of subterranean and short range endemic fauna, in collaboration with the Western Australian Museum (WAM) and in association with the Department of Parks and Wildlife (Parks and Wildlife).
- Predicting and managing water quality in pit voids.
- The palaeoclimatic history, geology and hydrology of the Fortescue Marsh.
- Recharge and hydrological process of Weeli Wolli Creek.
- Adaptive responses of fish to altered flow regimes and Pilbara regional study of bioaccumulation of metals in fish.

Key research collaborators in these projects include the University of Western Australia, Parks and Wildlife and WAM.

2.1.1 Demand for Iron Ore

Mining is an important component of the WA and national economies. The value of Western Australia's mineral and petroleum industry in 2014 reached just over $114 billion (DMP 2015). Iron Ore remained the State's highest value commodity, accounting for a $65 billion (75%) of total mineral sales in 2014. This represents a decrease of 6% from 2013, which can be attributed to the sharp drop in Iron Ore prices in the second half of the year. In total 697 million tonnes of Iron Ore were exported which was an increase of 25% on the previous calendar year (DMP 2015).

Mining and petroleum contributed approximately 91% of WA's merchandise exports in 2014. China remained the state's largest market, accounting for 51% of the state's total merchandise exports. As at March 2015, Western Australia had an estimated $179 billion worth of resource projects under construction or in the committed stage of development. A further $118 billion has been identified as being allocated to planned or possible projects in coming years (DMP 2015).

2.2 Evaluation of development alternatives

2.2.1 Evaluation of crusher and ore transport alternatives

A number of crusher and conveyor configurations were investigated based on varying saleable ore product tonnages to test crushing and conveying as an alternative to trucking to the plant. Some of the various conveyor routes and crusher locations examined are shown in **Figure 3**.

Two crusher locations were assessed; one to the east of the orebody, and one to the west, using a combination of trucking to the crushers and then conveying to the existing processing plant(s). From the analysis carried out, the crusher facilities at the existing

Yandi Operations will be utilised and trucking is the preferred ore transport option for the Proposal.

2.2.2 Evaluation of options for crossing Weeli Wolli Creek

A crossing at Weeli Wolli Creek is required to enable ore movement from the Proposal deposits to the various JSE and JC processing plants. As the Proposal deposit is entirely located east of Weeli Wolli Creek, a creek crossing via a culvert-floodway structure will be required to access facilities at the existing Yandi Operations, located entirely west of Weeli Wolli Creek. A number of locations for a creek crossing were identified, with the aim of minimising disturbance and water velocities and thus the potential impact to Weeli Wolli Creek and any heritage or environmentally sensitive areas.

The following three options for design of the crossing on Weeli Wolli Creek were considered:

- an engineered bridge;
- the existing Marillana-type floodway option; and
- a culvert-floodway consisting of cement stabilised base-course overlaid with a crushed rock wearing course, overlying eight 3.6 m corrugated steel pipes over the low-flow channel.

Following consultation with technical representatives on the study team for water, environment and heritage, the culvert-floodway concept was chosen as the option preferred. The culvert-floodway appears to be a more stable design than the existing Marillana-type floodway in a flooding situation, and is anticipated to cause less disruption to the flow of Weeli Wolli Creek during construction and operation.

2.2.3 Evaluation of water management options

Dewatering for the Proposal will be fully integrated with the existing Yandi Operations whole-of-site water demand; however, a substantial volume of surplus water is likely to be generated over the life of the Proposal, ranging from the existing approved approximately 16 GL/y[3] up to 78 GL/y. Some of the groundwater abstracted is expected to be used for on-site purposes such as dust control, camp usage and ore processing. The remainder will be discharged into the Marillana and Weeli Wolli Creek systems at controlled, release discharge points. Water discharge for the Proposal will tie in with the existing Yandi Operations water disposal infrastructure in the lower reaches of Marillana Creek towards the Weeli Wolli Creek confluence.

[3] Note that this limit relates to JSW and Oxbow, and does not include JC and JSE surplus water discharge. Total surplus water discharge is approximately 48 GL/y for existing Yandi Operations.

Iron Ore (WA)

Figure 3
Proposal development alternatives

Drawn: M.Swebbs Plan No: PDE0128630v2
Date: October, 2015 Proj: MGA94 Zone50

Geospatial Information and Mapping

Alternative options for the use of surplus water over and above the existing approved discharge limits for the Yandi Operation have been investigated during the pre-feasibility study, in line with the *Pilbara Water in Mining Guidelines* [Department of Water (DoW) 2009)] and *Strategic Policy 2.09: Use of mine dewatering surplus* (DoW 2013) including consideration of:

- reuse on-site;
- transfer to other current and future mining projects;
- aquifer recharge info aquifers;
- re-injection into aquifers;
- storage and evaporation;
- seasonal storage and release of water; and
- continuous surface release of water.

Additional options that have been investigated include the transfer of water to other sites such as Koodaideri and/or Hope Downs 1 and storage of water in the JC pit lake. These options and the rationale behind the selected option are described in detail in Section 13.3.4.

2.2.4 Evaluation of alternative office and workshop locations

A workshop for daily and weekly maintenance and potentially heavy vehicle refuelling facilities are proposed to be constructed, along with new office facilities consisting of an administration building for daily crew shift change meetings and a crib room with toilets. Three options were identified for the location of the workshop, refuelling and office facilities, taking into account considerations for minimal potential impact to heritage and environmental sites (**Figure 3**). An alternative location to the three options originally identified was selected due to optimisation of the location based on existing facilities.

2.2.5 No development option

The 'do nothing' alternative would result in the loss of opportunity to add value to Australia's raw materials exports, the loss of economic, social and employment opportunities and the loss of potential for future developments in downstream processing of raw materials. If the Proposal does not proceed, the State of WA would forego substantial economic benefits, including:

- viable Iron Ore deposits at the Yandi Operations remaining undeveloped; and
- the decline and eventual end of production from the existing mines at Yandi Operations.

Not proceeding will prematurely reduce the existing workforce at the Yandi Operations and opportunities for supporting local communities and infrastructure would also be foregone. The ore quality within the Proposal deposits will maintain product quality specifications from the existing Yandi Operations and the Proposal will also prolong the use of the existing ore processing and transport infrastructure at Yandi.

If the Proposal did not proceed, the world's demand for Iron Ore would then be met through the development of alternative ore deposits and processing facilities (which may have greater potential environmental impacts than the Proposal) or the development of equivalent projects located overseas with the resultant loss of benefits to the Pilbara, WA and Australia.

3. Stakeholder engagement

3.1 Key stakeholders

The following key stakeholders have been identified for the Proposal:

- Government agencies:
  - Office of the Environmental Protection Authority (OEPA).
  - Department of the Environment (DoE; Commonwealth).
  - Department of Aboriginal Affairs (DAA).
  - Department of Parks and Wildlife (Parks and Wildlife) – Pilbara regional office and Perth office Environmental Management Branch.
  - Department of Environment Regulation (DER).
  - Department of Mines and Petroleum (DMP).
  - Department of State Development (DSD).
  - Department of Water (DoW) – Pilbara regional office and Perth office.
  - Shire of East Pilbara.
- Non-government organisations:
  - Conservation Council of WA.
- Community:
  - Traditional Owners (Gumala Aboriginal Corporation).
  - Marillana Pastoral Station operators.
- Industry:
  - BHP Billiton Iron Ore (BHP).

3.2 Stakeholder engagement process

Discussions regarding the Proposal have been held with a number of stakeholders (**Table 2**).

The timing of the consultation program has enabled topics raised to be considered in the early design phase of the Proposal, during determination of management measures and as part of the preparation of the PER.

3.3 Stakeholder comments and Proponent responses

The main common topics/issues raised by stakeholders as part of the stakeholder engagement process were:

- impacts to vegetation and flora (particularly riparian vegetation and relationship to MS 914 clearing limits);
- surface and groundwater impacts, and water management;
- potential impacts to the Marillana and Weeli Wolli Creek systems;
- cumulative impacts (particularly to the creek systems);
- rehabilitation and closure (including the development of pit lakes); and
- employment opportunities for Traditional Owners.

These are outlined in more detail in **Table 3**, with the Proponent responses.

3.4 Ongoing consultation

The Proponent will continue consultation with relevant stakeholders during the environmental assessment process and through the implementation of the Proposal. In addition to the Traditional Owner groups represented by the Gumala Aboriginal Corporation and the pastoral station operators, the Proponent will consult with regulators including, but not limited to:

- DoW on the management of water resources and other matters related to the WA *Rights in Water and Irrigation Act 1914* (the RIWI Act) licensing requirements for the operations.
- DAA on the management of Aboriginal heritage sites and other matters related to the WA *Aboriginal Heritage Act 1972* requirements.
- Parks and Wildlife regarding Threatened and Priority flora and fauna species, and the Fortescue Marsh.
- DER regarding licensing matters (Part V of the EP Act).
- DSD regarding approval of the Proposal pursuant to the provisions of the *Iron Ore (Yandicoogina) Agreement Act 1996* (WA).
- OEPA regarding details of the Proposal and environmental offsets.
- DMP and other relevant stakeholders regarding closure objectives and indicative completion criteria for the Proposal.

Table 2: Stakeholder consultation relevant to the Proposal

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
OEPA		
21 March 2014	Proposal Pre-referral Presentation to OEPA. The Proponent discussed the Proposal being a Revised Proposal and provided a summary of the results of the biological surveys, potential impacts and preliminary key environmental factors for assessment. The OEPA queried why Billiard North was not included. Also queried why Billiard North was included in the Closure Plan update if not being included in the referral. Cumulative impacts – OEPA indicated that FMG's Nydinghu project and BHP's Jinidi project would need to be considered with the Proposal impacts. Queried if FMG had consulted with the Proponent on their Project. OEPA suggested that because this was a Revised Proposal that Rio would need to identify the key changes for this project in relation to the existing Yandi Operations as approved under MS 914. OEPA indicated that management of surplus water was a key focus, and recommended early consultation with the Department of Water. OEPA also queried disturbance in avoidance areas as delineated in MS 914 i.e. where/how the MS 914 avoidance area was delineated and what we were proposing in terms of disturbance. The Proponent also discussed the expected schedule for formal referral to the OEPA and a proposed Commonwealth referral.	The Billiard North project is not currently at a stage of evaluation where enough information is available to support an Environmental Impact Assessment. It was included in the Closure Plan to support a change in approach to the existing Closure Plan for JC and JSE, and to illustrate the broader life of mine closure objectives as required by DMP. A description of the Proposal and a comparison to the existing Yandi Operations is outlined in Sections 1 and 4 of this PER. The assessment process and referral timing is outlined in Section 8. Potential impacts to hydrological processes, and vegetation and flora are outlined in Sections 13 and 14 respectively. Cumulative impacts are discussed within the environmental factor sections.
21 March 2014	Presentation of the New Yandicoogina Life of Mine Closure Plan Including: • Yandicoogina project overview. • Closure objectives and criteria. • Preferred closure strategy. • Landform design.	Rehabilitation and closure associated with the Proposal is outlined in Section 17.

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	• Water management. • Habitat considerations for rehabilitation (and proposed wetland rehabilitation trial). • Unexpected closure. • Further study focus areas. • Compliance review. Key queries included salinity range of pit lakes, modelling undertaken, potential for metals to be released with increased salinity, interaction of saline pits and fresh water pits, and interactions with the creeklines, frequency of flushing of the pit lakes. Also access to pit lakes and safety issues. Discussion on development of completion criteria. Interest in wetland rehab trial and interest in rehabilitation success.	
21 April 2014	The Proponent provided detailed overview of Proposal, current/planned environmental studies, potential environmental impacts and proposed management. The preferred approvals pathway was discussed – existing management in place via MS914 – Level of Assessment will depend on significance of proposal. OEPA queried: • Closure - why Billiard North was not included in the referral if it is included in the Yandi life of mine Closure Plan. • Cumulative impacts – FMG Nyidinghu would need to be included in the cumulative impact assessment as well as Jinidi. • Avoidance areas in MS 914 – queried where they were derived from and what Hamersley Iron was proposing in terms of disturbance. • Referral – to focus on key changes for this Proposal in relation to the existing Yandi Operations.	The Proponent believes that existing conditions and management required under MS 914 for Yandi Operations would adequately address key potential impacts for the Proposal. An increase in disturbance, additional water management, and consideration of cumulative impacts are the key additional features for the Proposal. The Billiard North project is not currently at a stage of evaluation where enough information is available to support an Environmental Impact Assessment. It was included in the Closure Plan to support a change in approach to the existing Closure Plan for JC and JSE and to illustrate the broader life of mine closure objectives as required by the DMP.
21 April 2014	The Proponent provided detailed overview of the life of mine Closure Plan for the Revised Proposal. OEPA were interested in approach to wetland rehabilitation and also rehabilitation success /	The Proponent provided a copy of the presentation to the OEPA and submitted the Yandi life of mine Closure Plan to the OEPA on 31 March 2014.

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	monitoring. Discussion on pit lakes and potential for Oxbow to be saline.	Rehabilitation and closure associated with the Proposal is specifically outlined in Section 17.
12 June 2014	Updated hydrological information discussed with OEPA. Discussion on Proposal pit encroachment into Weeli Wolli Clearing Avoidance Area depicted on MS 914. Referral – to focus on key changes for this proposal in relation to the existing project (Flora and Vegetation, Fauna, hydrological processes, Closure and Rehabilitation). Context and justify impacts to environmental values identified in MS 914.	The referral document was updated to include further details on Proposal pit encroachment on the clearing avoidance zone depicted in MS 914, and focus on key changes from the existing Yandi Operations.
5 November 2014	Updated presentation on hydrogeological aspects of PBS Timing. Latest data. Surface water update – flood modelling and discharge extent modelling. Groundwater update – modelling and pump test data. Surplus water management – run through of all of the options investigated and discussion of discharge option into Marillana – Weeli Wolli creek as the only feasible option. Closure update. Other items discussed included details of the proposed levee including design, height, flood Annual Recurrence Interval (ARI) design, materials, changes to the low-flow line, and impacts on riparian vegetation from construction of the levee. Closure – stability of the pit lakes and how they will be designed and water quality.	Modelling results and predicted impacts to hydrological processes is outlined in Section 13. The Yandi life of mine Closure Plan has been updated to include the Proposal, with rehabilitation and closure of the Proposal specifically outlined in Section 17.
9 February 2015 4 March 2015	Brief update and discussion of aspects of the Proposal. Discussion of timeframes for PER and ESD. Details of the ESD discussed. Minor or Preliminary works discussion for element of the Proposal. Monitoring bores at the Tree Health monitoring sites discussed including number of sites, type of rig, clearing required and timelines.	Application for Minor or Preliminary works to be submitted. Notice for proposed monitoring works in Weeli Wolli submitted to compliance branch in June 2015.
21 April 2015	Update on Proposal Environmental Impact Assessment, including presentation of DVD's to	Information regarding hydrological processes is outlined in

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	convey: • Updated impact predictions from discharge. • Updated impact predictions from drawdown. • Timeframes. Discussion undertaken covering current altered environment and change from current to change from baseline. Discussion of any mitigation the Proponent was proposing to manage uncertainty on predictions, using an adaptive management approach, such as uncertainty of rate of change of water availability.	Section 13.
EPA		
9 June 2014	Discussed Proposal including Minor or Preliminary Works application and upcoming draft PER. Key queries raised by EPA included: *Closure.* • Details of pit lakes, including size, depth, water quality (metals and salinity), interactions with the creeklines, potential for plumes and impacts on Fortescue Marsh, long term implications. • Rehabilitation. • The Proponent's current understanding, science, results, gaps, timeframes.	Information regarding rehabilitation and closure is outlined in Section 17.
9-10 September (Site Visit: EPA / OEPA)	Site visit to Yandi Operations to specifically view and discuss the Proposal Presentation and DVD presentation of the project, predicted environmental impacts and current scientific knowledge Fly over of existing Yandicoogina Operations including review of Marillana and Weeli Wolli Creeks from Weeli Wolli Spring to the alluvial outwash fan near Fortescue Marsh Discussion of the environmental values of the Fortescue and Weeli Wolli Creek catchment and principles around operating in the Weeli Wolli Creek catchment Review of existing Yandicoogina Operations and the proposed PBS pit	Updates to the revised draft PER document including, but not limited to: articulate the Environmental Values Statement; and to clearly show the configuration of Weeli Wolli Creek and vegetation associations to more clearly present the impacts of the flood protection levee.

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	Review of wetland rehabilitation trial Discussion of closure aspects including pit depths, interactions of the pit lakes with groundwater and surface water. Discussion and look at the Weeli Wolli Creek Riparian zone and existing Clearing Avoidance Area – highlighted differences between the vegetation of the Major Creeks (the open riparian woodland around the low-flow line) and the broader floodplain (including the high flow lines). Discussion of the changes to the vegetation (augmentation) from upstream discharge An example of the existing Yandi Operations pit walls adjacent to Marillana Creek was viewed – showing the disconnect between the alluvial aquifer supporting the creek and the lower CID aquifer which had been drawn down to 60m bgl. The vegetation of Marillana Creek was sustained even with adjacent drawdown for over a decade. Discussion of existing environmental management on-site and how Yandi Operations was tracking against original impact predictions.	
Parks and Wildlife		
5 April 2014	The Proponent provided detailed overview of Proposal, current/planned environmental studies, potential environmental impacts and proposed management, with focus on biological issues. Updated details on Fortescue Marsh hydrogeology presented. The Yandi life of mine Closure Plan was presented. Key queries from Parks and Wildlife included how the 'avoidance areas' in MS 914 were developed, how water would be managed, interactions of surface water and groundwater in terms of riparian vegetation; results of biological surveys and significant flora, fauna; if the Proposal was a new assessment or would be amalgamated (as a Revised Proposal) with MS 914. Discussion of other projects in the vicinity.	The Proposal is considered a Revised Proposal of the existing Yandi Operations. The Proponent believes that existing conditions and management required under MS 914 for the existing Yandi Operations would adequately address key potential impacts for the Proposal. Results of investigations and discussion of potential impacts for key factors raised by Parks and Wildlife are outlined in Section 13 (Hydrological processes and inland waters environmental quality), Section 14 (Flora and vegetation) and Section 15 (Terrestrial fauna).
8 September 2014	Proposal update presentation including latest flora and vegetation, terrestrial fauna and hydrological investigations. Subterranean fauna also discussed.	Results of surveys/investigation, impact assessment and mitigation for key environmental factors is outlined in Section 13

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	Surplus water management options presented, including challenges of some options. Parks and Wildlife indicated that it did not require a further update on the Proposal unless any substantial changes or impacts predicted.	(Hydrological processes and inland waters environmental quality), Section 14 (Flora and vegetation), Section 15 (Terrestrial fauna) and Section 15 (Subterranean fauna).
16 April 2015	Update Presentation provided to Parks and Wildlife based on updated hydrological modelling and impact predictions. Proposal in final stages of completion to integrate the surface water and groundwater modelling and to assist with predictions of environmental impacts based on water availability in the alluvials. Discussed riparian vegetation in the Proposal Area is mostly sustained by surface water inputs, and very little dependency on groundwater. Predicted water availability changes in the alluvial aquifer as a result of drawdown from developing the Proposal deposit presented. Discussed that the key functioning elements of the system will be maintained to support longer term system function: alluvial substrate retained, which contains riparian seed bank and habitat for aquatic fauna (and subterranean fauna); flow paths (low-flow line) undisturbed; and water quality maintained. Flooding regime would still continue. System is expected over time to recover and return to pre-mining ecosystem – with some changes to the ecosystem communities upon closure. URS study has quantified this from a water availability perspective. Discussed extent of current wetting footprint in Weeli Wolli Creek remains within a 5-9 km extent from the Marillana – Weeli Wolli Creeks confluence since 2009. Modelling for the Proposal indicates that the range is still predicted to be within the existing approved 17 km limit. Options to address the environmental impacts as a result of the predicted change of water availability (and rate of change) are currently being investigated. However, the system is expected to return to that similar to pre-mining conditions (and water availability), hence the overall change in water availability to the end of mine life and closure is not proposed to be mitigated. Management plan updates: Updates to the existing Yandi Management Plans and Environmental Values Statement – values will be amended to specific environmental values, rather than broader factors e.g. hydrological processes.	Impacts to hydrological processes and, flora and vegetation is outlined in Sections 13 and 14 respectively.
14 September 2015	Brief Proposal update as part of a broader Rio Tinto Projects update.	Provide a copy of the updated EVS and MMP to Parks and Wildlife

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	Brief discussion of proposed changes (and rationale of the changes) to: • the Yandicoogina Weeli Wolli Catchment High level Environmental Values Statement (EVS; updated from 2012 version); and • the updated Yandicoogina Monitoring and Management Plan	Copy of the updated MMP and EVS sent 12/10/15 The MMP and EVS is attached in **Appendix 3**
DoE		
29-30 April 2014 (Site visit)	The Revised Proposal presented including a fly over of existing Yandi Operations and of the Proposal. DoE were interested in Matters of National Environmental Significance species found in the Revised Proposal Development Envelope. Northern Quoll not captured, however sightings at the warehouse near the camp have occurred on one occasion. Pilbara Olive Python found at the camp and sampled in Weeli Wolli Creek within the Proposal Area. No populations encountered. Significant species management procedures discussed. Outline of the Proposal presented and discussion of surveys completed and results. Discussion of proximity to Fortescue Marsh and water management. Discussion of proposal timing. Threatened Species Offset Plan for Revised Proposal discussed, including status.	A referral under the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) was proposed for the Proposal in Q3 2014, subsequent to the State referral. The Proposal was determined to be not a controlled action.
DER		
10 June 2014	Non-standard operation approval – Test pumping for Proposal. Test pumping requested for two bores, 3.8 GL over six months.	Approved by DER on 19 June 2014. Proponent notified DER on commencement (18 September 2014) and completion (24 November 2014) of test pumping regime
15 June 2015	Telephone discussion of Proposal including components relevant to DER: • additional discharge point (DO9A); • potential WWTP facilities; • potential mobile crushing and screening plants involved with construction works; and • potential workshop / washbay facilities with associated oily water treatment systems.	Presentation will be provided to DER. Awaiting confirmation of a suitable date.

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	Request to present broader Proposal.	
DoW		
21 March 2014	Presentation of the new Yandi life of mine Closure Plan.	No significant issues raised or outcomes.
10 April 2014	Pre-referral meeting to present the Proposal details and provide a high level summary of the groundwater and its abstraction and the proposed water management options including the hierarchy of use and the proposal to discharge into Marillana/Weeli Wolli Creeks. DoW queried what was in place for tree health monitoring and frequency of monitoring. Existing Yandi Operations management plan details discussed and provided. Discussed hydrological monitoring including the potential use of alluvial bores and nested bores to understand the interactions with tree health. EC and in situ loggers are currently used in the existing monitoring bores and at the discharge outlets. Flood protection levees discussed and surface water modelling associated with the location of the levees and other infrastructure. Levees would be backfilled into the Proposal pit upon closure. Discussion of what the Proponent had found in the way of stygofauna and troglofauna at the Proposal Area, and how habitat will be maintained in different areas as drawdown impacts across the entire operations variable at different times. Existing flood regime maintained to provide habitat connection.	Impacts to hydrological processes and inland waters environmental quality are outlined in Section 13; impacts to flora and vegetation are outlined in Section 14. Results of surveys and impacts to subterranean fauna are outlined in Section 15.
21 April 2014	Rio Tinto provided detailed overview of Yandi life of mine Closure Plan, including the Proposal. DoW queried the pit lakes and options if future deposits were not approved; likely salinity ranges; interactions for saline and fresh water pits; metals released in hypersaline conditions.	Rio Tinto has looked at 'early closure' contingencies and has addressed the possible options of future deposits not being approved. Further details regarding pit lakes are outlined in Section 17 (Rehabilitation and closure).
23 September 2014	An update was presented on the Proposal Environmental Impact Assessment including: • Timing. • Latest data. • Environmental Scoping requirements, including requirement for DoW endorsement of	Results of investigations and impacts to hydrological processes are outlined in Section 13.

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	consultants used for peer reviewers – selection discussed. DoW will discuss with OEPA. • Surface water update – flood modelling and discharge extent modelling. • Groundwater update – modelling and pump test data. • Surplus water management – run through of all of the options investigated and discussion of discharge option into Marillana – Weeli Wolli Creek system as the only feasible option. • Other items discussed included details of the proposed levee including design, height, flood ARI design, materials, base foundation conditions and control of subsurface water.	
26 November 2014 (site trip)	Site trip to Revised Proposal Development Envelope with DoW to present the existing Yandi Operations and specifically the Proposal. Discussed proposed plan for water management for the Proposal and discharge into Marillana/Weeli Wolli Creeks. Reviewed and discussed tree health monitoring data and limitations. Discussed existing hydrological monitoring - DoW indicated their interest in having monitoring bores located with tree health monitoring sites and if feasible to undertake with a Sonic rig. Infiltration testwork presented, discussing extremely high infiltration rates to the north of the Marillana - Weeli Wolli Creeks confluence and discussion on how this work supported Shawan Dogramaci's paper on the discharge from the existing Yandi Operations, as well as current observations of the wetting front from discharge (still in the range of 5-9 km past the confluence – similar since 2010). Discussed hydrological modelling, taking into account cumulative impacts. Discussed details of the recent hydrogeological pump test program, and future programs.	Results of investigations and impacts to hydrological processes are outlined in Section 13.
22 April 2015	The Proponent presented a series of DVD's to provide an environmental impact update and outline the baseline ecological regime, with a focus on riparian (phreatophytic) vegetation and water availability. • Discussed riparian vegetation in the Proposal Area is mostly sustained by surface water inputs, and very little dependency on groundwater. This is reflected in both current and historical riparian communities / species. No mature C1 vegetation (containing Melaleuca argentea,	Impacts to Flora and vegetation are outlined in Section 14.

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	which is the environmental value defined in the Environmental Value Statement) occurs in the Proposal Area. Vegetation community composition changes have occurred in Weeli Wolli Creek as a result of increased water availability including recruitment of Melaleuca argentea. • Discussed that the key functioning elements of the system will be maintained to support longer term system function: alluvial substrate retained, which contains riparian seed bank and habitat for aquatic fauna (and subterranean fauna); flow paths (low-flow line) undisturbed; and water quality maintained. Flooding regime would still continue. Ecosystem is robust and adaptive to changed conditions. • Significant ecosystem monitoring and management currently occurring (trees, water quality, aquatic fauna), and will continue to occur throughout the life of mine and through to closure. • Predicted water availability changes in the alluvial aquifer as a result of drawdown from developing the Proposal deposit presented. The likely result is increased drought stress (and some tree deaths) through this reach as a result of the Proposal. • System is expected over time to recover and return to pre-mining ecosystem – with some changes to the ecosystem communities upon closure. URS study has quantified this from a water availability perspective: A net reduction of about 10% in total water availability is expected upon closure. • Updates to the existing Yandi Operations management plans and Environmental Values Statement – values will be amended to specific environmental values, rather than broader factors e.g. hydrological processes. • DoW queried the Melaleuca recruitment and if this was a result of elevated water table from Hope Downs 1. • DoW queried the root morphology changes and about the rate of change of the phreatophytic root system in response to water availability. Also how this contexts with historical riparian communities in the catchment. Queried what would be the rate of change of water availability in the alluvials i.e. How long normal residence time was compared to changed (mining drawdown)	

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	conditions. Options to address the environmental impacts as a result of the predicted change of water availability (and rate of change) are currently being investigated. However, the system is expected to return to that similar to pre-mining conditions (and water availability), hence the overall change in water availability to the end of mine life and closure is not proposed to be mitigated.	
29 September	The Proponent discussed DoW comments on the draft PER document. • Design criteria for surface water infrastructure • Stygofauna habitat and cumulative impacts • Dewatering volumes and consistency between reports • Historical / baseline groundwater levels Boundary conditions used in modelling including in relation to Fortescue Marsh	Updates made to the Revised draft PER document.
DMP		
21 March 2014	Presentation of the new Yandi life of mine Closure Plan, including: • Yandicoogina project overview. • Closure objectives and criteria. • Preferred closure strategy. • Landform design. • Water management. • Habitat considerations for rehabilitation (and proposed wetland rehabilitation trial). • Unexpected closure. • Further study focus areas. • Compliance review. Key queries included salinity range of pit lakes, modelling undertaken, potential for metals to be released with increased salinity, interaction of saline pits and fresh water pits, and interactions with the creeklines, frequency of flushing of the pit lakes. Also access to pit lakes and safety issues.	Rehabilitation and closure is outlined in Section 17.

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	Discussion on development of completion criteria. Interest in wetland rehab trial and interest in rehabilitation success.	
21 April 2014	The Proponent provided a detailed overview of the Yandi life of mine Closure Plan for the Revised Proposal. DMP discussed that their guidelines are being changed so that Section 4 flows better. DMP commented about future unapproved projects in the Closure Plan. Discussed focus on rehabilitation in the Pilbara; access to pits and safety issues post-closure; completion criteria – want to target frames as "not to exceed" – need a way in which to measure/assess completion criteria.	Rehabilitation and closure is outlined in Section 17.
20 November 2014	Joint Yandi Operations site trip with DSD and DMP to Yandi to discuss rehabilitation and closure planning. Discussed the Closure Plan at a high level. DMP noted that the plan contained a lot of very technical information. Wetland rehabilitation trial area visited and discussed. DMP interested to see the outcomes. Progressive rehabilitation discussed including planning process and seed collection. Topsoil management, Tailing storage facility, Landfill, Turkey's nest management discussed.	No significant issues raised or outcomes.
27 May 2015	Brief update presentation and DVD's of updated Yandi life of mine Closure Plan to support the Proposal PER, including closure objectives and conceptual completion criteria. Aspects of closure discussed included the establishment of a wetland rehabilitation trial so as to better determine what plants will do best and how far away from the water table they need to be located in order to be sustained.	Rehabilitation and closure is outlined in Section 17.
3 August 2015	Presentation and DVD's of updated Yandicoogina life of mine Closure Plan to support the Proposal PER, including closure objectives and conceptual completion criteria. Items discussed included: Plan for backfill areas including sloped walls Impact of flood events and remedial work required	The Proponent acknowledged the importance of ongoing stakeholder consultation to developing the final land use and detailed completion criteria. The updated Closure Plan contains a risk assessment to identify gaps and support a process to address. The PER document will be updated to include further information

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	Wetland rehabilitation trial details Abandonment bunds Final land use & completion criteria – plan for developing details Water quality including salinity and other potential leachates Timing for closure DMP were interested if closure and waste management would be integrated with BHP's Yandicoogina Operations	from the updated Closure Plan.
DSD		
20 August 2014	Overview of 2015-2017 Pilbara mine plan including Proposal.	No significant issues raised or outcomes.
20 November 2014	Joint Yandi Operations site trip with DSD and DMP to discuss rehabilitation and closure planning. Discussed the Closure Plan at a high level. DMP noted that the plan contained a lot of very technical information. Wetland rehabilitation trial area visited and discussed. DMP interested to see the outcomes. Progressive rehabilitation discussed including planning process and seed collection. Topsoil management, Tailing storage facility, Landfill, Turkey's nest management discussed.	No significant issues raised or outcomes.
18 June 2015	High level overview of the Proposal provided.	DSD requested to be provided with further information in writing, which was provided on 25 June 2015.
31 August 2015 (Site visit)	Site visit to Yandicoogina Operations to present the Pocket and Billiard South Proposal The overall scope of the Proposal was presented Details of the Environmental Impact Assessment including predicted impacts and timing for the PER document discussed. Predicted impacts to Weeli Wolli Creek were discussed.	DSD requested to be provided with ongoing updates of the Proposal, including the PER timing.
DAA		
7 July 2014	The Proponent met with DAA and provided a high level overview of the Proposal.	The Proponent confirmed with DAA that a large portion of the Proposal Area has already been surveyed and that surveys will

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	DAA requested information on disturbance of sites when available.	be conducted prior to the commencement of any ground disturbance as per Rio Tinto's protocols. The Proponent is also reviewing designs to avoid areas of concern (including heritage sites) to avoid/minimise impact. The Proponent will continue to liaise with DAA and the Traditional Owners through its existing meeting forums to provide updates on the Proposal, the existing operations and where approvals may be required to disturb sites.
Gumula – Traditional Owners		
June 2013	Yandicoogina Land Use Agreement Monitoring and Liaison Committee meeting. An overview of the mine closure process was presented to the Gumala Aboriginal Corporation board members. It was agreed at the meeting to form a sub-committee/working group to address issues relating to closure and land management. The terms of reference for the sub-committee/working group are yet to be resolved.	The Proponent subsequently (October 2013) met with the Gumala Aboriginal Corporation Lore and Culture Committee to discuss participation of Elders in the closure working group. A decision on Elder's participation and representation is still pending.
4 February 2014 5 May 2014 12 August 2014 15 December 2014 15 April 2015 13 May 2015 16 July 2015	Monitoring and Liaison Committee Meeting update presentations of Yandicoogina Closure Plan. Topics discussed included: • Preservation of remaining ecosystems and protection for creek banks. • Lake water quality. • Ongoing importance of ethnographic and archaeological surveys. • Role of Gumala Aboriginal Corporation in closure planning. • Importance of including Elders and young people in consultation. • Management of artefacts at closure. • Potential community use of site infrastructure after closure. • Access through and around the mine and into the lake areas. Presentations and DVD presentations on the Proposal. Topics discussed included: • Overview of the Proposal including tie in with existing Yandi Operations.	A copy of the Draft PER will be provided to Gumala Aboriginal Corporation. Presentation of the Proposal was provided at the Hope Downs 1 Weeli Wolli Co-Management Board Forum.

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	• Timing of the Proposal. • Infrastructure requirements. • Outline of baseline biological surveys and findings. • Water related impacts presented and discussed, including drawdown and discharge into Marillana and Weeli Wolli Creeks and predicted environmental impacts on the system. Existing creeklines artificially altered from many years of discharge – especially Weeli Wolli and so currently look different to their original ephemeral state. Water availability after mining will revert back to pre-mining levels and therefore will not be able to sustain current water availability for trees and fish – some tree stress and death expected and less waterholes for fish/fishing. • Access to Weeli Wolli Creek will be permanently limited in the vicinity of the Proposal. • Discussion on cumulative impacts from the Proposal and other mines in the area and how this may change the water in the creeklines – query on Hope Downs 1 and if they will continue to discharge. • Presentations and discussion of tree health and water quality monitoring. Discussion of potential involvement of Traditional Owners in future monitoring. • Traditional Owners also expressed interest in the expected life of mine, water quality, water quality of pit lakes, ecosystems recovery, particularly along the creeklines, rehabilitation and involvement with rehabilitation.	
13 May 2015	An ethnographic survey was conducted with Gumula during which the focus was on: • Surface water management and discharge in relation to Weeli Wolli Creek. • Proposal dewatering requirements. • Ongoing management of Weeli Wolli Creek. • Hydrogeological drilling program.	The Proponent to consult Gumala Aboriginal Corporation about the potential for business and employment opportunities for the new Yandi developments. A number of archaeological sites identified to be avoided across the existing Yandi Operations.
Ongoing	Any issues relevant to the Gumula People are raised at quarterly Monitoring and Liaison meetings. It is a condition of the Agreements that notification of any activities is provided to Gumula prior to works	The Proponent will continue with regular consultation with Gumula through the Monitoring and Liaison meetings and through the pre-feasibility and feasibility studies.

Date	Topics/Issues Raised	Outcome and Proponent response where relevant
	taking place and effort is made to address any areas of concern raised by the group. Key concerns raised relate to potential impacts (including clearing, drawdown and discharge) within the Marillana and Weeli Wolli Creek systems, final life of mine closure landform, and future access.	Regular technical updates are provided including the approval process; Environmental Impact Assessment predictions and findings; and closure workshops.
Pastoral Station – Marillana Station		
20 April 2015	Informal discussion on upcoming Proposal and Closure Plan. Details of the Proposal requested to be provided, including key dates.	Updated presentation package including key dates provided to Marillana Station on 22 June 2015.
Shire of East Pilbara		
23 April 2015	Provided update of current Rio Tinto operations in the Pilbara with proposed projects for the Shire of East Pilbara. This included the Proposal and the proposed PER seeking feedback around September 2015.	Proposed to provide an update on the PER at next meeting (August 2015), and 'big picture' overview of clearing requests.
28 August 2015	Presentation of the Proposal details and estimated timing for Public Environmental Review.	No significant issues raised or outcomes.
BHP		
22 April 2015	Consultation on closure planning for BHP and the Proponent's Yandi Operations. Discussion to understand: • The Proponent's underlying strategy for closure; • the key driving assumptions; and • outcomes that are important for consideration in the upcoming revision of the BHP Closure Plan which may also have implications for the Proponent's Yandi Operations. Given the water focus for water and closure planning in the Fortescue Marsh area (particularly when considering the relationship between the closure strategies for the sites) and due to adjacent pits at Oxbow, a presentation and discussion on closure strategies and assumptions was undertaken. It was agreed that any presented materials would be publically available, but elaborated on through discussion.	Further discussion may be required at various stages of Closure planning to ensure closure model assumptions are understood and to avoid misalignment of adjacent (boundary) model predictions. Publically available material to be agreed on a case by case basis.

Part 2 – Description of the Proposal

This part describes the Proposal to be implemented, including information on the key characteristics, design, exclusions and scheduling of the Proposal.

4. Development overview

4.1 Key characteristics

The Proposal will involve construction and operation of a new mine pit, waste dumps and associated infrastructure. The Proposal deposits occur across the eastern extents of an 80 km long CID characterised by relatively continuous iron mineralisation along a palaeo-channel. Mining will consist of a single, below water table open cut pit along the CID palaeo-channel.

Key aspects of the Proposal include:

- **A new below water table open cut iron ore pit** to the east of the existing Yandi Operations within the CID.
- **Temporary surface waste dumps**, including mineral waste dumps, sub-grade dumps, low grade ore dumps and topsoil and subsoil stockpiles.
- **Major infrastructure, including:**
  - **A flood protection levee** along the western margin of the pit.
  - **A diversion drain** along the eastern margin of the new mine pit.
  - **A culvert-floodway** creekline crossing structure.
  - **Supporting mine infrastructure** – haul roads and ramps, mine access and internal road network, dewatering pumps and associated pipelines, discharge outlet(s), power and communications.

In addition, a number of the Yandi Operation's existing facilities and processes will be upgraded or integrated as part of the Proposal including:

- **Trucking ore** back to the existing Yandi Plant.
- **Yandi plant** including JC and JSE processing plants (including a wet plant), and associated conveyors, stackers, reclaimers, train load-out and other materials handling infrastructure.
- **A water management system** including on-site reuse of water abstracted from pit dewatering, and discharge of surplus volumes into creek systems. Discharge infrastructure servicing the existing Yandi Operations will be used where possible.
- **Mine support facilities** (e.g. power supply infrastructure, communications infrastructure, offices, explosives storage, waste water treatment plants etc.).

The Proposal is scheduled to be commissioned with first ore production from the first half of 2019, however these project schedules may change, depending on business priorities.

Rio Tinto's existing rail network will be used to transport mined and processed ore from the Revised Proposal to existing port operations at Dampier and Cape Lambert.

A preliminary summary of key features for the Proposal are described in **Table 3**.

Table 3: Summary of the Proposal

Component	Project Characteristic	Detail
General	Project life	~ 16 years
	Resources	The current resource consists of 452 million tonnes of CID ore
	Production rate	Up to 31 Mtpa
Development footprint	Approximate disturbance area – mining/waste stockpiles and infrastructure	Up to 1,800 ha (69 ha of riparian zone vegetation)
Mining	Ore type	Pisolite (Channel Iron Deposit)
	Mining in relation to the watertable	99% BWT mining
	Mineral waste disposal	Surface waste dumps, with progressive backfilling once individual pit stages are completed
Processing	Processing type	Both wet and dry processing using existing Yandi Operations facilities
	Residue disposal	Current Yandi Operations in pit and new WFSFs will be used for residue from wet processing
	Water demand	Peak demand (with wet processing) approximately up to 11 GL/y
	Roads	Existing and new access roads to approach/depart the Proposal and internal road system
	Ore transport	Haul road to transport ore from the Proposal to the existing Yandi Operations processing plants and use of existing rail
	Power spur	Connection into the existing Yandi Operations 220 kV power line

4.2 Development of the mining operation

4.2.1 Site plan

The existing Yandi Operations is outlined in **Figure 2**. A conceptual site plan for the Proposal is shown in **Figure 4**, which also shows the Proposal in relation to the Revised Proposal Development Envelope and existing roads.

4.2.2 Ground disturbance

The Proposal will result in up to 1,800 ha of new ground disturbance, within the Revised Proposal Development Envelope of 19,351 ha. The majority of the proposed 1,800 ha of disturbance will occur within the Proposal Area, with a small portion of this disturbance required for infrastructure tie-ins with the existing Yandi Operations.

As planning for the Proposal is ongoing, the exact locations of some ancillary infrastructure and tie-ins with the existing mines is dependent on final engineering design. The specifics of the infrastructure require flexibility in terms of siting once detailed designs are finalised. A conceptual site plan is indicated in **Figure 4**.

4.2.3 Vegetation clearing and topsoil

Topsoil is an important resource for rehabilitation as it contains a natural seed bank and, typically, contains organic material and nutrients. Topsoil layers in the Pilbara region are

highly variable in thickness, ranging from very little soil development on rocky slopes to approximately 300 mm in valley areas.

The open pit, waste dumps, low grade dumps, haul roads and lay down areas will be cleared of all vegetation. Topsoil (approximately 200 mm) and subsoil (approximately 600 mm) will be collected prior to mining and stored in stockpiles for use in post-mining rehabilitation. Topsoil and subsoil will be collected from both the pit and dump areas, while only topsoil will be collected from the other areas (lay down areas and other infrastructure). The topsoil and subsoil will be cleared in a phased manner as and when the new pit and dumping areas come into operation.

Throughout the life of the Proposal, an estimated 2.1 million m^3 of topsoil and 6.72 million m^3 of subsoil will be collected. All the topsoil and subsoil collected from pit and other areas will be stockpiled in line with the Proponent's standards. Cleared vegetation will also be stockpiled. This material will be used during rehabilitation (Section 17).

4.2.4 Mining

The scope of mining for the Proposal includes CID ore resources located within existing tenure ML274SA. The Proposal will involve developing a single pit, of which approximately 99% of the ore is below the water table. The pit will be approximately 10 km from end to end (~7 km strike length) and mining will involve conventional drill, blast, load and haul methods, as currently used at the existing Yandi Operations. For ore blending purposes, several faces within the mine pit will be worked simultaneously.

Based on current knowledge, the total quantity of extractable ore from the proposed pit is estimated to be ~452 Mt over the life of the Proposal. The maximum depth of mining is expected to be approximately 85 m below the surface.

Mining (pre-stripping) is proposed to start from 2018 and progress northwards and southwards consecutively from an initial mining area. The initial mining area location, rate and sequence of mining will ultimately be dictated by ore blending requirements to meet product specification from the Revised Proposal. A small portion of the proposed mine pit (approximately 17 ha) will encroach into the riparian woodland community of Weeli Wolli Creek to access the CID ore, which extends below the floodplain alluvials (see **Figure 55** in Section 14).

Figure 4
Proposal conceptual site plan

Drawn: M.Swebbs
Date: Sept, 2015

Plan No: PDE0128514v3
Proj: MGA94 Zone50

Geospatial Information and Mapping

Overburden and waste will be used to progressively backfill the depleted pit, where possible. If the development sequence changes, temporary surface storage options will be required.

Mining is estimated to produce approximately 272 Mt of waste rock. Above ground stockpiles and mineral waste dumps have been provided for in the mine design. It is planned that all of the waste material will be used progressively to backfill the mine pit. However during development of the pit, temporary ex-pit waste dumps will be required and will be located in close proximity to the mine pit. The quantity of material to be placed in temporary storage areas will depend on the mine design, mining and dewatering sequence, and managed in line with the closure strategy.

A portion of the overburden from the initial mining area will be used as 'borrow material' for construction activities. As a result, the total area that would otherwise be disturbed during construction will be reduced.

Initial start-up mining crusher feed rates will be in the order of 28 Mtpa, which may increase up to 36 Mtpa, bringing the Revised Proposal crusher feed rates up to a total of 70 Mtpa.

4.2.5 Ore handling, processing and transport

The existing Yandi Operations are well established with central administration and workshop facilities at JC. Some new infrastructure will be required to accommodate the Proposal including:

- Civil infrastructure such as light and heavy vehicle road networks to connect the Proposal deposits to existing plant and facilities.
- The main workshop and storage areas will remain at JC. Heavy vehicle refuelling facilities and a workshop for daily and weekly maintenance may be constructed closer to the Proposal deposits.
- Small office facilities will be developed central to the Proposal Area. These facilities will consist of an administration building for daily crew shift change meetings and a crib room with toilets.
- A crossing at Weeli Wolli Creek is required to enable ore movement from the deposits to the various processing plants via heavy haulage trucks. As these deposits are entirely located on the east side of Weeli Wolli Creek, a creek crossing (via a culvert-floodway structure) will be required to access the facilities at the existing Yandi Operations, located entirely on the western side of Weeli Wolli creek.
- Local drainage and flood management protecting against stormwater runoff as well as water ingress into the pit adjacent to Weeli Wolli Creek.
- Electrical distribution via additional 33 MW installations will be required to support the Proposal.

Dewatering to enable mining of the Proposal wherein the orebody is essentially 99% below the water table. Based on initial hydrogeological modelling, dewatering of the pit will be required to occur at least a year prior to productive mining.

The existing capacity of the processing plants at JC (secondary and tertiary crushing and screening) with minor upgrades will accommodate all of the production from the Proposal. Any plant expansion requirements at JC will be subject to the provisions of the EP Act.

The existing waste fines cells at JSE in addition to new waste fines storage facilities (WFSF) in JSE will be used for the disposal of waste generated by wet processing. In accordance with existing operational practices, any water reclaimed through a decant process will be recycled back into the wet processing cycle.

Processed ore will be trucked from the Proposal to one of the existing operations wet or dry processing plants, where it will then be conveyed to the Loop Stockyard for rail loading and export. The existing capacity of the Loop Stockyard is expected to accommodate all of the production from Proposal. Upgrades or extensions to the existing Yandi Operations plants are a consideration, and would be managed under Part V of the EP Act.

4.2.6 Mineral waste

Overburden and waste rock will be used to backfill the depleted pit where mine pit sequencing and schedules allow. However, temporary surface storage options for waste and low grade ore stockpiles will be required over the life of the Proposal. The quantity of material to be placed in temporary storage areas will depend on the final mining and processing sequence selected.

Locations for waste dumps are presented in **Figure 4**, which provides for a conservative case should mine sequencing or dewatering sequencing change over the life of the operation. However, in line with the closure strategy, there will be sequential in pit disposal of waste, and stockpiling of low grade ore.

The existing Yandi JSE pit, which is adjacent to the Proposal Area, will serve as an in pit fines tailings storage facility (WFSF) for any material from the Proposal which is wet processed during the life of operations. The JC and JSE pits are currently used as a waste fines storage facility for the existing Yandi Operations.

Asbestiform minerals are not known from the CID orebody. However, there is a risk of encountering asbestiform material in the surrounding banded iron formation (BIF) and alluvium. Asbestiform fibres have been identified in the alluvium within the current mine operations at Yandi JC. Any fibrous waste encountered during construction or mining of the Proposal pit will be disposed of at the existing on-site facilities (store, encapsulate and record in the same waste dump), in accordance with the current Yandi Operations fibrous mineral protocols and procedures.

4.2.7 Dewatering and water management

The Proposal deposit is situated almost entirely (approximately 99%) below the water table and will require dewatering to commence approximately 12 months before mining activities start. Groundwater modelling has indicated that the dewatering required for the Proposal ranges from approximately 30 – 50 GL/y (cumulative peak of 83 GL/y when combined with existing Yandi Operations), of which up to 70% is not new dewatering; rather, it is the result of re-abstraction and discharge of upstream operations' surplus discharge water that has passively re-entered into the orebody (recirculation of water).

Dewatering will be undertaken using vertical bore holes completed in curtain or cluster arrangements within or adjacent to the mine pit; permanent bores will be placed along the western perimeter of the Proposal pit and permanent and sacrificial bores will be placed within and around the Proposal pit. The sacrificial bores will be decommissioned and replaced as the pit advances over time. Pumping of residual groundwater from in pit sumps will also be used when the mine pit reach final bench elevation.

Dewatering supply from the Proposal will be integrated with the existing Yandi Operations site water demand. It is estimated that approximately 5 GL/y will be used for on-site purposes (dust control, camp usage and ore processing) and approximately 48 GL/y to 78 GL/y will be discharged to Marillana and Weeli Wolli Creek systems over the life of the Revised Proposal, with a forecast average of 61 GL/y. Discharge will occur at controlled, release discharge points (refer to Section 13 for further details regarding surplus water management).

4.2.8 Surface water management

Two key surface water management structures will be required to protect the mine pit from accumulating water during large surface water flow events. This will result in localised disruptions to hydrological flow regimes. These structures include:

- An 8 km long flood protection levee along the western margin of the Proposal pit, adjacent to Weeli Wolli Creek. This will encroach into the Weeli Wolli Creek floodplain in some areas to facilitate the proposed pit extent.
- A diversion drain along the eastern edge of the pit, collecting rainfall runoff from hills to the east.

The preliminary design of the levee has been undertaken by a team of engineers who are familiar with the local conditions and have had experience with design and construction of levees at the existing Yandi Operations. The detailed design of the flood protection levee will be undertaken by experienced civil design engineers based on findings from geotechnical, geomorphological and hydraulic technical studies. The investigations and analysis undertaken to date are at a higher level than would normally be undertaken at the current stage of the Proposal in recognition of the importance of the levee and have been reviewed by the Proponent's engineers, consultant design engineers and independent third party geotechnical and hydrology experts.

The purpose of the levee is to prevent flooding of the open mine pit mine during high flow periods within Weeli Wolli Creek which is located adjacent to the proposed pit. The proposed levee is approximately 8 km in length; a crest width of 5 m, with a height ranging in the order of 2.5 to around 7 m (subject to final engineering designs) including a freeboard allowance of 0.5 m, and with upstream and downstream slopes of 1:3 (V:H; refer to **Figure 5**). The levee has been designed as a homogenous structure constructed from clayey gravels sourced from in situ materials along the alignment. Additional borrow material for the construction of levee and haul road embankments may be sourced from the proposed footprint of the Proposal pit (i.e. pre-strip waste). Laboratory analysis of samples collected during testing pitting activities for this study suggests that two thirds of the surficial soils in the pit footprint would be suitable for use. A potential source of dolerite rock for use in scour protection has also been identified.

A keyway is considered necessary to limit the risk of piping failure under the crossing structure and to key it in to the existing alluvial soils of the Weeli Wolli Creek. A minimal depth of 5 m depth and a minimum width of 2 m can be expected at this stage of design.

Risk assessments will be undertaken prior to construction, to ensure public safety is maintained and environmental risks are identified and managed. During operations, the levee will be subject to regular post-wet season inspections. The objective of the inspections is to ensure the long term stability of the levee and identify any deterioration in the condition of the levee before it becomes a risk to its integrity. If deterioration in the

levee condition is identified, geotechnical engineers will assess the potential impact and identify any required remedial works.

Numerical slope stability analyses, using the limit equilibrium slope stability software package SLIDE Version 6.0, against the design acceptance criteria of a Factor of Safety (FOS) of greater than 1.5, was carried out at three critical sections. Relatively conservative effective stress (drained) shear strength parameters were attributed to each of the geological units based on correlations with field investigation, laboratory testing results and experience.

Three cases of levee stability analysis were assessed under static conditions based on a standoff distance of 30 m, 65 m and 100 m from the pit crest to the downstream toe of the levee. The analysis carried out under seismic loading only for dry conditions and for Peak Ground Accelerations (PGA) of 0.063 and 0.1g. The FOS for failure of the levee during either flood events or earthquakes exceed the required acceptance criteria (e. g. FOS=1.5 and FOS=1.1, respectively). The groundwater phreatic surface and location of the levee with respect to the pit crest has negligible effect on the stability of the levee.

A numerical analysis was also carried out using the finite element software package Plaxis, to assess the minimum offset required between the levee and the alluvial pit slope. The analysis indicates that the surcharge load from the levee structure has only marginal influence on the pit slope.

Limited potential for piping failure of fine dispersive materials in the levee and its foundation structure was determined in the engineering geotechnical study. As the levee will be constructed of compacted non-dispersive clayey gravel/gravelly clay materials and due to short duration of the flood events, the wetting front is not expected to penetrate more than 1-2 m into the levee materials. Therefore piping within the levee embankment is not expected and not considered a significant risk.

4.2.9 Water supply

Process water will be sourced from groundwater abstracted through the mine dewatering process. Potable water will be sourced from the borefields servicing the existing Yandi Operations.

4.2.10 Power supply

Power supply will be derived from the existing distribution system at the Yandi Operations, sourced from the Rio Tinto power grid network. Power connections to the Proposal will be largely aligned with other infrastructure corridors (e.g. roads).

Back-up power supply will be provided by the existing on-site 10 MW diesel-fired generator, currently servicing the existing Yandi Operations.

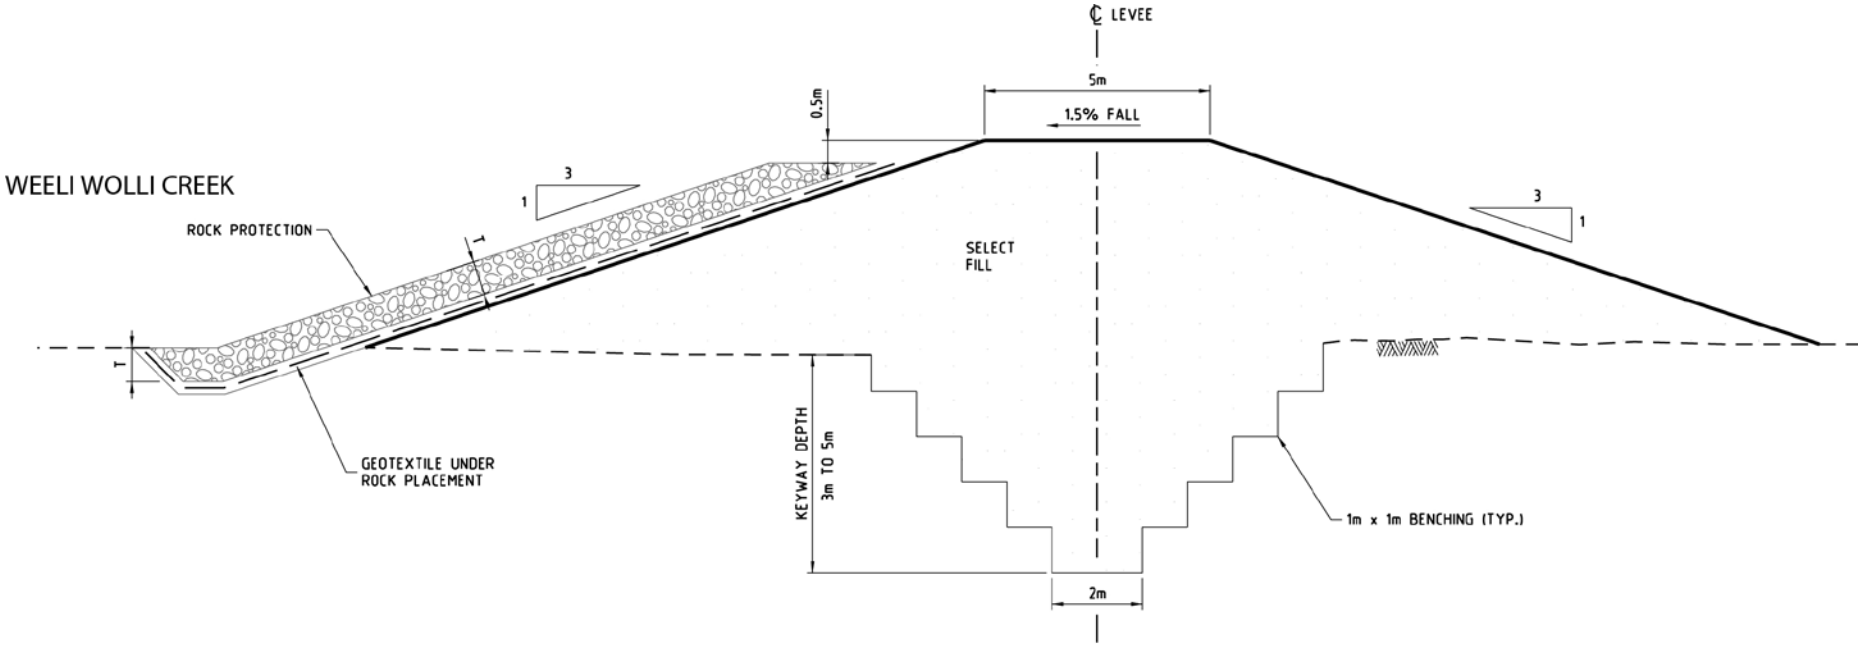

Figure 5: Typical levee cross section.

4.3 Mine support facilities and other infrastructure

4.3.1 Workforce and accommodation

The existing Yandi Operations currently employs around 1,400 people (including construction workforce and contractors) who are accommodated in a well established permanent village and a temporary construction camp. The workforce currently operates on a Fly In-Fly Out (FIFO) basis from Perth or other WA regional centres using the Barimunya airport.

The existing operational workforce is not expected to increase to support the Proposal and as such the existing accommodation village is expected to meet anticipated FIFO workforce requirements.

The recently re-commissioned construction camp for JSW and Oxbow operations comprises single and double storey rooms which will be maintained to accommodate the additional construction capacity (approximately 450 personnel) required for the Proposal.

The permanent village and construction camp are both part of the existing mining operation and approved under MS 914.

4.3.2 Wastewater treatment

Wastewater generated by the existing Yandi Operation is treated using the licensed wastewater treatment plants at the JC mine site and the recently expanded facility servicing the accommodation village. These will continue to be used over the life of the Proposal.

The Proposal mining areas are not anticipated to need new wastewater treatment facilities. However, existing facilities may need to be expanded for construction and future operations, and septic facilities will be required for offices and administration buildings. If any new facilities are required (to treat more than 20 m^3/day), appropriate licences will be obtained under Part V of the EP Act.

4.3.3 Non-mineral waste

Current systems servicing the existing Yandi Operations will be used to collect and recycle a number of waste streams including: hydrocarbon wastes (oil, drums, rags, filters etc.), tyres, batteries, scrap metal, printer cartridges, paper and cardboard, conveyor belting and computing equipment.

The licensed landfill facilities servicing the existing Yandi Operations will be used to dispose of putrescibles and inert materials, such as household waste, cardboard, furniture, fill and demolition material. Appropriate licences under the EP Act will be obtained if any new landfill facilities are required.

Hazardous wastes will be collected and sent off-site for treatment by licensed contractors. An existing land farm bioremediation facility used to treat hydrocarbon contaminated soils, will continue to be operated over the Proposal life. Contaminated soil is spread in a thin layer (approximately 300 mm) on an impermeable base. The soil is watered and tilled to stimulate aerobic microbial activity resulting in the degradation of hydrocarbon products into non-hazardous materials suitable for conventional disposal.

4.3.4 Fuel

The fuel storage and handling facilities at the existing Yandi Operations may be upgraded to service the Proposal mining operations. These are likely to be supplemented by local heavy vehicle refuelling facilities near the Proposal pit.

4.3.5 Road Access

Mine roads will be developed in and alongside the Proposal pit. The roads will provide access to mining areas, soil and waste stockpiles and supporting infrastructure. The mine road network is expected to change to some extent during the life of the Proposal, in accordance with the mine plan.

A bypass track around the Proposal will be constructed to allow for public access and to manage public safety as the current access track extending from Hope Downs 1 to Fortescue Marsh runs directly through the proposed borefield and mining area. This track will also ensure separation of the public from the construction work related to the Proposal.

Based on the current mine plan, the primary heavy vehicle access road for the Proposal will be aligned along the perimeters of the mine pit. A culvert-floodway crossing will be constructed across Weeli Wolli Creek, together with an upgrade to the existing Weeli Wolli Creek crossing (Greys' crossing) to create an engineered floodway with culverts to support heavy vehicle traffic and reduce ponding and upstream impoundment of flow. Larger rain events will continue to overtop the floodway as designed.

Road access from the Great Northern Highway is provided through the existing sealed Yandi Operations access road shared with BHP.

4.3.6 Other facilities/infrastructure

Other facilities that will be required for the Proposal include heavy/light vehicle maintenance workshops, offices and laydown areas. Locations of these facilities are depicted in **Figure 4**. Additional facilities may also include an ammonium nitrate storage facility and fabrication workshops.

4.4 Work excluded from the proposal

The scope of the Proposal subject to this Environmental Impact Assessment specifically excludes:

- Associated site offices, access roads, temporary concrete batch plant, borrow pit/quarry for suitable material, temporary services (communications, water supply, on-site power generation), upgrades to existing access roads/tracks and lay down areas and drilling/geotechnical/water investigation activities (to be subject to relevant provisions of Part V of the EP Act and DoW RIWI Act water licensing requirements).
- Low impact activities, including drilling activities associated with geology (including resource drilling), geotechnical and water investigations (including bore installation and test pumping) and power generation investigations (to be subject to relevant provisions of Part V of the EP Act and DoW RIWI Act water licensing requirements).

Iron Ore resources held by Rio Tinto (or its related companies) are present outside and proximate to the Proposal. These may be subject to future development proposals, but are

outside the scope of the Proposal. Any proposals to develop these resources will be subject to separate environmental approval processes.

Part 3 – Overview of existing environment

This part provides an overview of relevant features of the existing environment. More detailed descriptions of the relevant existing environmental features of each of the preliminary key environmental factors are provided in Part 5.

5. Physical environment

5.1 Biogeographic region

A biogeographic regionalisation of Australia has been developed collaboratively, in which bioregions (broad-scale regionalisations) are formally recognised and mapped in the Interim Biogeographic Regionalisation for Australia (IBRA), currently version 7. IBRA provides a landscape-based approach to the classification of the land surface of Australia, with bioregions being classified according to common climate, geology, landform, native vegetation and species information. Bioregions each reflect a unifying set of major environmental influences which shape the occurrence of flora and fauna and their interaction with the physical environment across Australia (DoE 2015a).

The Proposal Area lies within the Pilbara bioregion, which comprises four subregions: Hamersley, Fortescue, Chichester and Roebourne. Subregions are more localised and homogeneous geomorphological units within each bioregion. The Proposal Area is located within the Hamersley and Fortescue subregions (**Figure 6**). The majority of the landscape within the Proposal Area is considered to be typical of the Hamersley subregion, while the creek systems have affinities with the Fortescue subregion. A description of the major characteristics of the two subregions is provided in **Table 4**.

The Hamersley subregion is approximately 6.2 million hectares in area, with the dominant land uses being grazing of native pastures, unallocated Crown land and Crown reserves, urban settlements, conservation and mining (Kendrick 2003a). The main land uses of the smaller (approximately 2 million hectares) Fortescue subregion include grazing, unallocated Crown land and Crown reserves, conservation and Aboriginal land (Kendrick 2003b).

Table 4: Hamersley and Fortescue Subregions of the Pilbara bioregion

Pilbara Subregion	Description
Hamersley	Recognised as the southern section of the Pilbara Craton. The Hamersley subregion consists of mountainous areas of Proterozoic sedimentary ranges and plateaux, dissected with gorges (basalt, shale and dolerite; Kendrick 2003b).
Fortescue	Consists of alluvial plains and river frontages (Kendrick 2003a). There are calcrete aquifers and localised springs in sections of the Fortescue system. It is the northern limit of the *Acacia aneura* complex (mulga).

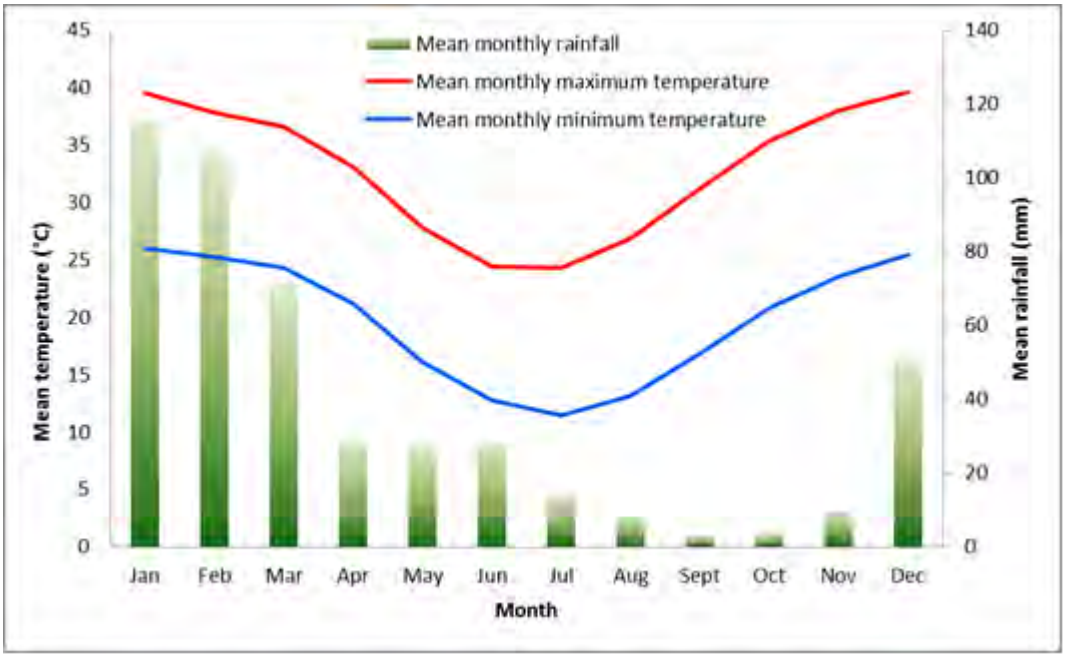
5.2 Climate

The Proposal Area is situated in the Pilbara bioregion of WA, which experiences a semi-arid to arid tropical climate that is characterised by hot humid summers (October to April) and relatively cool, dry winters (May to September). The mean monthly maximum temperature is approximately 40°C during the summer months (December/January), and drops to approximately 24°C in winter (June/July; BoM 2015). See **Figure 7** for further details.

The majority of the Pilbara has a bimodal rainfall distribution; from January to March rains result from tropical storms producing sporadic thunderstorms. Tropical cyclones moving south also bring heavy rains. From May to June, extensive cold fronts move eastwards across the state and sometimes reach the Pilbara. These fronts usually produce only light rains.

Long term, mean annual rainfall at the Yandicoogina locality is estimated to be approximately 400 mm, but is highly variable among years and over longer timescales. Annual evaporation is estimated to be between 3,200 mm to 3,600 mm and evaporation typically exceeds rainfall on a monthly basis throughout the year (MWH and Equinox Environmental 2011).

The closest operating meteorological station to the Proposal Area recording both temperature and rainfall data is the Wittenoom Weather Station (Station Number 005026), located approximately 95 km away. A summary of climate data recorded at the Bureau of Meteorology Wittenoom Weather Station is provided in **Figure 7**.



Source: BoM (2015)

Figure 7: Mean monthly rainfall, maximum and minimum temperatures recorded at the Wittenoom Weather Station between October 1951 to April 2015

5.3 Geology

The Yandicoogina CIDs represent an accumulation of pisolitic iron that formed during the Tertiary Period. The CIDs are located in the Yandicoogina, Marillana and Weeli Wolli Creek regional catchments and comprise a palaeo-channel system that extends for a strike distance of approximately 80 km (Rio Tinto 2014a).

Most of the Yandicoogina area CID outcrops occur in association with Marillana Creek and its floodplain, or are covered by colluvium and alluvium up to 60 m thick. The palaeo-channel is between 450 and 750 m wide, with the main ore zone being 40-60 m thick in the centre of the channel and thinning out towards the channel margins, giving it a saucer-shape in cross-section. The top of the ore zone is generally weathered, silicified or clay rich due to infiltration of clays along joints, fractures, faults and tree roots (Rio Tinto 2014a). The stratigraphy of the CID includes six main material types:

- Eastern Clay Conglomerate/Laterite.
- Weathered Channel.
- Goethite Vitreous Upper.
- Goethite Vitreous Lower.
- Limonite Goethite Channel.
- Basal Conglomerate.

The proposal area marks the eastern extent of the CID palaeo-channel prior to entering and fanning out onto the Fortescue Plains. The palaeo-channel follows a north easterly course, located to the east of the JSE deposit, and continues along the borders of the Weeli Wolli valley before infiltrating the Fortescue Plains in the north. The Proposal deposit lies to the east and runs parallel to the floodplain of the current Weeli Wolli Creek for a total length of approximately 7 km (when measured in a straight line; Rio Tinto 2014a). The surface geology of the Proposal Area is presented in **Figure 8**.

5.4 Landform and land systems

The Proposal Area is dominated by Weeli Wolli Creek and its associated floodplains and hill slopes (Biota 2014a). The Creek flows in a northeast direction and ends in an alluvial fan at the Fortescue Marsh, outside of the Revised Proposal Development Envelope. The confluence of Weeli Wolli Creek and Marillana Creek is located in the north west of the Proposal Area. Four major landforms occur within the Proposal Area:

- **Major creeklines and tributaries**: predominately *Eucalyptus victrix* open woodland over *Acacia* low woodland over tussock grassland, with some sections of *Eucalyptus camaldulensis* and *E. victrix* woodland over *Melaleuca* and *Acacia* open woodland.
- **Minor creeklines, floodplains and valleys**: Predominantly *Eucalyptus leucophloia*/*Corymbia hamersleyana* scattered low trees to low open woodland over *Acacia* shrubland, over *Triodia* hummock grassland.
- **Hills ridges and breakaways**: Predominantly *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Hakea chordophylla*, *Acacia inaequilatera*, *Grevillea wickhamii* tall open shrubland over *Triodia* sp. *Shovelanna Hill* (S.van Leeuwen 3835) hummock grassland.
- **Plains**: *Eucalyptus leucophloia* subsp. *Leucophloia* and *Corymbia hamersleyana* scattered low trees over *Acacia* low open woodland over open *Acacia*, *Eremophila* shrubland over *Triodia* open hummock grassland.

The physical resources of the Pilbara region have been characterised and mapped into a number of land system units based on landforms, soils, vegetation and drainage patterns (Van Vreeswyk et al. 2004). Four land systems as mapped by Van Vreeswyk et al. (2004) were identified as occurring within the Proposal Area (Biota 2014a). These land systems and their associated descriptions are presented in **Table 5** and spatially depicted in **Figure 9**. The River land system includes the major drainage lines of the area (Marillana, Yandicoogina and Weeli Wolli Creeks). All of the land systems are widely represented across the central Pilbara region.

Table 5: Major land systems within the Proposal Area

Land system	Description	Extent in Proposal Area (ha)	Proportion of Proposal Area (%)
Newman	Rugged ironstone ridges, plateaux and mountains; hard spinifex pastures in Good to Excellent condition; no erosion	1,161	26
Boolgeeda	Stony lower slopes and plains below hill systems; not degraded or eroded	1,491	33
River	Active flood plains and major rivers supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands	1,336	30
McKay	Hills, ridges, plateaux remnants and breakaways of metasedimentary and sedimentary rocks supporting hard spinifex grasslands	499	11

5.5 Hydrogeology

Conceptually, three main hydro-stratigraphic units are recognised in the Yandicoogina region. They are comprised of the:

- relatively impermeable basement of the Weeli Wolli Formation;
- overlying highly permeable fractured CID; and
- semi-permeable floodplain alluvium of the creeks.

The aquifers are recharged primarily by direct infiltration of rainfall and via creek bed alluvials as a result of surface water flows during and/or following heavy rainfall (Rio Tinto 2010).

The Yandicoogina Iron Ore deposits infill the dissected palaeo-river valley of the Marillana - Yandicoogina - Weeli Wolli Creek system to form the CID (Rio Tinto 2014a). The CID aquifer is characterised by a relatively high water yield associated with secondary porosity. The CID is overlain and flanked by both alluvium and unconsolidated materials, which are also relatively transmissive and variably connected with the CID aquifer (Rio Tinto 2014a). Together, the CID and alluvium aquifers range in width from 1,000 to 2,000 m. The overall groundwater system is bounded by low transmissivity parent rocks, and the depth of the CID channel diminishes towards the flanks of the flood plain (Rio Tinto 2014a).

The natural depth to groundwater at the existing Yandi Operations pre-mining varied from 3 - 20 m below ground level (Rio Tinto 2010). However, due to leakage into the CID aquifer from surplus water discharge associated with upstream operations, the depth to groundwater has decreased with the general flow direction to the east within the Marillana Creek catchment and to the northeast at the Proposal locations, along Weeli Wolli Creek (Kirkpatrick and Dogramaci 2010a, 2010b).

Groundwater values of the Proposal Area are described in further detail in Section 13.

5.6 Surface hydrology

The topography of the central Pilbara region generally supports well defined surface catchments. Most rivers in the Pilbara are ephemeral and flow only occasionally, usually after heavy rainfall events. Larger flows are correlated with storms or high intensity cyclonic events, which bring heavy rain over a large area of the catchment. The Revised Proposal is located in the Weeli Wolli Regional Catchment within the Upper Fortescue River Catchment, near the intersection of Marillana/Yandicoogina Creek, Phil's Creek and Weeli Wolli Creek (**Figure 10**).

Weeli Wolli Creek is the dominant drainage feature which enters the Proposal Area from south of the Proposal deposit. Weeli Wolli Creek is a major Pilbara drainage system, with a catchment area of 4,769 km^2, and length of approximately 71 km. Weeli Wolli Creek drains parallel to the Proposal deposit in a predominantly north easterly direction, which runs downstream of the deposit and the Marillana Creek confluence. It then drains into the fluvial outwash fan south of Fortescue Marsh, with Fortescue Marsh located approximately 40 km to the north of the Revised Proposal. As Weeli Wolli Creek approaches Fortescue Marsh, the creekline becomes increasingly braided and ill-defined within the fluvial outwash fan (Rio Tinto 2014b).

Weeli Wolli Creek and its tributaries are altered systems, receiving surplus water from existing mining projects specifically Yandi Operations, BHP's Marillana Creek (Yandi) operations and Hamersley HMS's Hope Downs 1 operation. The Hope Downs 1 surplus water release into Weeli Wolli Creek, which commenced in 2007, together with surplus water discharge from JSE into Weeli Wolli Creek (near the southern end of the Proposal

deposit) during late 2006, has temporarily shifted the section of Weeli Wolli Creek adjacent to the Proposal from an ephemeral to a perennial system (Rio Tinto 2014a).

6. Biological environment

6.1 Environmental Values Statement

As part of the approval for the existing Yandi Operations, under MS 914, an Environmental Values Statement (EVS) was required to be developed for Weeli Wolli Creek, as per condition 6-1 and 6-2:

- *Condition 6-1: The proponent shall ensure that the discharge of excess water from the Yandicoogina Iron Ore Project - Expansion to include Junction South West and Oxbow Deposits as a result of mining does not cause long term impacts to environmental values of the Weeli Wolli Creek System.*

- *Condition 6-2: To verify that condition 6-1 is being met, the proponent shall develop an Environmental Values Statement for the Weeli Wolli Creek System that defines the environmental values of the Weeli Wolli Creek System to the satisfaction of the CEO in consultation with the DEC.*

The high level values identified related to hydrology/hydrogeology, flora and vegetation, fauna, heritage and social aspects. This EVS was developed in consultation with the former Department of Environment and Conservation (DEC) and approved by the CEO of the OEPA on 14th October 2012 (**Table 6**).

Table 6: High level values statement for Weeli Wolli Creek catchment, October 2012

Value	Description
Hydrology/ hydrogeology	Marillana and Weeli Wolli Creeks are ephemeral watercourses supported by a combination of groundwater flows and surface run off. This system ultimately drains into Fortescue Marsh, approximately 40 km downstream of Yandicoogina.
Flora and vegetation	A number of populations of the DRF (Declared Rare Flora) *Lepidium catapycnon* occur within the Project Area. The species is listed as a DRF under the *Wildlife Conservation Act 1950* and as Vulnerable under the *Environmental Protection and Biodiversity Conservation Act 1999* (EPBC Act). Four main Riparian woodland vegetation communities exist along the Weeli Wolli and Marillana creekline areas within the Yandicoogina Project footprint. One community (open riparian woodland of *Eucalyptus victrix, Eucalyptus camaldulensis, Melaleuca argentea, M. glomerata*) is considered to have local significance due to its association with a major creekline in the area.
Fauna	The riparian woodland and ephemeral nature of the Weeli Wolli and Marillana Creeks, together with the underlying CID aquifer provide habitat for a range of fauna, including terrestrial, avian, aquatic and subterranean. Assemblages include aquatic fauna (micro and macroinvertebrates and fish), stygofauna, and animals of the hyporheic zone. The Project Area does not contain any permanent pools as refuge for aquatic fauna, and as a result there is no elevated conservation significance for aquatic fauna in the Project footprint. A number of stygofauna fauna species are known only from the Marillana-Weeli Wolli Catchment. In the wider catchment the Weeli Wolli Spring (upstream from the Project Area) is known to support a significant microbat species assemblage, which includes the most northerly population of the Chocolate Wattle Bat (*Chalinobolus morio*). No threatened fauna are known from the Weeli Wolli and Marillana creeklines in the Yandicoogina Project Area; however it may contain habitat for the Northern Quoll and the Pilbara Olive Python.
Heritage and social	Aboriginal culture is spiritually and physically connected to the landscape through *Jukurppa* (Dreaming) stories, ceremony, and physical places such as ethnographic and archaeological heritage sites. Weeli Wolli Creek is an important ephemeral water source, food source, camping and meeting place and has been visited by the Traditional Owners of the area for many thousands of years. Significant ethnographic and archaeological heritage sites are also associated with the Marillana and Weeli Wolli water courses. Weeli Wolli Creek is significant for tourism in the region.

These original values are proposed to be amended to reflect specific identified environmental values (rather than processes). This alteration is being undertaken in consultation with Parks and Wildlife. The updated EVS for the Weeli Wolli Creek catchment, included in the revision to the Yandicoogina Monitoring and Management Plan (**Appendix 4**), is described in **Table 7**.

Table 7: High level values statement for Weeli Wolli Creek catchment, October 2015

High Level Values	Description
Fortescue Marsh	The Fortescue Marsh is the largest ephemeral wetland in the Pilbara region and is listed on the Directory of Important Wetlands of Australia as a wetland of national significance. The diverse ecosystem includes endemic flora, fauna and supports a rich diversity of restricted aquatic and terrestrial invertebrates. The Fortescue Marsh is classified as a Priority Ecological Community (PEC). Marillana and Weeli Wolli Creeks are ephemeral watercourses supported by a combination of groundwater flows and surface run off. This system ultimately drains into Fortescue Marsh, approximately 40 km downstream of Yandicoogina.
Flora and vegetation	A number of populations of the DRF (Declared Rare Flora) *Lepidium catapycnon* occur within the Yandicoogina Development Envelope. The species is listed as a DRF under the Wildlife Conservation Act and as Vulnerable under the EPBC Act. Five broad riparian woodland vegetation communities exist along the Weeli Wolli and Marillana creekline areas within the Yandicoogina Development Envelope. One community (C1A - open riparian *eucalypt* woodland containing a mature and co-dominant *Melaleuca argentea* component) is considered to have local conservation significance due to its groundwater dependency, associated values, somewhat restricted distribution, and association with a major creekline in the area. This community is similar but of different structure and reduced significance to the vegetation community of Weeli Wolli Spring (significant *Melaleuca argentea* woodlands).
Stygofauna	A number of subterranean fauna species are known only from the Marillana-Weeli Wolli Catchment. The riparian woodland and ephemeral nature of the Weeli Wolli and Marillana Creeks, together with the underlying CID aquifer provide habitat for a range of fauna, including terrestrial, avian, aquatic and subterranean. Assemblages include aquatic fauna (micro and macroinvertebrates and fish), stygofauna, and animals of the hyporheic zone. The Development Envelope does not contain any permanent pools as refuge for aquatic fauna, and as a result there is no elevated conservation significance for aquatic fauna in the Development Envelope.
Other Recognised Values	**Description**
Fauna	In the wider catchment, the Weeli Wolli Spring (upstream from the Development Envelope) is known to support a significant microbat species assemblage, which includes the most northerly population of the Chocolate Wattle Bat (*Chalinobolus morio*). This bat species has been recorded in the south west corner of the Development Envelope. The Pilbara Olive Python (*Liasis olivaceus barroni*) has been recorded within Weeli Wolli Creek within the southern area of the Development Envelope, and the Development Envelope may contain habitat for the Northern Quoll (*Dasyurus hallucatus*). The Weeli Wolli Creek catchment also contains records of listed migratory birds and Priority species.
Heritage and Social	Aboriginal culture is spiritually and physically connected to the landscape through Jukurppa (Dreaming) stories, ceremony, and physical places such as ethnographic and archaeological heritage sites. Weeli Wolli Creek is an important ephemeral water source, food source, camping and meeting place and has been visited by the Traditional Owners of the area for many thousands of years. Significant ethnographic and archaeological heritage sites are also associated with the Marillana and Weeli Wolli water courses. Heritage and social values are recognised and are addressed by the Heritage of Western Australia Act 1990. Weeli Wolli Creek is also a significant tourism destination in the region.

6.2 Vegetation and flora

6.2.1 Context

6.2.1.1 Surveys in the region

Numerous flora and vegetation surveys have been conducted in the wider Yandicoogina locality, with surveys commencing in 1994 (refer to Section 14.2 for further details), to varying levels of detail. Within the Revised Proposal Development Envelope, 30 vegetation units (**Figure 11** to **Figure 19**) have been identified within the following broad landscape categories (Biota 2015a):

- Major creeklines and tributaries - A total of five vegetation types were associated with creeklines that supported true riparian vegetation, as characterised by the presence of the tree species *Eucalyptus camaldulensis* (River Red Gum), *E. victrix* (Coolibah) and/or scattered stands of *Melaleuca argentea* (Cadjeput).
- Minor creeklines, floodplains and valleys - A total of five vegetation types were associated with minor creeklines, floodplains and valleys.
- Hills, ridges, gorges and breakaways - A total of 11 vegetation types were associated with hills, ridges, gorges or breakaways.
- Plains - A total of nine vegetation types were associated with stony plains.

A total of 548 native vascular flora taxa from 173 genera and 53 families have been recorded within the Revised Proposal Development Envelope, based on all survey in the area to date. This includes one Threatened species (*Lepidium catapycnon*) and five Priority flora species. A total of 36 introduced flora species were also recorded (Biota 2015a).

6.2.1.2 Establishment of Clearing Avoidance Area

During assessment and approval of the existing Yandi Operations, a Clearing Avoidance Area (CAA) was defined as part of MS 914. The CAA was developed in recognition of the local conservation significance of the creeklines (as described in detail in the original EVS) and their ecological function. The boundary of the CAA was based on vegetation mapping specifically delineating riparian vegetation and encompassing creekline vegetation communities representing the broader floodplain.

The CAA was originally developed for the JSW and Oxbow environmental assessment whereby a Development Envelope was defined and key areas for reduced or limited clearing were delineated along Marillana Creek. This included delineating areas of the creekline not proposed to have any clearing undertaken during implementation of the proposal. However, during a subsequent s46B amendment under the EP Act to include the existing operations (JC and JSE), the boundary of the CAA was extended from Marillana Creek to also include Weeli Wolli Creek to match the expanded Development Envelope, and delineated areas which were not intended to have any clearing associated with implementation of the operations which were included and approved in MS 914.

The applicability of the CAA delineated in MS914 was therefore related to implementation of the JSW, Oxbow, JC and JSE deposits only, and not intended to apply to potential future developments (such as this Proposal). To avoid confusion, the CAA and Restricted Clearing Area polygons have been revised to an overall Restricted Clearing Area as depicted in **Figure 79**, Section 24.

6.2.1.3 Riparian vegetation trends

Riparian vegetation along Pilbara watercourses are often dominated by dense, tall, large trees of *Melaleuca argentea, Eucalyptus camaldulensis* and *E. victrix*. These species occur in an environment subject to ecological shifts that can be quite large and dynamic, with episodic occurrences of drought, defoliating wildfire, severe flood and stand replacement by regeneration, even when in a “natural and protected” condition. Shifts in species composition and in tree health are inevitable over time.

Disturbed
Disturbed

The Proponent monitors riparian tree health utilising a variety of methods, specifically ground transects (record flora present, structure and visual rating of crown health condition), Digital Cover Photography, and aerial photography. Monitoring results show varying changes to riparian vegetation (when comparing reference and impact sites). Some areas show increased health, others decreased (including dead trees) and others that have changed little (Eastham 2015). These results indicate that the vegetation even at reference sites in the Pilbara is not static, but is highly dynamic in its responses to altered environmental conditions.

The hydrology of the Weeli Wolli Creek system is complex. In addition to a high level of natural variation in rainfall and surface water flow, the creek is also influenced by dewatering, spur irrigation, discharge and re-injection associated with mines operating in the catchment. Ecological changes are inevitable where an ephemeral creek system is altered to a perennial system for a number of years. **Plate 1** shows the extent and density of vegetation associated with the Weeli Wolli Creek system prior to hydrological alterations by mining operations, when the system was ephemeral. The vegetation is much sparser in comparison to **Plate 2**, which shows the extent and density of vegetation subsequent to hydrological alterations where the system is now perennial and natural regeneration from local seed sources is occurring.

Plate 1: Vegetation associated with portion of Weeli Wolli Creek system in 2006

Plate 2: Vegetation associated with portion of Weeli Wolli Creek system in 2014

Tree responses to drought and waterlogging (associated with dewatering and surplus water discharge) will differ between the three dominant riparian species (*M. argentea, E. camaldulensis* and *E. victrix*), as well as being influenced by the proximity of the trees to the disturbance (dewatering or discharge), the ecological niche occupied by individual trees (especially elevation above water table), valley shape and soil type.

6.2.2 Vegetation

The Proposal Area lies within the Fortescue Botanical District of the Eremaean Botanical Province as defined by Beard (1975a). Vegetation of this province is typically open and frequently dominated by spinifex, wattles and scattered eucalypts. The Proposal Area intersects two of the vegetation units defined by Beard (1975b), all of which have the majority of their pre-European extent remaining. These vegetation units are described in

Table 8: Broad vegetation of the Proposal Area

Beard Vegetation Association	Description
Fortescue Valley_29	Sparse low woodland; mulga, discontinuous in scattered groups
Fortescue Valley_82	Hummock grasslands, low tree steppe; Snappy Gum over *Triodia wiseana* (equivalent to Hamersley_82)

Source: Beard (1975b)

Biota Environmental Sciences (Biota) has mapped and described vegetation sub-associations (referred to herein as vegetation units) within the Proposal Area (Biota 2014a); and additional refined riparian vegetation mapping has been undertaken along Marillana and Weeli Wolli Creek (Rio Tinto 2015a). The vegetation units have been grouped according to major landform, with the following relevant to the Proposal Area:

- Vegetation of Major Creeklines and Tributaries.
- Vegetation of Minor Creeklines, Floodplains and Valleys.
- Vegetation of Hills, Ridges and Breakaways.
- Vegetation of Plains.

Most of the vegetation was in Excellent or Good condition (utilising the scale by Trudgen 1988), however the creekline and floodplain vegetation ranged from Good to Very Poor condition. This was due to dense weed invasion (particularly by *Cenchrus ciliaris*) and disturbance from cattle in the form of tracks, grazing, trampled vegetation and scats (Biota 2014a).

Details of the vegetation recorded within the Proposal Area, including the conservation significance of vegetation communities and vegetation condition, are described further in Section 14.

6.2.3 Flora

A total of 455 native vascular flora taxa from 147 genera and 47 families have been recorded from the Proposal Area, based on all survey effort to date (Biota 2014a). This includes one Threatened species and two Priority flora species, with an additional three Priority species potentially occurring in the Study area. When compared to other studies within the region, the total number of native flora taxa recorded from the Proposal Area is in the range that would be expected and does not contain a particularly high level of vegetation or plant species diversity for the Pilbara bioregion (Biota 2014b). Eighteen introduced flora species have also been recorded.

The flora recorded in the Proposal Area, including conservation significant flora, are described further in Section 14.

6.3 Terrestrial fauna

6.3.1 Terrestrial fauna habitats

Five fauna habitat types have been categorised in the Proposal Area, classified on the basis of landform, substrate and vegetation (Biota 2014c). In addition, disturbed areas were identified. The fauna habitats included:

- Alluvial Plain (Flood Plain).
- Mulga woodland.
- Hilltops and Slopes.
- Pediment Slope.
- Major Drainage Line.

The major drainage channels of the Marillana and Weeli Wolli Creeks provide suitable habitat for conservation significant fauna species such as the Pilbara Olive Python (*Liasis olivaceus barroni*). Habitat for the conservation significant Northern Quoll (*Dasyurus hallucatus*) is limited, but some small areas of rocky breakaway habitat do exist throughout the Proposal Area (Biota 2014d).

Terrestrial fauna habitats are described further in Section 15.

6.3.2 Terrestrial vertebrate fauna

A total of 147 vertebrate fauna species have been recorded in the Proposal Area, including five conservation listed species under the EPBC Act, the *Wildlife Conservation Act 1950* (WC Act) and/or the Parks and Wildlife Priority List. An additional species, the Chocolate Wattled Bat (*Chalinolobus morio*), while currently not listed under Commonwealth or State legislation, was also identified to be of significance. A further 11 conservation listed species have been identified as likely or potentially occurring within the Proposal Area (Biota 2015b; 2014c).

The terrestrial vertebrate fauna of the Proposal Area, including conservation listed species, are described further in Section 15.

6.3.3 Short range endemic terrestrial invertebrate fauna

Species are identified as potential short range endemics (SREs) if they have a known distribution less than 10,000 km^2 (Harvey 2002). SRE invertebrate fauna were targeted during recent fauna surveys of the Proposal Area. Genetic analysis from collected specimens determined four potential SRE putative species from two families of mygalomorph spiders (Biota 2014c, 2015b). The SREs of the Proposal Area are described further in Section 15.

6.3.4 Aquatic fauna

Aquatic fauna surveys have been conducted biannually (wet and dry seasons) since September 2007 by Wetland Research and Management (WRM 2015a, b) in Marillana Creek and Weeli Wolli Creek. The most recent survey in September/October 2013 (late dry) and April/May 2014 (late wet) found the following number of taxa in the Proposal Area:

- 108 microinvertebrate taxa.
- 141 macroinvertebrate taxa.

- 34 hyporheic fauna taxa: 15 taxa classified as occasional hyporheos stygophiles, 7 taxa as stygobites, and 12 were possible hyporheic taxa.
- 3 fish species.

Several undescribed hyporheic taxa were considered to be new species, and five stygobitic amphipod/isopod species were considered to be potential SREs, with *Maarrka weeliwolli* and *Pygolabis weeliwolli* appearing to be restricted to Marillana Creek and Weeli Wolli Creek. The aquatic fauna sampled within the Proposal Area are described further in Section 15.

6.4 Subterranean fauna

Subterranean fauna can be classified into two main groups:

- Stygofauna which are obligate groundwater-dwelling aquatic fauna that spend their entire life cycle below ground, occasionally occurring very close to surface waters as well as deep aquifers; and
- Troglofauna which are obligate subterranean terrestrial fauna that inhabit caves and the many small voids and tunnels that occur within some unconsolidated and rocky substrates above the water table.

Subterranean fauna in WA are generally invertebrates and often exhibit high levels of endemism. The absence of light in subterranean ecosystems results in limited energy resources originating from surface environments. As a consequence, subterranean fauna have evolved to survive in unique environments, often being highly specialised with morphological, physiological and biological adaptations that reflect severe environmental constraints (Gibert & Deharveng 2002 as cited in EPA 2013b). WA's subterranean fauna is recognised as being globally significant because of its extraordinarily high species richness and high levels of endemism (EPA 2013b).

In total there were 2,761 stygofauna specimens from 62 taxa found in the Proposal Area to date. There is limited troglofauna habitat within the Proposal Area, and the CID formation proposed for excavation (known to provide habitat for troglofauna in other areas of the Pilbara) is located 99% below the water table. Three troglofauna specimens (three taxa) have been recorded within the Proposal Area.

Subterranean fauna of the Proposal Area are described in further detail in Section 15.

7. Social environment

7.1 Socio-economic setting

The Pilbara is one of the largest regions in WA, encompassing 507,896 km^2 (Pilbara Development Commission 2015). In June 2014, the estimated resident population of the Pilbara region was 67,503 people, with almost 60% of the population aged between 20 and 49 years. The mining and construction industries account for 60% of all jobs in the region. In 2014, the gross regional product for the Pilbara was almost $35 billion (REMPLAN 2015).

The Proposal Area lies within the Shire of East Pilbara, which has an estimated population of 25,000 people, including FIFO workers. The East Pilbara economy is primarily based on mining and associated supporting industries, tourism and pastoral activities. The main regional centres of the East Pilbara are Newman, Marble Bar and Nullagine. There are a number of Aboriginal Communities within the Shire, including Jigalong, Punmu, Parngurr, Irrungadgi and Parnpajinya (Shire of East Pilbara 2014).

Newman, with a population of 9,000 people, is the nearest significant population centre to the Proposal Area, located approximately 90 km to the south east. Newman is an important regional centre due to its proximity to mining and mineral exploration sites, and airport that supports the FIFO mine workforces. The 54 km bitumen access road into Yandicoogina, shared by the Proponent and BHP, is located 135 km north west of Newman on the Great Northern Highway.

7.1.1 Land use

The principal land use in the region is pastoral cattle production. The Proposal Area co-exists with Pastoral Lease N50368 which is currently held by a BHP subsidiary and operated as Marillana Station (**Figure 20**). A number of the Proponent's existing Yandi Operations deposits (JC, JSE, and part of JSW) also co-exist with this pastoral lease. Marillana Station has a long history of cattle grazing and is still used for this purpose.

There are a number of other mining projects that occur in the vicinity of the Proposal and existing Yandi Operations. These are operated by Rio Tinto (or its subsidiaries) or a number of other third party operators (**Figure 21**).

Other regional land uses include tourism and conservation. The Proposal Area is located approximately 70 km from the nearest boundary of the Karijini National Park, approximately 200 km from the Millstream Chichester National Park and approximately 115 km from the Mungaroona Range Nature Reserve (**Figure 22**).

Additionally, the Proposal Area is located in the catchment of the Fortescue Marsh, which has regionally and nationally important conservation values and is listed in the Directory of Important Wetlands of Australia (Environment Australia 2001; EPA 2013a). Fortescue Marsh is almost 1,050 km^2 in size, the largest ephemeral wetland in the Pilbara, within a larger management area of over 5,800 km^2 (EPA 2013a). The northern section of the Revised Proposal Development Envelope is located in this broader management area, Zone 2b Poonda Plain, which has a medium environmental significance (EPA 2013a). However, the Proposal Area is primarily located outside this zone and the only potential impact from the Proposal is related to the surplus discharge wetting front (see Section 13). The highly diverse ecosystem of the Fortescue Marsh is an important regional conservation asset and supports populations of restricted aquatic and terrestrial invertebrates, threatened vertebrate fauna and Priority flora (DPaW 2014).

7.1.2 Tenure

The Revised Proposal is located on mining lease 274SA (ML274SA) held by Hamersley Iron – Yandi Pty Ltd established under the *Iron Ore (Yandicoogina) Agreement Act 1996* (**Figure 20**).

The Proponent operates a railway corridor that runs in a west, and then north westerly direction, extending from the rail load-out facility located near JC. Part of this railway runs through BHP's Yandicoogina Operation to the west of the existing Yandi Operations on Mining Lease 270SA. The Proponent has been granted Lease L21124 under the *Land Administration Act 1997* for this section of the railway. The railway corridor connects with existing Rio Tinto port facilities at Dampier and Cape Lambert.

The Proponent's workforce for the existing Yandi Operations is accommodated in the village/camp facilities located on Lease L21123 under the *Land Administration Act 1997,* which abuts the northern boundary of ML274SA.

BHP operates a railway line and power transmission corridor which crosses ML274SA in a north south direction immediately east of the Oxbow deposit.

7.2 Aboriginal heritage, culture and Native Title

7.2.1 Native Title

There are more than 31 Aboriginal cultural groups (socio-linguistic groups) recognised in the Pilbara region (Pilbara Development Commission 2015). In the Shire of East Pilbara, over 16% of the population identify as Aboriginal (REMPLAN 2015).

Rio Tinto's Yandi Operations are covered by the YLUA, which has been in place since 1997 and was negotiated with Gumala Aboriginal Corporation, a representative body for the Traditional Owners of the Yandicoogina area.

At the time the YLUA was entered into, the Innawonga (now 'Yinhawangka'), Bunjima (now 'Banjima') and Niapaili (now 'Nyiyaparli') claimant application (NNTT number: WC 96/61, Federal Court number: WAD 6096/98; "IBN Claim") was registered over the Revised Proposal Development Envelope in its entirety.

Since 1998, native title claims for the area have undergone some significant changes, namely Yinhawangka and Banjima have separated out their claims and Martu Idja Banyjima and Bunjima are now native title holders as part of a single 'Banjima' language group. Both Nyiyaparli and Yinhawangka have separate Claim Wide Participation Agreements with Rio Tinto in their own right, however, the YLUA is not superseded by the existence of these newer commercial agreements.

Rio Tinto works with Gumala Aboriginal Corporation as the representative body for these claimant groups in relation to Hamersley Iron's Yandicoogina mining lease area (ML274SA). The Agreement provides financial and other benefits to the Aboriginal parties over the life of the mining operations for education, training, employment, business and community development.

7.2.2 Heritage sites

Archaeological and ethnographic heritage surveys have been completed across the Proposal footprint and for the majority of the Proposal Area. These surveys have documented artefact scatters, rock shelters and engravings (Rio Tinto 2014a). Extensive surveys have also been undertaken within the Revised Proposal Development Envelope; these surveys have identified numerous Aboriginal archaeological sites in addition to those listed above, including quarries, stone structures and scarred trees. These sites range from low to high archaeological and cultural significance. Possible burial sites (high significance) have also been identified within the area.

Weeli Wolli Creek and Marillana Creek have been identified as ethnographic sites. These creeks have important associations with camping, ceremonies and cultural activities.

Aboriginal heritage values in the Proposal Area are described further in Section 19.1.

Part 4 – Approach to Environmental Impact Assessment

Part 4 of the PER outlines the State and Commonwealth environmental assessment processes and the applicable legislative context. This part also describes the approach taken in considering the potential environmental impact of the Proposal and the environmental studies conducted to support the assessment of impacts.

8. Environmental assessment process

8.1 State environmental assessment process

The Proposal was referred to the WA EPA under Section 38 of the EP Act on 4 July 2014. The EPA determined that the Proposal required environmental assessment at the level of PER (with a six week public review period), whereby the Proponent must fulfil the requirements of the *Environmental Impact Assessment (Part IV Division 1) Administrative Procedures 2012* (EPA 2012b) for environmental assessment prescribed under the EP Act.

The EPA issued an Environmental Scoping Document (ESD; **Appendix 1**) for the Proposal on 31 December 2014. The ESD provides an outline of the key environmental factors, a description of the scope of the assessment of the Proposal and an indicative timeline for the assessment process.

The key aim of the PER is to present an assessment of impacts to environmental factors relevant to the Proposal in accordance with the ESD. The Environmental Impact Assessment uses various EPA guidance documents to determine the significance of the environmental effects of the Proposal (Section 8.2).

The EPA will need to confirm the PER document as suitable for a public review period on the basis that it adequately addresses the expectations of the EPA set out in the ESD. Following the public review period, the EPA will provide to the Proponent copies (and a summary) of all submissions received. The Proponent will respond to matters raised in the submissions to the satisfaction of the EPA.

The EPA will then assess the PER document, submissions received, the Proponent's response to submissions, and obtain advice from any other persons it considers appropriate before submitting its assessment report on the Proposal to the Minister for Environment.

The Minister will then publish the EPA report. Any person may lodge an appeal to the Minister for Environment against the content of, or recommendations in the EPA assessment report within 14 days of its publication. Subsequent to the determination of appeals (if any), the Minister then decides whether or not the Proposal should be implemented and if so, under what conditions.

The environmental assessment process for a PER is depicted diagrammatically in **Figure 23**.

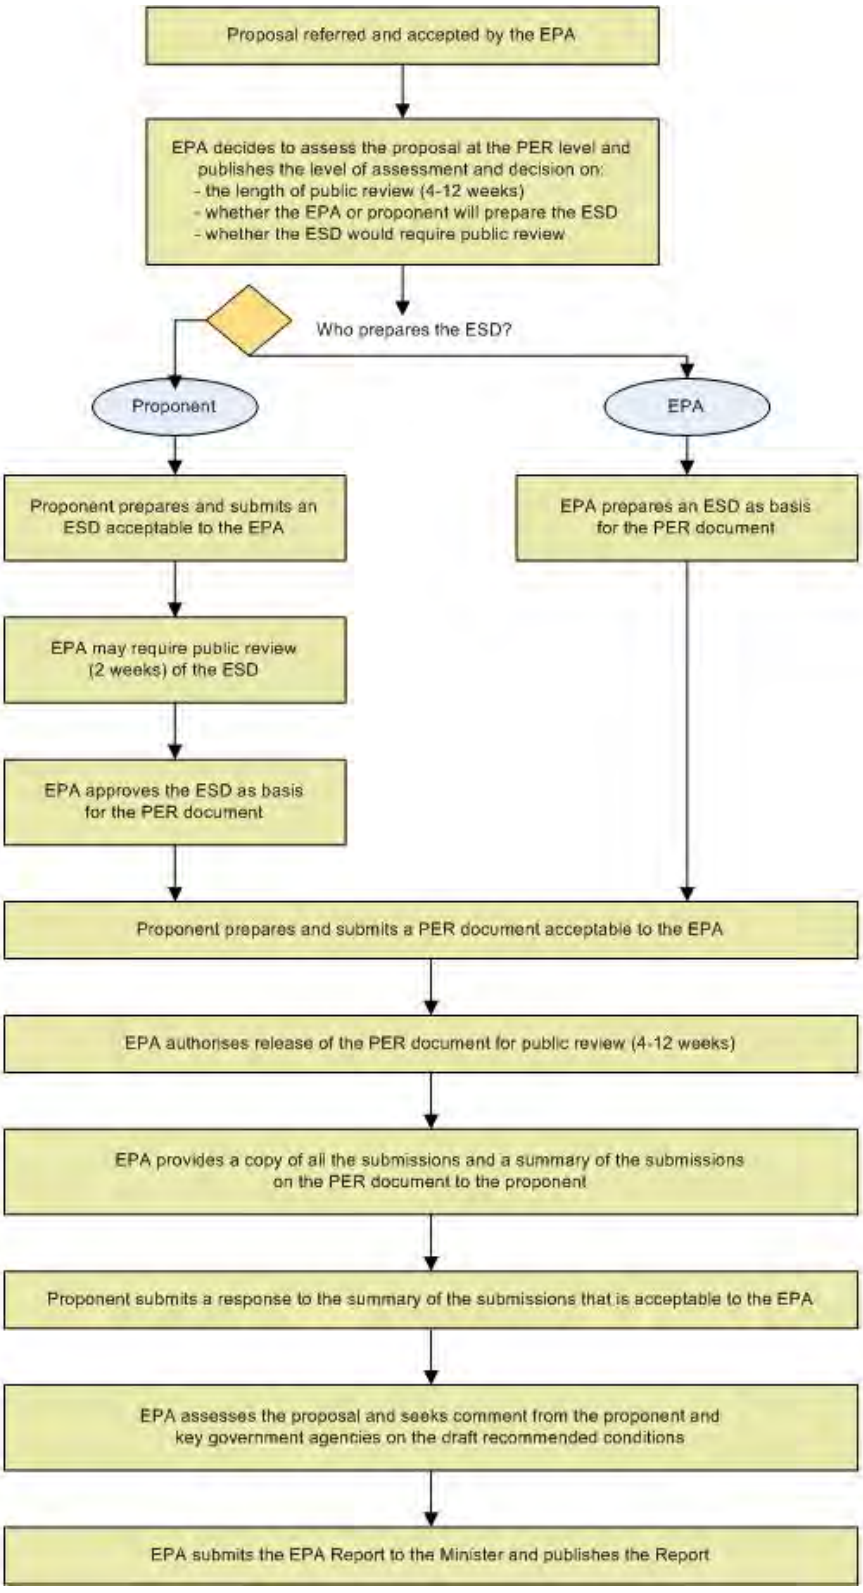

Figure 23: Public Environmental Review assessment process

8.2 State legislation, policy and guidance

The Proposal is subject to compliance with relevant state legislation and regulations and is guided by relevant key over-arching state policies and strategies. In addition, there are EPA Position Statements and Guidance Statements that have been used to determine the significance of the environmental effects of the Proposal. The relevant state legislation/regulations, policies, strategies, EPA Position Statements and Guidance Statements, and other guidance documents, are listed in Section 8.2.1 to Section 8.2.5.

8.2.1 State legislation and any subsidiary regulations

- *Aboriginal Heritage Act 1972*.
- *Biosecurity and Agricultural Management Act 2007.*
- *Bush Fires Act 1954.*
- *Contaminated Sites Act 2003.*
- *Country Areas Water Supply Act 1947.*
- *Dangerous Goods Safety Act 2004.*
- *Electricity Act 1945.*
- *Environmental Protection Act 1986.*
- *Health Act 1911.*
- *Heritage of Western Australia Act 1990.*
- *Iron Ore (Yandicoogina) Agreement Act 1996.*
- *Land Administration Act 1997.*
- *Local Government Act 1995.*
- *Main Roads Act 1930.*
- *Mines Safety and Inspection Act 1994.*
- *Mining Act 1978.*
- *Native Title (State Provisions) Act 1999.*
- *Occupational Health and Safety Act 1984.*
- *Poisons Act 1964.*
- *Public Works Act 1902.*
- *Rights in Water and Irrigation Act 1914.*
- *Soil and Land Conservation Act 1945.*
- *Waste Avoidance and Resource Recovery Act 2007.*
- *Waterways Conservation Act 1976.*
- *Wildlife Conservation Act 1950.*

8.2.2 State policies and strategies

- State Water Quality Management Strategy Document No. 6 – Implementation Framework for Western Australia for the Australian and New Zealand Guidelines for Fresh and Marine Water Quality and Water Quality Monitoring and Reporting (Government of Western Australia 2001).
- Hope for the Future: The Western Australian State Sustainability Strategy (Government of Western Australia 2003).
- Western Australian Greenhouse Strategy (Government of Western Australia 2004).
- Pilbara water in mining guideline (Government of Western Australia 2009).
- WA Environmental Offsets Policy (Government of Western Australia 2011).
- WA Environmental Offsets Guidelines (Government of Western Australia 2014).
- Western Australian Water in Mining Guideline (Government of Western Australia 2013a).

8.2.3 EPA Position Statements

- Environmental Protection Bulletin No. 1 – Environmental Offsets (EPA 2014a).
- Position Statement No. 2 – Environmental Protection of Native Vegetation in WA (EPA 2000).
- Position Statement No. 3 – Terrestrial Biological Surveys as an Element of Biodiversity Protection (EPA 2002).
- Position Statement No. 7 – Principles of Environmental Protection (EPA 2004a).

8.2.4 EPA Guidance Statements

- No. 6 – Rehabilitation of Terrestrial Ecosystems (EPA 2006).
- No. 20 – Sampling of Short Range Endemic Invertebrate Fauna for Environmental Impact Assessment in WA (EPA 2009a).
- No. 33 – Environmental Guidance for Planning and Development (EPA 2008).
- No. 41 – Assessment of Aboriginal Heritage (EPA 2004b).
- No. 51 – Terrestrial Flora and Vegetation Surveys for Environmental Impact Assessment in WA (EPA 2004c).
- No. 54a – (Draft) Sampling Methods and Survey Considerations for Subterranean Fauna in WA (EPA 2007).
- No. 56 – Terrestrial Fauna Surveys for Environmental Impact Assessment in WA (EPA 2004d).

8.2.5 Other guidance documents

- Environmental Assessment Guideline (EAG) 8 – Environmental Factors and Objectives (EPA 2013a).
- Environmental Assessment Guideline (EAG) 12 – Consideration of subterranean fauna in Environmental Impact Assessment in Western Australia (EPA 2013b).
- Cumulative environmental impacts of development in the Pilbara region (EPA 2014b).

- Guidelines for Preparing Mine Closure Plans (DMP and EPA 2015).
- EPA and DEC Technical Guide - Terrestrial Vertebrate Fauna Surveys for Environmental Impact Assessment (EPA and DEC 2010).
- DoW – Water Quality Protection Notes.

8.3 Commonwealth environmental assessment process

The Proposal was referred to the DoE under the requirements of the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) on 26 September 2014. DoE determined that the Proposal is 'not a controlled action' on 25 October 2014, which means the Proposal does not require assessment and approval under the EPBC Act.

8.4 Principles of environmental protection

The Proponent acknowledges the environmental protection principles listed in Section 4a of the EP Act and presented in EPA Position Statement No. 7 (EPA 2004a). These environmental principles are:

- The precautionary principle.
- The principle of intergenerational equity.
- The principle of the conservation of biological diversity and ecological integrity.
- Principles relating to improved valuation, pricing and incentive mechanisms.
- The principle of waste minimisation.

Consideration has been given to these principles in the assessment of the potential environmental impacts associated with the Proposal. These principles are addressed in Part 7.

8.5 Principles of EIA

The *Environmental Impact Assessment (Part IV Division 1) Administrative Procedures 2012* (EPA 2012b) outlines the principles of Environmental Impact Assessment (EIA) for the Proponent, as follows:

1. Consult with all stakeholders, including the EPA, decision making authorities (DMAs), other relevant government agencies and the local community as early as possible in the planning of their proposal, during the environmental review and assessment of their proposal, and where necessary during the life of the project.

2. Ensure the public is provided with sufficient information relevant to the EIA of a proposal to be able to make informed comment, prior to the EPA completing the assessment report.

3. Use best practicable measures and genuine evaluation of options or alternatives in locating, planning and designing their proposal to mitigate detrimental environmental impacts and to facilitate positive environmental outcomes and a continuous improvement approach to environmental management.

4. Identify the environmental factors likely to be impacted and the aspects likely to cause impacts in the early stages of planning for their proposal. The onus is on the Proponent through the EIA process to demonstrate that the unavoidable impacts will meet the EPA objectives for environmental factors and therefore their proposal is environmentally acceptable.

5. Consider the following, during project planning and discussions with the EPA, regarding the form, content and timing of their environmental review:

(a) The activities, investigations (and consequent authorisations) required to undertake the environmental review.

(b) The efficacy of the investigations to produce sound scientific baseline data about the receiving environment.

(c) The documentation and reporting of investigations.

(d) The likely timeframes in which to complete the environmental review; and use best endeavours to meet assessment timelines.

6. Identify in their environmental review, subject to the EPA's guidance:

(a) Best practicable measures to avoid, where possible, and otherwise minimise, rectify, reduce, monitor and manage impacts on the environment.

(b) Responsible corporate environmental policies, strategies and management practices, which demonstrate how the proposal can be implemented to meet the EPA's environmental objectives for environmental factors.

The Proponent has considered these principles of EIA throughout the PER process for the Proposal.

9. Identification of key environmental factors

Scoping of relevant environmental factors was completed as part of the EPA process in preparing and finalising the ESD for the Proposal. The ESD was prepared with input from other WA DMAs and the Proponent (**Appendix 1**).

The EPA identified seven preliminary key environmental factors relevant to the Proposal that require detailed consideration by the Proponent. These preliminary key environmental factors are:

- flora and vegetation;
- terrestrial fauna;
- subterranean fauna;
- hydrological processes;
- inland waters environmental quality;
- rehabilitation and closure (integrating factor); and
- offsets (integrating factor).

Table 2 of the ESD sets out for each preliminary environmental factor:

- the EPA objective;
- the relevant aspects;
- the identified potential impacts;
- the work required to be undertaken; and
- the relevant policy/guidance documents.

The EPA identified other environmental factors that it considers relevant to the Proposal; air quality, amenity and (indigenous) heritage. These other environmental factors also warrant attention as part of the environmental review of the Proposal to the extent that the PER must demonstrate how these factors will be mitigated and the extent to which other statutory decision making processes can regulate the potential effects to meet EPA objectives and principles of Environmental Impact Assessment.

A compliance table has been developed (**Appendix 2**) showing where the ESD listed work requirements for each of the preliminary key environmental factor (and the other environmental factors) have been addressed or presented in the PER.

10. Cumulative impact assessment approach

10.1 Cumulative impact assessment overview

Cumulative impact assessment (CIA) is the process of assessing the impacts from all relevant historical, current and reasonably foreseeable future activities that may affect one or more specific components of the environment. This is in contrast to conventional 'project specific' EIA, which typically focuses on the impacts caused by a single development within a limited temporal or spatial boundary. CIA provides a spatial and temporal extension to conventional EIA and considers both direct and indirect impacts that may combine over time and/or space. Assessment of cumulative impacts can provide a means to identify potentially significant effects that may not be evident in conventional EIA, such as the potential for multiple mining projects to incrementally affect environmental values.

In its advice to the Minister for Environment under Section 16(e) of the EP Act (EPA 2014b), the EPA expressed concerns about cumulative environmental impacts to key environmental values in the Pilbara region, due to current and future mining developments in the region, combined with threatening processes of other land uses such as pastoralism and tourism. Consequently, CIA is an important consideration for Pilbara mining developments. The EPA identified cumulative impacts as a key issue for the Proposal in the ESD and specified the following required work:

- Flora and vegetation: "Provide a detailed description of the cumulative impacts associated with the proposal, including direct impacts from clearing, and indirect impacts such as groundwater drawdown, surface discharge of excess groundwater, altered drainage, changes in water quality, dust emissions and fragmentation of vegetation".
- Flora and vegetation: "Discuss potential direct and indirect (including downstream) and cumulative impacts to flora and vegetation as a result of the proposal, and provide quantitative data on impacts of the proposal to species of conservation significance".
- Terrestrial fauna: "Discuss potential direct/indirect (including downstream) and cumulative impacts to fauna as a result of the proposal, and provide quantitative data on impacts of the proposal to species of conservation significance".
- Hydrological processes: "Investigate groundwater drawdown due to groundwater abstraction associated with the proposal. Analyse and discuss any impacts to groundwater levels and flows taking into consideration the cumulative impacts with other proposals. Analyse, discuss and assess surface water and groundwater impacts, including changes in groundwater levels and changes to surface water flows associated with the proposal together with cumulative impacts with other projects and referred proposals (including the BHP strategic proposal) for which relevant information is publicly available".
- Inland waters environmental quality: "Model cumulative impacts with other mines in the catchment (currently operating and referred proposed mines, including the BHP strategic proposal, where information is publicly available). Develop strategies and controls to minimise the impacts".

The scope of the CIA conducted for the Proposal was defined with regard to the spatial boundary (Section 10.2), the key environmental receptors considered for each preliminary key environmental factor (Section 10.3) and the mining projects and referred proposals considered (Section 10.4). The outcomes of the CIA are provided in *Part 5 – Assessment of Environmental Values* of this document for each of the individual factors and is also summarised in *Part 6 – Summary of cumulative impacts*.

10.2 Spatial boundary

When approaching a CIA, decisions are required to be made regarding the spatial boundary; it is seldom practical or appropriate to include everything in the assessment. A balance needs to be found between the practical constraints (e.g. publically available data) and the rigour of the analysis. Including too little will lead to insufficient insight in the analysis, while including too much has the potential to overwhelm and obscure insight into meaningful trends.

The spatial boundary defined for the Proposal CIA was the Upper Fortescue River Catchment, which is approximately 30,000 km^2 (EPA 2013c), surrounds the Fortescue Marsh area and extends to the south of the Great Northern Highway (**Figure 24**). The proposed disturbance footprint of the Proposal is wholly contained within this catchment.

The Upper Fortescue River Catchment was regarded as the largest extent of potential cumulative impacts from the Proposal. For some receptors (Section 10.3), a smaller boundary within the Upper Fortescue River Catchment was defined where appropriate; for example, where the receptor was spatially restricted and/or not expected to be significantly affected by projects or referred proposals outside this boundary, for which or where available information (e.g. mapping) was restricted.

The distribution of some of the key environmental receptors considered extends beyond the spatial boundary used for the Proposal CIA. This assessment may therefore overstate the potential impacts to these receptors. The results of the assessment should be considered in the context of the spatial boundary used and are not necessarily applicable to the full extent or distribution of the receptor, where it extends beyond the catchment in question.

10.3 Key environmental receptors

Unlike conventional EIA, in which a single project is typically the focus of the assessment, CIA requires the identification of environmental receptors that provide the investigative focal point for the assessment (Hegmann et al. 1999). Environmental receptors tend to be at the end of ecological pathways and are therefore the ultimate recipients of impacts; they integrate the cumulative effects of different pressures and activities (IFC 2013).

Key environmental receptors relevant to the Proposal CIA were identified from the requirements of the ESD and findings of ecological surveys undertaken in the Proposal Area. They are outlined in Sections 10.3.1 for flora and vegetation receptors, Section 10.3.2 for terrestrial fauna receptors, and Section 10.3.3 for receptors related to hydrological processes and inland waters environmental quality.

10.3.1 Flora and vegetation

Flora and vegetation receptors considered for assessment in the Proposal CIA were those that have been recorded, or are considered likely to occur, in the proposed disturbance footprint of the Proposal and that meet one of the following criteria:

- Threatened flora species – species listed as Specially Protected under the WC Act and published under Schedule 1 of the Wildlife Conservation (Rare Flora) Notice and/or listed as Critically Endangered, Endangered or Vulnerable under the EPBC Act.
- Threatened Ecological Communities (TECs) – communities endorsed by the Western Australian Minister for Environment as Presumed Destroyed, Critically Endangered, Endangered or Vulnerable and/or listed as Critically Endangered, Endangered or Vulnerable under the EPBC Act.
- Any other flora species or vegetation community identified in the Proposal ESD and/or from findings of ecological surveys undertaken in the Revised Proposal Development Envelope as being of confirmed or potential elevated significance at the local level.

Flora and vegetation receptors that met one of the aforementioned criteria and were therefore included in the Proposal CIA were:

- Riparian vegetation along Weeli Wolli and Marillana Creeks, characterised by the presence of the tree species *Eucalyptus camaldulensis* (River Red Gum) and/or *E. victrix* (Coolibah) and/or *Melaleuca argentea* (Cadjeput). In the Revised Proposal Development Envelope, Biota (2014a, 2015a) mapped riparian vegetation as vegetation types C1, C2, C3, C4 and C5. These communities have been further refined by the Proponent (Rio Tinto 2015a) into 13 riparian sub-associations.

Lepidium catapycnon (Vulnerable, WC Act and EPBC Act) has been recorded in the Revised Proposal Development Envelope (Biota 2014a), including in the Proposal Area; however, this species has been avoided and does not occur within the proposed disturbance footprint of the Proposal. All known and recorded populations are avoided and therefore this species was not included in the CIA.

10.3.2 Terrestrial fauna

Terrestrial fauna receptors considered for assessment in the Proposal CIA were those that have been recorded, or are considered likely to occur, in the proposed disturbance footprint of the Proposal and that meet one of the following criteria:

- Threatened fauna species – species listed as Specially Protected under the WC Act and published under Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice and/or listed as Critically Endangered, Endangered or Vulnerable under the EPBC Act.
- Migratory birds – species listed as Specially Protected under the WC Act and published under Schedule 3 of the Wildlife Conservation (Specially Protected Fauna) Notice, and/or listed as Migratory under the EPBC Act.
- Other Specially Protected fauna species – species declared to be in need of special protection other than for the reasons for Schedules 1 (Threatened), 2 (Presumed Extinct), or 3 (Migratory) and listed as Specially Protected under the WC Act and published under Schedule 4 of the Wildlife Conservation (Specially Protected Fauna) Notice.

- Any other fauna species identified in the Proposal ESD and/or from findings of ecological surveys undertaken in the Revised Proposal Development Envelope as being of confirmed or potential elevated significance at the local level.

Terrestrial fauna receptors that met one of the aforementioned criteria and were therefore included in the Proposal CIA were:

- Pilbara Olive Python – listed as Vulnerable under the WC Act and EPBC Act. This species has been recorded in the Proposal Area (Biota 2015b) and may utilise habitats in the proposed disturbance footprint of the Proposal.
- Chocolate Wattled Bat – not listed under the WC Act or EPBC Act, but locally restricted within the Pilbara region, being recorded only in Marillana and Weeli Wolli Creeks. This species has been recorded in the Proposal Area (Biota 2015b) and may utilise habitats in the proposed disturbance footprint of the Proposal.
- Potential SRE invertebrate fauna recorded from the Proposal Area, comprising four mygalomorph spiders: Idiopidae sp. I1, Idiopidae sp. I9, Nemesiidae sp. N42 and Nemesiidae sp. N44.

The following terrestrial fauna receptors met one of the criteria for consideration in the Proposal CIA, but were excluded from the CIA:

- Pilbara Leaf-nosed Bat – listed as Vulnerable under the WC Act and EPBC Act. Weeli Wolli Creek is considered to be potential foraging habitat for the Pilbara Leaf-nosed Bat and the species is considered likely to occur in the Proposal Area; however, the species has not been recorded in the Revised Proposal Development Envelope (Biota 2014c). There was no evidence of roost caves suitable for the species despite extensive searches along the ridgelines of the Proposal Area. Consequently, while the Proposal Area as a whole could be considered dispersal habitat for the species, it was not considered core habitat as there was no evidence that a roost occurs within 15 km (the maximum foraging distance of individuals; Biota 2013).
- Peregrine Falcon – listed under Schedule 4 of the WC Act. One individual of this species has been recorded from the Robe land system in the Yandicoogina Junction Central Project area; however, it was considered likely to be a transitory or foraging individual (Biota 2015b). The species has not been recorded in the Proposal Area (Biota 2015b).
- Rainbow Bee-eater – listed under Schedule 3 of the WC Act and as Migratory under the EPBC Act. This species has been recorded in the Revised Proposal Development Envelope. The Rainbow Bee-eater is widespread throughout much of Australia and typically occurs in open country in most vegetation and landform types; however, the habitats in the Revised Proposal Development Envelope are not considered core habitat for this species (Biota 2015b).
- Fork-tailed Swift – listed under Schedule 3 of the WC Act and as Migratory under the EPBC Act. This species has been recorded in the Revised Proposal Development Envelope. The Fork-tailed Swift would not rely on any terrestrial habitats in the Revised Proposal Development Envelope since it is an aerial species and the habitats in this area are not considered core habitat for this species (Biota 2015b).
- Eastern Great Egret – listed under Schedule 3 of the WC Act and as Migratory under the EPBC Act. One individual Eastern Great Egret was observed flying

over Weeli Wolli Creek; however, this species is considered either uncommon or not a regular visitor in the Revised Proposal Development Envelope (Biota 2015b).

- Common Greenshank – listed under Schedule 3 of the WC Act and as Migratory under the EPBC Act. This species has been recorded previously within 10 km of the Revised Proposal Development Envelope and may be present on occasion in drainage line habitats with water in this area (Biota 2015b). This species is not considered to be a regular visitor.

10.3.3 Hydrological processes and inland waters environmental quality

The key hydrological receptors near the Proposal are Marillana Creek, Weeli Wolli Creek and Fortescue Marsh. Of these, an assessment of potential cumulative impacts has been conducted for Marillana and Weeli Wolli Creeks (Section 13.4). Fortescue Marsh will not be affected by the Proposal and therefore has been excluded from the CIA. The wetting front of surplus water discharge from the Proposal is expected to be contained within the current MS 914 limit of 17 km downstream of the confluence of Marillana and Weeli Wolli Creeks. Therefore, there is no additional impact proposed as a result of the Proposal.

10.4 Mining projects considered

At the scoping stage of a CIA, current and future actions with potential cumulative impacts need to be identified. Firm boundaries need to be drawn around the extent of future actions to be included. Best practice is to include actions determined to be certain and those actions that are reasonably foreseeable (and can be reasonably considered to contribute to significant cumulative impacts). Deciding how long into the past and the future (temporal boundaries) to examine and assess impacts is also a critical part of the scoping phase. It is rarely practical for the temporal boundaries to extend back in time to a pre-impact condition or to a time into the future when, for example, a sensitive receptor has recovered. In practice, CIA's typically commence with current conditions and extend to a point in time when there is meaningful certainty in the key inputs such as future activities.

Publically available information was reviewed to determine existing and reasonably foreseeable future mining projects located within each spatial boundary defined for this CIA. From this review:

- 23 existing mining projects were identified within the Upper Fortescue River Catchment. These mining projects were operational and/or approved under the EP Act at the time of writing. Of the 23 identified projects, five were excluded as they are a significant distance from the Proposal Area and/or from key environmental receptors within the catchment, such as Fortescue Marsh. These were Atlas Iron's FerrAus Pilbara Project and BHP's Jimblebar, Mt Whaleback, Orebodies 29, 30 and 35, and Wheelarra Hill Expansion projects. Five of the remaining 18 projects were also located within the Weeli Wolli Creek regional catchment (**Table 9**; **Figure 24**).
- Two reasonably foreseeable future projects were identified within the Upper Fortescue River Catchment (excluding Proposal). Of these, none were located within the Weeli Wolli Creek regional catchment (**Table 9**; **Figure 24**). These mining projects had been referred under the EP Act at the time of writing. The BHP Strategic Assessment was also identified and is specifically referred to in the

ESD for the Proposal; however, at the time of writing, only the scoping document was publically available and information on potential impacts of the BHP Strategic Assessment was not included (or publically available). The BHP Strategic Assessment was therefore excluded from the Proposal CIA. The Proposal (this assessment) is also included as a reasonably foreseeable future project in **Table 9** and shown in **Figure 24**.

Table 9: Existing and reasonably foreseeable future mining projects considered for inclusion in the Proposal cumulative impact assessment

Project	EP Act Assessment No.	EPBC Act Ref.	Proponent/ Operator

11. Environmental studies

The Proponent conducted a number of environmental studies as part of the Environmental Impact Assessment (EIA) process for the Proposal. Previous studies have also been undertaken as part of the approvals process for the original Yandicoogina mine (JC) and the previous Yandicoogina mine developments (Yandi JC Expansion, JSE, JSW and Oxbow Deposits), some of which overlap the Proposal Area. The requirement and scope of the environmental studies was defined through the preliminary risk assessment, sustainable development assessment, stakeholder consultation and scoping of the Proposal as part of the ESD. The studies provided the basis for assessing the significance of the potential environmental impacts for each key environmental factor identified in the ESD. Where applicable, the studies were undertaken using commonly accepted methodologies and in accordance with relevant EPA Guidance Statements.

Key reports generated by these studies are listed in **Table 10** (many are also attached in **Appendix 3**). All environmental studies applicable to the Proposal, as well as other supporting studies and documentation, are referenced as appropriate throughout the PER. A number of the studies form part of an ongoing monitoring and survey effort to establish a baseline for ongoing environmental management.

Table 10: Studies and investigations supporting the PER

Environmental factor	Studies, investigations and/or reports
Hydrological Processes and Inland Waters Environmental Quality	• Environmental risk assessment for riparian zones on Weeli Wolli Creek (URS 2015; **Appendix 3**). • Revised discharge extent modelling in Weeli Wolli Creek based on measured channel loss rates (Rio Tinto 2014c; **Appendix 3**). • Peer review of surface water modelling (WorleyParsons 2015; **Appendix 3**). • Groundwater model setup, calibration and estimation of dewatering requirements (Rio Tinto 2014d; **Appendix 3**). • Peer review of groundwater modelling (Hydrogeologic 2015; **Appendix 3**). • Geomorphological assessment of Weeli Wolli Creek (MWH 2015; **Appendix 3**). • Weeli Wolli Creek Ecohydrology (Rio Tinto 2015b; **Appendix 3**). • Hydrogeology and groundwater dynamics of Weeli Wolli and Marillana Creeks and Fortescue Marsh (Fellman et al. 2011; Dogramaci et al. 2012; Dogramaci and Skrzypek 2015; Dogramaci et al. 2015; Burke et al. 2014a; Burke et al. 2014b; Burke et al. 2015; Skrzypek et al. 2013; Skrzypek et al. 2015 Roullard et al. 2015).
Flora and Vegetation	• March 2014 and July 2014 flora and vegetation survey of Yandi Pocket and Billiards South Deposits Phase 1 and 2 (Biota 2014a; **Appendix 3**). • Riparian vegetation of Marillana and Weeli Wolli Creeks: Mapping refinement and assessment of values and significance (Rio Tinto 2015a; **Appendix 3**). • Yandi Vegetation and Flora Integration Report (Biota 2015a; **Appendix 3**). • Environmental risk assessment for riparian zones on Weeli Wolli Creek (URS 2015; **Appendix 3**). • Understanding riparian vegetation responses to groundwater drawdown and discharge from below water table mining in the Pilbara (Eastham

Environmental factor	Studies, investigations and/or reports
	2015; **Appendix 3**).
Terrestrial Fauna	• October 2009 Targeted Northern Quoll survey at Yandi (Biota 2009). • July 2008 and March 2010 fauna surveys of the Yandi Expansion Billiard Deposit (Biota 2011; **Appendix 3**). • March 2014 and September 2014 fauna surveys of Pocket and Billiards South Deposits – Phase 1 and 2 (Biota 2014c, 2014e; **Appendix 3**). • August 2014 Targeted Northern Quoll survey at Yandi Billiards Deposit (Biota 2014d; **Appendix 3**). • October 2013 and April 2014 aquatic fauna surveys at Marillana & lower Weeli Wolli Creeks (WRM 2015a, 2015b; **Appendix 3**). • Yandi Terrestrial Fauna Integration Report (Biota 2015b; **Appendix 3**).
Subterranean Fauna	• Stygofauna sampling was conducted in 2003, 2005 and between 2008 and 2014 (Biota 2015c; **Appendix 3**). • Troglofauna phase 1 sampling was conducted in 2009. Phase 2 sampling was completed between 17th May and 10th July 2014 (Biota 2015d; **Appendix 3**).
Rehabilitation and Mine Closure	• Yandicoogina Closure Plan (Rio Tinto 2015c; **Appendix 4**). • Yandicoogina Billiard acid and metalliferous drainage risk (Rio Tinto 2014e; **Appendix 3**). • Water balance modelling for pit lakes (RPS 2015; **Appendix 3**).
Offsets	• Refer to Section 18.
Aboriginal Heritage	• Refer to Section 19.1.
Air Quality	• Refer to Section 19.2.
Amenity	• Refer to Section 19.3.

12. Environmental management system

Environmental management controls to be implemented as part of the Proposal, consistent with the information presented in this PER, are described in the Proponent's Environmental Management System (EMS), together with the Yandi Operations site specific management plans.

All Rio Tinto businesses, their managed sites and functional locations (including its Pilbara iron ore operations) must implement, or demonstrate conformance to an EMS, which is an integrated health, safety, environment and quality management system and outlines environmental standards that must be adhered to.

The Rio Tinto environment standards have been in place for over ten years, and have supported its operational environmental performance over this period. The current standards have been developed to provide consistency across all of Rio Tinto managed operations and to support the Group's approach to avoid and minimise impacts to the environment. The EMS covers key environmental risk areas and provides detail for their application to operational sites. The process includes internal site and Rio Tinto Corporate audits to ensure conformance with the five environment standards and one management system standard as outlined below.

12.1 Health, Safety, Environment and Quality (HSEQ) Management System Standard

The HSEQ Management System Standard details the requirements for Rio Tinto Group businesses to implement an integrated system for the management of health, safety, environment, communities and social performance and quality. Statutory and permitting requirements take precedence over Rio Tinto standards, except where the Rio Tinto standards are more stringent.

The standard comprises 17 key elements including:

- HSECQ policy;
- legal requirements;
- hazard identification and risk management;
- management improvement planning;
- organisational resources, accountabilities and responsibilities;
- training, competency and awareness;
- supplier and contractor management;
- documentation and document control;
- communication and consultation;
- operational control;
- management of change;
- business resilience and recovery;
- monitoring and measuring;
- incident and action management;

- data and records management;
- performance assessment and auditing; and
- management review.

12.2 Environmental standards

Rio Tinto has five environment standards:

- E11 Water Quality Protection and Water Management.
- E12 Air Quality Protection.
- E13 Chemically Reactive Mineral Waste Control.
- E14 Land Disturbance Control and Rehabilitation.
- E15 Hazardous Materials and Non-Mineral Water Control and Minimisation.

12.2.1 E11 Water Quality Protection and Water Management

The E11 Water Quality Protection and Water Management Standard addresses all activities associated with water withdrawal, use, storage, treatment, and discharge. It is applicable to any impacts or risks associated with water abstraction and discharge, including changes in water level, flow and quality. The E11 Standard outlines performance requirements to mitigate water related impacts, control water quality, optimise water use efficiency and adequately design and operate water related infrastructure to manage predicted variability and control risks.

12.2.2 E12 Air Quality Protection

The E12 Air Quality Protection Standard addresses air emissions from all sources including point sources and diffuse sources. The E12 Standard outlines performance requirements to monitor and manage emissions to prevent harm from air impacts, quantify the constraints that cumulative air impacts may pose, and prevent breaches of applicable criteria.

12.2.3 E13 Chemically Reactive Mineral Waste Control

The E13 Chemically Reactive Mineral Waste Control Standard addresses all mineral wastes including waste rock and overburden, tailings, rejects and other mineral processing residues. It covers all potential and actual releases from reactive mineral waste including primary waste material (erosion, fugitive dust) and reaction by-products (eg. acid mine drainage). The E13 Standard outlines performance requirements to monitor and manage chemically reactive mineral waste so contaminant release does not cause harm, and avoids riverine impacts.

12.2.4 E14 Land Disturbance Control and Rehabilitation

The E14 Land Disturbance Control and Rehabilitation Standard addresses all land owned, leased or managed by the business or for which the business may have liability. It includes both land directly disturbed by activities, as well as undisturbed land held as a buffer or for other reasons. The E14 Standard outlines performance requirements to confine disturbance within legally designated areas, locate and design facilities to limit new disturbance footprints, design and construct mineral waste facilities in a manner that facilitates successful rehabilitation, rehabilitate consistent with planned final land use, undertake rehabilitation as soon as practicable on land that is no longer needed, and define impact acceptance criteria for land, biodiversity and ecosystem services.

12.2.5 E15 Hazardous Materials and Non-Mineral Waste Control and Minimisation

The E15 Hazardous Materials and Non-Mineral Waste Control and Minimisation Standard addresses the import, storage, use and ultimate disposal of hydrocarbons, reagents, process fluids, non-mineral wastes and other materials which could pose environmental risks because of their physical and chemical properties. The E15 Standard outlines performance requirements to prevent contamination of surface water, groundwater and soil from hazardous materials and non-mineral wastes, minimise impacts of non-mineral waste disposal, and remediate or manage for the long term contaminated sites where investigation has demonstrated an unacceptable impact or risk.

12.3 Yandicoogina Environmental Management

The existing Yandi Operations environmental management utilises the Rio Tinto EMS, together with site specific management plans and procedures for environmental aspects that are potentially impacted by the Yandi Operations.

The existing Yandi Operations environmental management is currently managed via:

- Management plans and commitments required by MS 914 or EPBC Decision 2011/5815 requiring endorsement from either a State or Commonwealth government department:
  - Yandicoogina Monitoring and Management Plan (MMP; **Appendix 4**) which includes:
    - Yandicoogina Vegetation and Groundwater Dependant Ecosystems Monitoring and Management Plan
    - Yandicoogina Surface Water Discharge Monitoring and Management Plan
  - Yandicoogina Closure Plan (**Appendix 4)**; and
  - EPBC Threatened Species Offset Plan.
- Management plans and commitments that support implementation of MS 914 or EPBC Decision 2011/5815 that do not require endorsement from either a State or Commonwealth government department:
  - Yandicoogina Weed Action Plan;
  - Yandicoogina Weed Monitoring Plan; and
  - Yandicoogina addendum to the Proponent's Pilbara-wide Significant Species Management Plan (SSMP; **Appendix 4**).
- Site related management and monitoring actions required to comply with Rio Tinto HSECQ Performance Standards (outlined above).

The existing MMP has been reviewed and updated to apply to the Proposal.

12.3.1 Yandicoogina MMP

The Yandicoogina MMP specifically addresses the requirements of Conditions 6 and 7 of MS 914, including the development of an Environmental Values Statement (EVS) and a comprehensive monitoring program for surface water and groundwater dependent ecosystems with associated management strategies.

The key environmental objectives of the plan are to ensure that ensure that dewatering activities required to implement the Yandi Project, and any contingency measures implemented, will not result in long term impacts to the environmental values identified.

The EVS of the Weeli Wolli Creek system was updated in the revision of the MMP and is outlined in Section 6.1.

The MMP includes monitoring the health parameters of riparian vegetation including Digital Canopy Photography (DCP), vegetation condition transects, and spectral imagery. Water quality parameters include monitoring the discharge wetting footprint, ground water levels, surface water quality, and erosion and sediment assessments.

12.3.2 Significant Species Management Plan

The Rio Tinto SSMP applies across all Pilbara based projects. The SSMP addresses Matters of National Environmental Significance (MNES) relevant to the Pilbara, outlining management measures to be applied across all Pilbara based operations and projects to avoid or reduce impacts to these MNES. The SSMP provides the framework for Rio Tinto to minimise impacts to Pilbara populations of significant species from activities associated with its operations. The scope of the SSMP includes extensions to existing operations and new mining and infrastructure projects. The SSMP outlines over-arching management measures to be implemented to avoid and minimise impacts to MNES across all projects.

Additionally, for each Pilbara based project or operation, a site specific addendum to the SSMP has been prepared, detailing management measures for MNES relevant to the project. The Yandicoogina SSMP addendum is included with the Pilbara-wide SSMP (**Appendix 2**). The Yandicoogina SSMP addendum addresses management measures relevant to EPBC Act listed threatened species occurring, or potentially occurring, within the Revised Proposal Development Envelope including the Northern Quoll, Pilbara Olive Python, Pilbara Leaf-nosed Bat and *Lepidium catapycnon*. The Yandicoogina SSMP addendum outlines key management actions and accountabilities for clearing and direct disturbance, indirect disturbance and other operational issues and outlines surveys/monitoring requirements.

12.3.3 Yandicoogina Closure Plan

The Yandicoogina Closure Plan (**Appendix 4**) has been prepared to meet MS 914 Condition 9-4 ('…review and revise the Yandicoogina Decommissioning and Rehabilitation Plan…'). It addresses the closure of several mining areas associated with the Revised Proposal, including future development areas such as the Proposal. This Plan documents the current closure knowledge base for Yandicoogina. It outlines the objectives that need to be met at closure, the strategies and plans to be employed to achieve them, and provides an indication of the criteria that will be used to assess closure success. It has been developed in consultation with key stakeholders and will be regularly reviewed and revised throughout the life of the Revised Proposal to incorporate new information. The Yandicoogina Closure Plan has been prepared in accordance with the DMP and EPA (2015) Guidelines for Preparing Mine Closure Plans, as well as Rio Tinto's Closure Standard.

Part 5 – Assessment of environmental factors

This part assesses the potential environmental impacts of the Proposal on each identified preliminary key environmental factor (and other environmental factors). Proposed management measures and predicted outcomes are also presented.

13. Hydrological processes and inland waters environmental quality

13.1 Key statutory requirements, environmental policy and guidance

13.1.1 EPA objective

The EPA has applied the following objectives for the Proposal to its assessment of hydrological processes and inland waters environmental quality:

"To maintain the hydrological regimes of groundwater and surface water so that existing and potential uses, including ecosystem maintenance, are protected.

To maintain the quality of groundwater and surface water, sediment and/or biota so that the environmental values, both ecological and social, are protected."

13.1.2 Regulatory framework

The following legislation is relevant to the Proposal Area with respect to the protection of surface water and groundwater and the above EPA objective:

- *Rights in Water and Irrigation Act 1914* (WA).
- *Environmental Protection Act 1986* (WA).

13.1.3 Relevant guidelines and policy

A number of State and Commonwealth policies are relevant to the protection of surface water and groundwater:

- Australian Water Quality Guidelines for Fresh and Marine Waters. (Australian and New Zealand Environment and Conservation Council (ANZECC) and Agriculture and Resources Management Council of Australia and New Zealand (ARMCANZ) 2000).
- State Water Quality Management Strategy Document No.6. Implementation Framework for Western Australia for the Australian and New Zealand Guidelines for Fresh and Marine Water Quality and Water Quality Monitoring and Reporting (Government of Western Australia 2001).
- Pilbara Water in Mining Guideline. Report No 34 (Government of Western Australia 2009).
- Western Australian Water in Mining Guideline. Report No 12 (Government of Western Australia 2013a).
- Statewide Policy No 5 - Environmental water provisions policy for Western Australia (WRC 2000).

- DoW Water Quality Protection Guidelines No. 1 to 11 and Water Quality Protection Note 22 (DoW 2008).
- Strategic policy 2.09: Use of mine dewatering surplus (DoW 2013).
- Environmental and water assessments relating to mining and mining related activities in the Fortescue Marsh management area (EPA 2013c).

13.2 Description of factor

Existing approved mining operations within the Weeli Wolli Creek catchment, including BHP's Marillana Creek (Yandi) and Mining Area C mine, Rio Tinto's Yandi Operations and Hamersley HMS's Hope Downs 1 Joint Venture undertake dewatering as well as discharge activities as part of their mining operations and have contributed to changes to the natural hydrological conditions of Marillana and Weeli Wolli Creeks since the mid 1990's and mid 2000's respectively. The BHP and Rio Tinto mining operations that occur within the CID (Rio Tinto's Yandi Operations, BHP's Marillana Creek [Yandi]), are within the same hydrological and hydrogeological setting as the Proposal, with the dewatering and discharge activities undertaken to manage the productive aquifers of the CID, in which the target mineralisation occurs. The aquifers associated with BHP's Mining Area C and Hamersley HMS's Hope Downs 1 operations occur in bedded ore deposits and dolomites with more alkaline groundwater conditions and are subject to different hydrological surface water-groundwater interactions.

The following sections provide a description of the pre-mining and modified hydrological and hydrogeological setting (Sections 13.2.1 to 13.2.3), identify the likely potential impacts of the Proposal, and propose mitigation measures to minimise potential impacts on the hydrological and hydrogeological regime.

The following studies provide an understanding of the hydrological setting of the Proposal:

- Hydrologic and hydraulic assessments undertaken as part of the Proposal Order of Magnitude study, to define the surface water hydrology and flow conditions of Weeli Wolli Creek (Rio Tinto 2013).
- A hydrogeological assessment of the CID to determine hydraulic properties as well as connectivity with the adjacent Weeli Wolli Creek floodplain alluvial aquifer, including bore installation and test pumping.
- A detailed geomorphological assessment of Weeli Wolli Creek (MWH 2015).
- Measurements of discharge and infiltration along Weeli Wolli Creek undertaken as part of the pre-feasibility Study, to better quantify the channel loss rates in reaches of the creek system and inform modelling of discharge scenarios (Rio Tinto 2014c).
- Investigations on the impact of current and proposed mine operations on the water quality and the potential for cumulative impacts on the Fortescue Marsh, including development of a surface water and groundwater model for the Proposal Area.
- Ecohydrological assessment to identify the likely changes to surface water flow regime as a result of implementing the Proposal and potential effects on riparian vegetation along Weeli Wolli Creek (Rio Tinto 2015b).

In addition to these studies, a number of additional research projects have been undertaken within both the Weeli Wolli Creek catchment and broader Fortescue Marsh catchment to understand the hydrogeological and hydrological processes of these catchments. This work underpins the hydrogeological studies undertaken for the Proposal.

13.2.1 Local hydrological setting of the Proposal

The Proposal Area is located within the Weeli Wolli Creek surface water catchment. Marillana Creek, a major tributary of Weeli Wolli Creek, discharges to Weeli Wolli Creek downstream of the Proposal (**Figure 25**). Approximately 10 km north of the confluence of Weeli Wolli and Marillana Creeks, Weeli Wolli Creek drains to a wide alluvial floodplain in the Fortescue Valley with flows terminating at the Fortescue Marsh (approximately 40 km north of the Weeli Wolli and Marillana Creek confluence). The Weeli Wolli Creek catchment, including Marillana Creek, represents approximately 10% of surface water flow into the Fortescue Marsh (Aquaterra 2001 as cited in Johnson and Wright 2003). The characteristics of the Weeli Wolli catchment are described in Section 5.6.

13.2.2 Pre-mining surface water hydrology

Weeli Wolli Creek is the dominant drainage feature which enters the Proposal Area from south of the Proposal deposit. This creek drains parallel to the Proposal deposit in a predominantly north easterly direction and drains into an alluvial fan on the southern flanks of Fortescue Marsh, outside of the Revised Proposal Development Envelope.

Marillana Creek is a major tributary of the Weeli Wolli Creek system. The lower Marillana Creek drains in an easterly direction through the existing BHP Yandicoogina (Marillana Creek) operations and the Revised Proposal Development Envelope. It continues its path downstream onto wide flat plains (400 – 600 m) located downstream of the existing Yandi Operations, before discharging into Weeli Wolli Creek (Rio Tinto 2014f). The confluence of Weeli Wolli Creek and Marillana Creek is located in the north west of the Proposal Area.

Weeli Wolli Creek is characterised by a generally singular, meandering low-flow channel set within a broader floodplain. The high flow channel comprises a gravel-bed stream, with large gravel bars present within the channel and more active anabranches (MWH 2015). These numerous anabranches of the Weeli Wolli Creek that cross the Proposal Area convey flows towards the creek as a result of episodic high rainfall events (**Figure 26**).

Long term stream flow records for Weeli Wolli Creek since 1985 to the present are available for sites located both upstream and downstream of the Proposal Area, at Tarina and Waterloo Bore respectively (**Figure 25**). The period until 1997 is representative of stream flow conditions prior to the commencement of discharge of surplus dewatering volumes as a result of mining operations within the catchment. Observations indicate that historically Weeli Wolli Creek was ephemeral, flowing only once or twice per year during episodic rainfall events. Baseline flow was widely variable with the initiation of runoff strongly dependent on antecedent conditions and the intensity and spatial distribution of rainfall. Generally only large rainfall events were sufficient to generate stream flow. During dry years, in which less than 300 mm of rainfall was experienced, surface water runoff was generally not sufficient to generate flow at either streamflow gauging station (URS 2015).

Natural perennial flows on the Weeli Wolli Creek did occur at Weeli Wolli Spring, located approximately 4.5 km upstream from Tarina (**Figure 25**). Pre-mining aerial photographs show that Weeli Wolli Creek was characterised by wetlands, pools and a shallow water table on reaches extending approximately 12 km downstream from Weeli Wolli Spring. As flow was not perennial at Tarina, this suggests a large proportion of the overflow from Weeli Wolli Spring was infiltrated to the underlying aquifer and transmitted as groundwater through-flow (URS 2015).

Geospatial Information and Mapping

13.2.2.1 Surface water quality

Water quality data indicates that surface water in the vicinity of the Proposal is (Rio Tinto 2013):

- Neutral to slightly alkaline with median total dissolved solids (TDS) content of approximately 550 mg/L.
- Comprised of trace elements such as aluminium, iron, manganese and zinc at low levels.
- Subject to nitrogen increases, which are considered to originate from natural elevations within groundwater.

13.2.3 Hydrogeology

Hydrogeological investigations have been undertaken within and surrounding the Proposal Area since the late 1970's. The regional hydraulic gradient and discharge of groundwater at the Proposal is in a north-northeast direction towards the Fortescue Marsh. Groundwater is also lost from the area through the process of evapotranspiration within the riparian floodplain zone.

There are three main hydro-stratigraphic units recognised within the Yandicoogina region (Rio Tinto 2014d; **Figure 29**). They comprise:

- the fractured and weathered basement of the Weeli Wolli Formation;
- the overlying fractured CID; and
- the surficial unconfined floodplain aquifer.

These hydro-stratigraphic units are described below.

13.2.3.1 Weeli Wolli Formation

The Weeli Wolli Formation is a fractured rock aquifer consisting of inter-bedded banded iron formation, banded chert, shale and dolerite. It underlies and surrounds the alluvial/in situ weathered aquifer. Aquifer permeability is largely dependent on the development of structural features. Groundwater in the basement rocks only occurs in secondary porosity associated with the weathered zone and within fractures in the bedrock, with lower hydraulic conductivities than both the CID and the floodplain aquifers. There may be transmissive structures in the basement aligned beneath Weeli Wolli Creek (Fowers et.al.; cited in URS 2015).

13.2.3.2 Channel Iron Ore deposit

The Tertiary CID constitutes a relatively narrow meandering palaeo-channel between 600 m to 1,000 m wide and 100 m deep, imbedded into the low transmissivity Weeli Wolli Formation. The highly-transmissive CID forms a channel aquifer system, some of which underlies the modern day Weeli Wolli Creek system. Recent drilling has indicated that the CID is bound by an alluvium and weathered bedrock aquifer between the CID aquifer and the Weeli Wolli aquifer. The CID is variably connected with the floodplain aquifer.

13.2.3.3 Alluvial floodplain aquifer

Overlying the CID aquifer, and more broadly the Weeli Wolli Formation, is the alluvial floodplain aquifer. The floodplain aquifer consists of three geological units that exhibit strong hydraulic connection. Coarse creek bed colluviums and alluvium underlie Weeli Wolli Creek. This is the major source of recharge to the alluvial aquifer. The creek bed unit is incised within and discharges to floodplain sediments, comprising mixtures of poorly sorted gravels, sand, silt and clay. These sediments lie adjacent to the CID. The

floodplain sediments unconformably overlie in situ weathered basement, heavily fractured and weathered in situ Weeli Wolli Formation.

Transmissivity is variable within the floodplain aquifer. Groundwater moves freely within the coarser less clayey sediments, but flow may slow within the underlying clayey sections of the weathered basement material. The coarse river gravels of the upper alluvium of the creek bed are highly permeable and, in locations of reasonable thickness, have the ability to transmit and store large volumes of groundwater. The thickness of the floodplain alluvials is estimated from 6 m to 24 m, with the greatest thickness adjacent to Weeli Wolli Creek and limited cover at locations away from the Creek.

13.2.3.4 Groundwater quality

Baseline groundwater quality is typically characterised as fresh, with TDS concentrations of approximately 500 mg/L. Groundwater hosted by the floodplain aquifer tends to be comparatively higher in salinity (although still considered fresh), with measured TDS concentrations up to 1,290 mg/L. At greater depth, within the CID aquifer, known groundwater qualities occur in the range 370 to 780 mg/L TDS and pH from 6.8 to 9.6 (URS 2015).

The groundwater samples obtained from the monitoring bores close to Weeli Wolli Creek displayed increasing chloride concentrations in comparison to the groundwater samples within the monitoring and production bores away from the Creek. This is likely due to infiltration of surface water from Weeli Wolli Creek into the surficial aquifer and subsequently into the CID aquifer (Rio Tinto 2014d).

13.2.3.5 Groundwater levels

In areas where Weeli Wolli Creek intersects the CID, the coarse colluviums and alluvium are considered to be the conduit for recharge to the CID aquifer primarily from surface flow. Historically, groundwater levels were recorded to rise by up to 10 m within the CID aquifer as a result of through-flow from the floodplain aquifer following intense or prolonged rainfall events. Pre-mining water table elevations in the Proposal Area are shown below in **Figure 26**. Groundwater levels show significant spatial and temporal variation due to rainfall, stream flow and evaporation. The depth to water table cyclic-low and episodic high snapshots are presented in **Figure 27** and **Figure 28**.

13.2.4 Current altered hydrological regime

13.2.4.1 Water flow

Surface water and groundwater in the Proposal locality has been modified and managed for a number of years (since the mid 1990s) as a result of mining activities in the area. This includes dewatering of groundwater and discharge of surplus water to Marillana and Weeli Wolli Creeks. **Figure 29** provides a conceptual water balance for mines operating within the Proposal Area including discharge locations, and **Figure 30** provides a waterfall graph to demonstrate the cumulative water abstraction and discharge volumes across these operations.

The following sections provide a summary of the abstraction, discharge, recirculation and water use regime in the Proposal Area. The summary provides a sequence of mining upstream along the CID and Marillana Creek through to the Proposal Area. **Table 11** summarises the water balance described below.

Dewatering and discharge:

- BHP discharge from its Marillana Creek (Yandi) Mine upstream of the Proposal at an upstream point in Marillana Creek on to the Proponent's tenure boundary. Historical averages have been in the order of 9 GL/y with a licence limit of 15 GL/y.
- Oxbow is scheduled to discharge surplus water from Discharge Outlet(s) (DO) along Marillana Creek with a modelled peak of approximately 8 GL/y. A commitment was made in the JSW and Oxbow approvals to maintain some upstream discharge (including D03) to manage water levels as a result of drawdown from the existing Yandi Operations to maintain areas of stygofauna habitat and allow for riparian readjustment.
- JC is currently near the end of its mine life and so is not actively being dewatered for mining purposes; however, the groundwater table is kept locally depressed by sump pumping to keep water levels manageable after wet seasons. JC historically discharged from several discharge locations along Marillana Creek (DO2*, DO3, DO5, DO8*) with limited discharges currently from DO3.
- JSW currently discharges from DO9 into Marillana Creek with an estimated operational peak of 23 GL/y.
- JSE has historically discharged from DO5, DO6 & DO9, however discharge into the future will be maintained from DO5 and DO9, with DO6 being decommissioned and the water being diverted for use in the JSE wet plant.
- Hope Downs 1 is approved to discharge up to 40.15 GL/y into the upper reaches of Weeli Wolli creek from two locations: into the Weeli Wolli Spring through a spur system to negate the impacts of drawdown; and also from a gabion structure downstream of the Spring.

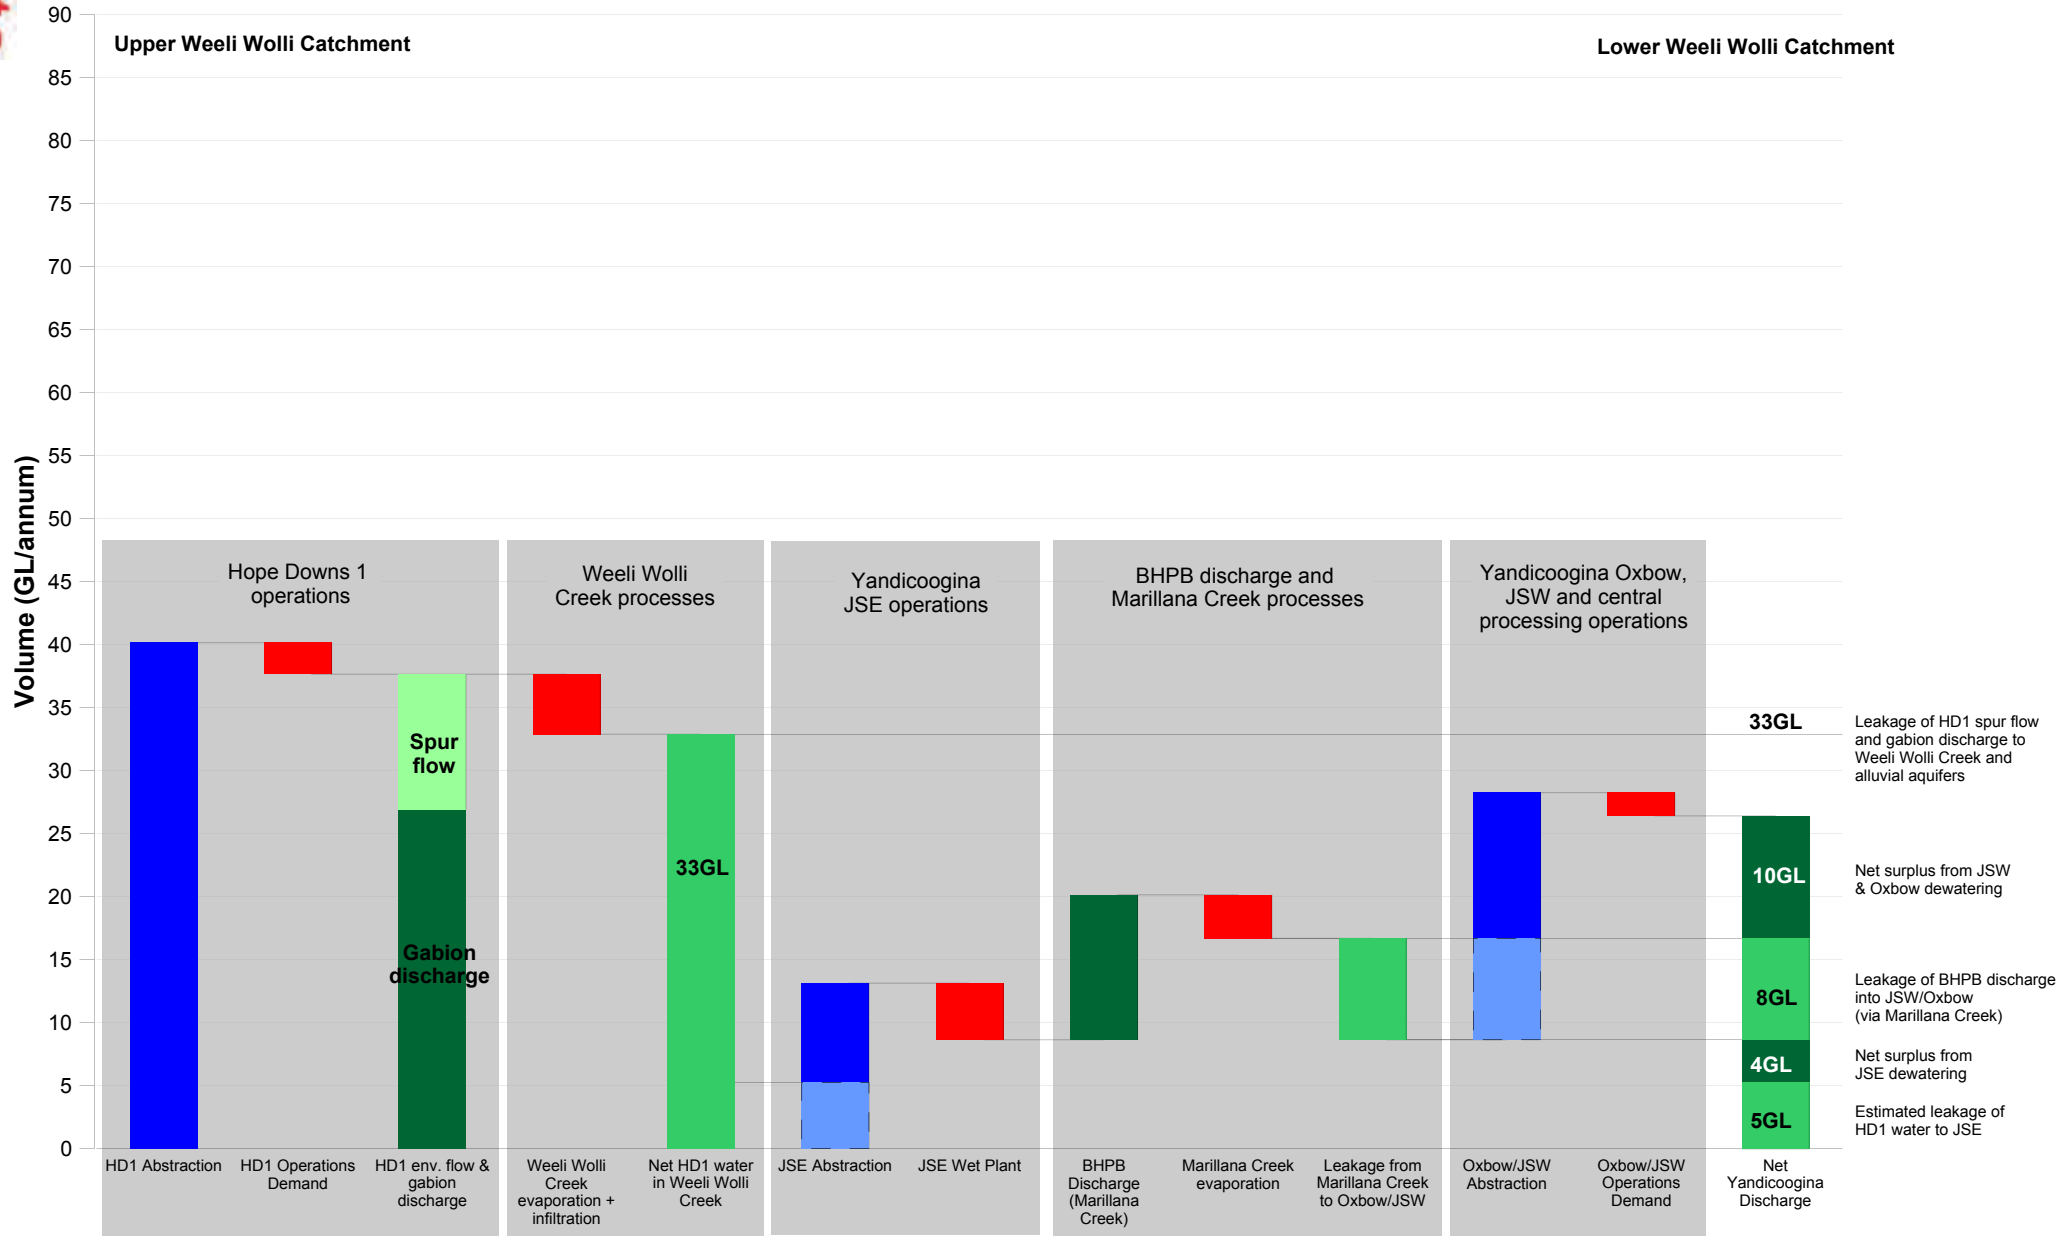
Weeli Wolli Catchment Water Balance

Pocket-Billiards South PER

Figure 30



Recirculation (re-dewatering of surplus water discharge):

Hydrogeological investigations into the catchment have shown that substantial amounts of the "dewatering" conducted by downstream operations is recirculation of surplus water discharged by upstream operations. This "recirculation" has been estimated between operations in the Proposal Area as follows:

- Up to 70% of BHP Marillana Creek (Yandi) Mine discharge is re-abstracted and discharged by the Proponent's Yandi Operations dewatering.
- A portion of the discharge from Hope Downs 1 has been recharging into JSE.

Water use:

- Approximately 5-6 GL/y of water is re-used on-site across the existing Yandi Operations for potable water supply, dust suppression and in the existing plants. A further 5 GL/y (total of 11 GL/y) is estimated to be used in the JSE wet plant which is currently being commissioned.

Table 11: Modified hydrological regime of the Proposal Area

Mine	Year commenced abstraction / discharge	Location of discharge	Creek	Abstraction Actual or proposed Individual pit contribution –(peak) (GL/y)	Abstraction Ministerial / licence limit (GL/y)	Site Use	Discharge Actual or Proposed (GL/y)	Discharge Ministerial limit (GL/y)	Recycling volume (or %)

Due to the continuous discharge of surplus dewater from multiple operations in the Proposal Area, permanent surface water within the low-flow channel occurs along Weeli Wolli Creek. MS 914 condition 6-3, currently limits the wetting front from surplus water discharge to 17 km downstream of the Marillana and Weeli Wolli Creek confluence. This limit also accommodates the surface water released from Hope Downs 1. The current wetting front reaches between 5 and 9 km downstream of the Weeli Wolli Creek and Marillana Creek confluence.

The current modified groundwater table is connected to the low-flow channel for the majority of the length of the surface water wetting front. The location of the surface water wetting front changes due to the capacity for infiltration of surface water flows to the floodplain and CID aquifer. Where groundwater levels are high and the profile is fully saturated, there is no additional capacity for infiltration to the aquifer, therefore surface water flows will propagate further downstream but still within accordance of MS 914. Where the aquifer is not fully saturated (i.e. the groundwater table is not at or near the surface) there is capacity for surface flows to infiltrate to the floodplain aquifer, which will result in a retreat of the surface water wetting front. The wetting front appears relatively stable, with observations since continuous discharge began indicating no further propagation of the wetting front further downstream (**Figure 31**).

Discharge of surplus water from mine dewatering operations to Weeli Wolli Creek has resulted in greater recharge within the creek bed alluvium to the floodplain aquifer (**Figure 32**), and has increased mounding below the alluvial aquifer when compared to pre-mining conditions (URS 2015; **Figure 32**). Drilling undertaken within the Proposal Area in 2013 recorded groundwater levels between 2 - 10 m below ground level (Rio Tinto 2014d).

An investigation has been undertaken to understand the impact that continuous discharge has had on the overall water balance of Weeli Wolli Creek and underlying aquifers (Dogramaci et al. 2015). For the purpose of the investigation, results of surface water and groundwater sampling were combined with field observations of surface saturation along Weeli Wolli Creek and recorded discharge rates at the Hope Downs 1 discharge location.

The major finding of the study suggests that the impact of recharge from continuous flow on the hydrological regime of the creek has not extended beyond 27 km from the discharge point, which is no further than 8 km from the Weeli Wolli Creek and Marillana Creek confluence. It was concluded that although more than 220 gigalitres (GL) of mine water discharge since 2007 has changed the nature of the connectedness of Weeli Wolli Creek to the underlying aquifer in the upper section, associated with the impermeable Weeli Wolli Formation, there has been negligible impact on the overall hydrological regime of the broader catchment. Most of the recharge to the groundwater aquifer along Weeli Wolli Creek occurs where the creek flows adjacent to or across the CID aquifer.

The calculated rates of recharge as a result of continuous discharge from Hope Downs 1 were found to be commensurate with those from large flooding events that occur in the region every few years (Dogramaci et al. 2015). It was noted, that changes in surface water connectivity and sustained periods of saturation may have localised impacts on the ecology of streams. Section 14.3.3 provides an assessment of the potential impacts on riparian vegetation from the modified hydrological regime.

13.2.4.2 Water quality

Water quality monitoring has been undertaken along Weeli Wolli Creek and Marillana Creek prior to and following abstraction and discharge activities. The analysis of water quality is based on a standard suite of water quality parameters including electrical conductivity, total suspended solids, TDS, alkalinity, pH, hardness and a range of nutrients and other elements such as barium, boron, calcium, chloride, magnesium, nitrate, total nitrogen, total phosphorus, potassium, sodium, sulphate, sulphur, and uranium.

Monitoring results to date indicate some minor variation in water quality parameters, however this is considered to be natural fluctuations and no significant effects on baseline water quality has occurred as a result of abstraction and discharge activities.

Water availability and discharge by transpiration and evaporation has resulted in salt accumulation within the groundwater environment. Chloride ion levels have increased slightly (by approximately 50 mg/L) along the surface water wetting front extending from Hope Downs 1 operations along Weeli Wolli Creek, which is considered to be a result of salt accumulation due to evaporation and transpiration losses along the flow path (Dogramaci et al. 2015).

13.3 Assessment of potential impact, mitigation and residual impact

The EPA has listed the following potential impacts for the Proposal in relation to hydrological processes and inland waters environmental quality:

- Impacts to natural surface water systems and flows as a result of placement, design and operation of a new mine pit and associated infrastructure (including surface waste dumps and stockpiles, and drainage structures).
- Impacts to surface water resources including Weeli Wolli Creek due to surface discharge of surplus mine dewater.
- Altered flow regime to the Fortescue Marsh due to groundwater drawdown and discharge of surplus water into Weeli Wolli and Marillana Creeks.
- Potential changes to the groundwater quality over time from pit lakes left by the proposal.
- Potential contamination of surface water and groundwater, if management of waste dumps containing at risk material (material with potential for acid or metalliferous drainage) is not appropriate.

The potential impacts as a result of the development of the Proposal are described in the following sections.

Impacts to groundwater dependent ecosystems and subterranean fauna as a result of groundwater drawdown are discussed in Section 14 and 15 respectively.

Cumulative impacts of groundwater drawdown and discharge of surplus water into Weeli Wolli and Marillana Creeks, and any potential impacts to Fortescue Marsh, are discussed in Section 13.4.

13.3.1 Natural surface water systems and flows

The construction and physical presence of the pit, overburden storage areas, roads and other associated mine infrastructure will modify local topography and intercept surface water flows. Modifications to surface drainage patterns have the potential to cause changes to flood depths and velocities in downstream environments.

There is the potential for high velocity water movement off areas with steep gradients to contribute to the erosion of cleared landforms and unconsolidated materials in the Proposal Area. This has the potential to result in increased sediment load into the downstream environment.

A local surface water management strategy for the Proposal has been prepared to address surface water risks associated with local runoff from catchments east of Weeli Wolli Creek (Rio Tinto 2014f). The strategy includes measures to minimise the impact of surface water movement by the construction of a comprehensive framework of stormwater management structures. This is likely to include (but not be limited to) levees around the pit, diversion drains around waste dumps, and culverts under roads. These management measures will aim to maintain surface water drainage regimes by diverting surface water flows around infrastructure and into downstream drainage lines, thereby limiting opportunities for sediment transport from disturbed surfaces. Any incident surface water intercepted within operational areas will be diverted to sediment traps or retained in in pit sumps, to minimise sediment load prior to discharge to the natural drainage system.

Stormwater management design in Australia is guided by Australia Rainfall and Runoff (Pilgrim 2001) and the AUSTROADS Waterway Design Guide (Flavell 1994). Using these guidelines, a minimum of a 1% Annual Exceedance Probability (AEP; or a 100 year Annual Recurrence Interval; ARI) flood protection criteria will be adopted for the design of the flood protection levee. A 2% AEP (50 year ARI) flood protection will be adopted for the design of local diversion drains.

13.3.2 Weeli Wolli Creek

Development of the Proposal will encroach into the Weeli Wolli Creek floodplain. Results of hydrologic modelling of catchment runoff and hydrodynamic modelling of flood conditions have been used to assist in the design of a flood protection levee for the Proposal. The results that have been derived from the modelling are considered to provide a reliable representation of flow conditions during the major flooding of Weeli Wolli Creek, and are therefore suitable for use in the development of concept designs for the proposed flood protection levee (WorleyParsons 2015), with further detailed engineering work to be undertaken as the Proposal progresses.

Disruption to the existing surface water flows along Weeli Wolli Creek is currently negligible during low-flow events. As the magnitude of the flood increases, changes to the flow regime also increase due to greater constriction and obstruction of flows imposed by the infrastructure along the creek. Overall change is confined to a section of creek adjacent to the proposed mine and unlikely to impact the wider creek area (URS 2015; **Figure 33**).

13.3.3 Dewatering and groundwater drawdown

Due to the nature of the orebody being located below the water table, dewatering will be required to allow for mining. A numerical groundwater model has been developed to simulate dewatering scenarios and assess resulting impacts to groundwater. This model

is a regional model covering the whole of the Revised Proposal Development Envelope, including the Oxbow, JSW and JSE pits together with the Proposal pit. It is based on a groundwater model first developed for the existing Yandi Operations in 2008.

The model predicts peak cumulative abstraction volumes from current and proposed operations from the Yandi Operations, including the Proposal of up to 83 GL/y may occur (**Figure 34** and **Figure 35**) within the first 6 years of dewatering. Local maximum drawdown during this period within the floodplain and CID aquifer system would be in the order of 45 to 50 m to enable dry mining conditions. Drawdown would be most pronounced along the CID aquifer, and would separate the groundwater and surface water flows that currently occur along the low-flow channel of Weeli Wolli Creek from continuous discharge of surplus dewatering from upstream mining operations. Predicted drawdown over the expected life of the mine is shown in **Figure 36** and **Figure 37** for Pocket and Billiard South respectively.

13.3.4 Discharge of surplus water

The Proposal is estimated to require, at its peak, approximately 50 GL/y of dewatering from the total dewatering volume of 83 GL/y produced by the Revised Proposal. Of the 50 GL/y, approximately 33 GL/y is modelled to be from re-dewatering of the discharge volumes from upstream discharge, equivalent to approximately 70% of the Proposal dewatering volume (**Figure 34** and **Figure 35**).

Dewatering volumes will be integrated with the existing and proposed site water demand, with approximately 5 GL/y (up to 11GL/y) to be used for on-site purposes at the Yandi Operations, such as dust control, camp usage and ore processing. Surplus water discharge will include the existing Yandi Operations approved 47 GL/y, which will increase up to 78 GL/y (average of 61 GL/y). The Proposal is predicted to contribute an additional 45-50 GL/y (**Figure 34** and **Figure 35**) of this discharge at its peak.

An extensive range of options (numbering over 20) were considered, with five possible options investigated in further detail for the management of surplus water from the Proposal. Detailed options assessments were carried out for the following:

- Storage of water in JC pit lake.
- Reduction of Hope Downs 1 discharge by reinjecting Hope Downs 1 dewatering volumes.
- Transfer to other current and future mining projects (including Koodaideri).
- Re-injection of Proposal water close to Yandi lease.
- Creek discharge to Marillana Creek.

The findings of these investigations are summarised in **Table 12** with the only technically feasible option being identified as potential to discharge to Marillana Creek.

Table 12: Options assessment for alternative surplus water management strategies

Option	Outcome
Store water in JC pit lake	This option was not feasible because it was found that 90% of the volume would recirculate to nearby dewatering wells.
Re-injection of Hope Downs 1 water	This option was not feasible due to the lack of third party tenure approval/access (to undertake preliminary drilling testwork to prove up suitable locations, and potentially for ongoing use), availability of unsaturated thickness of suitable host aquifers, and limited technical feasibility.
Early transfer to other options	This option cannot manage volumes from the Proposal during peak dewatering periods. Transfer to other projects will continue to be investigated as opportunities arise (including a potential option for the Koodaideri Project).
Re-injection of Proposal water close to Yandi lease	This option was eliminated because the target aquifers were found to be small and would fill quickly. In addition, the proximity of target aquifers to Fortescue Marsh was highlighted as a constraint.
Creek discharge to Marillana Creek	Discharge was determined to be a technically feasible option.

Given the limitations of the water management options, surplus water produced by the Proposal is proposed to discharge in Marillana Creek from a new discharge outlet

adjacent to D09. Discharge has been occurring from D09 since the second half of 2013. The water is constrained to a well defined low-flow line, and is not predicted to extend beyond the existing MS 914 approved extent of 17 km beyond the Marillana – Weeli Wolli Creek confluence. By discharging from D09, the impact footprint along Weeli Wolli Creek is constrained to within currently approved limits.

Given the wetting front is modelled to be within existing approved limits, it is considered that there will be minimal additional effects on the downstream hydrological system of Weeli Wolli Creek. **Figure 38** to **Figure 42** shows a time series of the groundwater drawdown and mounding sequence throughout the Proposal mine life.

13.3.5 Fortescue Marsh

The results of modelling the potential wetting front as a result of discharge from Proposal is not expected to extend beyond the current approved wetting footprint limit in MS 914 of 17 km beyond the Marillana – Weeli Wolli confluence. Given that the current wetting footprint limit is set 28 km from the boundary of the Fortescue Marsh and that wetting front is predicted to be within existing approved limits, it is considered there will be negligible impacts on Fortescue Marsh.

The controlled nature of CIA (impact of the Revised Proposal, Hope Downs 1 and BHP Yandi on Fortescue Marsh water balance) in terms of volume of discharge, and the extent of surface water expression and extensive transient sampling of the surface water and groundwater for chlorine concentration and environmental isotope composition, allowed partitioning of components of water balance that otherwise would not have been possible by water mass balance method alone. The study concluded that although mine water discharge has changed the nature of the connectedness of Weeli Wolli Creek to the underlying aquifer in the upper section associated with the impermeable Weeli Wolli Formation, there has been negligible impact on the overall water balance of the broader catchment.

Most of the recharge to the groundwater aquifer along Weeli Wolli Creek occurs where the creek flows adjacent or across the CID aquifer. The calculated rates of recharge are also commensurate with large flooding events that occur in the region every few years. Changes in surface water connectivity and sustained periods of saturation may nevertheless have localised and probably relatively short term impacts (until the next flood) on the ecology of streams.

Groundwater modelling results suggest that the maximum extent of the drawdown in the CID is 2 km downstream from the Proposal (Rio Tinto 2014d; updated addendum 2015). The location of zero drawdown is approximately 7 km upstream from the Weeli Wolli fluvial plan and 35 km from the Fortescue Marsh.

The cumulative impact of creek discharge and dewatering clearly shows no measurable chlorine concentration change in CID groundwater 4 km up gradient from Weeli Wolli fluvial plane and 32 km from the Fortescue Marsh.

For further details, please see Dogramaci et al. (2015), Dogramaci and Skrzypek (2015), Skrzypek et al. (2013) and Rouillard et al. (2015).

13.3.6 Water quality

As described in Section 13.2.4.2, water quality monitoring to date indicates some minor variation in water quality parameters. However, this is considered to be within natural fluctuations and no significant effects on baseline water quality has occurred as a result of abstraction and discharge activities.

Given the abstraction and discharge of water from the Proposal is from the same water source as the current approved operations, and the wetting front would remain within the limits of MS 914, it is expected that there will not be any significant effects on water quality as a result of the Proposal activities.

Water monitoring will continue in accordance with the Surface Water Discharge and Groundwater Dependent Ecosystem Monitoring and Management Plan.

13.3.7 Contamination of surface and groundwater from waste dumps

Appropriate management of waste dumps will ensure that risks of contamination of surface and groundwater are minimised. Rio Tinto has developed practice standards for handling and managing mineral wastes, as described in the following internal standards:

- Iron Ore (WA) Mineral Waste Management Plan.
- Iron Ore (WA) Spontaneous Combustion and Acid Rock Drainage (SCARD) Management Plan.
- Iron Ore (WA) Rehabilitation Management Plan.
- Iron Ore (WA) Landform Design Guidelines.

Operational waste dumps will incorporate water management features to reduce the potential for sediment-laden surface water runoff, such as continuous windrows around the base of the dumps and on-site drainage structures being stabilised to minimise erosion. Stormwater will be directed to sedimentation traps to reduce sediment loads in surface water discharged off-site.

The risk of acid rock drainage at the Revised Proposal has been assessed as low based on geochemical interpretation and analytical testing of drill hole samples. As a result, waste rock stockpiles are not considered to present a risk to water quality in the surrounding environment.

Ongoing geochemical sampling and analysis will be undertaken during the life of the Proposal and if the risk from acid rock drainage increases, an Acid Rock Drainage Management Plan for Yandicoogina will be prepared and implemented with endorsement of the relevant decision making authority.

13.3.8 Contamination of surface water from hydrocarbons

Site drainage will be designed to minimise or eliminate surface runoff into areas where activities with a potential risk of hydrocarbon contamination occur.

All areas where there is risk of hydrocarbon contamination will be contained and stormwater collected in these areas will be treated to remove hydrocarbons. These locations may include:

- Bulk fuel storage and handling.
- Heavy vehicle refuelling.

- Light vehicle refuelling.
- Bulk lubricant storage and handling.
- Heavy vehicle workshop.
- Light vehicle workshop.
- Fixed plant maintenance workshop.
- Heavy vehicle wash down.
- Light vehicle wash down.

Treated oily water will be discharged to local evaporation ponds. Treated water from the evaporation ponds may be used for dust suppression on roads within the Revised Proposal Development Envelope. Provision will be made in operating plans for periodic removal of sludge residue from the oily water separators to a licensed disposal facility.

The Proposal will comply with all relevant Australian Standards (e.g. Australian Standard 1940-2004) and statutory requirements (e.g. Operating Licence conditions) for the transport, handling and storage of hydrocarbons, ammonium nitrate and other chemicals required on-site for operations and maintenance purposes.

13.3.9 Post-mining hydrology and pit lakes

Discussion of the post-mining hydrology, including information regarding the two pit lakes that will be formed is addressed in Section 17.

13.4 Cumulative impacts

13.4.1 Cumulative impacts to Marillana and Weeli Wolli Creeks

A preliminary assessment of cumulative impacts to surface water hydrology in the Marillana-Weeli Wolli Creek system was conducted based on a review of the potential impacts of the Proposal, the existing Yandi Operations and six other projects identified as being potentially relevant based on their location in the Weeli Wolli Creek or Marillana Creek sub-catchments of the Upper Fortescue River Catchment (**Table 13**).

The average of existing discharge to the Marillana - Weeli Wolli Creek system is approximately 46 GL/y, with a peak of approximately 70 GL/y. Average discharge is expected to increase to approximately 97 GL/y and may reach a peak of approximately 140 GL/y. The Proposal (this assessment), is predicted to account for approximately 50 GL/y of discharge (approximately 35% of the total peak discharge), with the Revised Proposal modelled to reach a peak discharge of approximately 78 GL/y (approximately 54% of the total catchment peak discharge; **Table 13**).

Table 13: Assessment of potential cumulative impacts to surface water hydrology in the Marillana-Weeli Wolli Creek system

Project	Surface water discharge to the Marillana-Weeli Wolli Creek system	Reference
Past and present actions		
Hamersley HMS's Hope Downs 1 Iron Ore Mine Expansion (EP Act Assessment No. 1308)	Approximately 28 GL/y (up to 36 GL/y) existing discharge. Up to 40 GL/y future discharge. Groundwater abstraction and associated surface discharge of excess water commenced in 2007. Average discharge from 2007 to 2013 was approximately 28 GL/y, with a peak of approximately 36 GL/y. Future discharge is expected to increase to approximately 40 GL/y.	URS (2015)
Iron Ore Holdings Iron Valley Iron Ore Project (EP Act Assessment No. 1905; EPBC Act Ref. 2012/6458)	0 GL. The Iron Valley Iron Ore Project, as referred in 2012, did not include mining below the water table, nor dewatering for pit excavation and ore extraction (and therefore did not include surface discharge of excess dewater).	URS (2012)
BHP Jinidi Iron Ore Mine (EP Act Assessment No. 1904; EPBC Act Ref. 2012/6299)	0 GL existing discharge. 1 GL/y, potentially up to 7 GL/y future discharge. As referred in 2011, construction of the Jinidi Iron Ore Mine was proposed to commence in 2012; however, the proposal is yet to commence. The 2011 referral documentation stated that the proposal could potentially discharge the maximum mine dewatering volume of approximately 7 GL/y to one or more nominated creek locations during discrete periods; however, approximately 6 GL/y was expected to be used during operations for ore conditioning and dust management.	BHP (2011)
BHP Marillana Creek (Yandi) (EP Act Assessment No. 1555)	Approximately 7 GL/y (up to 13 GL/y) existing discharge. Up to 15 GL/y future discharge. Average discharge from 1997 to 2013 was approximately 7 GL/y, with a peak of approximately 13 GL/y. The licensed limit is for a discharge of 15 GL/y.	URS (2015)
BHP Mining Area C (EP Act Assessment No. 1108)	0 GL. The Mining Area C Project, as documented in 1997, did not include mining below the water table, nor dewatering for pit excavation and ore extraction (and therefore did not include surface discharge of excess dewater).	Woodward-Clyde (1997)
Mineral Resources Phil's Creek Iron Ore Mine (EPBC Act Ref. 2009/5107)	0 GL. The Phil's Creek Iron Ore Mine, as referred in 2009, did not include mining below the water table, nor dewatering for pit excavation and ore extraction (and therefore did not include surface discharge of excess dewater).	URS (2009)

Project	Surface water discharge to the Marillana-Weeli Wolli Creek system	Reference
Rio Tinto Yandicoogina Iron Ore Project, comprising: • Junction Central (EP Act Assessment No. 809 & 946) • Junction South East (EP Act Assessment No. 1590) • Junction South West and Oxbow (EP Act Assessment No. 1726; EPBC Act Ref. 2011/5815)	Approximately 11 GL/y (up to 25 GL/y) existing discharge. Average discharge from 1998 to 2013 was approximately 11 GL/y, with a peak of approximately 25 GL/y. The expected future discharge from the Yandicoogina Iron Ore Project (as approved under MS914), is up to 47 GL/y.	URS (2015)
Anticipated project actions		
Rio Tinto Yandi PBS Proposal (this assessment)	The forecast discharge is approximately 50 GL/y from the Proposal. The Revised Proposal will include a combined cumulative peak discharge of up to 78 GL/y and average of approximately 61 GL/y (which includes recycling of discharge from upstream operations).	URS (2015)
Reasonably foreseeable future actions		
NA – none located in the Weeli Wolli Creek or Marillana Creek sub-catchments		
Cumulative impact		
All projects	Existing discharge 46 GL/y (average) up to 70 GL/y (peak). Future discharge 97 GL/y (average/standard) up to 140 GL/y (peak).	As above

13.5 Key management actions

Surface and groundwater values in the Revised Proposal Development Envelope will be protected through implementation of measures set out in the Yandi MMP (**Appendix 4**); the Yandicoogina Groundwater Operating Strategy (GWOS); the E11 Standard: Water Quality Protection and Water Management; the E13 Standard: Chemically Reactive Mineral Waste Control; the E15 Standard: Hazardous Materials and Non-Mineral Waste Control and Minimisation; the Yandicoogina Closure Plan; and existing DoW and DER licence conditions. Key measures include:

- Establishing baseline surface water quality for the local catchment, including the development of site specific trigger values (**SSTV**s) in accordance with ANZECC guidelines. This has also included a hazard analysis to focus on key analytes of concern for the local ecosystem.
- Monitoring of surface water quality at discharge outlets, at upstream inputs of surface water discharge and downstream pools 'mixing zones' to enable a comprehensive understanding of any changes to water chemistry as a result of upstream operations discharges, Revised Proposal discharge, and cumulative downstream water chemistry.
- Monitoring the surface water discharge wetting extent on a monthly basis to ensure that the discharge footprint remains within a 17 km limit from the Marillana – Weeli Wolli confluence.

- Monitoring of aquifer groundwater levels and groundwater quality on a monthly basis via a network of monitoring bores to ensure pH, TDS and hydrocarbons are within acceptable limits.
- The borefield design is optimised and informed by numerical groundwater modelling, field test pumping programs, and the existing monitoring bore network.
- Contaminants such as hydrocarbons are managed via appropriate storage and containment facilities (eg. secondary containment such as bunding); and leak detection systems installed for any below ground storage. Hydrocarbon treatment facilities are used at wash down and workshop areas to minimise potential release into the environment.
- Non-mineral waste is disposed of in engineered, controlled and approved facilities.

13.5.1 Status of existing Yandi Operations management

The ESD prepared by the EPA required provision of information on:

- The current status and outcomes of surface water discharge management actions required by MS 914 Condition 6 – Surface water discharge (Weeli Wolli Creek).
- The effectiveness of the current water management scheme and provide a comparison of its actual operation versus what was predicted including discussion of accuracy. Also detail any problems with how the system has operated and what management measures have been taken when it is not operating as expected.
- Surface water and groundwater quality collected from the existing mining operation at the site. Identifying any adverse changes caused by the mining operation and outlining avoidance, minimisation and management methods to be used to prevent further impacts.

This information is provided in the following sections.

13.5.1.1 Current status and outcomes of MS 914 Condition 6

Condition 6 requires that the Proponent ensures discharge of excess water from the existing Yandi Operations does not cause long term impacts to environmental values of the Weeli Wolli Creek system, and that it does not cause water flow or pooling further than 17 km downstream from the Marillana Creek and Weeli Wolli Creek system confluence.

Surface expression of discharge is managed through implementation of the Yandi MMP. Surface water discharge modelling predicted that the discharge wetting footprint for the Revised Proposal would have a maximum perennial surface expression up to 17 km downstream from the confluence of Marillana and Weeli Wolli Creeks, assuming that Hope Downs 1 and BHP Yandi Operations are discharging at their full licensed capacity.

Ongoing monitoring indicates that since implementing JSW in 2013, the wetting footprint has ranged between 4 and 10 km downstream from the confluence. Historical measurements of the wetting footprint since 2010 has ranged between 5 and 9 km from the confluence, so the current risk of extending beyond the predicted wetting footprint is deemed low. This is also supported by more recent hydrogeological studies.

The dewatering infrastructure network includes six active discharge outlets, and accommodates an adaptive approach to discharge management. Riparian vegetation condition is monitored concurrently with discharge, taking into account the relationship between vegetation health and water availability. Monitoring results inform the discharge management regime, and discharge volume is adjusted at individual outlets where it is deemed appropriate to support the riparian communities. This adaptive functionality is also taken into consideration in the planning and design phase of new dewatering infrastructure, to maintain capacity to respond to monitoring results throughout the life of mine, as outlined in the management actions of the Yandi MMP.

13.5.1.2 Effectiveness of current water management scheme

Hydrogeological conceptualisation for the Revised Proposal has been refined through numerous investigations, with aquifer geometry, hydraulic properties, response to dewatering stress and groundwater / surface water interactions and is well understood. This detailed level of hydrogeological understanding has allowed for development of appropriate dewatering strategies over time to allow mining of the below water table component of the CID deposit.

The dewatering requirements are reviewed annually to determine if the planned mining progression can be achieved with current dewatering infrastructure. A numerical groundwater model is used to predict temporal and spatial variations in groundwater levels for the period of the mine plan and dewatering targets for each bore and borefield are developed and updated regularly and are set against current mine (medium term plan and Life of Mine) and abstraction licence volumes.

For input into the groundwater model and for reporting purposes, monthly water level data gathered from observation bores across the site is analysed against historical data, taking into account seasonal trends. Water levels generally rise and fall due to seasonal activity and water levels in some monitoring bores can vary significantly due to adjacent operational pump activity, which itself varies over time.

Review of historical abstraction performance shows that actual abstraction was between 90-100% of modelled volumes from 2010 to 2012, decreasing to approximately 70-75% of model target volumes in during 2013 and 2014. These dewatering volumes are lower again from the Groundwater Licence volume allocation which allow for a conservative buffer between the modelled volumes and the licence limit. Therefore the actual volume of dewatering at Yandi Operation has been up to 30% less than the licensed limit. This divergence of actual from modelled volumes has been attributed to: periodical mining disruptions; delay in fit-out of bores during 2013; achievable rates from installed bores being less than model-assumed rates; and engineering design matters resulting in non-continuous bore pumping (i.e. oversized pumps and electrical faults).

To date, the mine plan has not been affected by the lower than expected (modelled) abstraction rates.

The effectiveness of the existing re-injection scheme in the vicinity of Billiard South has been limited with the system never reaching full capacity as designed. The maximum re-injection reached was 6.0 GL/y, with an average re-injection rate of around 3.4 GL/y. The limiting factors being attributable to clogging of the bores from iron-reducing bacteria; suitability of localised geology at individual bores to receive large volumes of water; and location of the re-injection scheme within an aquifer receiving discharge from upstream operations, which has been effectively “filling up” the aquifer, limiting available storage to

receive re-injection water. The re-injection scheme was subsequently decommissioned in mid 2014.

13.5.1.3 Review of surface and groundwater quality

Surface water quality is managed in alignment with ANZECC/ARMCANZ (2000) guidelines, to protect the environmental values of Weeli Wolli Creek listed in the Environmental Values Statement. Water quality is monitored at each active discharge outlet, and in the surface waters of Marillana and Weeli Wolli Creeks, upstream and downstream from operational discharge. A conservative approach has been adopted by establishing baseline water quality conditions in Marillana and Weeli Wolli Creeks individually, and selecting the 80th percentile of the baseline range as outlined in the ANZECC/ARMCANZ guidelines, as a trigger to investigate water quality trends downstream from discharge outlets. Investigation includes water quality trends within the catchment up to the furthest extent of the wetting footprint, and reviewing the potential impacts of water quality on aquatic fauna.

A specialist consultancy (Wetland Research and Management) has been engaged to complete extensive studies on aquatic fauna, and provide annual wet and dry season monitoring and reports to validate the impacts of discharge water quality to the surrounding catchment.

Complementary to the aquatic fauna program, a hazard analysis was completed for operational discharge into Marillana and Weeli Wolli Creeks. The hazard analysis took into consideration baseline information on aquatic fauna monitoring along with the Environmental Values Statement, and provided a risk ranking for individual analytes naturally occurring in the groundwater being discharged. Stress from nitrates and carbonate were identified as the most notable risks, as they can support processes which lead to eutrophication and creek bed 'armouring' as a result of deposition of precipitate, which has the potential to remove suitable habitat for aquatic fauna. Toxicity from a range of analytes was acknowledged as posing a lower risk to the catchment.

Ongoing monitoring and analysis of both water quality and aquatic fauna has improved the understanding of aquatic ecology within the lower Weeli Wolli Creek catchment. The 2014 Annual Compliance Assessment Report (required by condition 4-6 of MS 914) details the results of water quality monitoring, including each individual water quality result which exceeded the 80th percentile trigger value. The 80^{th} percentile trigger value was exceeded at least once during the reporting period for hardness, alkalinity, bicarbonate alkalinity, electrical conductivity, total suspended solids, total dissolved solids, barium, boron, calcium, chloride, magnesium, nitrate, total nitrogen, total phosphorus, potassium, sodium, sulphate, sulphur, and uranium. These exceedances have triggered the "focus" and "investigate" actions (including resampling to check for potential sampling issues such as cross contamination during the sampling process). The occurrence of exceedances is not unexpected given the triggers have been established using a conservative 80^{th} percentile value to ensure that any management response (if necessary) can be implemented sufficiently soon to ensure environmental impacts are minimised. To date, no management or control actions in response to water quality exceedances have been necessary.

Field observations, which included localised variation in aquatic fauna assemblages and habitat both upstream and downstream of operational discharge, indicate that the existing Yandi Operations discharge is not causing long term impacts to the values of Weeli Wolli Creek. Taxa richness of microinvertebrates, macroinvertebrates, hyporheic invertebrates

and fish does not appear to be adversely impacted by water quality, indicating that eutrophication and creek bed 'armouring' risks are currently low. Algal growth, nitrate concentrations and nutrient cycling remain key components of ongoing monitoring, and a continually developing understanding of the relationships between these components at a local scale will ensure that the correct approach is taken to evaluate ecosystem health.

13.6 Predicted outcome

A range of measures have been or will be implemented to reduce potential impacts to the environmental values of hydrological processes and inland waters environmental quality (**Table 14**).

Table 14: Mitigation hierarchy for hydrological processes and inland waters environmental quality values

Mitigation measure	Description
Avoidance	Direct disturbance to Weeli Wolli Creek will largely be avoided and low-flow lines will be maintained. Impacts to the Fortescue Marsh are predicted to be avoided. No impacts from acid mine drainage are expected due to the low risk presented by the geochemistry of the waste rock and pit wall material.
Minimisation	Infrastructure in Weeli Wolli Creek designed to avoid disruption of low-flow line and flood flows. Discharge would occur from existing approved locations. The surface water wetting front is predicted to remain within existing approved limits.
Rehabilitation	Disturbed areas will be rehabilitated consistent with the Yandicoogina Closure Plan. Key functional creek elements retained (e.g. flood pathways, vegetation seed bank) to support natural rehabilitation upon closure.

After the mitigation hierarchy has been applied, it is expected that the Proposal will result in the following residual outcomes in relation to hydrological processes and inland waters environmental quality:

- **Natural surface water systems and flows** – potential impacts likely to be minor and can be managed through typical stormwater management measures such as levees around the pit, diversion drains around waste dumps, and culverts under roads.
- **Surface water resources including Weeli Wolli Creek due to surface discharge of surplus mine dewater** – wetting front will be within existing approved limits, and therefore there will be negligible additional impacts on the downstream hydrological system of Weeli Wolli Creek.
- **Altered flow regime to the Fortescue Marsh** – surface water wetting front associated with the additional discharge from the Proposal is predicted to remain within existing approved limits of MS 914.
- **Potential contamination of surface water and groundwater** – acid rock drainage at the Revised Proposal has been assessed as low due to the geology. Site drainage will be designed to minimise or eliminate surface runoff into areas where activities with a potential risk of hydrocarbon contamination occur. Management of waste dumps will ensure that risks of contamination of surface and groundwater are minimised.

With the exception of the development of pit lakes upon closure (which are addressed further in Section 17), the above residual outcomes are potential environmental impacts that may occur during the mine life and are not predicted to result in long term or significant changes for hydrological processes and inland water quality.

14. Flora and vegetation

14.1 Key statutory requirements, environmental policy and guidance

14.1.1 EPA objective

The EPA has applied the following objective for the Proposal to its assessment of flora and vegetation:

"To maintain representation, diversity, viability and ecological function at the species, population and community level."

14.1.2 Regulatory framework

The following legislation is relevant to the Proposal with respect to the protection of flora and vegetation values and the above EPA objective:

- *Wildlife Conservation Act 1950* (WA) and associated Wildlife Conservation (Rare Flora) Notice 2014.
- *Conservation and Land Management Act 1984* (WA).
- *Environmental Protection Act 1986* (WA) and associated Native Vegetation Regulations 2004.
- *Environment Protection and Biodiversity Conservation Act 1999* (Commonwealth).

14.1.3 Relevant guidelines and policy

The following guidelines are relevant to the Proposal with respect to the protection of flora and vegetation values and the above EPA objective:

- EPA Position Statement No. 2: Environmental Protection of Native Vegetation in Western Australia (EPA 2000).
- EPA Position Statement No. 3: Terrestrial Biological Surveys as an Element of Biodiversity Protection (EPA 2002).
- EPA Position Statement No. 7: Principles of Environmental Protection (EPA 2004a).
- EPA Guidance Statement No. 51: Terrestrial Flora and Vegetation Surveys for Environmental Impact Assessment in Western Australia (EPA 2004c).

14.2 Description of factor

14.2.1 Flora and vegetation surveys

Biota conducted a number of flora and vegetation surveys within the Proposal Area and in the wider Yandicoogina locality (Biota 2014a, Biota 2015a). A consolidated list of all flora and vegetation surveys completed to date is provided in **Table 15**. In March and July of 2014 Biota conducted seasonal surveys of the Proposal Area (Biota 2014a).

A total of 121 quadrats and 28 relevés have been sampled in the study area to date, with 46 quadrats and eight relevés established during Phase 1 of the most recent survey, and three additional quadrats established during Phase 2. In total, 68 quadrats have been sampled twice within the Proposal Area, including quadrats sampled prior to this survey (**Table 16**; **Figure 43**).

In addition to the Biota vegetation mapping, a Rio Tinto botanist further refined the mapping within major creeklines and tributaries and identified 12 additional riparian associations (**Table 16**; Rio Tinto 2015a).

Limitations of the flora and vegetation surveys primarily constituted the following factors:

- While targeted searches for conservation significant flora were undertaken and opportunistic taxa were recorded during representative traverses through all habitats in the study area, the entire study area was not systematically searched. The list of vascular flora documented from the study area is therefore not exhaustive.
- The Phase 1 survey was undertaken in March 2014 and was optimally timed for the collection of annual flora. The Phase 2 survey was undertaken in July, which is typically a dry time of year in the Pilbara, however, above average rainfall was received prior to this survey. Given the favourable rainfall conditions, most species should have been present during the field surveys, however, it is possible that some annual fire ephemeral or cryptic perennial species would have been absent during the Phase 2 survey due to the seasonal timing.
- Consistent with the accepted level of effort for a survey of this type and scale, fungi and nonvascular flora (algae, mosses and liverworts) were not sampled.
- One Hills, Ridges and Breakaways vegetation type (H5) was described from relevés rather than quadrats. Quadrats could not be established in this vegetation type due to the narrow dimensions of the habitat and the steep, rocky terrain.
- Areas already cleared for drilling and associated activities were not surveyed.

Table 15: Flora and vegetation survey effort within the wider Yandicoogina locality

Study (Reference)	Area Surveyed Within Study Area (Total Area of Survey)	Survey Description Survey Timing (Conditions for Plant Growth)
Yandi Billiards – Phase 1 and Phase 2 (Yandi PBS; Biota 2014a)	8,640 ha (8,640 ha)	Two phase (seasonal) vegetation and flora survey of the PBS survey area to expand the existing data for the area to a Level 2 standard. 8 – 20 March 2014 (favourable); 7 – 11 July 2014 and 14 July 2014 (favourable)
Yandi Junction South West (JSW)/Oxbow (YOX) Vegetation and Flora Integration Report (Biota 2014b cited in Biota 2015a)	2,133 ha (2,192 ha)	Integration of existing data with a further botanical survey to provide additional information on the values associated with the JSW and YOX survey areas. 27 February – 4 March 2012 (favourable)
Yandi Additional Areas (Biota 2014c cited in Biota 2015a)	2,807 ha (2,828 ha)	Establish additional quadrats to validate vegetation mapping of additional areas around the JSW and YOX deposits to match the project footprint. 12 – 18 June 2012 (favourable)
Yandicoogina Additional Vegetation Mapping (Biota 2011a cited in Biota 2015a)	2,806 ha (3,030 ha)	Mapping of additional areas around the JSW and YOX deposits to match the project footprint. 29 November – 3 December 2010

Study (Reference)	Area Surveyed Within Study Area (Total Area of Survey)	Survey Description Survey Timing (Conditions for Plant Growth)
		(unfavourable)
Vegetation and Flora Surveys of the Oxbow and Junction South West Deposits, near Yandicoogina (Biota 2010a cited in Biota 2015a)	YOX: 665 ha (725 ha) JSW: 1,460 ha (1,460 ha)	Two phase (seasonal) vegetation and flora survey of the JSW and YOX survey areas. YOX: 27 July-6 August 2008 (unfavourable); 3-9 June 2009 (favourable). JSW: 4 – 16 June 2007 (unfavourable); 27 July – 6 August 2008 (unfavourable); 3 – 9 June 2009 (favourable)
A Flora and Vegetation Survey of the Billiards Deposit, near Yandi (Biota 2009a cited in Biota 2015a)	1,512 ha (1,512 ha)	Two phase (seasonal) vegetation and flora survey of the Billiards survey area. 11 – 20 June 2007 (unfavourable); 27 July – 6 August 2008 (unfavourable); 3 – 9 June 2009 (favourable)
Yandicoogina Waste Dumps, Topsoil Stockpiles and Haulroads Native Vegetation Clearing Permit Report (Biota 2009b cited in Biota 2015a)	406 ha (406 ha)	Single phase vegetation and flora survey of four development areas to support a Native Vegetation Clearing Permit. 4 – 7 September 2008 (unfavourable)
Vegetation Mapping and Rare Flora Searches of Yandi Backfill Hill (Biota 2005 cited in Biota 2015a)	189 ha (189 ha)	Vegetation mapping and systematic Rare Flora searches of the Yandi Backfill Hill survey area. 31 May – 2 June 2005 (unfavourable)
Yandi Expansion Vegetation and Flora Survey (Biota 2004a cited in Biota 2015a)	2,245 ha (2,245 ha)	Single phase vegetation and flora survey of the Yandi Expansion area, near the YJC deposit. 30 August – 5 September 2004 (unfavourable)
Flora and Vegetation Survey of the Hope Downs Rail Corridor Extension through the Hamersley Range (Biota 2004b cited in Biota 2015a)	1,492 ha (3,977 ha)	Single phase vegetation and flora survey of the Hope Downs Rail Corridor Extension through the Hamersley Range. April 2003 (favourable)
Vegetation and Flora of the Hope Downs Rail Corridor from Port Hedland to Weeli Wolli Creek (Biota 2002 cited in Biota 2015a)	805 ha (2,774 ha)	Single phase vegetation and flora survey of the Hope Downs Rail Corridor from Port Hedland to Weeli Wolli. 25 April – 14 May 2001 (favourable) 29 May – 10 June 2001 (favourable)
Hope Downs Rail Corridors Biological Surveys (Halpern Glick Maunsell 2000a cited in Biota 2015a)	2,594 ha (16,420 ha)	Single phase vegetation and flora survey of the Hope Downs Rail Corridors. 25 November – 3 December 1999 (unfavourable)
Flora and Vegetation: Yandicoogina Junction Area (Mattiske 1995a cited in Biota 2015a)	3,591 ha (3,745 ha)	Single phase vegetation and flora survey of the YJC survey area. January and March 1994 (unknown) February 1995 (unknown)
Flora and Vegetation: Northern Transport Corridor, Yandicoogina Junction Project Area (Mattiske 1995b cited in Biota 2015a)	3,035 ha (24,703 ha)	Single phase vegetation and flora survey of the Yandi Northern Transport Corridor. February 1995 (unknown)
Flora and Vegetation: Southern Transport Corridor, Yandicoogina	2,450 ha (30,103 ha)	Single phase vegetation and flora survey of the Southern Transport

Study (Reference)	Area Surveyed Within Study Area (Total Area of Survey)	Survey Description Survey Timing (Conditions for Plant Growth)
Junction Project Area (Mattiske 1995c cited in Biota 2015a)		Corridor. January and March 1994 (unknown) February 1995 (unknown)
Ecological appraisal of the Yandicoogina Project Area (Integrated Environmental Services 1981)	25,000 ha	Single phase Flora, fauna and vegetation survey of the area in favourable conditions

Table 16: Flora and vegetation survey effort within the Proposal Area

Survey	Timing	Methodology
Riparian vegetation of Marillana and Weeli Wolli Creeks: Mapping refinement and assessment of values and significance (Rio Tinto 2015a)	April 2015	Desktop and mapping traverses
Yandi PBS flora and vegetation survey (Phase 2; Biota 2014a)	July 2014	Three new quadrats established and 30 quadrats resampled
Yandi PBS flora and vegetation survey (Phase 1; Biota 2014b)	March 2014	46 quadrats established, 32 quadrats resampled and eight relevés recorded
Yandi additional areas Level 2 flora and vegetation survey (Biota 2014c cited in Biota 2015a)	June 2012	11 quadrats and five relevés established
Vegetation and flora survey of the Billiards deposit, near Yandi (Biota, 2009a cited in Biota 2015a)	June 2007	29 quadrats and 14 relevés established
	July/August 2008	Seven new quadrats established and 11 quadrats resampled
	June 2009	Six quadrats resampled
Flora and Vegetation Survey of the Yandi Expansion Area (Biota 2004a cited in Biota 2015a)	Aug/Sept 2004	13 quadrats and one relevés established
Flora and Vegetation Survey of the Hope Downs Rail Corridor Extension through the Hamersley Range (Biota 2004b cited in Biota 2015a)	April 2003	Nine quadrats established
Vegetation and Flora of the Hope Downs Rail Corridor from Port Hedland to Weeli Wolli Creek (Biota 2002 cited in Biota 2015a)	April/May 2001	Two quadrats established
Hope Downs rail Corridor Biological Surveys (Halpern Glick Maunsell 2000a cited in Biota 2015a)	Nov/December 1999	One quadrat established

14.2.2 Vegetation

14.2.2.1 Vegetation communities present in the Proposal Area

The Proposal lies within the Fortescue Botanical District of the Eremaean Botanical Province as defined by Beard (1975a, 1975b). The Proposal intersects two of the vegetation units defined by Beard (1975a, 1975b), both of which have the majority of their pre-European extent remaining (Table 17).

Table 17: Beard's (1975b) mapping units that occur in the study area and their extent in the Pilbara bioregion

Beard's vegetation mapping unit	Current extent in the Hamersley/Fortescue subregion (ha) (% remaining)	Extent within the study area (% of the current mapped extent)
Fortescue Valley 29	893,222 (>99.9%)	2,586 (0.3%)
Hamersley 82	2,165,235 (99.4%)	1,909 (0.1%)

Source: Government of Western Australia (2013b)

Biota (2014a) mapped and described 23 vegetation sub-associations ('vegetation units') within the Proposal Area (**Figure 44** to **Figure 47**). A full list of the Biota (2014a) mapping units are provided in **Appendix 3**. The Biota (2014a) vegetation units have been grouped according to the major landform with which they are associated. In addition to the Biota vegetation mapping, a Rio Tinto botanist further refined the mapping within the riparian zones in Marillana and Weeli Wolli Creeks. Biota's original C1-C5 units were further differentiated and a total of 13 riparian sub-associations throughout the greater Yandicoogina area (**Appendix 3**). The vegetation units shown in **Figure 44** to **Figure 47** are the Biota mapping units, the refined riparian vegetation mapping is shown in **Figure 48** to **Figure 52**. Refer to Appendix 3 for full descriptions of all refined riparian vegetation units (Rio Tinto 2015a).

Vegetation of Major Creeklines and Tributaries

Of Biota's five original riparian units, four (C1-C4) were mapped within the Proposal Area. Further refinement of these units by Rio Tinto (2015a) identified 13 sub-associations of which 10 occurred in the Proposal Area. These units were characterised by the presence of *Eucalyptus camaldulensis* and *E. victrix* and to a lesser extent *Melaleuca argentea*. All of these units are associated with the "all major ephemeral water courses" ecosystem at risk listed by Kendrick (2003a, 2003b).

The major creekline vegetation units comprised 18% of the Proposal Area.

Vegetation of Minor Creeklines, Floodplains and Valleys

Five vegetation units (F1-F5) have been mapped in minor drainage lines, floodplains and valleys. The minor creekline, floodplain and tributaries vegetation units comprised 8% of the Proposal Area.

Vegetation of Hills, Ridges and Breakaways

Five vegetation units (H1-H5) have been mapped associated with hills, ridges and breakaways. These units comprised 28% of the Proposal Area and supported the recorded populations of the Threatened *Lepidium catapycnon*.

Vegetation of Plains

Eight vegetation units (P1-P8) have been mapped associated with plains. The Priority 4 *Goodenia nuda* is associated with claypans of the Plains units. Plains vegetation units comprised 46% of the Proposal Area.

Geospatial Information and Mapping

Vegetation condition

Surveys within the Proposal Area recorded vegetation condition (after Trudgen 1988) to be Excellent to Very Poor (Biota 2014a; see **Table 18** and **Figure 53**). The main disturbance factors in the area are weed invasion and disturbance from livestock (cattle) including grazing, tracks, and trampled vegetation. Approximately 3% of the study area is mapped as Disturbed or Completely Degraded. These areas comprised current and historic vehicle roads and tracks, drill lines and drill pads. The majority of the Proposal Area is comprised of vegetation in either Good or Excellent condition (73%).

Table 18: Vegetation Condition (%) in the Proposal Area

Vegetation condition	% of Project Area
Excellent	26.6
Very Good	7.0
Good	46.0
Poor	0.8
Very Poor	16.5
Completely Degraded	3.1

Most creekline and floodplain vegetation types were rated as being in Good condition, although some areas were rated as Very Poor due to the high weed cover and evidence of extensive grazing and trampling by cattle. Buffel grass (**Cenchrus ciliaris*) was the most prolific weed in these habitats, sometimes occurring together with **Cenchrus setiger*. **Cenchrus* species were present as a continuous population along the edges of Weeli Wolli and Marillana Creeks and on adjacent floodplains (Biota 2014a).

The vegetation condition of the plains ranged from Good to Excellent. Some weed species were recorded, although they were usually only present as scattered individuals. Occasionally a very open tussock grassland of **Cenchrus ciliaris* was present, usually on plains adjacent to creeklines or floodplains. Evidence of cattle was also occasionally noted on the plains (Biota 2014a).

The hills, ridges and breakaways of the study area were in Excellent condition and were mostly free from any form of disturbance. Some of the hills and slopes of the study area had been recently burnt. Fire is a natural process in the Pilbara region, and natural fire regimes need not affect the overall condition of vegetation (Biota 2014a).

14.2.2.2 Conservation significance of vegetation communities

Threatened and Priority Ecological Communities

None of the vegetation types recorded in the Proposal Area represent Threatened Ecological Communities or Priority Ecological Communities.

Vegetation units of elevated conservation significance

A number of "other ecosystems at risk" are identified for the Hamersley and Fortescue subregions of the Pilbara bioregion (Kendrick 2003a, 2003b). These are ecosystems with some level of significance that are at risk of degradation from a variety of factors including development, groundwater drawdown, frequent fires, grazing and weed invasion. One of these is relevant to the Proposal Area:

- 'All major ephemeral water courses' in the Hamersley subregion (Kendrick 2003a). These water courses are described as supporting "Eucalyptus forests with a shrubby understorey", which are under threat of degradation from weed invasion and grazing and trampling by feral herbivores (Kendrick 2003a). Groundwater drawdown could also potentially impact such vegetation if it included phreatophytic (groundwater dependent) species such as *Melaleuca argentea* (Cadjeput) or *Eucalyptus camaldulensis* (River Red Gum).

While Kendrick (2003a) referred to this ecosystem at risk being represented by the National Vegetation Information System (NVIS) major vegetation sub-group 4 (Eucalyptus open forests with a shrubby understory), no communities in the Proposal Area are classified as having Eucalyptus species consistently of this density (30-70%). Despite this, many of the C coded vegetation units occurring in the main incised channel of the Proposal Area are generally considered representative of this ecosystem at risk.

The Biota C1 vegetation unit was initially considered to be of elevated conservation significance however this unit was further differentiated into the C1B community and three closely associated sub-associations (C1/C2A, C2/C1 and C2A units). These four units are now considered to represent the key riparian communities of elevated significance. Of these units, the C1B unit is considered more significant; C1/C2A and C2/C1 are those units which have been interpreted by Rio Tinto (2015a) as being discharge augmented versions of the C2A community; and the C2A unit represents the regionally well represented *Eucalyptus camaldulensis* and *Eucalyptus victrix* open woodland community of large creek systems in the Pilbara. These communities are associated with Marillana and Weeli Wolli Creeks and are considered to be of elevated significance due to their inherent ecological values, restricted distribution in the Hamersley subregion, and their similarity to the Kendrick (2003a) ecosystem at risk (**Table 19**). The remaining C coded vegetation types comprise riparian vegetation but do not generally feature eucalypt forests and are widespread in moderate-sized creek systems throughout the Pilbara (Biota 2014a).

Table 19: Vegetation units of elevated significance in the Proposal Area

Vegetation unit	Condition	Total extent (ha)
C1B	Good	6
C1/C2-A	Good	3
C2/C1	Poor	11
C2A	Good - Poor	115
C2Asb	Very Good	52

14.2.3 Flora

A total of 455 native vascular flora taxa from 154 genera and 47 families have been recorded from the Biota (2014a) study area. This level of species richness is high for the broader locality but within the range that would be expected for a survey area of this size (Biota 2014a).

14.2.3.1 Conservation listed flora

Threatened (Declared Rare) Flora

One species, *Lepidium catapycnon* (Hamersley Lepidium), listed under the WC Act as Threatened (Declared Rare) Flora has been recorded in the Proposal Area. *L. catapycnon* is also listed as Vulnerable under the EPBC Act. *L. catapycnon* was recorded from two locations in the Proposal Area during previous surveys (Biota 2015a).

Searches undertaken during the Phase 1 survey at the locations of existing records, as well as targeting areas deemed potentially suitable habitat, found no individuals of *L. catapycnon*. Further targeted searches undertaken during the Phase 2 survey recorded *L. catapycnon* from 26 locations comprising three separate populations, two of these represented new populations for the area (Biota 2014a; **Figure 54**). A total of 777 individuals were recorded in the wider Yandicoogina locality during the Phase 2 surveys, with 948 recorded in this area to date. At present the Rio Tinto Rare and Priority flora database contains 1317 records of *L. catapycnon* totalling approximately 27,400 individuals.

It is noted that the conservation status of *L. catapycnon* is currently under review due to the extent of new records in the Pilbara.

Priority flora

One Priority flora species, *Goodenia nuda* (Priority 4), was recorded in the Proposal Area (Biota 2014a; **Figure 54**). Seventy-two *Goodenia nuda* individuals were recorded in the Proposal Area.

A Priority 3 species, *Sida* sp. Barlee Range (S. van Leeuwen 1642), was located 1.5 m (three individuals) and 11 m (two individuals) outside the southern boundary of the Proposal Area. Additional historical records of *Sida* sp. Barlee Range (S. van Leeuwen 1642), Themeda sp. Hamersley Station (M.E. Truden 11431; Priority 3), *Rhynchosia bungarensis* (Priority 4), *Eulalia* sp. (Three Rivers Station B. Forsyth AQ6789133; species of interest) and *Glycine* sp. aff. *arenaria* (species of interest) are located between 0.25 – 3.7 km from the Proposal Area (Biota 2015a; see **Figure 54**). As these populations are outside the Proposal Area, they will not be disturbed as part of the Proposal.

14.2.3.2 Introduced flora species

Eighteen introduced flora species were recorded within or in the vicinity of the Proposal Area (Biota 2014a). One species, **Argemone ochroleuca* (Mexican Poppy) is listed as a Declared Plant for the whole of WA under the *Biosecurity and Agricultural Management Act 2007*. None of the species recorded were ranked as Very High or High Management priorities for the Pilbara under the Parks and Wildlife Weed Prioritisation Process (DPaW 2013). **Acetosa vesicaria* (Ruby Dock) is ranked by Parks and Wildlife as a Medium management priority and all other species were ranked as Low, Negligible or were not listed. It is important to note that some species are ranked as lower priorities more because of the difficulty of control rather than their perceived invasiveness (e.g. Buffel grass, **Cenchrus ciliaris*; Biota 2014a).

Geospatial Information and Mapping

14.3 Assessment of potential impact, mitigation and residual impact

Potential impacts associated with the Proposal in relation to flora and vegetation were identified by the EPA in the ESD as follows:

- The proposal involves additional clearing that will increase the disturbance footprint in the Revised Proposal Development Envelope from 5,600 ha to 7,400 ha for the mine and supporting infrastructure.
- The clearing includes up to 69 ha of riparian zone vegetation within Weeli Wolli Creek, consisting of approximately 16 ha for the mine pit and 9 ha for flood protection levees. There are potential for impacts on Priority flora species and *Lepidium catapycnon*, which is a Threatened Flora species.
- Groundwater drawdown from the mine has the potential to impact on the health of riparian vegetation along an 8 - 10 km stretch of Weeli Wolli Creek.
- Discharge of surplus water from mine pit dewatering has the potential to impact on riparian vegetation along Marillana and Weeli Wolli Creeks.
- There is the potential for the introduction of weeds through vehicle movements and earthworks.
- There is also the potential to impact on vegetation through the generation of dust from mining operations.

14.3.1 Clearing of native vegetation and potential loss of important vegetation communities

Vegetation clearing is an unavoidable component of mine development and infrastructure construction. Clearing will be required to enable development of the mine pit and associated infrastructure that were outlined in Section 4. The conceptual layout of each element of the Proposal is shown in **Figure 4**. Where practicable, the final mine site layout and infrastructure alignment will be designed to minimise clearing within the Clearing Restriction Area and areas containing vegetation and flora of elevated significance subject to mine planning and engineering constraints.

The Proposal Area covers 4,363 ha of which 1,327 ha of vegetation is currently proposed to be cleared (**Table 20**; note that vegetation mapped as Completely Degraded condition has been excluded from this clearing total as it has already been cleared). The majority of the clearing is of vegetation of Plains and Hills, Ridges and Breakaways (clearing of vegetation units P4, P5, and H1 makes up 1,061 ha or 80% of all proposed clearing). Vegetation within the proposed clearing footprint is largely typical of that occurring in similar habitats elsewhere in the same section of the Hamersley and Fortescue subregions, or is considered relatively widespread in the Pilbara beyond the Proposal Area. The majority of vegetation proposed to be cleared was assessed to be in Good condition (71% of all mapped vegetation, ranging from Very Poor to Excellent condition) and has been historically impacted by grazing and trampling by domestic and feral animals, weed invasion, frequent fire and mining and exploration activities (Biota 2014a).

While 1,327 ha of vegetation is currently proposed to be cleared within the Proposal Area as part of the current mine layout, consisting of the pit, waste dumps, levee and support infrastructure, approval for clearing of up for 1,800 ha of the Proposal Area is being requested as part of the Proposal, to allow for flexibility with mine planning and development.

A total of 69 ha of vegetation is proposed to be cleared to support the development of the Proposal from within what is currently depicted as the Clearing Avoidance Area (CAA) within MS 914; however the current clearing requirement (prior to finalisation of detailed engineering designs) is approximately 51 ha within this area (proposed Restricted Clearing Area; RCA). The 69 ha is being requested as part of the Proposal to allow for flexibility to accommodate changes to engineering deigns. The majority of vegetation proposed for clearing within the RCA (96% or 49 ha of the total 51 ha) is of units C4 and F2 and not the higher local conservation value vegetation discussed in Section 14.2.2.3. Both of these units proposed to be cleared are associated with the floodplain of Weeli Wolli Creek and not the denser open forests of the creek itself.

Vegetation unit C4 is composed of *Eucalyptus victrix* open woodland over *Acacia citrinoviridis, A. pruinocarpa, Atalaya hemiglauca* low woodland over **Cenchrus ciliaris* tussock grassland and F2 represents floodplain vegetation comprised of *Acacia pruinocarpa, A. citrinoviridis* tall open shrubland over **Cenchrus ciliaris* tussock grassland. Neither of these units contains the Eucalyptus open forests characteristic of the riparian ecosystem at risk described by Kendrick (2003a; 2003b) and additionally they are mapped as being in Poor condition, comprising a tussock grass layer dominated by Buffel grass. A further 851 ha of C4 and 145 ha of F2 vegetation is represented within the RCA outside of the Proposal Area. Clearing of these units is unlikely to affect the integrity of the higher local conservation value vegetation that the RCA aims to protect.

Three vegetation units identified by Rio Tinto (2015a) to be of elevated significance are proposed to be directly affected by the Proposal:

C2/C1 - **Thin strips of vegetation lining the low flow channel of:** *Eucalyptus camaldulensis* subsp. *refulgens* scattered (to open woodland), over low open woodland (to low open forest generally dominated by saplings to young trees) of *Eucalyptus camaldulensis* subsp. *refulgens* and *Melaleuca argentea* (and to a lesser extent *E. victrix*), over scattered tall-shrubs/shrubs of *Melaleuca glomerata*, *Acacia coriacea* subsp. *pendens*, *Atalaya hemiglauca*, and *Melaleuca glomerata* over very open sedgeland of *Cyperus vaginatus* and other mixed sedges often accompanied by fringing strips of *Typha domingensis*. Clearing proposed 0.04 ha, mapped condition Good to Poor.

C2A - *Eucalyptus camaldulensis subsp. refulgens, E. victrix woodland, over Acacia coriacea subsp. Pendens and Atalaya hemiglauca scattered low trees, over Melaleuca glomerata and Acacia citrinoviridis tall open shrubland, over mixed shrubland/low shrubland typically dominated by Corchorus crozophorifolius and Tephrosia sp. Fortescue creeks and outcrops of Cenchrus ciliaris open tussock grassland.* Clearing proposed 0.55 ha, mapped condition Good to Poor.

C2B - *Eucalyptus victrix and E. camaldulensis subsp. refulgens open woodland, over E. victrix scattered low trees, over Acacia citrinoviridis, A. pruinocarpa, and Atalaya hemiglauca tall open shrubland, over Atalaya hemiglauca, Gossypium sturtianum and Corchorus crozophorifolius scattered shrubs over *Cenchrus ciliaris tussock grassland.* Clearing proposed 0.83 ha, mapped condition Poor.

These communities commonly occur along larger creek systems throughout the Hamersley subregion (the C2/C1 community to a lesser extent) and as only 1.43 ha is proposed to be cleared as part of the Proposal the impact is not considered significant at a local or regional scale. Additionally a further 579 ha of the higher significance C1

(including C1/C2-A, C1A, and C1B) and C2 (including C2/C1, C2A, C2Asb, C2B, and C2C) vegetation units within the RCA are not proposed to be cleared. It is also important to note that riparian communities in the vicinity of the Proposal Area have been affected by surplus water discharge into Weeli Wolli Creek from upstream discharge since 2007. The most significant change has been the appearance of *Melaleuca argentea* saplings/young trees which have been sustained by the presence of an unnatural, perennial stream flow (Rio Tinto 2015a). Within the Proposal Area, the C2/C1 community is representative of the key structural and compositional changes which have occurred due to the provision of perennial water flow in the low-flow channel.

Internal ground disturbance procedures will be followed prior to commencing clearing of vegetation (subject to relevant regulatory approvals). The boundaries of vegetation to be cleared will be clearly defined as spatial coordinates in a Global Positioning System, including within earthworks machinery, or in some instances (particularly areas of higher significance) with ground markings (e.g. flagging), thus ensuring that personnel are aware of clearing limits prior to commencement of ground-disturbing activities.

14.3.2 Potential loss of conservation listed flora species

14.3.2.1 Threatened (Declared Rare) Flora

The design of the conceptual layout (**Figure 4**) has been cognisant of the presence of *Lepidium catapycnon* populations in the Proposal Area. *L. catapycnon* was recorded in areas that were originally designated for waste dumps in earlier versions of the conceptual design. However, the Proponent configured the waste dumps to avoid known and recorded populations of *L. catapycnon*. Further, all recorded populations of *L. catapycnon* have currently been designated as 'areas of special protection from ground disturbance' and therefore excised from the ground disturbance footprint.

L. catapycnon is known from a number of locations in the Hamersley Range and extends broadly from Tom Price across to Newman (Biota 2014a). There are over 30 known populations of *L. catapycnon* through this area, including one population in Karijini National Park. The populations recorded within the Proposal Area are within the known range of *L. catapycnon* and do not represent a range extension or edge of range population. Eleven separate populations of *L. catapycnon* have been recorded in the

wider Yandicoogina locality (Biota 2015a), all on hills and slopes. The populations within the Proposal Area are therefore unlikely to be either regionally or locally significant.

There is limited potential for *L. catapycnon* to be indirectly affected by changes to natural hydrological flows and runoff from waste dumps as the waste dumps are all on the downstream side of the recorded populations. Buffers of 50 m have been placed around populations to reduce the risk of accidental impacts from dumping of waste material.

14.3.2.2 Priority flora

Four records (37 individuals) of *Goodenia nuda* (Priority 4) will be impacted by the Proposal. *Goodenia nuda* is associated with clay substrates and has a broad distribution over a range of 500 km throughout the Pilbara bioregion and has been recorded from the broader Yandicoogina locality (190 individuals; Biota 2014a). Rio Tinto records show that *Goodenia nuda* has been recorded at 551 locations during Pilbara surveys, with 5,862 plants. The plant is a small, inconspicuous herb and it is therefore possible it occurs in other similar (floodplain) habitat elsewhere in the wider Yandicoogina locality. The loss of the individuals recorded from the Proposal Area is therefore not considered significant and would not alter the species' conservation status.

14.3.3 Effect of groundwater drawdown and discharge of surplus water on riparian vegetation

14.3.3.1 Existing altered hydrological environment

Riparian vegetation in the vicinity of the Proposal Area has been subject to the effects of groundwater drawdown and discharge of surplus groundwater by existing approved mining activities within the catchments of Marillana Creek since the mid 1990s and Weeli Wolli Creek since the mid 2000s. The presence of a permanent surface expression of discharge water in Weeli Wolli Creek (24-27 km downstream of the Hope Downs 1 discharge outlet) has in some sections of creek resulted in altered vegetation community structure, composition and health of the dominant riparian tree species *Eucalyptus victrix* and *E. camaldulensis* (Mattiske 2014; Rio Tinto 2015a; Eastham 2015). The surface water hydrology of Weeli Wolli Creek has changed from being an ephemeral system experiencing periodic (cyclonic) large flow events followed by extended dry periods to one of permanent surface flow, allowing increased recruitment, increased biomass and the establishment of riparian species (namely obligate phreatophytes such as *Melaleuca argentea*).

14.3.3.2 Drawdown

Groundwater modelling predicts that dewatering associated with the Proposal will lower the water table in the CID by approximately 50 m over two to three years (75 to 85 m bgl), with the water table remaining at that depth for the duration of mining (URS 2015). This drawdown would be below that of pre-mining levels and would translate to deficits in water availability for vegetation in the riparian zone (URS 2015). This will result in the disconnection of the current surface and groundwater systems within the low-flow channel of Weeli Wolli Creek, returning it to its more natural state (URS 2015). Perennial stream flow in the low-flow channel, and opportunities for flooding the adjacent riparian zone remain unchanged as a result of the Proposal (URS 2015). The low-flow channel was assumed to incorporate a 6 m zone that transmits perennial stream flow, and a 20 m corridor either side of this where the vegetation is able to access stream flow or pore water (46 m total corridor; URS 2015).

Groundwater monitoring data indicate that pre-mining depth to water tables within the Proposal Area CID occurred between 12 - 20 m below ground level, suggesting there

would have been low dependency of the vegetation in this area on groundwater, and most plants would have been reliant on soil (pore) water instead (URS 2015). Limited historical water level data exists within the adjacent riparian zone, however historical vegetation data (Integrated Environmental Services 1981) does not identify the presence of obligate phreatophytes (strictly groundwater dependent) species in the vicinity of the Proposal and recent vegetation mapping within this area has identified a predominance of young trees of the only obligate phreatophyte recorded, *Melaleuca argentea* (URS 2015; Rio Tinto 2015a). The vast majority of these trees are most likely to have established relatively recently, following commencement of discharge of surplus water into Weeli Wolli Creek from Hope Downs 1 operations upstream and discharge from Yandi JSE. Mature *Eucalyptus camaldulensis* and *E. victrix* (facultative phreatophytes; URS 2015) present as the dominant overstorey layer would have previously met their ecological water requirements from both soil and groundwater depending on its availability under pre-mining conditions.

Refined riparian vegetation mapping (Rio Tinto 2015a) revealed that three vegetation units contained a co-dominant component of *M. argentea* in the vicinity of the Proposal Area. Of these three units the C1B community was determined to contain *M. argentea* populations possessing a structure and size class range indicative of a community likely to have existed prior to discharge. Three small areas of this vegetation occupying a combined 420 m stretch of creekline (6.3 ha) were mapped in the Proposal Area, near the southern section of the proposed pit. The remaining two units (C1/C2A and C2/C1) were considered to contain *M. argentea* populations that had only established due to the increase in surface water availability as a result of Hope Downs 1 discharge. *M. argentea* populations have been interpreted by Rio Tinto (2015a) to be augmented by the presence of surplus discharge within Weeli Wolli Creek since late 2006 and the stem diameters (= size/age class) of the main population are considered representative of young recruits (ranging from 5-10 cm, with scattered individuals with stem diameters of 10-20 cm; Rio Tinto 2015a, see **Plate 3**).

Source: Rio Tinto (2015a)

Plate 3: Stands of young *Melaleuca argentea* fringing the low-flow channel within the Proposal Area and likely to have established since the commencement of surface water discharge at Hope Downs 1, Weeli Wolli Creek

As groundwater levels within Weeli Wolli Creek are lowered in response to the dewatering required for the Proposal, individuals of *M. argentea* outside the low-flow channel and immediate banks (a strip of approximately 10-20m either side of the 6m low-flow channel zone) are likely to lose condition and die unless their ecological water requirements are met through rainfall/cyclone events (to supplement the pore water radiating out from the low-flow channel; **Table 21**). The majority of the *M. argentea* populations interpreted to be present pre-discharge (associated with the C1B community) are contained within this zone and are unlikely to be impacted by dewatering. The *M. argentea* populations which extend outside this zone, and which are therefore most likely to see impact (the C1/C2A and C2/C1 communities), are those interpreted as not being present pre-discharge. **Figure 55** shows vegetation (including *Melaleuca* communities) in relation to high and low-flow channels adjacent to the mine pit and levee structures. Mine pits have been successfully developed next to riparian vegetation communities in the existing Yandi Operations; **Plate 4** shows a photo of the riparian vegetation associated with Marillana Creek adjacent to the existing JSW pit wall (~60 m bgl) in October 2015.

Despite the potential for the younger, post discharge C1/C2A and C2/C1 communities to experience mortality within *M. argentea* populations, only a small percentage of these communities are likely to occur within the impact zone (beyond the banks adjacent to the low-flow channel; **Figure 55**). Therefore, as the majority of the *M. argentea* populations most likely to experience decline or death as a result of drawdown are considered to have been established and augmented by discharge from other approved mining activities in the catchment, an impact to these populations brought about by a return to a more 'natural' hydrological regime is not considered significant and hence no active mitigation is proposed.

* If present

Adapted from URS (2015)

Eucalyptus camaldulensis and *E. victrix* woodland communities are considered to be facultative phreatophytes (relying on soil and groundwater to differing degrees depending on their availability and the local setting in which individual plants have become established). They are also likely to be impacted by groundwater drawdown associated with the Proposal if they have become dependent on surplus water associated with Hope Downs 1. The magnitude of this impact will depend on the rate of drawdown, the extent and frequency of surface water inputs and the ability of individual trees to access stored soil water as the groundwater declines. Monitoring of riparian eucalypts at Hope Downs 1 suggests the dominant riparian eucalypt species are resilient to drawdown if surface water (irrigation, rainfall, stream flow and overland flow) availability remains unaffected (Eastham 2015). Impacts are most likely to be seen once the water table drops below 5 m (the observed range of fluctuation after recharge events) and will be dependent on differences in adaptability of stands of vegetation to respond to sources and supply of water (URS 2015).

While flood regimes will be maintained in the creekline, overland flow within the floodplain zone will be diminished in an 8 km section adjacent to Weeli Wolli Creek where drainage tributaries from the east are being temporarily diverted around the Proposal mining operation via a diversion drain (that re-joins Weeli Wolli Creek further downstream). Modelling suggests that the baseline contribution of this surface flow amounts to approximately 2.5% of the local Weeli Wolli Creek catchment in the Proposal Area. Surface flow will be maintained on the western side of the creek and within the creek itself. Trees on the eastern side of Weeli Wolli Creek may experience increased drought stress as groundwater levels drop below pre-mining levels of 12 - 20 m with the reduction of overland surface water inputs. However, regular creekline flood events are more effective at supplying surface water inputs to this zone.

Figure 56 presents the risk (using the methodology outlined in URS, 2015) to the relevant riparian woodland communities of declining water availability within the riparian zone (based on 2019 drawdown predictions) and shows that an approximately 3 km stretch of vegetation is at medium – high risk and approximately 2.8 km at high risk of decline due to reduced water availability. A further 5 km is at medium risk. Within these stretches of creek it is expected that there will be deaths of *M. argentea* where it is present beyond the low-flow channel and immediately adjacent banks. Additionally, within these stretches of creek, it is expected that there will be decline of *E. camaldulensis* especially during periods of drought, with some deaths possible (beyond that typically expected to occur under natural climatic variability). *E. victrix* will decline in condition, again particularly during periods of drought where soil pore water is not being replenished as a result of rainfall and stream flow events.

The current health of some eucalypts due to waterlogging associated with surplus water discharge in Weeli Wolli Creek combined with additional stress of groundwater drawdown may cause rapid decline of some trees in this section of creek due to cumulative stresses (Eastham 2015). Similarly trees with enhanced canopies due to surplus water may be sensitive to groundwater decline; these localised impacts will depend on the position of individual trees in relation to the current and predicted water table depth. Areas of the creekline vegetation which have more recently established in areas of artificially elevated water table levels are generally immature and dominated by eucalypt and Melaleuca saplings and young individuals. These populations are expected to show significant decline and death as water levels are drawn down.

The dewatering activities associated with the Proposal are likely to produce losses of individual trees within the Weeli Wolli Creek riparian zone. It is expected that the potential for losses is greatest in those areas currently experiencing the greatest access to soil moisture, such as within and adjacent to the low-flow channel. However, the current perennial flow will be maintained within the low-flow channel of Weeli Wolli Creek in the vicinity of the Proposal by the continuation of discharge from Hope Downs 1 and is expected to circumvent a significant proportion of this potential for tree death. Recruitment within and adjacent to the perennial flow zone is likely to remain elevated for the duration of discharge and during wetter periods (cyclone/flood events), which may assist with offset the remaining losses which may be attributed to dewatering activities).

It is expected that the creek system will revert to a system similar to its ephemeral pre-mining state without active restoration through natural process such as cyclones and resultant flood events which provide optimum conditions for the establishment and survival of new propagules. Landscape-scale ecosystem processes such as nutrient cycling, flooding, fire and recruitment will remain unaffected by the Proposal.

14.3.3.3 Discharge

Approximately 50 GL/y of surplus water is proposed to be discharged from a new discharge outlet, adjacent to the existing discharge outlet (DO9) as a result of developing the Proposal, with the total discharge from the Revised Proposal being approximately 78 GL/y. Surface water modelling indicates that the alluvial aquifer and fractured Brockman Iron Formation bedrock in the downstream reaches of Weeli Wolli Creek could accommodate the maximum predicted discharge rate at DO9 without exceeding MS 914 condition 6-3, which limits the perennial surface water wetting front to 17 km downstream from the Marillana and Weeli Wolli Creek confluence.

Experience from the existing Yandi Operations and work undertaken by Eastham (2015) suggests that prolonged surface water discharge could result in:

- Artificial recruitment of riparian vegetation
- Increasing the leaf area index and biomass of vegetation exposed to higher water availability
- Decreasing biomass and waterlogging stress in areas exposed to prolonged soil saturation, resulting in tree health decline or death
- Drought stress in samplings unable to re-adjust to the withdrawal of artificial water supply on cessation of discharge
- Changes in vegetation structure including an enhanced potential for weed invasion

Discharge increases water availability in the unsaturated zone of the downstream creek bed alluvium, and can result in persistent waterlogged conditions in the soil profile within channel sections. The potential effects include tree health decline in established trees due to prolonged saturation of root systems, enhanced recruitment of new trees and the establishment of waterlogging tolerant species including sedges and rushes.

Monitoring of responses in eucalypt foliage cover to discharges into Weeli Wolli Creek indicate variable impacts of discharge on tree health. The Proponent's riparian vegetation health monitoring program suggests that individual tree responses range from no discernible impact to severe stress or tree death in extreme cases. Foliage cover has

displayed negative responses to discharge rates particularly at higher volumes at the existing Yandi Operations, with the greater impact on foliage cover related to shallower (artificially elevated) water tables in the alluvium (Eastham 2015).

Relationships between foliage cover and depth to water showed statistical reductions in foliage cover with rising water levels at some sites in Weeli Wolli Creek adjacent to the proposed pit, however, the response of individual trees at a site was not uniform, and at most of the sites there were some trees that increased their foliage cover. This finding indicates that a proportion of trees at each site likely occupy an ecological niche which has allowed them to maintain or increase their canopy (Eastham 2015). Trees occurring at higher elevations tended to maintain or increase foliage cover at some, but not all, sites.

Localised impacts around the discharge outlet and within the low-flow channel of the downstream reaches of Marillana Creek are most likely to experience waterlogging, which may result in declining health or death of some species, particularly *E. victrix,* and particularly if located within lower elevations of the creek bed such as directly within the low-flow or on lower elevations of the incised channel such as the scoured bed zones fringing the low-flow channel. Further downstream in Weeli Wolli Creek, the impacts will be largely restricted to the low-flow channel and lower scoured bed sections of the incised channel, and are likely to reduce with distance further downstream as surplus water infiltrates into the alluvial aquifer. Impacts will also include increased vegetation biomass as a result of increased vigour and associated recruitment by riparian species.

Hydrological modelling and infiltration tests predict that by maintaining the additional discharge from DO9, the surplus water wetting front will remain within the 17km footprint approved under MS914, and hence the impact footprint will be constrained to this section of the creekline. Given the wetting front is predicted to be within existing approved limits, it is considered that there will be negligible impacts on Fortescue Marsh due to a minor decrease in catchment area. However, if the discharge location were to be shifted further downstream, there is risk of extending the wetting footprint within Weeli Wolli Creek and towards the Fortescue Marsh.

14.3.3.4 Management of riparian systems

Drawdown can potentially reduce the availably of groundwater to species able to access this water source. Most Pilbara flora do not utilise groundwater but use stored soil moisture (derived from surface inputs) to meet their water use requirements. Riparian systems of the Pilbara bioregion are subjected to extremely seasonal and variable hydrologic regimes, in which stream flow typically occurs following cyclonic rainfall events. In the Proposal Area, the hydrological connection along Weeli Wolli Creek will be maintained throughout the development of the Proposal, which will allow the natural flood flows to persist and replenish the riparian system. Concurrently, discharge flows from Hope Downs 1 are modelled to continue to persist within the low-flow channel adjacent to the proposed PBS pit, which will assist in managing localised impacts from drawdown as a result of implementing the Proposal. As a result, additional long term supplementary irrigation of Weeli Wolli Creek adjacent to the Proposal is considered limited in its potential effectiveness to further mitigate potential groundwater drawdown impacts on the riparian system.

Historically, the Proponent and other mining companies in the region have sought to manage surplus water by discharging directly into creeklines. This approach has met with varying levels of success, and it can be argued that the approach has also generated

alternate ecosystem impacts, for example artificially generating permanent pools, waterlogging of existing healthy systems; and artificially enhancing biomass and recruitment. Permanent supplementary irrigation via discharge as an approach to negate the effects of groundwater drawdown during mining could result in the continuation of surface water flows along the low-flow channel of Weeli Wolli Creek and potentially maintain an artificially augmented system, which may not necessarily effectively mitigate the potential impacts on the riparian systems.

Creek ecosystem health observations at existing mining operations in the area suggest that local environmental conditions other than the groundwater level (i.e. topographic position, soil type and surface water runoff) can influence local soil water availability and thus offset the degree of impact experienced by individual vegetation communities due to dewatering. Consequently, managing the impact of dewatering on the environment through discharge spurs would is not proposed at this stage.

To enable the most effective management of the riparian system for the Proposal, a detailed study is being undertaken to further understand plant-water requirements, and refine appropriate management measures. Management measures may include forms of temporary irrigation within targeted mature parts of the riparian system, with the aim to allow the system to adapt and gradually return to the lower pre-mining water levels that are predicted to persist following cessation of mining and discharge in the area. It is considered that this approach will avoid unnecessarily maintaining younger (artificial) parts of the system by ongoing irrigation, which inevitably would not survive after cessation of mining and discharge. This approach aims to align with the adaptive management framework and includes:

- investigations to resolve local environmental (baseline) conditions;
- ongoing monitoring and investigations, until a causative link between dewatering drawdown and changes in ecosystem health can be determined; and
- design of mitigation solution options, targeted to deliver localised outcomes, to enable timely implementation if mining related water availability is determined to contribute to a significant decline in ecosystem health.

This approach was successfully applied for the management of potential impacts to the Mt Bruce Flats PEC as part of the Marandoo below water table operation; where, as a consequence of the management approach, it was demonstrated that water availability in the woodland was not linked to groundwater elevation and irrigation of the PEC was not required to maintain the persistence of the long term community.

The proposed program to determine appropriate management would include:

1. Investigative study to be undertaken as part of the Proposal Feasibility Study.

- Refined hydrogeological sampling and geochemical analysis.
- Installation of long term water monitoring bores at tree health monitoring sites and areas identified as higher risk.
- In situ neutron probe measurements to determine spatial and in situ variability in soil water content.
- Refined definition of baseline conditions.

- Riparian zone environmental risk assessment.

2. Development of mitigation solutions based on the findings of the investigation with a detailed plan for implementation should mitigation be necessary. This may include options for targeted irrigation in mature riparian areas considered to be of high local value and at high risk of impact due to groundwater drawdown.

3. Continuation and refinement of the existing operational monitoring network including:

- Ecosystem health.
- Groundwater levels.
- Ecological water availability.

14.3.4 Introduction and/or spread of weeds

Weeds can spread into natural environments by many vectors, including wind, water, and the movement of soils, people, vehicles, machinery and fauna (including native animals and livestock). The most relevant of these in relation to the Proposal is vehicle and earth movements, and discharge activities. Weeds are often able to rapidly invade locations subject to disturbance, land clearing and/or altered fire regimes, and altered hydrological regimes. This can result in smothering and replacement of native plants and domination and simplification of natural ecosystems.

The most common areas within the Proposal in which weeds were recorded were creeklines and floodplains. The most commonly recorded weeds were **Cenchrus ciliaris* and **C. setiger* which in many areas formed a continuous tussock grassland community resulting in low numbers of native understorey species along the banks of Weeli Wolli and Marillana Creeks. These species have the potential to spread further with cattle activity, water movement and clearing (Biota 2014a). Despite this fact it is noted that within the key habitats available on Marillana and Weeli Wolli Creeks, only a small areal extent remains un-colonised by these species.

Limited clearing will occur in these communities as part of the Proposal, however, weed management measures will be implemented in accordance with Yandicoogina Weed Action Plan **(Appendix 4**) to minimise the risk of weed introduction and spread. Some of the key actions that will be implemented are:

- Vehicle and equipment hygiene practices.
- Weed monitoring.
- Periodic weed control.

14.3.5 Effects of dust

Dust deposition on vegetation from the Proposal is likely to be restricted to immediately adjacent vegetation and will be mitigated by periodic high rainfall events, which would remove built-up materials on leaves. As per much of the vegetation in the Pilbara, native vegetation in the area is also expected to be reasonably tolerant to dust deposition and would not be at risk of significant physiological impacts. Research conducted at West Angelas mine site, 60 km to the west of the Proposal, showed no detectable negative impact of dust on plant function for a number of different leaf types (Butler 2009). Background dust levels in the vicinity of the Proposal Area are high relative to urban areas in the south west of WA. Located in the arid Pilbara region, dust lift off occurs naturally from sparsely vegetated landscapes.

Dust deposition on vegetation has not been identified as a key environmental issue in the wider Yandicoogina locality and to date management has been as per standard Rio Tinto practices. The ore being mined as part of the Proposal is below water table and as such has a high moisture content. Additionally, there is sufficient surplus water for dust suppression if required.

The Proposal will be managed in accordance with the Yandi Operations MMP and the E12 Standard (Air Quality Protection), which includes the following management measures:

- using existing tracks where possible;

- implementing speed limits to reduce dust generation;
- minimising clearing and conducting rehabilitation; and
- water application (heavily trafficked areas, stockpiles etc.).

14.4 Cumulative impacts

14.4.1 Cumulative impacts to riparian vegetation

A preliminary assessment of cumulative impacts to potentially groundwater dependent riparian vegetation (herein defined as vegetation supporting *Eucalyptus camaldulensis* and/or *E. victrix* and/or *Melaleuca argentea*) was conducted based on a review of the potential impacts of the Proposal (Rio Tinto), the existing Yandi Operations and 19 other projects identified as being potentially relevant based on their location in the Upper Fortescue River Catchment (three Rio Tinto and 17 third party projects; **Table 22**).

Of the projects reviewed, insufficient information was available in the documentation reviewed for some projects to enable their inclusion in the cumulative impact assessment (**Table 22**). Further, it was not possible based on the information available at the time of the review to determine the extent of overlap (if any) between areas of groundwater dependent vegetation mapped for different projects.

Of the approximately 14,946 ha of potentially groundwater dependent riparian vegetation mapped for the projects considered (including the Proposal), up to 2,159 ha will be disturbed (including areas cleared and areas subject to potentially significant impacts due to groundwater drawdown), which represents approximately 14% of the mapped extent (**Table 22**).

Table 22: Assessment of potential cumulative impacts to riparian vegetation in the Upper Fortescue River Catchment

Project	Baseline	Potential impact to riparian vegetation	Reference

14.5 Key management actions

Flora and vegetation values in the Proposal Area will be protected through implementation of measures in accordance with the Yandicoogina Weed Action Plan; the E11 Standard: Water Quality Protection; the E14 Standard: Land Disturbance and Rehabilitation Control; the Yandicoogina Closure Plan; and the MMP which includes Water Discharge Management and Monitoring, as well as Vegetation and Groundwater Dependent Ecosystems Management and Monitoring. Key management measures include:

- Ongoing monitoring of the health and cover of riparian vegetation within the Revised Proposal Development Envelope and drawdown and discharge footprints using a number of techniques, along with their associated trigger and threshold levels including:
    - DCP monitoring; which measures canopy foliage density of mature riparian eucalypts. Foliage density in eucalypts is correlated with plant available water in accordance with the principle of ecological optimality (O'Grady et al. 2011; Ellis & Hatton 2008); and is regarded as a reliable indicator of water related stressors such as drought;

- Digital Multi-Spectral Imagery (DMSI) remote sensing of riparian vegetation; which provides a quantitative measure of change in vegetation condition based on a multiple spectral indexes;
- Riparian vegetation monitoring; involving direct measurement of vegetation attributes (*e.g.* structure and composition) in transects within the riparian vegetation communities;

- Ongoing monitoring and management of weeds, including established baseline and reference sites; implementing vehicle hygiene procedures; and targeted control.
- Maintaining a Clearing Restricted Area around the Marillana and Weeli Wolli Creeklines to limit clearing within riparian vegetation zones.
- Limiting the pit encroachment into edge of floodplain within less significant shrubland communities of the riparian zone and avoiding riparian woodland vegetation.
- Maintaining major creekline floodflows and minimising erosion on the creeklines by limiting the disturbance within the creeklines, and undertaking surface water modelling and geomorphological assessments on infrastructure required within the creeklines.
- Maintaining creekline discharge upstream of the Proposal to partially negate the potential impacts of groundwater drawdown.
- Monitoring surface water discharge extent within Weeli Wolli Creek.
- Monitoring discharge water quality, including pH, TDS, TSS and a range of analytes.
- Monitoring groundwater levels within monitoring bores to establish causative links between groundwater levels and tree health.
- Weed monitoring and management.

Disturbed areas will be rehabilitated following completion of mining. Refer to Section 17 for further details regarding rehabilitation and closure.

14.5.1 Status of existing Yandi Operations management

The ESD prepared by the EPA required provision of information on the current status and outcomes of the riparian vegetation management actions required by MS 914 Condition 7 – Riparian Vegetation, and Condition 8 – Weeds. A summary, based on the 2014 Annual Compliance Assessment Report, is outlined in the sections below.

14.5.1.1 Riparian vegetation

The Yandicoogina Surface Water Discharge and Groundwater Dependent Ecosystems Monitoring and Management Plan has been prepared and approved by OEPA. The outcome-based conditions identified in regard to riparian vegetation have been met, specifically:

- Water abstraction did not cause clearing or loss of vegetation or groundwater dependent ecosystems outside of prescribed zones.
- Dewatering discharge did not cause clearing or loss of vegetation or groundwater dependent ecosystems outside of prescribed zones.

- No irreversible impact occurred to riparian vegetation or groundwater dependent ecosystems within prescribed zones.

Monitoring and investigations using vegetation transects, visual qualitative assessments and a review of correlative environmental parameters confirmed that trigger levels for 'no impact' and 'no irreversible impact' had not been exceeded and therefore no contingency actions have been required to be implemented.

Overall, the Digital Canopy Photography and transect monitoring indicated some areas of riparian vegetation that were showing signs of stress (including foliage cover less than baseline data) while other areas showed increased foliage cover. The results from the DMSI align with DCP and vegetation transect results, showing variation in condition across both Marillana and Weeli Wolli Creeks. Some individual trees around the low-flow channels show reduced condition when compared to baseline, however, the overall green-ness indicates high recruitment rates of eucalypts and other strata.

14.5.1.2 Weeds

Weed monitoring sites have been developed in consultation with Parks and Wildlife and accepted by OEPA. Monitoring undertaken in 2014 showed that weed coverage in all monitored areas was lower than baseline cover.

14.6 Predicted outcome

A total of up to 1,800 ha of flora and vegetation will be required to be cleared for the Proposal. A range of measures have been or will be implemented to reduce potential impacts to flora and vegetation values (**Table 23**).

Table 23: **Mitigation hierarchy for flora and vegetation values**

Mitigation measure	Description
Avoidance	Re-designed waste rock dumps to avoid recorded *L. catapycnon* populations.
Minimisation	Clearing will be minimised to that required for safe construction and operation. Optimising waste dump designs and mine plan to minimise overall waste dump ex-pit clearing. Maintaining a Clearing Restricted Area which limits clearing of riparian vegetation, as far as practicable, to that required for key infrastructure to enable development of the Proposal (such as creek crossing points). Clearing of significant riparian vegetation communities containing mature Melaleuca communities avoided. Pit encroachment into edge of floodplain is located within less significant shrubland communities of the riparian zone. Limited physical disturbance to the low-flow channel (for infrastructure crossings only). Low flows in Weeli Wolli Creek will be maintained to support phreatophytic vegetation. Discharge location and wetting front extent designed to limit wetting front extent beyond existing approved 17km limit from the Marillana – Weeli Wolli confluence.
Rehabilitation	Disturbed areas will be rehabilitated using local native vegetation species, consistent with the Yandicoogina Closure Plan. Key functional creek elements retained (e.g. flood pathways, vegetation seed bank) to support natural rehabilitation upon closure.

After the mitigation hierarchy has been applied, it is expected that the Proposal will result in the following residual outcomes in relation to flora and vegetation:

- Clearing of up to 1,800 ha flora and vegetation (including 69 ha riparian zone vegetation).
- Stress and loss of some riparian vegetation associated with dewatering activities (drawdown), particularly more groundwater dependant vegetation and younger recruitment/augmented areas of riparian vegetation sustained by pre-existing discharge, with the vegetation expected to return to a more 'natural' state (i.e. pre-mining).
- Loss of some riparian vegetation associated with surplus water discharge, particularly waterlogging affects and the establishment of waterlogging tolerant species including sedges and rushes, though overall impacts will be limited to the currently approved footprint limit within MS 914 (17 km downstream from confluence of Marillana and Weeli Wolli Creeks).
- No loss of known and recorded individuals of *Lepidium catapycnon* (Hamersley Lepidium); redesign of the waste dumps has avoided recorded individuals and they have been designated 'areas of special protection from ground disturbance' and therefore excluded from the ground disturbance footprint.
- Removal of some individuals of Priority 4 flora species (*Goodenia nuda*), though it is recorded throughout the Pilbara and it is considered that this will not alter the species' conservation status.
- Rehabilitation of areas disturbed by the Proposal, consistent with the draft Yandicoogina Closure Plan.

Consistent with current guidelines and EPA approaches, the clearing of up to 1,731 ha of native vegetation in Good to Excellent condition and 69 ha riparian zone vegetation[4] within the Proposal Area will be offset as part of the Proposal (Section 18).

[4] For the purposes of the offset calculation, riparian zone vegetation is classified as vegetation units within the riparian zone comprising C-coded and F2 coded vegetation located within the RCA.

15. Terrestrial fauna

15.1 Key statutory requirements, environmental policy and guidance

15.1.1 EPA objective

The EPA has applied the following objective for the Proposal to its assessment of terrestrial vertebrate and short range endemic invertebrate fauna:

"To maintain representation, diversity, viability and ecological function at the species, population and assemblage level."

15.1.2 Regulatory framework

The following legislation is relevant to the Proposal with respect to the protection of terrestrial fauna values and the above EPA objective:

- *Wildlife Conservation Act 1950* (WA).
- *Conservation and Land Management Act 1984* (WA).
- *Environmental Protection Act 1986* (WA).
- *Environment Protection and Biodiversity Conservation Act 1999* (Commonwealth).

15.1.3 Relevant guidelines and policy

The following guidelines and international agreements are relevant to the Proposal with respect to the protection of terrestrial vertebrate, short range endemic invertebrate and aquatic fauna and the above EPA objective:

- EPA Position Statement No. 3: Terrestrial Biological Surveys as an Element of Biodiversity Protection (EPA 2002).
- EPA Guidance Statement No. 20: Sampling of Short Range Endemic Invertebrate Fauna for Environmental Impact Assessment in WA (EPA 2009a).
- EPA Guidance Statement No. 56: Terrestrial Fauna Surveys for Environmental Impact Assessment in WA (EPA 2004d).
- Technical Guide - Terrestrial Vertebrate Fauna Surveys for Environmental Impact Assessment (EPA and DEC 2010).
- Survey Guidelines for Australia's Threatened Bats (DEWHA 2010).
- Survey Guidelines for Australia's Threatened Mammals (DSEWPaC 2011a).
- Survey Guidelines for Australia's Threatened Reptiles (DSEWPaC 2011b).
- Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC/ARMCANZ 2000).
- Pilbara Water in Mining Guideline Report No.34 (DoW 2009).
- Japan-Australia (JAMBA), China-Australia (CAMBA) and Republic of Korea-Australia (ROKAMBA) Migratory Bird Agreements.

- The Convention on the Conservation of Migratory Species and Wild Animals (also known as the Bonn Convention).

15.2 Description of terrestrial vertebrate fauna

15.2.1 Terrestrial fauna surveys

There have been five previous vertebrate fauna and invertebrate SRE surveys overlapping or conducted in the Proposal Area (**Table 24** and **Figure 57**; surveys have been given codes for ease of recognition):

- Yandi Expansion Project - Conservation Significant Vegetation, Flora, Fauna and Fauna Habitat Assessment (JSE; Biota 2005).
- Yandicoogina Targeted Northern Quoll Survey (YNQ; Biota 2009).
- Yandicoogina Expansion Billiard Deposit Fauna Survey (BIL; Biota 2011).
- Pocket and Billiards South Level 2 Seasonal Fauna Survey (PBS; Biota 2014c, 2014e).
- Yandi Billiards Targeted Northern Quoll Survey (YBNQ; Biota 2014d).

Sampling methodology differed among the surveys, depending on the target fauna group. However, surveys typically included the following sampling methods:

- Systematic sampling for non-volant mammals, reptiles, amphibians and SRE fauna via pitfall and funnel trapping grids and medium and large Elliott trap transects.
- Systematic volant mammal (bat) sampling via harp nets.
- Systematic avifauna surveys.

A range of non-systematic techniques were also used to identify animals not commonly recorded through trapping. These techniques included:

- Searching of specific habitats (targeted surveys).
- Identification of road kills and other animal remains.
- Opportunistic sightings and records.
- Secondary signs including tracks, scats and diggings.
- Motion camera trapping.
- Nocturnal searches.
- Echolocation call recorders such as Anabat SD2 and Song Meter SM2 for bat sampling.
- Audio recording for night birds and amphibian calls using the Song Meter SM2.

The location of systematic and non-systematic trapping sites within the Proposal Area is shown in **Figure 58**.

The description of fauna values has been adapted from the Biota survey reports (2005, 2009, 2011, 2014c, 2014d, 2014e) unless otherwise stated. Biota desktop reports (2010, 2013, 2014f, 2015b) have also been referenced.

Geospatial Information and Mapping

15.2.2 Terrestrial fauna habitats

Five fauna habitats were identified in the Proposal Area by Biota (2014c). These habitats were based on a combination of larger landform patterns (floodplains, hills etc.) and smaller landform elements (breakaways, slopes etc.), on the basis that fauna utilise many components of a landform, and are not specific to a certain element. Fauna habitats are described in **Table 25** shown in **Figure 59** and consist of:

- Alluvial Plain (Flood Plain).
- Mulga woodland.
- Hilltops and Slopes.
- Pediment Slope.
- Major Drainage Line.

Disturbed areas within the Proposal Area were also mapped.

Table 25: Landforms and descriptions of fauna habitats mapped within the Proposal Area

Landform Pattern	Fauna Habitat	Description	Current Area within the Proposal Area (ha)
Flats	Alluvial Plain (Flood Plain)	An area of land adjacent to a drainage line that stretches from the banks of its channel to the base of the enclosing valley walls. It experiences flooding during periods of high discharge but does not experience a strong current.	402
Flats	Mulga Woodland	Mulga woodlands in Proposal Area occur on areas of alluvial plain. They are delineated as a discrete fauna habitat because they support a distinct fauna assemblage not present in other habitats within the Proposal Area.	111
Hilltops and Slopes	Hilltops and Slopes	Hilltops and slopes make up much of the Proposal Area and consist of a number of landform elements, notably (from highest to lowest elevation): Crests, Free Faces, Breakaways (not always present), Transitional Slopes and Foot Slopes.	1,434
Hilltops and Slopes	Pediment Slope	The large, gently inclined lower slopes below hills underlain by bedrock at varying depths. Pediments in the Proposal Area vary in width and exhibit sharp breaks of slope between the pediment and the steeper hillside above them. Water passes across the pediment by laminar sheet flow, but if this is disturbed, the flow becomes turbulent and gullies develop.	1,542
Drainage	Major Drainage Line	A linear, sinuous open depression forming the floor of the major drainage channel (Weeli Wolli Creek) that is eroded or aggraded (built-up) by stream flow. In the Proposal Area this supports taller eucalypts, dense shrublands and reedbeds around water pools that are semi-permanent due to upstream mine dewatering.	859
Disturbed		Areas of disturbed land originating from clearing.	138

15.2.3 Terrestrial fauna occurrence

Of the 249 vertebrate fauna species that could potentially occur in the vicinity of the Proposal Area (based on a desktop review of database searches and the results of previous surveys in the general locality; Biota 2013), 147 species have been recorded within the Proposal Area (Biota 2015b, 2014c). The following numbers of species were recorded from each vertebrate fauna group:

- 10 native non-volant mammals;
- 3 introduced non-volant mammals;
- 5 volant mammals (bats);
- 78 birds;
- 48 reptiles; and
- 3 amphibians.

15.2.4 Terrestrial vertebrate fauna species of conservation significance

Six conservation listed species have been recorded in the Proposal Area, including four species listed under the EPBC Act and WC Act and one species listed in the Parks and Wildlife Priority Fauna List (**Table 26, Figure 60** and **Figure 61**). An additional species, the Chocolate Wattled Bat (*Chalinolobus morio*), while currently not conservation listed under Commonwealth or State legislation, is of regional significance as it is geographically restricted within the Pilbara region to Weeli Wolli Creek and Marillana Creek (Biota 2014c).

The locations of the records of these species within the Proposal Area are shown in **Figure 61**.

Table 26: Number of individuals of conservation significant terrestrial vertebrate fauna species found within the Proposal Area

Common Name	Species Name	Conservation Status		Number of individuals recorded/survey	
		State	Commonwealth	BIL	PBS
Pilbara Olive Python	*Liasis olivaceus barroni*	Schedule 1	Vulnerable	0	1
Fork-tailed Swift	*Apus pacificus*	Schedule 3	Migratory	0	9
Eastern Great Egret	*Ardea modesta*	Schedule 3	Migratory	0	1
Rainbow Bee-eater	*Merops ornatus*	Schedule 3	Migratory	21	42
Western Pebble-mound Mouse	*Pseudomys chapmani*	Priority 4	-	1	0 (9 mounds)
Chocolate Wattled Bat	*Chalinolobus morio*	-	-	0	1

Note: Survey codes are explained in Table 24.

Source: Biota (2015b). An additional seven Western Pebble-mound Mouse mound records were recorded in the Proposal Area opportunistically during a Rare Flora survey in 2014.

NatureMap, EPBC Act Protected Matters Search Tool (PMST) and Atlas of Living Australia (ALA), species distributions and habitat preference suggest a further 17 conservation significant species may potentially occur.

Species identified through these means have been further assessed to determine their likelihood of occurrence within the Proposal Area (**Table 27**). The assessment took into account results of field surveys undertaken within the Proposal Area and the wider Revised Proposal Development Envelope, along with existing data for the broader region; the habitat requirements and known distribution of each species and professional judgement from technical report authors. The likelihood of occurrence has been determined as follows (Biota 2014c):

Recorded: The species has been recorded in the Proposal Area during recent or previous surveys.

Likely: The species has a high probability of occurring in the Proposal Area based on records in the Revised Proposal Development Envelope or within 20 km to the Proposal Area. The specific or suitable habitat is present in the Proposal Area.

Has potential: The species has a medium probability of occurring in the Proposal Area based on existing records within 40 km. However, depending on the species habitat preferences:

- a small amount of the specific habitat is present in the Proposal Area;
- only some suitable general habitat is present; or
- suitable habitat is present, but the species is recorded infrequently in the locality.

Unlikely: The species has a low to very low probability of occurring in the Proposal Area based on its known distribution, habitat preference and/or historical records. Depending on the species habitat preferences:

- the specific habitat is absent from the Proposal Area;
- suitable habitat is present, however there are no existing records of the species from the locality; or
- some suitable habitat is present, however the species is recorded very infrequently in the locality.

Would not occur: The species would not occur in the Proposal Area. This is due to its restricted range, or absence of specific habitat that the species is linked to strongly.

Based on the likelihood of occurrence, the following species are considered likely to occur in the Proposal Area:

- Pilbara Leaf-nosed Bat, *Rhinonicteris aurantius* (Vulnerable, Schedule 1).
- Common Greenshank, *Tringa nebularia* (Migratory, Schedule 3).
- Peregrine Falcon, *Falco peregrinus* (Schedule 4).
- Blind Snake, *Anilios ganei* (Priority 1).
- Pilbara Barking Gecko, *Underwoodisaurus seorsus* (Priority 2).
- Brush-tailed Mulgara, *Dasycercus blythi* (Priority 4).

- Ghost Bat, *Macroderma gigas* (Priority 4).

The following species were considered to have potential to occur:

- Northern Quoll, *Dasyurus hallucatus* (Endangered, Schedule 1).
- Grey Falcon, *Falco hypoleucos* (Schedule 1).
- Australian Painted Snipe, *Rostratula australis* (Schedule 1).
- Cattle Egret, *Ardea ibis* (Migratory, Schedule 3).

The following species were considered to be unlikely to occur:

- Night Parrot, *Pezoporus occidentalis* (Endangered, Schedule 1).
- Bilby, *Macrotis lagotis* (Vulnerable, Schedule 1).
- Oriental Plover, *Charadrius veredus* (Migratory, Schedule 3).
- Long-tailed Dunnart, *Sminthopsis longicaudata* (Priority 4).
- Short-tailed Mouse, *Leggadina lakedownensis* (Priority 4).

One species was considered to not occur in the Proposal Area:

- Northern Marsupial Mole, *Notoryctes caurinus* (Endangered, Schedule 1).

There is a history of taxonomic confusion regarding the genus *Dasycercus*. The most recent analysis has resulted in the recognition of two species in Australia, the Crest-tailed Mulgara (*D. cristicauda*) and the Brush-tailed Mulgara (*D. blythi*). Due to habitat preferences and distribution of Brush-tailed Mulgara, it was assumed that the burrows recorded in close proximity to the Proposal Area belonged to this species; however, the identification has yet to be confirmed due to a lack of direct captures (Biota 2014c). For the purposes of this PER, it has been assumed that Brush-tailed Mulgara is the species present in the vicinity of the Proposal Area.

Adapted from Biota (2014c)

15.3 Description of short range endemic invertebrate fauna

Short range endemic (SRE) species are those that display naturally restricted distributions (less than 10,000 km^2) and are therefore at greater risk of population extinctions than more widely distributed taxa (EPA 2009a). Taxa that exhibit short range endemism are generally characterised by poor dispersal, low growth rates and low fecundity. They are commonly reliant on habitat types that are discontinuous, and are often confined to fragmented 'refugial' habitats, having persisted from a time when moist conditions were more evenly distributed throughout the Australian landscape (Harvey 2002). SRE invertebrate species are historically poorly studied and, in many cases, lack formal descriptions or adequate taxonomic frameworks. Extensive, reliable taxonomic evaluations of many orders have only relatively recently commenced, and the availability of literature relevant to SREs is thus relatively scarce (Harvey 2002).

SRE invertebrate species are a relevant factor to consider during EIA, as their restricted distribution leaves them vulnerable to changes in conservation due to habitat loss (EPA 2009a).

Consultation was undertaken with the WA Museum to identify specific invertebrate groups to target in the area as those most likely to support SRE fauna (Biota 2015b). These comprised:

- Mygalomorphae (trapdoor spiders).
- Diplopoda (millipedes).
- Scorpionida (scorpions).
- Pulmonata (land snails).
- Pseudoscorpiones (pseudoscorpions).

15.3.1 Short range endemic invertebrate fauna surveys

Surveys and assessment of the SRE invertebrate fauna of the Proposal Area have been undertaken.

Field surveys were conducted in accordance with EPA Guidance Statement No. 20: "Guidelines for the Assessment of SRE Invertebrate Fauna for Environmental Impact in Western Australia" (EPA 2009a). SREs were systematically sampled via pit trap lines (seven study sites within the Proposal Area) during the Proposal surveys. Three non-systematic (targeted searching) invertebrate fauna surveys were also undertaken in the broader Revised Proposal Development Envelope, with 25 sites located within the Proposal Area. All surveys undertaken within the Proposal Area are summarised in **Table 24**. In addition, opportunistic searches were also undertaken during an earlier survey in the Proposal Area in 2009; the exact search effort was not recorded (Biota 2015b). Systematic and targeted sampling sites are presented in **Figure 62**. SRE data from a recent SRE survey conducted by Biota for BHP that overlapped the Proposal Area has also been included (records are lodged with the WAM; survey code JML; Biota 2015b).

Pit-trapping sites were selected to provide representative sampling for terrestrial fauna within the range of land systems and habitats present; SRE fauna were collected as by-catch (refer to Sections 5.4 and 6.3.1). In addition to pit-trapping, the surveys used a variety of targeted search methods to collect potential SREs (Biota 2014c, 2015b), including:

- overturning and searching under rocks and in rock crevices;
- raking soil and leaf litter;
- sieving soil and leaf litter;
- excavating leaf litter and soil around the base of spinifex (*Triodia* spp.) hummocks (land snails only);
- searching on trees and beneath bark (pseudoscorpions only); and
- visually locating burrows (mygalomorph spiders only).

Specimens from all taxonomic groups were lodged with the WA Museum for morphological identification. Molecular (DNA) analysis was used to infer relationships within the mygalomorph spiders and putative species boundaries.

Species recorded in these surveys that have a known distribution exceeding 10,000 km^2 were considered to be non-SRE species, while those with a distribution of less than 10,000 km^2 were considered 'potential SREs'. The criteria used to determine the SRE status of putative species recorded are detailed in Biota (2014c). Some taxa were determined as being of uncertain SRE status due to a lack of available data and taxonomic framework.

15.3.2 Short range endemic invertebrate fauna habitats

Four land system units are found within the Proposal Area; the Newman, River, Boolgeeda and McKay (**Table 5**). All land systems were sampled for SREs during the targeted search surveys and by pit-trapping lines.

SREs were targeted in a variety of landforms (such as drainage lines, hills and slopes and flats) and microhabitats (like large spinifex hummocks, Mulga groves, bark, leaf litter, soil and rock piles) that are known to be prospective.

15.3.3 Short range endemic invertebrate fauna occurrence

Twenty potential SRE specimens were collected from within the Proposal Area (Biota 2015b). Genetic analysis determined six putative species (**Table 28**); five from two families of mygalomorph spiders (Idiopidae and Nemesiidae), and one pseudoscorpion specimen from the genus *Beieroipium* (family Olpiidae). All species have been previously recorded outside the Proposal Area. Four of the mygalomorph spider putative species are considered potential SREs, as their known distribution is less than 10,000 km^2:

- Idiopidae sp.I1 and I9; and
- Nemesiidae sp. N42 and N44.

The distribution of some putative species is uncertain in olpiid pseudoscorpions due to limited taxonomic resolution. The SRE status of some Olpiidae taxa is therefore also uncertain, however the characteristics of this family's dispersal mechanism (phoretic, or animal-assisted dispersal) mean *Beierolpium* sp. is not considered likely to represent an SRE (Biota 2015b). **Figure 63** shows the locations of the potential SRE species within the Proposal Area. All four potential SRE species have been recorded outside of the Proposal Area (Biota 2015b).

Table 28: **Summary of potential SREs found within the Proposal Area**

Invertebrate Group Family	Taxon	No. of Specimens	Land Systems Represented	Survey Code	SRE Status	Occurs Outside Proposal Area?
Pseudoscorpions						
Olpiidae	*Beierolpium* sp.	1	River	PBS	Unlikely to be a SRE	Unknown
Mygalomorph Spiders						
Idiopidae	Idiopidae sp. I1	2	River	JML	Potential SRE	Yes
	Idiopidae sp. I9	1	River	JML	Potential SRE	Yes
Nemesiidae	Nemesiidae sp. N16	6	Boolgeeda, McKay, River	PBS/JML	Not an SRE	Yes
	Nemesiidae sp. N42	1	Boolgeeda, River	PBS/JML	Potential SRE	Yes
	Nemesiidae sp. N44	9	Boolgeeda, Newman, River	PBS/JML	Potential SRE	Yes

15.4 Description of aquatic fauna

15.4.1 Aquatic fauna surveys

Aquatic fauna surveys have been conducted biannually (wet and dry season) since September 2007 by Wetland Research and Management (WRM 2015a, 2015b) in Marillana Creek and Weeli Wolli Creek, with additional sites added in October 2008 and May 2009. The results of the September/October 2013 (late dry) and April/May 2014 (late wet) surveys are presented in Section 15.4.3 below. Fourteen sampling sites were located within the Proposal Area; three sites in Marillana Creek (MAR2-7 - MAR2-9) and ten sites in Weeli Wolli Creek (WW3-3 - WW3-6 and WW4-1, WW4-3 - WW4-6 and WW4-8; **Figure 64**).

The Marillana Creek sites (Marillana Reach Two; MAR-Two) were located downstream of the Yandi Operations D09, as far as the reach of the perennial surface water flows. The Weeli Wolli Creek Reach Three (WW-Three) sites were located upstream of the junction of Marillana Creek, as far as the Yandi Operations D06, with the Reach Four (WW-Four) sites located downstream of the Marillana Creek confluence, towards the Fortescue Marsh.

Aquatic microinvertebrates, macroinvertebrates and fish species were targeted, with survey methods including mesh pond netting, seine netting, gill nets, dip nets and electrofishing. Hyporheic fauna were sampled using the Karaman-Chappuis method. Fish were identified in the field, then released alive; aquatic invertebrates were preserved in 70% ethanol for later identification.

Dissolved oxygen, water temperature and pH were measured in the field, and water samples were collected for laboratory analysis to determine major ions, alkalinity, dissolved metals and nutrients.

15.4.2 Aquatic fauna habitats

The aquatic fauna were sampled from a variety of microhabitats (as per WRM 2015a, 2015b):

- Microinvertebrates (i.e. zooplankton); in the water column.
- Hyporheic fauna; in alluvial gravels adjacent to the water's edge.
- Benthic macroinvertebrates; riffle habitat (selected to allow comparisons between sites).
- Fish; in the water column, with shallow areas where there was little vegetation or large woody debris targeted for smaller species and juveniles.

During the field surveys, habitat characteristics of each site were recorded, including parameters such as substrate composition, cover by inorganic sediment, submerged macrophyte, floating macrophyte, emergent macrophyte, algae, large woody debris, detritus, roots and trailing vegetation.

Geospatial Information and Mapping

15.4.3 Aquatic fauna occurrence

15.4.3.1 Microinvertebrates

A total of 108 microinvertebrate taxa were recorded from the Marillana sites (n=70) and Weeli Wolli Creek Reach Three sites (n=40) and Reach Four sites (n=66) during the late dry and late wet surveys (WRM 2015a, 2015b). The microinvertebrate taxa consisted of Protista, Rotifera, Copepoda, Cladocera (water fleas) and Ostracoda (seed shrimp), and were more prolific during the wet season sampling.

Six endemic or rare microinvertebrate species were collected during the most recent surveys, and are summarised below (WRM 2015a,2015b).

- *Lecane noobijupi* is an endemic WA rotifer. It was originally described from specimens collected in south west WA, but has since been recorded from multiple locations within the Pilbara region. It was recorded at sites MAR2-8, WW3-3 and WW4-1.

- *Nebela penardiana* was recorded at all WW-Three sites within the Proposal Area. Weeli Wolli Creek is the only known location of this protist within WA, and the second record of this species in Australia.

- *Lecane* 'bulloid' n. sp. has similar morphology to *Lecane noobijupi*, but is larger than *L. bulla*. This morphotype is endemic to WA, and was recorded at site WW4-5.

- *Cephalodella* n. sp. did not conform to any described species and is likely to be a new species. It was collected from WW4-4, and represents the first record of this taxon.

- *Heterolepadella heterostyla* is a rarely collected rotifer, but is thought to have a cosmopolitan distribution. It is usually found in stagnant waters, and has also been collected from the nearby Mindy Mindy Creek. It was recorded at site MAR2-9.

- *Australoeucyclops karaytugi* is an endemic Australian cyclopoid copepod. It has previously been collected in the Pilbara from Fortescue Marsh and southern Weeli Wolli Creek, upstream of Hope Downs 1. It was collected from site MAR2-9.

15.4.3.2 Hyporheic fauna

The hyporheic zone is the region where riverine surface water and groundwater combine (Boulton 2001). Hyporheic fauna are aquatic invertebrates that reside in the alluvium below the streambed where water percolates through spaces between the rocks and cobbles (WRM 2015a). All taxa recorded from hyporheic samples were classified by WRM (2015a) using categories described by Boulton (2001):

- Stygobite: obligate groundwater species, with special adaptations to survive in this habitat.

- Permanent hyporheos stygophiles: species living on or near the surface of the ground that can occur in both surface and groundwater, but are a permanent inhabitant of the hyporheos.

- Occasional hyporheos stygophiles: these species use the hyporheic zone seasonally or during early life history stages.
- Possible hyporheic species: these species require further research to determine their status.

Stygoxene are species that appear rarely and apparently at random in groundwater habitats, either by accident or seeking refuge during flood or drought. They are not specialised for groundwater habitats, and are not considered to be part of hyporheos fauna.

A total of 113 taxa were recorded from hyporheic samples from the Marillana sites (n=52) and Weeli Wolli Creek Reach Three sites (n=62) and Reach Four sites (n=87) during the late dry and late wet surveys (WRM 2015a, 2015b). Of the 113 taxa collected, 6% were stygobites, 13% were considered occasional hyporheos stygophiles and 11% were considered to be possible hyporheic taxa. All sites within the Proposal Area were considered to support taxa that were restricted to the hyporheic zone; these taxa are described in WRM (2015a, b), and include a number of undescribed species that are new to science. Five stygobitic amphipod and isopod species were also considered to be potential SREs:

- Paramelitidae sp. D (equivalent to Paramelitidae Genus 2 sp. B3), recorded at MAR2-8 and WW3-4.
- Paramelitidae sp. B (equivalent to Paramelitidae Genus 2 sp. B2), recorded at all sites with the exception of WW4-4 and WW4-5.
- *Chydaekata* sp., recorded at sites WW3-3, WW3-4, WW3-5, WW4-1, WW4-3.
- *Maarrka weeliwolli*, recorded from sites WW3-5, WW3-6, WW4-1, WW4-3 and WW4-4.
- *Pygolabis weeliwolli*, recorded at site WW3-5.

The amphipod *Maarrka weeliwolli* and the isopod *Pygolabis weeliwolli* appear to be restricted to Marillana Creek and Weeli Wolli Creek (WRM 2015b). The other three taxa have been collected from outside these creek systems.

15.4.3.3 Macroinvertebrates

A total of 141 macroinvertebrate taxa were recorded were recorded from the Marillana sites (n=116) and Weeli Wolli Creek Reach Three sites (n=65) and Reach Four sites (n=87) during the late dry and late wet surveys (WRM 2015a, 2015b). Macroinvertebrate taxa richness was greatest at sites MAR2-9 during the late dry and WW4-8 during the late wet sampling (n=50), while site MAR2-8 recorded the least taxa (n=20; late dry sampling), and was correlated with stream size, flow duration, habitat heterogeneity and macrophyte abundance (WRM 2015a).

Recorded taxonomic richness in the wet season has increased at Marillana Creek since surveying began in 2008. This is likely to be due to surface water discharge from the existing Yandi Operations, which has altered the aquatic fauna habitat to increase habitat size, heterogeneity and flows (WRM 2015a).

Seven of the macroinvertebrate taxa from the Proposal Area are considered Pilbara endemics, including the four stygobitic amphipod species also recorded in the hyporheic

zone (see '*Hyporheic fauna*' above). The additional three species are summarised below.

- *Nannophlebia injibandi* (Pilbara Archtail Dragonfly); while this species has a relatively broad distribution throughout the Pilbara, it is not commonly recorded. It was observed at sites WW4-1, WW4-3, WW4-4, WW4-6 and WW4-8 during the most recent surveys.
- *Eurysticta coolawanyah* (Pilbara Pin Damselfly) is currently listed on the IUCN Redlist as Near Threatened (Hawking 2009); though WRM (2015a) suggest the conservation status of this species should be downgraded due to the addition of new records throughout the Pilbara. This species was recorded at site WW3-2.
- *Tiporus tambreyi*; a Pilbara endemic, this beetle appears to be common throughout the region. It was recorded at site MAR2-9.

15.4.3.4 Fish

A total of 4,455 freshwater fish samples were recorded from the Marillana sites (n=474) and Weeli Wolli Creek Reach Three sites (n=1297) and Reach Four sites (n=2684) during the late dry and late wet surveys (WRM 2015a, 2015b); 72% of these samples were recorded during the late wet survey.

Of the 12 known species of freshwater fish of the Fortescue River system, three were recorded in the Proposal Area:

- *Leiopotherapon unicolor* (Spangled Perch);
- *Neosilurus* sp. (Pilbara Tandan); and
- *Melanotaenia australis* (Western Rainbowfish).

The Western Rainbowfish was the most commonly observed species, consisting of 76% of all records. The Spangled Perch and Pilbara Tandan were recorded in lower numbers at Weeli Wolli Creek sites during the dry season (WW-Three, n=75; WW-Four, n=70) in comparison to the wet season (WW-Three, n=336; WW-Four, n=492), likely due to less suitable habitat being available during this season.

The sites at WW-Four appeared to be a nursery and recruitment zone for both Western Rainbowfish and Pilbara Tandan, as significantly higher proportions of new recruits recorded from these sites than in comparison to the WW-Three sites (WRM 2015b).

15.5 Assessment of potential impact, mitigation and residual impact

The EPA has listed the following potential impacts for the Proposal in relation to terrestrial fauna:

- habitat removal and fragmentation due to vegetation clearing; and
- indirect impacts that may occur through altered fire regimes, groundwater drawdown and discharge of surplus water, altered water regimes, changes to feral animal populations, the introduction or increase in spread of weed species, noise and light spill.

15.5.1 Impacts to fauna species of conservation significance

Five conservation listed species were recorded in the Proposal Area, with an additional 11 species assessed as likely, or potentially occurring. Impacts to these species are

discussed below. The Chocolate Wattled Bat (*Chalinolobus morio*), while currently not conservation listed under Commonwealth or State legislation, has also been included in the assessment. While common through much of its Australian range, the isolated Pilbara population is geographically restricted (Biota 2014c).

15.5.1.1 Threatened species (EPBC Act/WC Act Schedule 1 listed)

Pilbara Olive Python (*Liasis olivaceus barroni*) - Schedule 1, Vulnerable (Recorded)

A single Pilbara Olive Python was recorded opportunistically swimming downstream in Weeli Wolli Creek during a nocturnal search (site YBLNoct04) during the 2014 survey (Biota 2014c). This species is known from 17 locations in the Pilbara, and appears relatively common in the vicinity of the Proposal Area, with records from Hope Downs (21 km southwest), Flat Rocks (37 km west) and Koodaideri (38 km north west; Biota 2014c). This species has also been recorded in the Revised Proposal Development Envelope previously, with several sightings made at the existing Yandi Operations, and in Marillana Creek (Biota 2014c).

Core habitat for the Pilbara Olive Python includes gorges, escarpments, rocky outcrops and water holes where it may hunt and/or seek shelter in caves, beneath boulders, in pools of water and occasionally in trees overhanging water (DoE 2015b). It is often associated with ephemeral or permanent water, which is an indicator of high quality habitat for the species. However, the species may also be recorded in rocky habitats some distance from these features, especially during cooler months (Doughty et al. 2011). These landforms are not uncommon within the Pilbara bioregion. Pilbara Olive Pythons have also been observed using post-mining landforms and other man-made water sources, such as pit lakes, sewerage treatment ponds and recreational lakes. Individuals have been recorded utilising overburden heaps and railway embankments at mine sites (Pearson 2003).

This species may have a large home range, with estimations between 88 and 449 ha (DoE 2015b). Within the Proposal Area, its core habitat is likely to comprise of the major riverine systems of Marillana and Weeli Wolli Creeks. There is 872.8 ha of core habitat for the Pilbara Olive Python within the Proposal Area (Biota 2014f; **Figure 65**).

Habitat loss associated with mining developments is a recognised threat to the persistence of the Pilbara Olive Python (DoE 2015b). The Proposal has the potential to directly affect habitat utilised by the Pilbara Olive Python as a result of clearing and ground disturbance. The site of the recorded observation (see **Figure 60**) and the majority of this habitat occur outside the proposed mine pit and waste dump locations for the Proposal (Biota 2014f). Approximately 87 ha of Major Drainage Line habitat within the Proposal Area (10% of the core habitat available in the Proposal Area) is proposed to be cleared as part of the Proposal. While some core habitat will be removed, 90% of this habitat will remain undisturbed within the Proposal Area. Additional habitat is also available outside the Proposal Area to the north and south in Weeli Wolli Creek and nearby at Marillana Creek. The Pilbara Olive Python has also been observed utilising man-made habitats at Mesa J Iron Ore Mine near Pannawonica (Pearson 2003), and it is possible this species will utilise similar areas within the Proposal Area.

MNES species core habitat mapping within the Proposal Area

Drawn: L Cowing Plan No: PDE0133374v2
Date: October, 2015 Proj: MGA94 (Zone 50)

Geospatial Information and Mapping

Altered hydrological regimes as a result of the Proposal are not expected to result in a significant indirect loss of habitat for the Pilbara Olive Python. Perennial stream flow in the Weeli Wolli Creek low-flow channel will continue during the life of the Proposal, and opportunities for flooding the adjacent riparian zone remain unchanged as a result of the Proposal (URS 2015).

Vehicle movements associated with construction and operation phases of the Proposal have the potential to harm Pilbara Olive Python individuals or their prey (DoE 2015b). Speed limits will be enforced on all roads within the Proposal Area to reduce the risk of impact to Pilbara Olive Python individuals and other fauna. Training and induction of personnel will ensure that all staff are made aware of significant species at risk from vehicle strikes. Predation by feral foxes and cats are also a risk to the Pilbara Olive Python (particularly juveniles; DoE 2015b) and will be managed within the Proposal Area during construction and operation phases of the Proposal. These management actions will be in accordance with the Yandi SSMP addendum (**Appendix 4**).

While the Proposal will cause some loss of core habitat via vegetation clearing, and impacts to the local population via loss of individuals due to vehicle collisions and predation by feral animals, the overall impact to this species will be low. It is considered unlikely that the conservation status of the Pilbara Olive Python will be affected as a result of the Proposal. Potential cumulative impacts to the Pilbara Olive Python are discussed in Section 15.6.2.

Pilbara Leaf-nosed Bat (*Rhinonicteris aurantius*) – Schedule 1, Vulnerable (Likely)

The Pilbara Leaf-nosed Bat was not recorded in the Proposal Area (Biota 2015b). The closest record of this species is from a single call recorded approximately 7 km north west of the Proposal Area (Biota 2014c). The Pilbara Leaf-nosed Bat is the Pilbara form of the Orange Leaf-nosed Bat, which occurs as two disjunct populations in Australia – one only in the Pilbara bioregion and the other across northern Australia, from the Kimberley in Western Australia to western Queensland. In the Pilbara there are three sub-populations, the eastern Pilbara, Hamersley Range and upper Gascoyne.

The Pilbara Leaf-nosed Bat occurs in colonies, which vary in size from tens to thousands of individuals, concentrated around significant roosting sites, which are often associated with disused mining infrastructure. Most of the known natural roosting sites coincide with areas of current or future interest for mining development; hence mining activities are an identified threat to Pilbara populations of the species (DoE 2015b).

The occurrence of pools of water is a critical component of the Pilbara Leaf-nosed Bat's foraging habitat. Roosting sites may occur in rocky breakaways, scarps and gorges as these areas have the greatest potential to support relatively warm humid microclimates. Foraging habitats also include these habitats, and may also include riparian vegetation and hummock grasslands (DoE 2015b).

The major drainage channels of the Marillana-Weeli Wolli Creek system in the Proposal Area may provide foraging opportunities for the Pilbara Leaf-nosed Bat, although due to the absence of suitable roost caves in close proximity to the Proposal Area, this habitat is not considered core (Biota 2014c). A colony of Pilbara Leaf-nosed Bats occurs within the Koodaideri Iron Ore Mine area, approximately 40 km north west of the Proposal Area. It is assumed that individuals can move distances up to 60 km, although not necessarily overnight (DoE 2015b). Therefore the species is considered likely to occur within the

Proposal Area, but only on an occasional foraging basis. Changes to the groundwater regime as a result of the Proposal may alter the suitability of foraging habitat for the species, as some riparian tree species are expected to be lost over the life of the Proposal (see Section 14). The loss of some of this habitat through altered hydrological processes and clearing may have localised impacts to the Pilbara Leaf-nosed Bat, however, the Proposal is not anticipated to affect the conservation status of this species.

Northern Quoll (*Dasyurus hallucatus*) – Schedule 1, Endangered (Potential)

The Northern Quoll is the smallest quoll species. This species has been recorded in all four of the Pilbara subregions, with the majority of the records occurring in the north and north west of the bioregion, in the Hamersley and Chichester subregions (Biota 2010). The Northern Quoll is a short lived mammal, with both sexes maturing at 11 months of age. Males frequently do not survive after their first breeding season, and females usually do not live longer than 2-3 years. They are opportunistic omnivores, and have been recorded consuming invertebrates, fruit and flowers, mammals, birds, bird eggs, frogs, road kills and from rubbish bins (DoE 2015b).

There have been two anecdotal sightings of Northern Quoll individuals at the existing Yandi Operations warehouse over a one month period in 2009 (Biota 2009), and an individual found at the nearby Yandi Operations village in 2013. However, these represent the only sightings within the existing Yandi Operations in the past 19 years, and come from a nearby higher elevation area encompassing landforms more suitable for the species than the Proposal Area (Biota 2014d). It is thought these individuals may have been temporarily foraging in the Revised Proposal Development Envelope, or that this small local population may have declined (Biota 2009).

There are three records of the Northern Quoll within 15 km of the Proposal Area, which were recorded in 2010 (Biota 2013). Since then, surveys undertaken have not recorded the species, with over 10,000 Elliott trap nights in the Revised Proposal Development Envelope, and two Targeted Northern Quoll surveys within the Proposal Area (Biota 2014d). In addition, recent habitat mapping indicates there is very limited core habitat for the Northern Quoll in the Proposal Area (4.4 ha), consisting of two small areas of rocky breakaway habitat at the periphery of the Proposal Area, outside the proposed mine pit and waste dumps (Biota 2014f; **Figure 65**). Core habitat for the Northern Quoll is considered to be rocky gorges, rocky free face and hills usually of high relief, with secondary habitat associated with drainage lines used for denning (DoE 2015b).

It is considered extremely unlikely that a significant population of the Northern Quoll is present in the Proposal Area; and any interactions of this species within the Proposal Area would be limited to dispersing individuals (Biota 2014d). Habitat clearing and fragmentation as a consequence of mining is a threat to the Northern Quoll (DoE 2015), however, due to the limited core habitat and the low likelihood of Northern Quoll presence in the Proposal Area, the Proposal is not predicted to significantly affect the conservation status of this species.

Grey Falcon (*Falco peregrinus*) – Schedule 1 (Potential)

The Grey Falcon is endemic to Australia, typically found in the arid and semi-arid interiors. It is a wide-ranging species and hunts smaller birds in a range of habitats (Morcombe 2007). The Grey Falcon may occur within the Proposal Area; it has been recorded within 40 km (ALA database search). This species is not considered likely to

rely on any particular habitat type present within the Proposal Area. It may use the Proposal Area to hunt occasionally, and has the potential to breed in the taller eucalypts associated with the Weeli Wolli Creek (Biota 2014c). Potential breeding habitat may be reduced within the Proposal Area as a result of groundwater drawdown causing deaths to tree species within the riparian zone (see Section 14). As the Grey Falcon has a low density and broad distribution in the Pilbara, it is unlikely the Proposal will result in any significant impacts on the conservation status of this species.

Australian Painted Snipe (*Rostratula australis*) – Schedule 1 (Potential)

The Australian Painted Snipe is a wader, and has been recorded in wetlands across Australia. It is considered to occur in a single, contiguous breeding population, with population estimates ranging between a few hundred to five thousand individuals (DoE 2015b).

The Australian Painted Snipe has been observed within 40 km of the Proposal Area at the Fortescue Marsh (NatureMap database). This species may potentially occur within the Proposal Area as suitable shallow, fresh water wetlands are present year-round, however it has not been previously recorded (Biota 2014c).

The reduction of riparian habitat as a result of the Proposal could cause a local impact to individuals of this species if present within the Proposal Area. However, given the NatureMap record at the Fortescue Marsh is the only record of this species in this database within 400 km of the Proposal Area, and the availability of suitable habitat outside the Proposal Area in both creeks and the Fortescue Marsh, the conservation status of the Australian Painted Snipe is unlikely to be affected by the Proposal.

15.5.1.2 Migratory species (EPBC Act)

Eastern Great Egret (*Ardea modesta*) - Schedule 3, Migratory (Recorded)

The Eastern Great Egret is a migratory waterbird that is likely to utilise the Fortescue Marsh on an occasional basis, which is located 40 km north of the Proposal Area. In 2014 a single opportunistic observation of one individual flying near Weeli Wolli Creek was made outside of the proposed mine footprint (Biota 2014c). This species is widespread across Australia and occurs in a range of wetland habitats, predominately in shallow waters (DoE 2015b). The low number of observations of this species indicates the Eastern Great Egret only utilises the Proposal Area on an occasional, transient basis. As a result, it is considered unlikely the Proposal will affect the conservation status of this species.

Fork-tailed Swift (*Apus pacificus*) – Schedule 3, Migratory (Recorded)

The Fork-tailed Swift is a common migrant throughout the Pilbara between October and April (Morcombe 2007) and is exclusively aerial in Australia, occurring here as a non-breeding visitor (Johnstone and Storr 1998).

This species potentially utilises the Proposal Area for aerial foraging during the migratory period. An opportunistic observation of nine Fork-tailed Swift individuals flying overhead of the Proposal Area was recorded on one occasion (Biota 2014c). Due to the wide range of the Fork-tailed Swift and its aerial nature, it is unlikely that the Proposal will significantly affect the conservation status of this species.

Rainbow Bee-eater (*Merops ornatus*) - Schedule 3, Migratory (Recorded)

Rainbow Bee-eaters are commonly found during the summer throughout most of southern Australia excluding Tasmania (Barrett et al. 2003). They migrate north at the onset of cooler weather in autumn, spending the winter in northern Australia, New Guinea, and some of the southern islands of Indonesia. It is thought that many populations in northern Australia are sedentary (Boland 2004). They occur in a wide range of habitats including open woodlands, shrublands, beaches, dunes, cliffs, mangroves, woodlands and parks and private gardens (Boland 2004), preferring areas near water and sandy substrates. This species requires these sandy substrates to build nest burrows (Higgins 1999).

The Rainbow Bee-eater was observed on numerous occasions opportunistically and while conducting systematic avifauna surveys throughout the Proposal Area (Biota 2014c). This species is common in the Pilbara and is either a breeding resident or non-breeding visitor to the Proposal Area, with the tall trees of Weeli Wolli Creek providing suitable foraging habitat (Biota 2014c). Some of this habitat may potentially be affected as a result of clearing and groundwater drawdown and discharge caused by mine pit dewatering for the Proposal. This species nests in sandy soils in burrows; no evidence of nesting was found within the Proposal Area (Biota 2014c). This migratory species has a broad distribution across Australia, and has over 11,000 records within Western Australia on the NatureMap database. It is very common and widespread in the Pilbara bioregion and is unlikely to be reliant on the habitats within the Proposal Area. As such, it is unlikely that the Proposal will significantly affect the conservation status of this species.

Common Greenshank (*Tringa nebularia*) - Schedule 3, Migratory (Likely)

The Common Greenshank is a wader, and can be observed singly or in small to large flocks, occasionally numbering in the hundreds. This species occurs in all types of wetlands and has the widest distribution of any shorebird in Australia; however, it does not breed in Australia (DoE 2015b). It is likely to occur within the Proposal Area, as it has previously been recorded within 10 km (Biota 2014c). In Australia, threats to this species include habitat loss and modification, introduced species, pollution and disturbance by humans (DoE 2015b). Given the presence of suitable habitat outside the Proposal Area, the conservation status of this species is unlikely to be affected by the Proposal.

Cattle Egret (*Ardea ibis*) - Schedule 3, Migratory (Potential)

The Cattle Egret is a migratory waterbird that is considered widespread and common across its range (DoE 2015b). It is found in temperate and tropical grasslands, woodlands and terrestrial wetlands, and is likely to utilise the Fortescue Marsh on an occasional basis. Due to the proximity of the Proposal Area to the Marsh, it is possible that this species may occur, utilising the damp grasslands neighbouring Weeli Wolli Creek after flooding. However, this would only be on an occasional, transient basis and therefore the conservation status of this species is unlikely to be affected by the Proposal.

15.5.1.3 Schedule 4 species (WC Act)

Peregrine Falcon (*Falco peregrinus*) – Schedule 4 (Likely)

The Peregrine Falcon has an almost cosmopolitan distribution and inhabits a wide range of habitats, including cliffs, rocky outcrops and rocky coastal islands; however, it will use trees to nest where cliffs are not available. It is uncommon, and is usually found in pairs or as single individuals. This species has been recorded once inside the Revised Proposal Development Envelope, outside the Proposal Area; and the individuals

recorded were likely to have been transitory or foraging. It is considered likely to occur within the Proposal Area.

The large trees adjacent to Weeli Wolli Creek may provide potential habitat for nesting and foraging by the Peregrine Falcon (Biota 2014c). Some of this habitat may be affected by the Proposal as a result of groundwater drawdown, discharge and vegetation clearing. However, as suitable habitat for the Peregrine Falcon is present outside the Proposal Area, it is unlikely that the Proposal will significantly affect the conservation status of this species.

15.5.1.4 Priority listed species

Blind Snake (*Anilios ganei*) - Priority 1 (Likely)

The Blind Snake is distributed over much of the Pilbara region; however it is poorly collected (Biota 2014c), and is known only from 41 records in Western Australia on the NatureMap database. This species has been recorded in moist gorges and gullies, Mulga Woodlands and rocky scree slopes (Biota 2014c). It has been observed within 10 km of the Proposal Area and as suitable habitat is present, it is considered likely to occur within the Proposal Area (Biota 2014c).

Potential impacts to the Blind Snake as a result of the Proposal include habitat loss and direct mortality of individuals. Up to 1,138 ha of potentially suitable habitat, consisting of Mulga Woodlands, Slopes and Hills and Pediment Slope habitat within the Proposal Area is expected to be cleared as a result of the Proposal. There are few records of this species, which could be due to difficulties in successfully sampling individuals or a naturally low abundance despite their wide distribution in the region. If present in the Proposal Area, the Proposal could result in localised impacts to this species. However, given its wide distribution (over 400 km), and the low number of records in the vicinity of the Proposal Area, the conservation status of this species is unlikely to be significantly affected by the Proposal.

Pilbara Barking Gecko (*Underwoodisaurus seorsus*) - Priority 2 (Likely)

The Pilbara Barking Gecko is a Hamersley Range endemic that was recently discovered in 2006. It is a large carphodactylid gecko, with a large head, long slender limbs and digits, and long tail terminating in a point (Doughty and Oliver 2011). The known distribution of this species extends from north of Tom Price to West Angelas mine in the south east. The Pilbara Barking Gecko is found in rocky areas, with some observations associated with major gullies and rocky gorges (Doughty and Oliver 2011). This species is classified as Priority 2, based on its relatively small distribution and rarity. It has been recorded nearby to the Proposal Area (Biota 2014c), and as suitable rocky slope habitat is present, it is considered likely to occur (Biota 2014c).

A total of 1,075 ha of Slopes and Hills and Pediment Slope habitat within the Proposal Area may be cleared as a result of the Proposal; localised impacts to Pilbara Barking Gecko as a result of the Proposal include direct mortality and loss of habitat due to vegetation clearing. If present in the Proposal Area, the Proposal could result in localised impacts to this species. However, there is extensive habitat available to this species in the vicinity of the Proposal Area and in the wider locality, thus the Proposal is unlikely to significantly affect the conservation status of this species.

Western Pebble-mound Mouse (*Pseudomys chapmani*) - Priority 4 (Recorded)

The Western Pebble-mound Mouse is endemic to the central and eastern Pilbara; it has a broad distribution in within this area and is considered quite common. This species builds mounds of small stones covering 0.5-0.9 m^2, and frequents stony hillsides with hummock grasslands (Biota 2014c). The Western Pebble-mound Mouse was the most frequently recorded mammal during surveys in the Proposal Area, with pebble mounds recorded at 18 locations (Rio Tinto database). One individual was also trapped at site BIL07 (Biota 2011). The majority of mounds appeared active (Biota 2014c).

It is anticipated five known mounds will be directly impacted by clearing for the Proposal footprint (**Figure 60)**. Threats to the Pebble-mound Mouse as a result of the Proposal include direct mortality and habitat loss due to vegetation clearing. A total of 1,075 ha of Slopes and Hills and Pediment Slope habitat within the Proposal Area may be cleared as a result of the Proposal.

However, this species is broadly distributed in the Hamersley and Chichester subregions of the Pilbara bioregion and is commonly recorded, with over 850 records within the Pilbara Bioregion on NatureMap. Extensive suitable habitat is present outside of the Proposal Area, and it is unlikely that the Proposal will affect the conservation status of this species (Biota 2011).

Brush-tailed Mulgara (*Dasycercus blythi*) – Priority 4 (Likely)

The Brush-tailed Mulgara is a medium sized solitary carnivorous marsupial. It has a characteristic tail, with a fat base and black hairs, hence the common name 'Brush-tail'. This species is found in sand plain, sand dune and gibber plain (rock and pebble covered flat plains) habitat (Pavey et al. 2011). There is a history of taxonomic confusion between *Dasycercus cristicauda* and *D. blythi*; this is discussed further in Section 15.2.4.

Mulgara burrows were recorded at three sites in the north eastern section of the PBS study area (Biota 2014c), in close proximity to each other in Minor Alluvial Fans and Hills and Slopes habitat. The burrows were recorded approximately 800 – 960 m from the Proposal Area, however no animals were observed. These burrows were thought to be inactive, due to a lack of scats, tracks or fresh diggings. Despite the lack of recent activity, Biota (2014c) considers the Mulgara to have been recently present in the area; however the individuals may have relocated to areas with new resources. Previous surveys in this area have recorded live individuals (S Ford pers. obs., cited in Biota 2014c). No burrows or individuals of this species have been identified within the Proposal Area to date; however suitable habitat is present.

The Proposal has the potential to cause direct mortality to individuals and will result in potential habitat loss due to vegetation clearing. However, this species has a wide distribution across the Pilbara on NatureMap, and suitable habitat is present outside the Proposal Area. It is therefore unlikely the Proposal will affect the conservation status of this species.

Ghost Bat (*Macroderma gigas*) - Priority 4 (Likely)

The Ghost Bat occurs in a wide range of habitats and has a fragmented distribution caused by the availability of suitable roost sites in caves and mines. The transient day roosts or feeding sites of Ghost Bats are often shallow overhangs and crevices with microclimates similar to ambient conditions, whereas roosts for breeding activity (maternity roost) have a relative humidity of above 80% (Armstrong and Anstee 2000). For this bat species to persist, a productive foraging area (usually containing riparian

vegetation) within 5-10 km of their maternity roost site is preferable (Biologic 2014). The Ghost Bat occurs in all four Pilbara subregions, and McKenzie and Bullen (2009) suggest this species is more common that previously supposed.

This bat species is likely to utilise the Proposal Area for foraging. There has been one recorded sighting of an animal flying over the Revised Proposal Development Envelope in 1998 (Biota 2013), and a cave containing scats was recorded 9 km south of the Proposal Area (Biota 2014c). No potential roost caves for any conservation significant bat species were located within the Proposal Area. However, due to the presence of riparian vegetation and a nearby recorded sighting and scats, this carnivorous predator may utilise the Proposal Area occasionally for foraging on small mammals, birds, reptiles and insects. As the Proposal Area does not contain any known roost caves, and given the large home ranges of this species, it is unlikely the Proposal will significantly affect the Ghost Bat.

15.5.1.5 Other species

Chocolate Wattled Bat (*Chalinolobus morio*) - (Recorded)

The Chocolate Wattled Bat is a microbat that is found in a range of habitats throughout Australia. This species roosts in tree hollows, man-made structures and caves. They feed almost exclusively on moths, which they catch by flying below the tree canopy (ALA 2015).

The Chocolate Wattled Bat is not currently listed under Commonwealth or State legislation. While common through much of its range in southern and eastern Australia, it is currently only known in the Pilbara from the productive riparian environment of the Weeli Wolli-Marillana Creek System (McKenzie and Bullen 2009). Extensive sampling throughout this region and the neighbouring bioregions of the Gascoyne and Murchison have failed to detect it elsewhere (McKenzie and Bullen 2009). It is possible that the isolated Pilbara population is genetically distinct; however this has not been tested. The microbat assemblage of the Priority 1 Weeli Wolli Spring Community PEC, located upstream from the Proposal Area, has been identified as an environmental value for Weeli Wolli Creek in an Environmental Values Statement (**Appendix 1**) by the Proponent.

A Chocolate Wattled Bat was recorded from one survey site within the Proposal Area (site YBQSM2-05; **Figure 60)**. This record is adjacent to the south west border of the Proposal Area at the entrance of a small cave close to Weeli Wolli Creek (Biota 2014c). There are an additional two records of this species to the north of the Proposal Area.

The clearing and degradation of riparian vegetation within the Proposal Area could impact this species. Approximately 85.9 ha of Major Drainage Line habitat is anticipated to cleared due to the Proposal, with additional potential breeding habitat reduced within the Proposal Area as a result of groundwater drawdown and discharge causing stress or mortality to tree species within the riparian zone (see Section 14). It is possible that their range extent may be temporarily increased due to increased water availability from discharge. However, at a community level, these effects are unlikely to significantly affect the broader riparian habitat and suitable breeding and foraging habitat is present outside the Revised Proposal Development Envelope, including the Weeli Wolli Spring, and will not be threatened by the Proposal. Consequently, the Proposal is considered unlikely to significantly affect the Chocolate Wattled Bat population in Weeli Wolli and Marillana Creeks.

15.5.2 Habitat removal and fragmentation

15.5.2.1 Terrestrial vertebrate fauna

Clearing of terrestrial fauna habitat is required to facilitate construction of the mine and associated infrastructure. Clearing will result in up to 1,800[5] ha of terrestrial fauna habitat loss within the Proposal Area, including up to 69 ha of riparian zone vegetation. The proposed clearing will potentially result in the loss of the following fauna habitats:

- 85.9 ha of Major Drainage Line;
- 308.1 ha of Hilltops and Slopes;
- 767.0 ha of Pediment Slope;
- 102.4 ha of Alluvial Plain (Flood Plain); and
- 63.3 ha of Mulga woodland.

Approximately 87 ha of core habitat will be lost within the Proposal Area for the EPBC Act/WC Act Schedule 1 listed species the Pilbara Olive Python (**Figure 65**). Five additional conservation significant species have been recorded within the Proposal Area; aside from one record of a Rainbow Bee-eater at site YBL006P, the records of the Western Pebble-mound Mouse are the only species recorded within the proposed mine pit and waste dump locations (**Figure 60**).

Impacts to fauna habitats from vegetation clearing will be managed through the implementation of measures described in the Significant Species Management Guideline and in the Yandicoogina MMP (**Appendix 4**). Habitat clearing will be restricted to the Proposal Area and will be the minimum necessary for safe construction and operation of the Proposal. Clearing will be undertaken progressively to allow mobile fauna movement into contiguous habitat beyond the clearing area. Native fauna encountered on-site (including during clearing) will be avoided. A dedicated fauna relocation specialist/carer will be available on-site at all times to safely relocate any fauna encountered.

The proposed mine pit and waste dumps will fragment fauna habitat with the Proposal Area, with an approximate 8 km almost continuous stretch of habitat removed to the east of Weeli Wolli Creek, of up to 2.6 km in width. This habitat is primarily associated with the hills and slopes landform. Some fauna groups will be affected more than others based on their movement modes and patterns (flight versus ground moving and long versus short range movements), with the proposed mine pit and waste dumps potentially causing a barrier to dispersion for non-aerial species.

The Proposal Area contains fauna habitats that are consistent with the surrounding landscape. Based on the distribution of land systems, fauna habitats occurring in the Proposal Area are likely to be well represented in the surrounding area, and connectivity will remain with the intact habitats outside the Proposal Area.

[5] The total disturbance to fauna habitat is 1,327 ha, however the Proponent is seeking approval for overall disturbance of up to 1,800 ha to accommodate for detailed design of mining operations and infrastructure.

15.5.2.2 SRE invertebrate fauna

Loss of SRE invertebrate fauna habitat will occur as a result of clearing to facilitate construction of the mine pit, waste dumps and associated infrastructure. Clearing will result in the direct removal of up to 1,800[6] ha of fauna habitat within the Proposal Area. With the exception of one site, all recorded Nemesiidae sp. N44 locations within the Proposal Area will be disturbed (see **Figure 63**).

However, all four predicted SRE taxa, Idiopidae sp.I1 and I9 and Nemesiidae sp. N42 and N44, have been recorded outside the Proposal Area. These species have been recorded in multiple land systems and substrate types, suggesting they not restrained to a specific landscape-scale habitat unit. Therefore the probability that these mygalomorph spiders possess a narrow spatial distribution is lower, and thus it is less likely that vegetation clearing within the Proposal Area will adversely affect these species (Biota 2015b).

Habitat clearing will be restricted to the Proposal Area and will be the minimum necessary for safe construction and operation of the Proposal. Clearing areas are well-defined and demarcated on the ground to ensure that operators clear only what is necessary. Upon mine closure, the Proposal Area will be rehabilitated to contain a wide variety of fauna habitats, many that will be appropriate for SRE invertebrate fauna species.

15.5.2.3 Aquatic fauna

Minimal aquatic fauna habitat associated with Weeli Wolli and Marillana Creeks will be lost or fragmented as a result of the Proposal, as habitat and surface water flows will be retained. Therefore the associated aquatic fauna habitat and its ecological values will be retained.

15.5.3 Indirect impacts

Indirect impacts from the Proposal may modify or disturb fauna habitats leading to changes in fauna behaviour and movement patterns and/or disruption to nesting and roosting habitats. These potential modes of impact include light, dust and noise emissions, altered fire and water regimes, and the introduction and/or spread of weeds and feral animals.

15.5.3.1 Altered Hydrological Regime

Surface water will continue to be discharged as part of the Proposal and from Hope Downs 1 operations during the life of the Proposal, with the reach of the surface water footprint between 5 and 9 km downstream of the Weeli Wolli Creek and Marillana Creek confluence. Therefore the current perennial stream flow in the Weeli Wolli Creek low-flow channel will continue during the life of the Proposal, and opportunities for flooding the adjacent riparian zone remaining unchanged as a result of the Proposal (URS 2015).

However, the Proposal will alter the groundwater and surface water system, potentially resulting in degradation of fauna habitat. Up to 10 km of riparian vegetation will be exposed to the effects of groundwater drawdown, which is likely to cause some tree mortality in riparian zones adjacent to Weeli Wolli Creek during the mining operations (see Section 14 for further details).

[6] The total disturbance to fauna habitat is 1,327 ha, however the Proponent is seeking approval for overall disturbance of up to 1,800 ha to accommodate for detailed design of mining operations and infrastructure.

There is no evidence that current surface water discharges associated with the JSE, JSW and Oxbow development have adversely affected aquatic fauna taxa richness of microinvertebrates, hyporheic invertebrates or macroinvertebrates to date (WRM 2015a). Any changes to the surface water flows of Weeli Wolli Creek, such as water quality, flow velocity, increased turbidity and water depth, have the potential to cause local impacts to aquatic fauna. The Proposal will require direct disturbance to a section of the Weeli Wolli Creek floodplain adjacent to the pit, as well as the construction of flood protection levees within the floodplain of the creek. Disruption to the existing surface water flows along Weeli Wolli Creek due to the construction of the levee will be negligible during low-flow events.

As the magnitude of the flow increases, changes to the flow regime will increase due to greater constriction and obstruction of flows imposed by the infrastructure along the creek (URS 2015). This will reduce the width of the creekline floodflows, and may potentially cause increased erosion and turbidity downstream (WRM 2015a). Further details on the impacts and management of surface and groundwater are discussed in Section 13. Aquatic fauna will continue to be monitored over the life of the Proposal to quantify the impact, if any, from the Proposal (WRM 2015a, 2015b).

15.5.3.2 Altered Fire Regimes

Fire prevention measures will be implemented in accordance with the Proponent's standard operating procedures. Fire monitoring will be undertaken annually to assess the condition of firebreaks and the condition, layout and use of all hydrocarbon storage areas and other ignition sources, to identify any potential on-site fire risks.

15.5.3.3 Light, Dust and Noise

Light, dust and noise emissions from construction and mining activities can affect native fauna by deterring individuals from their habitats and subsequently altering species' foraging, roosting or breeding behaviour in the area immediately around the source of light, dust and noise. These impacts will be mitigated for EPBC Act listed threatened species in the SSMP and Yandi SSMP addendum (**Appendix 4**).

Impacts on fauna due to light emissions will be managed by implementing lighting controls, including, where appropriate, minimising light broadcast, installing sodium lights, using yellow-coloured lights at night, using motion sensors to limit the unnecessary light, and installing reflectors in strategic locations to deter bats from operational areas.

15.5.3.4 Introduced Species

Ground disturbance and poor waste management can result in the increase in numbers or introduction of weeds or feral animals, increasing predation of, or competition with, native fauna. These impacts will be mitigated in the Yandicoogina Weed Action Plan and for EPBC Act listed threatened species in the SSMP and Yandi SSMP addendum (**Appendix 4**).

15.6 Cumulative impacts

15.6.1 Cumulative impacts to the Chocolate Wattled Bat

A preliminary assessment of cumulative impacts to the Chocolate Wattled Bat was conducted based on a review of the potential impacts of the Proposal, the existing Yandi Operations and six other projects identified as being potentially relevant based on their location in the Weeli Wolli Creek or Marillana Creek sub-catchments of the Upper Fortescue River Catchment (**Figure 24**).

The Chocolate Wattled Bat is currently known to occur in the Pilbara only in the productive riparian environment of the Weeli Wolli-Marillana Creek System (McKenzie and Bullen 2009). Therefore, the preliminary assessment of cumulative impacts to this species has been based on potential impacts to riparian vegetation within the Weeli Wolli Creek and Marillana Creek sub-catchments.

The Chocolate Wattled Bat has been recorded at only one of the projects considered, being the Proposal (this Proposal; **Table 29**). The area of potential Chocolate Wattled Bat habitat (riparian vegetation) has been quantified for three of the projects considered (including this Proposal; **Table 29**). The three projects for which habitat has been quantified were included in this preliminary assessment of cumulative impacts to the Chocolate Wattled Bat.

Of the approximately 859 ha of potential Major Drainage Line habitat for the Chocolate Wattled Bat occurring in the Proposal Area, up to 85.9 ha will be cleared for the Proposal. This represents approximately 10% of the extent of this habitat in the Proposal Area. Taken together with the remaining projects for which habitat has been quantified, the cumulative impact is a loss of up to 1,463 ha of potential Chocolate Wattled Bat habitat, which represents approximately 5.6% of the 2,902 ha of riparian habitat mapped across the four projects (**Table 29**).

Table 29: Assessment of potential cumulative impacts to Chocolate Wattled Bat habitat

15.6.2 Cumulative impacts to the Pilbara Olive Python

A preliminary assessment of cumulative impacts to the Pilbara Olive Python was conducted based on a review of the potential impacts of the Proposal, the existing Yandi Operations and 19 other projects identified as being potentially relevant based on their location in the Upper Fortescue River Catchment (**Figure 24**).

The Pilbara Olive Python has been recorded at 12 of the projects considered (including this Proposal) and the area of potential Pilbara Olive Python habitat has been quantified for seven of the projects considered (including this Proposal; **Table 30**). The projects for which habitat has been quantified were included in this preliminary assessment of cumulative impacts to the Pilbara Olive Python.

Of the approximately 873 ha of potential habitat for the Pilbara Olive Python occurring in the Proposal Area, up to 87 ha will be cleared for the Proposal. This represents approximately 10% of the extent of this habitat in the Proposal Area. Taken together with the remaining projects for which habitat has been quantified, the cumulative impact is a loss of up to 5,447 ha of potential Pilbara Olive Python habitat, which represents approximately 15% of the 37,376 ha of habitat mapped across the seven projects (**Table 30**).

15.6.3 Cumulative impacts to potential Short Range Endemic invertebrates

A preliminary assessment of cumulative impacts was conducted for each of the four potential SRE invertebrate taxa recorded in the Proposal Area, being Nemesiidae sp. N42, Nemesiidae sp. N44, Idiopidae sp. I1 and Idiopidae sp. I9. Of these four taxa, only Nemesiidae sp. N44 has been recorded in the indicative disturbance footprint; the remaining three taxa have been recorded in the Proposal Area outside the indicative disturbance footprint.

The preliminary assessment of cumulative impacts to the four potential SRE invertebrate taxa was based on a review of the potential impacts of the Proposal and the existing Yandi Operations. The assessment considered each species' currently known distribution based on currently known records, and the extent of this distribution located in the Proposal Area and the Revised Proposal Development Envelope.

15.6.3.1 Nemesiidae sp. N42

The currently known distribution of Nemesiidae sp. N42 is approximately 11,300 ha. Of this, approximately 1,439 ha (13%) is located in the Revised Proposal Development Envelope, including less than 1 ha (<1%) in the Proposal Area.

15.6.3.2 Nemesiidae sp. N44

The currently known distribution of Nemesiidae sp. N44 is approximately 2,600 ha. Of this, approximately 1,638 ha (63%) is located in the Revised Proposal Development Envelope, all of which (63%) is in the Proposal Area.

15.6.3.3 Idiopidae sp. I1

The currently known distribution of Idiopidae sp. I1 is approximately 255,900 ha. Of this, approximately 18,606 ha (7%) is located in the Revised Proposal Development Envelope, including approximately 4,231 ha (2%) in the Proposal Area.

15.6.3.4 Idiopidae sp. I9

The currently known distribution of Idiopidae sp. I9 is approximately 6,500 ha. Of this, approximately 157 ha (2%) is located in the Revised Proposal Development Envelope, including approximately 50 ha (<1) in the Proposal Area.

15.7 Key management actions

Potential impacts to fauna values will be mitigated through the implementation of measures described in the SSMP and the E14 Standard (Land Disturbance and Rehabilitation Control). Measures relating to rehabilitation of disturbed areas will be implemented in accordance with the Yandicoogina Closure Plan.

Key measures in the SSMP (including the Yandi SSMP addendum) and Yandi Operations site measures include:

- Baseline surveys (following EPA Guidance Statements) will be completed in all areas with planned mining developments and infrastructure.
- Ensure any sightings or potential records of MNES encountered by the workforce during clearing operations are reported to site Environmental Advisors and are recorded in a register. Site environmental inductions and educational posters should include information to raise awareness of MNES species and specify protocols for reporting sightings.
- Location of MNES and their habitats identified within and adjacent to the Proponent's project boundaries will be recorded on the Rio Tinto GIS database.

- Targeted surveys will be undertaken to identify any significant species, habitat or communities for any new projects/developments. Methods will be investigated to minimise or avoid the clearing of significant species if identified. Riparian vegetation will be managed as per the Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan.
- Proposed clearing and disturbance will be assessed through the internal approvals coordination process. This internal process will ensure:
    - disturbance remains within approved boundaries;
    - clearing is minimised to meet specific demands;
    - planned clearing is adjusted where possible to avoid disturbance of significant areas; and
    - planned clearing meets legal obligations.
- All areas to be cleared will be demarcated prior to disturbance.
- Rehabilitation success will be assessed through vegetation monitoring and monitoring for habitat use indicators, in accordance with the completion criteria established within the Yandicoogina Closure Plan.
- Weed management measures will be implemented in accordance with Yandicoogina Weed Action Plan and equipment hygiene procedures to ensure weeds are controlled and recorded and equipment is cleaned to minimise the spread of weeds.
- Feral animal control will be undertaken by:
    - prohibiting feeding animals;
    - prohibiting keeping pets;
    - appropriate waste disposal for food scraps and other wastes as per the Waste Management Guidelines; and
    - regular feral animal reduction programs.
- Dust control measures (including road watering, water sprays and dust suppression systems) will be used to minimise dust from sites.
- Native fauna encountered on-site will be given the opportunity to move on if there is no threat to personnel safety in doing so.
- Injured fauna encountered on-site will be handled and transported in accordance with the Proponent's Wildlife interaction guidelines.
- Feeding of native fauna, hunting, keeping of firearms or pets on-site will be prohibited.
- Appropriate speed limits for mining equipment and light vehicles will be implemented, sign-posted and enforced, and communicated via education of site personnel.
- Vehicles will remain on designated roads and will not be permitted off designated roads unless in the case of emergency.
- Animal strikes by vehicles will be recorded and documented.
- Control fires caused by operations.

Implementation of snake handling and relocation procedures as required (this includes Pilbara Olive Python relocation protocol for any individuals encountered within the Yandi operational area). The Yandi SSMP addendum (**Appendix 4**) addresses management measures specifically to relevant EPBC Act listed species occurring, or potentially occurring, in the Revised Proposal Development Envelope. It outlines key management actions and accountability for issues relating to clearing and direct disturbance, indirect disturbance and other operational issues and outlines survey/monitoring requirements. These management actions are already been successfully implemented for the existing Yandi Operations.

15.8 Predicted outcome

A range of measures have been or will be implemented to reduce potential impacts to terrestrial fauna values (**Table 31**).

Table 31: **Mitigation hierarchy for terrestrial fauna values**

Mitigation measure	Description
Avoidance	Clearing will only occur within the approved Revised Proposal Development Envelope.
	Modify land clearing plans and evaluate alternative mine plans to avoid impacts on the conservation significant fauna species.
	Pets will be prohibited within the Proposal Area.
Minimisation	Clearing will be minimised to that required for safe construction and operation.
	Modify land clearing plans and evaluate alternative clearing options to minimise impacts on conservation significant fauna species.
	Clearing of vegetation will be staged allowing for the progressive movement of fauna into areas outside the proposed disturbance areas
	Infrastructure in creeklines designed to avoid disruption of low-flow line and flood flows. Low flows will be maintained in the low-flow line to support vegetation habitat.
	Vehicles will remain on designated roads and will not be permitted off designated roads unless in the case of an emergency.
	Any native animals encountered on-site will be given the opportunity to move on if there is no threat to human safety.
	Potential noise impacts to fauna will be minimised by selecting and locating equipment start-up alarms so that they reduce noise impacts.
	Lighting and dust controls will be implemented.
Rehabilitation	Disturbed areas will be progressively rehabilitated.

After mitigation and management measures have been applied, the Proposal is expected to result in the following residual outcomes in relation to terrestrial fauna:

- Clearing of up to 1,800[7] ha of terrestrial fauna habitat over the life of the Proposal.
- Habitat degradation due to the altered surface water and groundwater regime (including stress and some deaths of trees within the riparian zone), which may lead to local reductions in fauna populations in the Proposal Area. The habitat types present in the Proposal Area are considered to be well represented in the

[7] The total disturbance to fauna habitat is 1,327 ha, however the Proponent is seeking approval for overall disturbance of up to 1,800 to accommodate for detailed design of mining operations and infrastructure.

local and regional area. It is considered likely that individuals will continue to forage in the remaining habitats within and adjacent to the Proposal Area.

- Clearing will result in the direct removal of up to 1,800 ha of vegetation that contains potential SRE habitat within Proposal Area; this habitat is considered widespread locally and regionally.
- Risk of alteration to aquatic fauna habitat in Weeli Wolli Creek (surface water flows); additional habitat is available to north and south of the Proposal Area.
- Fragmentation of fauna habitat caused by the pit, waste dumps and association infrastructure; the mine footprint may also cause a barrier to dispersion for non-aerial species.
- Direct loss of some individual fauna through impact with machinery and vehicles, particularly during vegetation clearing.
- Rehabilitation, with consideration given to restoring fauna habitat values where practicable.

Clearing of up to 1,731 ha of native vegetation in Good to Excellent condition and 69 ha of riparian zone vegetation[8], including fauna habitat, within the Proposal Area will be offset as part of the Proposal (Section 18).

[8] For the purposes of the offset calculation, riparian zone vegetation is classified as vegetation units within the riparian zone comprising C-coded and F2 coded vegetation located within the RCA.

16. Subterranean fauna

16.1 Key statutory requirements, environmental policy and guidance

16.1.1 EPA objective

The EPA has applied the following objective for the Proposal to its assessment of subterranean fauna:

"To maintain representation, diversity, viability and ecological function at the species, population and assemblage level."

16.1.2 Regulatory framework

The following legislation is relevant to the Proposal with respect to the protection of subterranean fauna values and the above EPA objective:

- *Wildlife Conservation Act 1950* (WA) *Environmental Protection Act 1986* (WA)
- *Environment Protection and Biodiversity Conservation Act 1999* (Commonwealth)

16.1.3 Relevant guidelines and policy

The following guidelines are relevant to the Proposal with respect to the protection of subterranean fauna and the above EPA objective:

- EAG 12: Environmental Assessment Guideline for Consideration of subterranean fauna in Environmental Impact Assessment in Western Australia (EPA 2013b)
- EPA Guidance Statement No. 54a: Sampling Methods and Survey Considerations for Subterranean Fauna in WA (EPA 2007)

16.2 Description of stygofauna

16.2.1 Stygofauna surveys

A total of 13 stygofauna surveys have been undertaken in and around the Revised Proposal Development Envelope since 2003, including the Proposal Area (Biota 2010a, 2011b, 2011c, 2013b; as cited in Biota 2015c). A total of 139 drillhole/boreholes have been sampled to date, encompassing JC, JSE, JSW, Oxbow and PBS deposits. Stygobitic fauna sampling has been undertaken using modified plankton haul nets lowered to the bottom of the drillholes and bore holes. Each site has been sampled in this way five times, unless the site recorded high water turbidity, in which case the drillhole/borehole was only sampled two or three times. A full description of the sampling methodology is outlined in the Biota (2015c) report (**Appendix 3**).

Of the 139 drillhole/boreholes sampled, 62 sites are located within the Proposal Area, including the 29 sites located within the proposed pit boundary. Sampling effort differed over the 13 stygofauna surveys, depending on the deposit-specific focus of the surveys and the access to and condition of drillhole/boreholes. Many sites were sampled over multiple phases; some sites were sampled in up to 11 surveys, while others were only sampled during a single survey. **Figure 66** shows the locations of the drillhole/boreholes used for the stygofauna surveys.

The methodology and approach used in all surveys were consistent with those outlined in EPA Guidance Statement No. 54a and EAG No. 12.

16.2.2 Stygofauna habitat

Stygofauna habitat is characterised by groundwater environments including porous, karstic and fractured rock aquifers, springs and the hyporheric zone of streams (Eberhard et al. 2005). Stygofauna inhabit voids, cavities and fractures in groundwater aquifers and a correlation exists between interconnectivity and transmissivity of the aquifer and suitability for stygofauna. Calcrete and alluvium are considered to be productive habitats for stygofauna, and pisolite and banded iron formations also considered to be suitable (Halse et al. 2014). The geological units found in the Proposal Area and their potential suitability for stygofauna as defined by Biota (2015c) are listed in **Table 32**.

Table 32: Geological units in the Proposal Area and their suitability for stygofauna

Geological time scale	Geological Formation Code	Description	Potential Habitat Suitability
Quaternary Period	Qw	Alluvium and colluvium – red-brown sandy and clayey soil; on low slopes and sheetwash areas.	High
	Qa	Alluvium – unconsolidated silt, sand, and gravel; in drainage channels and on adjacent floodplains. **Superficial aquifer**.	High
Cenozoic Era	Czk	Calcrete – sheet carbonate; found along major drainage lines.	High
	Czp	Pisolite (CID) – Pisolitic limonite deposits developed along ancient river channels (Palaeo-channel). **Deeper aquifer.**	Mod*
Proterozoic Eon	PLHj	Weeli Wolli Formation: banded iron formation (commonly jaspilitic), pelite, and numerous matadolerite sills.	Low

Adapted from Biota (2015c) * Typically classified as High, but classified as Moderate based on depth of CID habitat in the Proposal Area and Biota assessment (Biota 2015c).

The pre-mining habitat has been modified as a result of discharge from the Hope Downs 1 mining operations upstream of the Proposal; discharge from the existing Yandi Operations at the upstream discharge point DO6; and surplus water re-injection into the Billiard South deposit from the existing Yandi Operations since late 2006. This change, coupled with seasonal variability from cyclones and flooding, has resulted in a shallow water table in the Proposal Area and superficial formations remaining saturated for extended periods compared to past (pre-mining) conditions (Biota 2015c).

The hydrogeology in the Proposal Area is generally well suited for stygobitic fauna utilisation, with the majority of the shallow stratigraphy comprised of saturated alluvium (**Figure 67**). This shallow alluvial aquifer overlays a deeper aquifer formed by the CID. These systems are recharged both directly and indirectly by rainfall, groundwater and surface water flow. The CID is primarily recharged by seepage in areas where the present day creek overlays the CID (**Figure 25**). The shallow water table and seasonally variable influx of water from storm events are also likely to aid in fauna dispersal and general hydraulic connectivity of subterranean habitats within the area (Biota 2015c).

16.2.3 Stygofauna occurrence

A total of 9,654 specimens of stygobitic fauna have been recorded from the Revised Proposal Development Envelope between 2003 and 2014 (Biota 2015c). These specimens were from eight phyla and at least nine classes. Specimens belonging to Gastropoda, Nematoda and Protozoa were unable to be classified beyond phylum, and turbellarian worms (phylum Platyhelminthes) could not be identified beyond class due to a lack of taxonomic framework for these groups in the Pilbara. Of the specimens that

could be identified to lower taxonomic levels, Copepoda (copepods), Ostracoda (Seed Shrimp) and Amphipoda (Landhopper) were the most prolific, accounting for 77% of all specimens.

Approximately 64% of the total stygofauna species identified within the Revised Proposal Development Envelope have been recorded elsewhere in Australia or globally (Biota 2015c). The highest abundance of specimens was located in or adjacent to the Weeli Wolli and Marillana Creeks (Biota 2015c). Where the taxonomic framework is limited, identification of specimens beyond order can be difficult and results in limited conclusions for Environmental Impact Assessment at species level.

In the Proposal Area, 62 drillholes/boreholes have been sampled for stygofauna, with 42 sites yielding stygofauna specimens. In total there were 2,761 specimens from 62 taxa found in the Proposal Area since sampling commenced in 2003. The most abundant taxon was *Diacyclops humphreysi humphreysi* (918 specimens; 33% of records within the Proposal Area), followed by *Gordanitocrella trajani* (297 specimens; 11% of records within the Proposal Area) and *Notacandona boultoni* (270 specimens; 10% of records within the Proposal Area). Of the 29 sites within the proposed pit boundary, 21 of these sites contained stygofauna specimens (refer to **Figure 67**). From the sites that were sampled within the proposed pit boundary, Biota (2015c) identified 1,014 specimens from 39 individual taxa. Of these 39 taxa, three were only found within the proposed pit boundary and are not known from records outside this area:

- *Notobathynella* sp.;
- *Billibathynella* sp. B02; and
- *Brevisomabathynella* cf. *pilbaraensis.*

None of these species are currently Specially Protected, Schedule or Priority species or MNES. *Notobathynella* sp. and *Billibathynella* sp. B02 were only recorded as single specimens (singletons), while the two specimens of *Brevisomabathynella* cf. *pilbaraensis* were recorded from the same site. *Brevisomabathynella* cf. *pilbaraensis* is morphological similar to *Brevisomabathynella pilbaraensis* (type locality is 85 km away), however most Bathnellids have small distributions. *Brevisomabathynella* is known for its similarities between taxa, with two of the described species of this genus from the Pilbara (Ethel Creek and Millstream) also having only small morphological differences between them. **Table 33** provides a summary of the stygofauna survey results, including stygofauna recorded within the proposed pit boundary.

16.3 Description of troglofauna

16.3.1 Troglofauna surveys

Two phases of troglobitic fauna surveys were undertaken across the Proposal Area. Phase one was undertaken in 2009 and sampled 52 sites across the Revised Proposal Development Envelope, with 34 of these sites located within the Proposal Area. Phase two, completed in 2014, sampled 32 sites across the Revised Proposal Development Envelope, with 26 of these sites located within the ProposalArea (**Figure 68**). In addition to these two phases, troglofauna were opportunistically collected from four sites during past stygofauna sampling of the Revised Proposal Development Envelope, three of these sites are within the Proposal Area (Biota 2015d).

The methodology and approach used in all surveys were consistent with those outlined in EPA Guidance Statement No. 54a and EAG No. 12.

16.3.2 Troglofauna habitat

The suitability of a geological formation as troglofauna habitat is predominantly determined by above water table environments, with availability and interconnectivity of void/cavity space; the potential for nutrient infiltration from the surface; and the ability of the inhabited substrate to maintain a stable humidity (Biota 2015d). The surface geological formations occurring within the Proposal Area (where troglofauna have previously been recorded) and their suitability for troglofauna is provided in **Table 34.**

Table 34: Geological units in the Proposal Area and their suitability for troglofauna

Geological Time Scale	Geological Formation Code	Description	Suitability
Quaternary Period	Qw	Alluvium and colluvium – red-brown sandy and clayey soil; on low slopes and sheetwash areas.	Low
	Qa	Alluvium – unconsolidated silt, sand, and gravel; in drainage channels and on adjacent floodplains.	Medium
Cenozoic Era	Czk	Calcrete – sheet carbonate; found along major drainage lines.	High
	Czp	Robe Pisolite (CID): Pisolitic limonite deposits developed along river channels.	Low*
Proterozoic Eon	PLHj	Weeli Wolli Formation: banded iron formation (commonly jaspilitic), pelite, and numerous matadolerite sills.	Medium

Adapted from Biota (2015d) * Typically classified as High, but classified as Low based on 99% of CID habitat in the Proposal Area being below the water table and Biota assessment (Biota 2015c).

The majority of the troglofauna specimens recorded within the Revised Proposal Development Envelope have been collected from shallow alluvium, colluvium and calcrete drill holes with less than 10 m to water table. The surface geology units therefore generally characterise the habitats that the fauna were using at that time, given that other geological formations at depth were below water table.

All troglofauna specimens were recorded from three surface geological units, alluvium (Qa), colluvium (Czc) and calcrete (Czk; **Figure 69**) and these represent habitats that the fauna currently utilise within the Proposal Area.

The unconsolidated alluvium, colluvium and calcrete geological units located adjacent to Weeli Wolli Creek can be seasonally inundated during flooding, periodically rendering areas of habitat unsuitable for use by troglofauna. Adjoining higher elevation landforms, such as the Brockman Iron Formation and the Weeli Wolli Formation, potentially represent an alternative refuge from inundation, and potentially provides refuge habitat over longer timeframes (Biota 2015d). Troglofauna has been

Figure 68). In addition to these two phases, troglofauna were opportunistically collected from four sites during past stygofauna sampling of the Revised Proposal Development Envelope, three of these sites are within the Proposal Area (Biota 2015d).

The methodology and approach used in all surveys were consistent with those outlined in EPA Guidance Statement No. 54a and EAG No. 12.

16.3.2 Troglofauna habitat

The suitability of a geological formation as troglofauna habitat is predominantly determined by above water table environments, with availability and interconnectivity of void/cavity space; the potential for nutrient infiltration from the surface; and the ability of the inhabited substrate to maintain a stable humidity (Biota 2015d). The surface geological formations occurring within the Proposal Area (where troglofauna have previously been recorded) and their suitability for troglofauna is provided in **Table 34.**

Table 34: Geological units in the Proposal Area and their suitability for troglofauna

Geological Time Scale	Geological Formation Code	Description	Suitability
Quaternary Period	Qw	Alluvium and colluvium – red-brown sandy and clayey soil; on low slopes and sheetwash areas.	Low
	Qa	Alluvium – unconsolidated silt, sand, and gravel; in drainage channels and on adjacent floodplains.	Medium

	Czp	Robe Pisolite (CID): Pisolitic limonite deposits developed along river channels.	Low*
Proterozoic Eon	PLHj	Weeli Wolli Formation: banded iron formation (commonly jaspilitic), pelite, and numerous matadolerite sills.	Medium

Adapted from Biota (2015d) * Typically classified as High, but classified as Low based on 99% of CID habitat in the Proposal Area being below the water table and Biota assessment (Biota 2015c).

The majority of the troglofauna specimens recorded within the Revised Proposal Development Envelope have been collected from shallow alluvium, colluvium and calcrete drill holes with less than 10 m to water table. The surface geology units therefore generally characterise the habitats that the fauna were using at that time, given that other geological formations at depth were below water table.

All troglofauna specimens were recorded from three surface geological units, alluvium (Qa), colluvium (Czc) and calcrete (Czk; **Figure 69**) and these represent habitats that the fauna currently utilise within the Proposal Area.

The unconsolidated alluvium, colluvium and calcrete geological units located adjacent to Weeli Wolli Creek can be seasonally inundated during flooding, periodically rendering areas of habitat unsuitable for use by troglofauna. Adjoining higher elevation landforms, such as the Brockman Iron Formation and the Weeli Wolli Formation, potentially represent an alternative refuge from inundation, and potentially provides refuge habitat over longer timeframes (Biota 2015d). Troglofauna has been recorded within the Brockman Iron Formation within hydrated zones (cavity-rich upper sections of the formation) at other locations such as Koodaideri within the bioregion (Biota 2015d).

16.3.3 Troglofauna occurrence

Table 35 provides a summary of the troglofauna survey results, including troglofauna recorded within the proposed pit boundary. Six potential troglobitic fauna specimens have been recorded in the

Revised Proposal Development Envelope, three of which have been recorded within the Proposal Area (**Figure 69**):

- *Myrmopopaea* sp. nov;
- *Draculoides* sp. indet; and
- Pauropoda sp. indet.

Two of the specimens recorded within the Proposal Area are confirmed troglobites; *Myrmopopaea* sp. nov. and *Draculoides* sp. indet. The ecological status of the Pauropoda sp. indet is unconfirmed, as the distribution of this species is unknown (Biota 2015d). *Myrmopopaea* sp. nov. is the only taxon recorded from within the proposed pit boundary and it is not known from any other locations. *Draculoides* sp. indet and Pauropoda sp. indet were recorded from sites within 50 m from the proposed pit boundary.

16.4 Assessment of potential impact, mitigation and residual impact

The EPA has listed the following potential impacts for the Proposal in relation to subterranean fauna:

- direct mortality and loss of habitat through subsurface disturbance; and
- loss of habitat through abstraction of groundwater for dewatering.

16.4.1 Stygofauna

Potential impacts on stygofauna arise from excavation of habitat and abstraction of groundwater for dewatering. Extraction of ore will result in the direct removal of stygofauna individuals and habitat and also reduces the ability to move around the system (i.e. reduces habitat connectivity). In the surrounding areas where there is no excavation, nutrient infiltration may be affected by stockpiling of overburden at the proposed waste dump locations.

As the proposed pit is located on the floodplain (with approximately 99% of the CID occurring below the water table), the taxa that are present in the proposed pit footprint, and directly adjacent to it, are most at risk from the Proposal. Almost half of the stygofauna assemblage recorded from the Revised Proposal Development Envelope is known from the wider region and the frequency of wider ranging taxa indicate there is unlikely to be geographically restricted taxa (Biota 2015c). Of the 39 taxa recorded within the proposed pit boundary, three species were only found within the proposed pit boundary and are not known from any other records outside this area: *Notobathynella* sp., *Billibathynella* sp. B02 and *Brevisomabathynella* cf. *pilbaraensis*. These species are not currently conservation listed. It is considered likely that the three taxa recorded only from the proposed pit would occur throughout the broader alluvial and CID aquifer and therefore would not be significantly impacted by the Proposal. The paucity of records may be an artefact of sampling, rather than an indication of an extremely restricted distribution (Biota 2015c).

The alluvial and CID aquifer in which the stygofauna occur is associated with the Weeli Wolli Creek system and extends north and south of the Proposal Area including northwards beyond the Marillana Creek confluence, which is further associated with alluvial units draining towards Fortescue Marsh (**Figure 67**). This extensive and hydrologically connected system of aquifers results in habitat that extends continuously beyond the predicted area of impact from pit excavation and groundwater drawdown. Seasonal flooding caused by cyclonic events may also assist in dispersing stygofauna taxa. This continuous aquifer linkage suggests that it is less likely that stygofauna species recorded in the proposed pit boundary and Proposal Area are restricted to this area (Biota 2015c). Potential stygofauna habitat and refuge areas within the local catchment are presented in **Figure 76**.

Figure 71 and **Figure 75** show the sequential modelled groundwater drawdown pattern during the life of the Proposal from 2017 to 2032. The peak dewatering period is predicted to occur within the first 6 years of dewatering in which the modelling shows the drawdown cone of depression would extend up to 85m bgl, encompassing the proposed pit area and extending to the mapped southern limit of the CID in the Proposal Area. This drawdown extent is modelled to continue from 2027 to 2031. Stygofauna that have been recorded within this drawdown area are likely to be affected.

While there will be a reduction in suitable habitat for stygofauna within the drawdown cone of depression, there is substantial habitat available within the adjacent alluvium (shallow aquifer) beneath Weeli Wolli Creek and also upstream and downstream both within the CID aquifer and shallow aquifer alluvium. The stygofauna habitat identification (Biota 2015d) was mapped and jointly considered with pre-mining depth to water table (Biota 2015e). This adopted a conservative approach of combining the most prospective geological units (**Table 32**), with areas where depth to water table was less than 40 m bgl. This is shown in **Figure 70**, along with the distribution of all stygofauna records from the Revised Proposal Development Envelope, which demonstrate the habitat mapping aligns with the known occurrence of this fauna.

Figure 70 also overlays the extent of predicted dewatering drawdown for the Proposal on the mapped stygofauna habitat. This illustrates that while sections of habitat in the Proposal Area may be effectively desaturated, equivalent and connected stygofauna habitat both upstream and downstream of the Proposal Area will remain suitable, allowing stygofauna to persist locally in the system over the life of the proposal. Reviews of stygofauna habitat indicate that there are no significant geological or hydrogeological barriers to dispersal within the broader Weeli Wolli – Marillana Creek system (Biota 2015d). This is consistent with both the habitat mapping shown in **Figure 70**, and reviews of the distributions of individual stygofauna species (Biota 2015d). Genetic and morphological determinations of stygofauna species, with representatives from most stygal orders, show that the same species occur within Weeli Wolli Creek and Marillana Creek, from higher in the catchment (e.g. Weeli Wolli Springs) to past the confluence of the two creeks (Biota 2015d, Finston and Johnson 2004). Sections of both Marillana Creek and Weeli Wolli Creek will remain unaffected by both the dewatering of the current Proposal, and that arising from other existing operations such as Hope Downs 1 and BHP's Yandi Operations, effectively representing habitat refugia for the stygal community that occurs within the local catchments (**Figure 76**).

Discharge of surface water from other operations may also serve to offset any impacts from dewatering. While the peak dewatering periods may reduce the ability for stygofauna to move through the Proposal Area, restricting the ability for some dispersal through the groundwater system towards Fortescue Marsh, the continuation of upstream discharge from Hope Downs 1 maintaining flow within the low-flow channel combined with natural seasonal flooding events, is expected to largely reduce this impact. Discharge from DO9 will likely increase the extent of downstream saturation within the alluvial aquifer within the downstream extents of Marillana and Weeli Wolli Creeks and potentially extend the available habitat and dispersal range. During the majority of mining and following cessation of mining activities, it is likely that there will be continual habitat connection upstream and downstream of the Proposal, allowing the ongoing dispersal of the stygofauna. It is considered unlikely that there will be a substantial regional impact to stygofauna (Biota 2015c).

Overland surface water flows into the pit from the east will be diverted through the construction of roads, pit, dumps and via a surface water diversion drain. This construction will potentially reduce localised replenishment and nutrient flows into subterranean fauna habitat, however major flood flows in Weeli Wolli Creek will continue to deliver nutrients to the system.

Water quality monitoring to date at the existing Yandi Operations indicates some minor variation in water quality parameters, however this is considered to be within natural fluctuations and no significant effects on baseline water quality has occurred as a result

of abstraction and discharge activities. Given the abstraction and discharge of water from the Proposal is from the same water source as the existing Yandi Operations, it is expected that there will not be any significant effects on stygofauna due to water quality changes as a result of the Proposal operation.

The post-closure landform will include the development of permanent pit lakes, which will influence the way surface and groundwater inputs are redistributed within and released from the Proposal Area. This could potentially influence aquifer water quality and riparian environments within the Proposal Area and to some extent, downstream. The post-closure landform has been designed to enable periodic flushing of the pit voids, thereby reducing the potential for long term aquifer salinisation and minimising potential ongoing impacts to stygofauna. The post-closure landform is discussed further in Section 17.2.

16.4.2 Troglofauna

The excavation of ore and removal of overburden material will result in the direct removal of the habitat for troglobitic fauna. In addition, discharge of additional surplus water from DO9 is likely to broaden the lateral extent and height of perennial flow in the low-flow channel which may increase inundation of some areas of downstream habitats beyond natural seasonal durations.

The only confirmed troglobite specimen recorded from within the proposed pit area was *Myrmopopaea* sp. nov., which was recorded within interconnected calcrete and alluvium formations. These largely interconnected geological formations are located adjacent to, and extend parallel to Weeli Wolli Creek and contain sufficient interstitial spaces and cavities to allow movement of troglobitic fauna. This habitat continuity suggests that the single record of *Myrmopopaea* sp. nov. is likely to occur more widely than the current record and its distribution likely extends beyond the area of impact for the Proposal (Biota 2015d), see **Figure 69**.

The singleton records of *Draculoides* sp. indet (confirmed troglobite) and Pauropoda *s*p. indet. (unconfirmed troglobite) were recorded in calcrete from sites less than 50 m outside the proposed pit area. However, it is considered that these species will not be directly affected, they are likely to occur more widely than the current records, and their distribution is expected to extend beyond the area of impact for the Proposal (Biota 2015d).

Although the primary habitat for troglofauna in the area is currently poorly defined, the CID deposit proposed for excavation in the Proposal Area is located 99% below the water table, and is therefore not suitable for troglofauna habitat. The continuous nature of the alluvium, colluvium and calcrete units indicates that geology is not a limiting factor in the distribution of the taxa currently known from the area of impact for the Proposal (Biota 2015c). The long term persistence of the fauna in the riverine habitat setting of the Proposal Area suggests these habitats are well connected with other older geological units that provide refugia habitat over longer timeframes (Biota 2015d).

16.5 Key management actions

Potential impacts to subterranean fauna values will be mitigated through the implementation of measures described in the Yandicoogina MMP, the Yandicoogina GWOS; the E11 Standard: Water Quality Protection and Water Management; the E15 Standard: Hazardous Materials and Non-Mineral Waste Control and Minimisation; and the Yandicoogina Closure Plan. Key mitigation and management measures are:

- Maintaining viable habitat by maintaining groundwater levels within predicted ranges, including maintaining upstream surface water discharge (perennial flows) during drawdown to partially negate drawdown impacts;
- Maintaining surface water discharge quality by managing erosion and sedimentation; and
- Maintaining groundwater and surface water quality by managing contamination (eg. hydrocarbon spills).

16.6 Predicted outcome

Stygofauna and troglofauna habitat will be affected by implementation of the Proposal. A range of measures have been or will be implemented to reduce potential impacts to subterranean fauna values (**Table 36** and **Table 37**).

Table 36: Mitigation hierarchy for stygofauna values

Mitigation measure	Description
Avoidance	Direct physical disturbance (excavation) to Weeli Wolli Creek floodplain and shallow alluvial aquifer (core habitat) will largely be avoided Weeli Wolli Creek flood flows will be maintained.
Minimisation	Maintain discharge flows/water availability in the Weeli Wolli low-flow channel adjacent to the proposed pit for the duration of mining to partially negate drawdown impacts in the alluvial aquifer. Areas of saturated habitat for stygofauna will be preserved across the Revised Proposal Development Envelope from staged sequence of mining. Water quality, including pollution and salinisation (surplus discharge water quality and groundwater quality) will be maintained and managed in accordance with the Yandi MMP; GWOS; E11 Standard: Water Quality and Protection Standard; E15 Standard: Hazardous Materials and Non-Mineral Waste Control and Minimisation; and the Yandicoogina Closure Plan.
Rehabilitation	Disturbed areas will be rehabilitated consistent with the Yandicoogina Closure Plan. Key functional creek elements retained (e.g. flood pathways, vegetation seed bank) to support natural rehabilitation upon closure.

Table 37: Mitigation hierarchy for troglofauna values

Mitigation measure	Description
Avoidance	Direct disturbance to Weeli Wolli Creek will largely be avoided and low-flow lines will be maintained.
Minimisation	Clearing will be minimised to that required for safe construction and operation. Limited direct impact on creekline alluvial habitat.
Rehabilitation	Disturbed areas will be rehabilitated consistent with the Yandicoogina Closure Plan. Key functional creek elements retained (e.g. flood pathways, vegetation seed bank) to support natural rehabilitation upon closure.

After management and mitigation measures have been applied, it is expected that the Proposal will result in the following outcomes for subterranean fauna:

- Direct mortality and reduction in available subterranean habitats as a result of pit excavation and groundwater drawdown.
- Potential impacts will be localised to the proposed pit area and the groundwater drawdown zone during mining operations. However, it is not expected to significantly impact subterranean assemblages and species persistence.
- The risk of pollutants being transported into the subterranean habitats is likely to be low and restricted to localised areas. There is some risk of aquifer salinisation from the pit lakes after mine closure. This is further addressed in Section 17.2.4.
- The continuous nature of the alluvium, colluvium and calcrete units in which the subterranean fauna were predominately recorded indicates that geology is not a limiting factor in the distribution of the taxa currently known from the proposed pit area and the groundwater drawdown zone within the Proposal Area.

The Proponent considers that there are no significant residual impacts to subterranean fauna that require an offset.

17. Rehabilitation and closure

17.1 Key statutory requirements, environmental policy and guidance

17.1.1 EPA objective

The EPA has applied the following objective for the Proposal to its assessment of rehabilitation and closure:

"To ensure that premises can be closed, decommissioned and rehabilitated in an ecologically sustainable manner, consistent with agreed outcomes and land uses, and without unacceptable liability to the State."

17.1.2 Regulatory framework

Key legislation relevant to the Proposal with respect to rehabilitation and closure includes:

- *Environmental Protection Act 1986* (WA).
- *Environment Protection and Biodiversity Conservation Act 1999* (Commonwealth).
- *Contaminated Sites Act 2003* (WA).
- *Iron Ore (Yandicoogina) Agreement Act 1996* (WA).
- *Mining Act 1978 (WA).*

A more comprehensive list of legislation and closure obligations for the Proposal are set out in the Yandicoogina Closure Plan (**Appendix 4**).

17.1.3 Relevant guidelines and policy

The DMP and EPA have issued the *Guidelines for Preparing Mine Closure Plans – May 2015* (referred to herein as Closure Guidelines) which establish standards for closure plans being submitted to Government (DMP and EPA 2015). The *Mining Act 1978* (WA) has been amended to specifically require closure plans that comply with the Closure Guidelines to be submitted with mining proposals, and reviewed on a three-yearly basis. For projects subject to State Agreements rather than the Mining Act, such as the Proposal, the EPA will expect compliant closure plans to be submitted as part of the assessment under Part IV of the EP Act.

The following regulatory position and Guidance Statements set the framework for the management of rehabilitation and mine closure for the Proposal:

- Guidelines for Preparing Mine Closure Plans – May 2015 (DMP and EPA 2015).
- EPA Guidance Statement No. 6: Rehabilitation of Terrestrial Ecosystems (EPA 2006).
- Strategic Framework for Mine Closure (ANZMEC and MCA 2000).
- Mine Closure and Completion (DITR 2006a).
- Mine Rehabilitation (DITR 2006b).

17.2 Description of rehabilitation and closure

17.2.1 Mine Closure Plan

A Closure Plan for the existing Yandi Operation was approved by OEPA on 23 January 2015, in accordance with the existing decommissioning and rehabilitation condition (Condition 9) within MS 914. This Closure Plan has been updated, consistent with the

Guidelines for Preparing Mine Closure Plans (DMP and EPA 2015), to detail the closure requirements for the Proposal Area.

The updated Yandicoogina Closure Plan (**Appendix 4**) provides an integrated closure vision for the entire Yandicoogina mine lease, consistent with the agreed closure objectives:

(1) rehabilitated landforms are stable and designed to manage floodwater appropriately;

(2) the environmental and cultural heritage values associated with creek flows and function are maintained post-closure;

(3) environmental values of Fortescue Marsh are not compromised;

(4) water quality within pit lakes support natural ecosystems and are compatible with post-mining land use;

(5) alluvial groundwater systems support remnant phreatophytic vegetation;

(6) final landforms are rehabilitated to be compatible with post-mining land use; and

(7) public safety hazards have been addressed.

Closure completion criteria to support the closure objectives have been recommended within the Yandicoogina Closure Plan. The completion criteria include processes, evidence and metrics to assess:

- erosion of the constructed landforms;
- preservation of surface water hydrological regimes, considering flow volumes, levels and quality;
- pit lake salinity;
- groundwater salinity;
- phreatophytic vegetation health; and
- prevalence of invasive species in rehabilitated areas.

These completion criteria will be refined based on information developed during implementation of the Proposal, from baseline studies and rehabilitation trials. The completion criteria will also evolve and grow as the expectations of the stakeholders and probable environmental outcomes are clarified.

Post-closure, environmental and other site management activities will continue until it is determined that the closure objectives have been met or it is otherwise agreed with Government to allow relinquishment of the site.

The volume of overburden and waste material generated by implementing the Proposal is relatively low compared to the volume of ore extracted. As a consequence, there is insufficient overburden and waste material available to backfill into the pit to cover the groundwater table on closure. Proximity to Weeli Wolli Creek is also an important consideration in development of the closure. Removal of the flood protection levee of closure will reduce the stressors on the riparian floodplain vegetation, but will also enable flood water to interact with the final mine void.

The proposed closure strategy, described within the Yandicoogina Closure Plan, has been developed in consideration of the closure objectives and proposed mine activity, to create a safe, stable, non-polluting landform that supports a native ecosystem. A conceptual design of the post-closure landform for the Proposal Area is presented in **Figure 77**.

The closure strategy includes the development of a native, self-sustaining wetland ecosystem within the final mine void. The wetland ecosystem will comprise two groundwater dependent pit lakes located in the Weeli Wolli Creek floodplain, away from the low-flow channel of Weeli Wolli Creek proper. On closure, the available overburden and waste materials will be utilised to stabilise the pit walls adjacent to the floodplain and to create a spillway that will facilitate flood water ingress into the final mine void during the peak of large flood events. The spillway will be engineered to minimise erosion as floodwater flows into the lake system.

Once the groundwater table recovers, the pit lakes will have an average water depth of 35 m to 45 m, storing approximately 80 GL of water. During significant flood events, when the spillway activates, the lakes will combine and can hold an additional 70 GL of flood water, increasing water depth by 60 m to 70 m. The maximum total storage capacity of the mine void is approximately 150 GL, beyond that capacity the water will overtop the northern tip of the mine void and will be returned to the Weeli Wolli Creek floodplain.

17.2.2 Mineral waste geochemical characterisation

Static geochemical tests have been conducted on all waste types, with more comprehensive sequential leach and kinetic tests undertaken to confirm that materials had indeed low geochemical risk. All tests were conducted in accordance with the *Global Acid Rock Drainage (GARD) Guide.*

No sulphides, the primary source of acid drainage issues, have been identified in the host geology or mineral waste at Yandicoogina. The total sulphur concentration of the 99th percentile of all sampled processed ore and waste at Yandicoogina is less than 0.02%, suggesting the overall acid rock drainage risk is low to nil.

In the Proposal Area, mineral waste will be returned to the mine voids, where it will form part of the groundwater aquifer. Post-closure, groundwater will flow from the existing aquifer systems, through the mineral waste aquifer, into pit lakes and, where not lost to evaporative processes, will flow back into the groundwater aquifer beneath the Weeli Wolli Creek floodplain. Tailored sequential extraction and submerged column test work are being conducted to understand how water quality may change as a consequence of these interactions.

Standard leach tests conducted on waste rock and waste fines presented circum-neutral pH values between 6.5 to 8.5 and EC values of around 650 µS/cm for waste rock and 70 µS/cm for waste fines, regardless of test conditions. Sequential extraction test work demonstrated that trace elements like arsenic, selenium and antimony are incorporated in the crystalline structure of iron oxides and silicates resulting in a reduced potential for these elements to be released. The potential for contaminant release under slightly alkaline and saline conditions are currently being investigated.

Saline drainage conditions are anticipated to evolve at Yandicoogina post-closure. Based on preliminary lab test results, alkaline conditions may occur for very limited periods of time, e.g. during prolonged drought periods, but are not expected to be sustained over

the long term. Ion exchange reactions and the release of contaminants under saline conditions are expected to be limited due to the combined effects of the sorption capacity of iron and aluminium oxides and low mineral solubility expected to occur under neutral pH conditions.

Readily detectable elements within the waste rock included the major elements Ca, Mg, Na, K, Cl, Si and SO4 and the trace elements Al, B, Ba, F, Fe, Sr and Zn. The highest concentrations of elements were recorded in the low contact ratio leach tests. The majority of the elements were source term limited, such that low masses were present in the samples and would be completely dissolve during the test. The test work also indicated that elements Al, Ba, F and Si may be solubility controlled.

The characteristics of the waste fines materials are similar to the waste rock, with the exception that low contact ratio leach tests contained low but detectable concentrations of Cd, Cr, Cu, Pb, Mn and Ni. These elements were not detected in the 2:1 L:S leach.

17.2.3 Mineral waste physical characterisation and waste landforms

Mineral waste generated at the site consists largely of overburden material and CID fines. Characteristics of the material are summarised as presented in **Table 38** and **Table 39**.

Table 38: General properties of the alluvial overburden material at Yandicoogina

pH	$EC_{1:5}$	$EC_{1:2}$	ESP	Potentially Dispersive	Exchangeable Cations (m.eq./100g)					ECEC
(-)	(dS/m)	(dS/m)	(%)		K	Ca	Mg	Na	Al	
6.5	0.02	0.04	3.1	No	0.42	1.85	0.82	0.1	0	3.2

Table 39: Particle size distribution of the alluvial overburden material at Yandicoogina

Rock >45mm (%)	Pebbles 22-45mm (%)	Gravel 2-22mm (%)	Fine Fraction <2mm (%)	Coarse Sand (%)	Fine Sand (%)	Silt (%)	Clay (%)
1	0	18	81	40	44	4	12

The majority of the mineral waste is expected to be of high erodibility, and will require conservative landform design parameters (e.g. batter angles of 20 degrees, in 5 m lifts with 10 m berm widths) to be used in order to create stable slopes.

All mineral waste in the Proposal Area will be returned to the mine void on closure, where it will be used, primarily, to buttress (strengthen) the pit wall that intersects Weeli Wolli Creek floodplain. This same strategy will be implemented in the event of unexpected closure.

The design of the buttress will evolve over the life of the mine, in consideration of the shape of the final mine void, associated geotechnical stability and location of progressive backfill. The conceptual design for the buttress, is presented in **Figure 77**, includes:

- An in pit waste slope that extends from the pit floor to the pit crest at an angle of 20 degrees, in 5 m lifts with 10 m berm widths widths (commensurate with the mineral waste material properties); and
- A spillway and central island used, in combination, to control floodwater from Weeli Wolli Creek floodplain as it flows into the lake areas. The design will

minimise erosion inside the mine void and within Weeli Wolli Creek floodplain, to maintain the integrity of the Weeli Wolli Creek hydrological regime.

As discussed in Section 4.2.5, the existing in pit waste fines cells at JSE will be used for the disposal of waste generated by wet processing. Mineral waste will be used to cover the waste fines cell and raise the surface to above the long term projected groundwater elevation.

Monitoring and, if required, corrective actions will be undertaken to ensure erosion does not threaten the long term stability of the landform. Erosion monitoring will include visual and measured assessments of rill and gull formation over time. Flow over the spillway will also be monitored, to validate the spillway function.

17.2.4 Post-closure water quality

Groundwater recovery in the Proposal Area is predicted to occur within a few decades. As the groundwater table recovers, permanent lakes will be established in the Proposal Area mine voids.

Once the groundwater table is recovered, and the system reaches steady state conditions, these pit lakes are expected to have an average depth of 35 - 45 m, 20 m below the pit crest, with a surface area of 2 - 4 km^2 (depending on the final buttress design), storing approximately 80 GL of water. The lake geometry suggests the lake water column will be fully mixed, however, density driven flow may occur during long dry periods.

Although the pit lakes will be groundwater dependent, the lakes are expected to receive flood water when the Weeli Wolli Creek floodplain activates. These flood events will deliver nutrients and aquatic fauna/flora to the lakes, but will also result in rapid increases in the lake water levels. Three times in every 200 years, Weeli Wolli Creek is predicted to flood with such magnitude that the mine void, which has a maximum storage capacity of approximately 150 GL, will be completely filled with flood water. The mine void will overtop via the northern point of the pit, contributing flow back into Weeli Wolli Creek floodplain. During these events, salts and nutrients will be flushed from the pit lakes. The volume of overtopping water will be very small relative to the volume of the water flowing down Weeli Wolli Creek during these flood events; and as a consequence, the salts and nutrients are not expected to have a measurable impact on Weeli Wolli Creek water quality or, by extension, the downstream Fortescue Marsh.

A preliminary stochastic water balance model has been developed, based on the conceptual buttress landform and using estimated aquifer parameters, to predict how water levels (**Figure 78**) and salinity may change over time. The stochastic modelling showed that the pit lake water quality will be strongly influenced by the future climate conditions. The modelling suggests that, over a 1,000 year period, salinity is likely to follow an increasing trend. During periods of simulated prolonged drought, when water levels dropped to their lowest levels, up to 11,000 mg/L salt was modelled. However, during simulated wet periods, salinity could also be reduced to as low as 200 mg/L salt. The stochastic model suggests there is a 50 percent probability that after 75 years pit lake water salinity would still be fresh (<1000 mg/L), and that after 1,000 years there was a 50 percent probability that the average annual salinity would be 3,000 mg/L or less.

The stochastic water balance also shows that during periods of drought, resulting in high salinity, the pit lake water levels drop below downstream groundwater levels. When this occurs, the lake system will stop functioning as a through-flow system, and revert to groundwater ‘sink’. Lake water levels and water quality are not expected to be restored to

average until the next large magnitude flood event, when the salts will be flushed out of the lake during the overtopping and water quality salinity will be reduced.

The stochastic water balance suggests that the average downstream groundwater flow contribution from the pit lakes could be around 0.1 GL per year to the aquifer under Weeli Wolli Creek. This represents less than 10 percent of the upstream groundwater inflow into the pit lakes and significantly less than 10 percent of the total aquifer flow. The quality as it enters the groundwater aquifer is expected to be similar to that of the pit lakes, which will be saltier than the groundwater aquifer. This saltier water is expected to be denser than the downstream groundwater aquifer, and is unlikely to move towards the surface or interact with the environment.

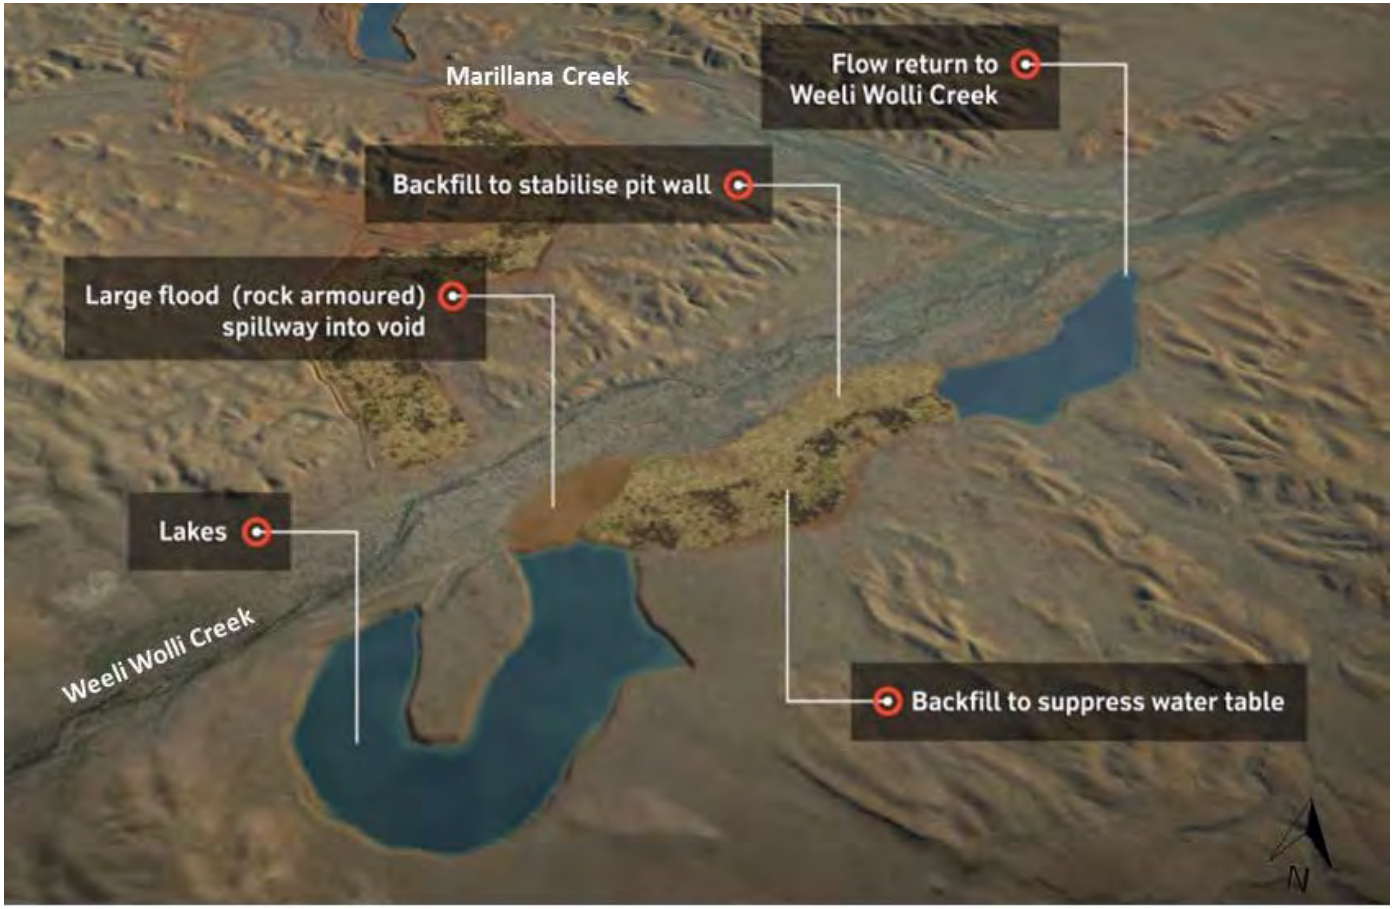

Figure 77: Post-closure landform of the Proposal

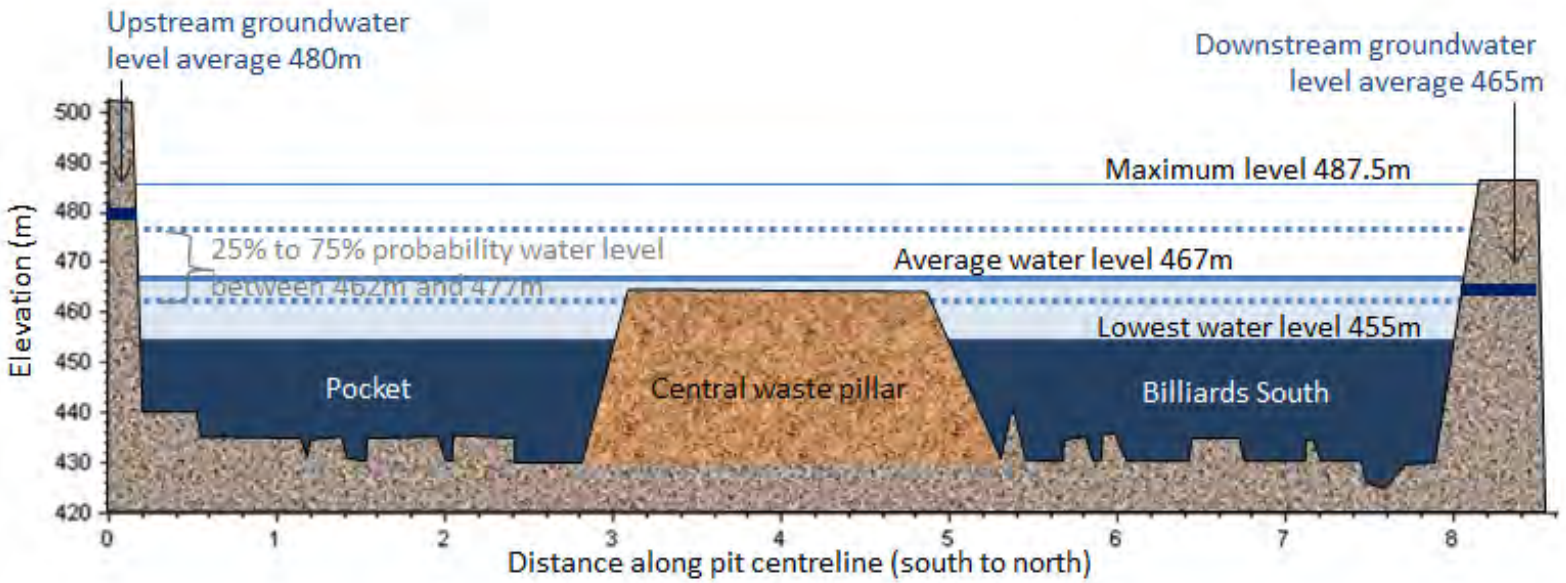

Figure 78: Proposal proposed pit lake cross-section

Rehabilitation strategies

17.2.4.1 Desktop Assessment of Rehabilitation

Rio Tinto has developed practice standards for rehabilitation, as described in the following standards:

- Iron Ore (WA) Rehabilitation Management Plan.
- Iron Ore (WA) Landform Design Guidelines.

The rehabilitation performance of Pilbara geologies and ecosystems that are similar to the Proposal Area were assessed via a desktop assessment to determine if Rio Tinto's standard practice would enable the Proposal's closure objectives to be met (**Table 40**; **Appendix 4**). The assessment was undertaken by comparing key indicators of rehabilitation success against benchmarks established in adjacent reference/control sites for different disturbance types, including:

- created landforms, e.g. the mineral waste buttress proposed to be developed within the mine void;
- long term disturbance areas, e.g. laydown areas, permanent facilities;
- short term disturbance areas, e.g. borrow pits and access tracks; and
- linear and fragmentation disturbances, e.g. road and powerlines.

Table 40: Examples of rehabilitation success across Rio Tinto's Pilbara operations

Rehabilitation Type	Key Similarities to the Proposal	Examples Reviewed	Applicability to Proposal
Created landforms (e.g. waste rock dump)	Channel Iron Style Deposit Detrital Ion Style Deposit	Mesa J Waste Dump S, Waste Dump T Brockman 2 Pit 2 Waste Dump	Rehabilitated mineral waste slopes within the pit area that are well above the water table
Short term disturbances (e.g. borrow pits and access tracks)	Minor earthworks in top few metres of the profile (topography), disturbed and rehabilitated in short time frames, minor earthworks in top few metres of the profile (topography),	Yandi Borrow Pits 363,374 & 417 Hope downs 4 Haul roads, Borrow Pits, Power Line & Railway construction rehabilitation	Borrow pits, access tracks
Long- term disturbances (e.g. construction camp, permanent accommodation villages)	Minor earthworks in top few metres of the profile (topography), generally flat areas, disturbed and rehabilitated in longer time frame	Yandi Landfill (disturbed for 3 and a half years prior to rehabilitation) Mesa A Fixed Plant	Laydown yards

Linear and/or fragmentation disturbances (e.g. roads, powerlines, bore fields)	Considered as similar to the short term disturbances – Minor earthworks in top few metres of the profile (topography), minor earthworks in top few metres of the profile (topography),	As per the short term disturbances examples	Roads, power lines

Created landforms are considered to be the most challenging areas to rehabilitate. Created landforms that will be developed as part of the Proposal's post-closure landform include rehabilitated slopes, associated with decommissioned infrastructure, and the development of the in pit buttress landform. There have been limited opportunities to undertake rehabilitation of created landforms at the existing Yandi Operations, as these features are used or modified as part of daily activities, e.g. in pit waste dumps are still under construction. However, mineral wastes with similar material type properties have been rehabilitated using the Proponent's standard practice at other Rio Tinto managed operations and provide a means of assessing expected rehabilitation performance for the Proposal Area (details are provided in **Appendix 4**).

In accordance with Rio Tinto's standard practice, created landforms and long term disturbances are rehabilitated by:

- considering the local climate conditions and physical properties of the soil and mineral waste properties when designing slopes;
- shaping the built or disturbed landform to blend with the surrounding topography;
- applying topsoil and salvaged vegetation, when available; and
- ripping along the contour then seeding.

Rehabilitation of the Dump S overburden waste dump at Robe River's Pannawonica Operation (a CID style deposit) was completed in 2001. Rehabilitation monitoring shows good perennial species diversity with 13 species present, which exceeds the slope benchmark of seven species. The lower storey vegetation, although present, was slow to develop and currently represents a very small proportion of the total cover. The cover composition differs across the rehabilitation area, and thus is slightly different to the reference sites. However, total plant cover percentages and density values are within or above the range exhibited within the reference sites, and rehabilitation is considered to be on track to provide a stable, native and self-sustaining ecosystem with habitat for native fauna present.

Overall, the Proponent's standard rehabilitation practices are considered sufficient to meet the Proposal's closure objectives for general created landforms, long term disturbance areas, short term disturbance areas and linear/fragmented disturbance area.

However, no rehabilitation activities have been completed adjacent to open water bodies on Rio Tinto managed operations, such as those proposed to be developed within the mine void post-closure (**Table 41**). These landforms, which form part of the dynamic wetland environment, will incorporate soil and water interactions that do not occur naturally in the neighbouring environment; although similar landforms are expected to be constructed throughout the Weeli Wolli Creek catchment as part of the existing Yandi Operations, and other mining company closure strategies.

Table 41: Rehabilitation types and gaps in knowledge

Rehabilitating Type	Applicability to Yandi	Knowledge Gaps
Created Landforms - backfilled alluvial waste that forms the pit lake fringes	Pit lake built edges (excludes pit walls)	• Landform design that will ensure alluvial materials will form stable slopes with undulating water levels. • Surface treatments required (if any) to enable vegetation growth and slope stability (eg. mulch, ripping, armouring, topsoil alone or rehab into alluvial materials with no treatment). • Species selection (what species will establish and grow with increased soil moisture, wet roots and survive with undulating water levels). • Species selection that are applicable to changing quality of water levels (increasing salinity and then flushes of fresh water).
Created Landforms - tailings storage facilities	In pit Tailings Storage Facility	• Landform design – particularly if capping is required and how much. • Species selection (what species will establish and grow with the growth medium which could be tailings and no capping, differing amounts of capping and topsoil).
Created Landform - backfilled pit large flat plains built of alluvial material	The backfilled pit areas that exist between the pit lakes	• Landform design to support stability and vegetation growth (e.g. gentle undulating peaks and troughs or very slight angle for drainage or completely flat). • Species selection (what species are best suited to flat alluvial areas that may be infrequently inundated).

The Proponent recognises the importance and challenges associated with creating these unusual habitats. In response, the Proponent has initiated research programs and rehabilitation trials, as described in the Yandicoogina Closure Plan, to investigate:

- how local creek species germinate, establish and grow in response to groundwater changes when grown in mineral waste (growth media);
- whether these species thrive post-germination with variable access to the groundwater table;
- which plant species combination(s) ensure wetland and floodplain vegetation communities are self-sustaining;
- what landform shapes support lake littoral zone development and other niche habitats; and
- what management is required to ensure water quality in the recovering lakes remain non-toxic and promotes ecosystem development.

The wetland rehabilitation trial at the existing Yandi Operations, which commenced in 2014, is an example of the ongoing research. This trial will establish how common Pilbara plant species of local provenance grow on sheltered lake fringes. The trial is being conducted on slopes created from mineral waste located on top of the exposed groundwater table, similar to the post-closure pit lake environment. Monitoring equipment has been installed to monitor moisture and temperature down the soil profile as the plants grow. The performance of mineral waste slope batter angles of 20 degrees and 10 degrees will also be reviewed as part of the study.

17.2.4.2 Rehabilitation Activities Undertaken to Date

Yandi Operations have completed 86 ha of rehabilitation since 1998. Rehabilitation opportunities have been limited as the majority of the disturbed areas are actively utilised as part of daily mining activities. Completed rehabilitation comprises of a small waste dump, numerous borrow pits and construction related rehabilitation, exploration related rehabilitation and completed landfill sites.

Borrow pits associated with the railway at the existing Yandi Operations were rehabilitated in the second half of 1998. In accordance with Rio Tinto's standard practice (applicable for short term disturbance and linear infrastructure) the borrow pits were rehabilitated by:

- re-shaping the disturbed area, where required, to ensure it is free draining and blends with surrounding topography;
- replacing stockpiled topsoil and salvaged vegetation; and
- ripping along the contour (no seed applied).

Monitoring completed in 2013 show that vegetation communities have similar number of species, plants per quadrant and percentage of perennial cover when compared to reference sites (**Table 42**), and are on target to achieve the closure objectives. Differences between the rehabilitated areas and reference sites are believe to result from changes to the vegetation communities after a bushfire. There is no evidence of erosion in any of the borrow pits.

Table 42: Selected monitoring results of the Borrow Pit rehabilitation areas and reference site values (shown in brackets).

Borrow Pit	Age of Rehabilitation (years)	Number of Species (Rehab)	Plants per Quadrant	% Perennial Cover	Summary
BP363	14	7 (8)	4.3 (4.2)	45 (64)	Site continues to compare favourably with the reference site
BP374	14	7 (13)	5.6 (20.3)	55 (53)	The 2007 burn in the reference site significantly changed a number of key parameters, making comparison of the two sites difficult. Overall, site is developing well.
BP417	14	7 (7)	3.3 (13.3)	49 (31)	Vegetation communities exhibiting similar trends to reference sites prior to a fire in 2010. Different trends apparent after fire. Overall, site is developing well.

17.2.4.3 Planned Progressive Rehabilitation at Yandicoogina

In 2017, the first substantive area of disturbance not required for future operational use is expected to be available for rehabilitation (subject to confirmation). Detailed rehabilitation designs for this area are expected to be included in the next update to the Yandicoogina Closure Plan.

17.2.5 Post-mining land use

Rehabilitation undertaken outside of the mine void is expected to be compatible with the pre-mining and adjacent (current) cattle grazing pastoral activities. However, the volume of overburden and waste material generated by implementing the Proposal is relatively low compared to the volume of ore extracted. As a consequence, there is insufficient overburden and waste material available to backfill into the pit to cover the groundwater table on closure or reinstate the natural surface, resulting in the creation of permanent pit lakes post-closure.

The mine void and resulting post-closure wetland, the pit lakes and the associated lake fringe proposed to be developed in the mine void of the Proposal Area, may not be compatible with cattle grazing pastoral activities. Alternatives to cattle grazing, for the created wetland, are under investigation in consultation with relevant stakeholders (including Pastoral Stations and Aboriginal Traditional Owners). Until an alternate land use is agreed for the pit lake areas, the Closure Plan has been prepared to ensure the area remains compatible with general Pilbara land uses, by:

- designing landforms that are stable for access by humans and native fauna;
- ensuring the water systems support existing riparian vegetation and are compatible with the natural system dynamics; and
- planning for a wetland ecosystem created from native vegetation that is compatible with the surrounding environment.

17.3 Assessment of potential impact, mitigation and residual impact

The impacts created by implementing the Proposal (beyond those generated by the existing Yandi Operations) include the loss of vegetation and habitat, soil disturbance, changes to the natural landforms and drainage features, and a lower groundwater table.

17.3.1 Post-mining land use

The values and constraints of the surrounding physical and biological environment need to be considered when selecting appropriate land use options for the Proposal Area post-mining. Heritage requirements and agreements with native title claimants, and other socio-economic aspects of the Proposal must also be taken into account.

Rehabilitation undertaken outside of the mine void is expected to be compatible with the pre-mining and adjacent (current) cattle grazing pastoral activities. However, the mine void resulting from implementation of the Proposal is not compatible with the pre-mining land use of cattle grazing pastoral activities. Other potential impacts could include unstable landforms, altered hydrology, changes to water chemistry, contamination and/or limited return of the native ecosystems.

17.3.2 Hydrological processes and inland environmental water quality

Groundwater modelling studies indicate that aquifer recharge and through-flow are important processes for maintaining water quality (principally low salinity), particularly for the Proposal.

The post-closure landform including the development of permanent pit lakes may influence the way surface and groundwater inputs are redistributed within, and released from, the Proposal Area. This in turn could influence aquifer water quality and riparian environments within the Proposal Area and to some extent, downstream. There is a risk that inappropriate landform design could result in increased salinity within the adjacent

aquifers, increased sediment load within the adjacent drainage network and subsequent ecosystem degradation.

Water quality will vary over time, depending on the different interactions between the groundwater source, surface water systems, the water levels, climatic conditions and whether groundwater or surface water can exit the pit lakes.

17.3.3 Vegetation

Disturbed areas, excluding the pit walls and pit lake water body, will be revegetated using locally occurring native species. The design of the final landform will influence its suitability for establishing particular vegetation communities and its long term persistence. Key factors include:

- Providing stable landforms with infiltration and runoff characteristics that support vegetation growth, reproduction and vegetation succession.
- Soil profiles with adequate water holding capacity and physiochemical characteristics, to enable plant root system development and access to water and nutrients.
- Minimising exposure to water quality conditions which may not support local vegetation, for example extremes of soil pH, salinity and exposure to toxic metal ions.
- Developing vegetation communities suited to the changed (wetland) environments.

Inappropriate landform construction may affect the rehabilitated area's ability to support native vegetation and meet revegetation completion criteria. Poorly designed and/or poorly implemented rehabilitation could also result in suboptimal vegetation re-establishment and increased numbers of weed species. Topsoil handling and storage practices are important for maintaining seed viability and enhancing rehabilitation success.

17.3.4 Fauna

17.3.4.1 Terrestrial Fauna

The final landform will be gradually recolonised by native fauna. The ability of fauna to use the area will be influenced by landform components and configurations, with some species being favoured and others disadvantaged. Inappropriately constructed habitat could lead to poor habitat use or favour undesirable species, such as feral animals.

17.3.4.2 Subterranean Fauna

Mining activities will result in the removal of subterranean habitat. The design of the post-mining landform will influence the amount of habitat retained in the Proposal Area, for the persistence of stygofauna assemblages post-mining. Factors that could detract from reinstating suitable habitat include:

- reduction of void space within the alluvials due to silt and sediment runoff from surrounding habitat;
- the development of saline pit lakes and saline groundwater aquifers;

- nutrient enrichment derived from the surface infiltration, e.g. due to a lack of buffering vegetation; and

- hydrology changes.

Aquatic fauna in Weeli Wolli Creek may also be impacted a result of changes to the hydrology of Weeli Wolli Creek system, development of a permanent pit lake and water quality (including salinity and nutrient enrichment).

17.3.5 Aboriginal Heritage

The post-mining landform could affect the accessibility of heritage sites and the ability of the Traditional Owners to use the Proposal Area for cultural and amenity purposes. These uses require safe and stable landforms that are suitably integrated with the wider landscape and environment.

17.4 Key management actions

Closure management, monitoring and mitigation measures required to achieve and demonstrate successful rehabilitation and closure of the Proposal Area are discussed within the Yandicoogina Closure Plan (**Appendix 4**).

Closure management includes regular review and update of the Yandicoogina Closure Plan, to account for changes resulting from:

- amendments to the mine plan;

- improvements of the site closure knowledge base (e.g. through daily activities, technical studies and research actions, progressive rehabilitation);

- new or amended regulation;

- changes to surrounding land uses; and

- evolving stakeholder expectations.

The review processes bring experts and stakeholders together to discuss current performance, proposed mine changes and opportunities to improve closure outcomes. A key aspect of the review process is the risk identification and management process. This process:

- Identifies hazards, aspects and opportunities, within the current closure strategy and associated with the current level of knowledge, that could influence the successful closure of Yandicoogina.

- Evaluates the hazards and opportunities with respect to the impact to people, property and / or the environment.

- Defines the actions required to improve knowledge, management guidance and / or the closure strategy.

Understanding of the local ecosystem will be advanced through implementation of the Proposal management programs and actions identified through the Closure Plan review process. As a result, the detail within the Yandicoogina Closure Plan will increase over the life of the Proposal.

The closure landform will be rehabilitated to include a wide variety of habitats, including:

- exposed bare rock areas, associated with the pit walls and rock armoured slopes;
- *Acacia* dominated plains-style habitat, similar to the pre-disturbance habitat;
- creek and floodplain habitat, similar to the pre-disturbance habitat; and
- created wetland habitats surrounding the pit lakes.

The mine void and post-closure landforms within the mine void, such as the fringe of the pit lakes, may not be compatible with cattle grazing activities that dominated the area prior to mining. Land capability assessments will be completed during the life of Proposal, based on post-closure ecosystem functionality, to guide discussions with key stakeholders on post-mining land use. Post-closure land uses will be resolved with key stakeholders prior to closure.

When the site approaches scheduled closure, location specific management plans will be finalised for each closure domain. These plans will detail the physical closure, dismantling and subsequent rehabilitation implementation, in accordance with the closure objectives and legal obligations. Stakeholder engagement and endorsement of the final completion criteria will be facilitated at this time, and the post-closure monitoring program will be finalised in alignment with the agreed completion criteria. These monitoring programs are expected to address:

- vegetation, erosion and ecological function;
- invasive species, including weeds and feral animals;
- terrestrial fauna and stygofauna;
- surface water and groundwater levels, quality and contaminants; and
- heritage.

Monitoring programs will define triggers and provide details of management actions and strategies to be implemented should the trigger levels be exceeded.

In the event of temporary closure, measures will be undertaken to transfer the site from operations into a care and maintenance regime and relevant authorities notified. A Care and Maintenance Plan will be developed prior to the care and maintenance period, which demonstrates how ongoing environmental obligations associated with the site will continue to be met during the period of care and maintenance. Social obligations and responsibilities will also be addressed in this plan.

17.5 Predicted outcome

Implementation of the Yandicoogina Closure Plan is expected to produce the following long term outcomes for the Proposal Area:

- Pit walls of the final mine void that are adjacent to Weeli Wolli Creek are stabilised in a way that prevents the creek from collapsing into the mine voids post-closure, ensuring continued function of Weeli Wolli Creek.
- All areas disturbed for mining (with the exception of pit walls) and infrastructure that are not required by the State (under conditions of applicable State

Agreements) are rehabilitated to a condition compatible with the post-mining land use following decommissioning.

- Creation of a dynamic wetland environment within the mine void, including two pit lakes and associated lake fringe, with water levels that will rise and fall in accordance with flooding of the creek systems.
- Regional hydrogeological impacts are minimised and adequately managed.
- Outside of the mining disturbance areas and more than 2 km from the Proposal mine voids, water levels are largely predicted to return to pre-disturbance levels.
- No impacts to the hydrological regime of the Fortescue Marsh as a result of closure of the site.

These outcomes suggest the Proposal is not likely to result in significant environmental impact. During the life of the Proposal, investigations and an adaptive management approach will be used to ensure that risks to closure are identified and addressed so as to meet the EPA's objective for rehabilitation and closure.

18. Offsets

18.1 Key statutory requirements, environmental policy and guidance

18.1.1 EPA objective

The EPA has applied the following objective for the Proposal to its assessment of residual risk management:

"To counterbalance any significant residual environmental impacts and/or uncertainty through the application of offsets."

18.1.2 Relevant guidelines and policy

Environmental offsets are "*actions that provide environmental benefits which counterbalance the significant residual environmental impacts or risks of a proposal. Unlike mitigation actions which occur on-site as part of the proposal and reduce the direct impact of that project, offsets are undertaken outside of the Proposal Area and counterbalance significant residual impacts*" (EPA 2014a).

The following guidelines and polices are relevant to the Proposal with respect to offsets and the above EPA objective:

- EPA Environmental Protection Bulletin No. 1 – Environmental Offsets – Biodiversity (EPA 2014a);
- WA Environmental Offsets Policy (Government of Western Australia 2011); and
- WA Environmental Offsets Guidelines (Government of Western Australia 2014).

18.2 Description of potential residual impacts

"*In general, significant residual impacts include those that affect:*

- *rare and endangered plants and animals (such as Declared Rare Flora and threatened species that are protected by statute);*
- *areas within the formal conservation reserve system;*
- *important environmental systems and species that are protected under international agreements (such as Ramsar listed wetlands); and*
- *areas that are already defined as being critically impacted in a cumulative context.*

Impacts may also be significant if, for example, they could cause plants or animals to become rare or endangered, or they affect vegetation which provides important ecological functions" (Government of Western Australia 2014).

The following elements are considered in quantifying the significant residual impact (Government of Western Australia 2014):

- extent of impact (hectares or numbers);
- quality of the environmental value;
- conservation significance of the environmental value;
- land tenure; and
- time scale.

Potential impacts associated with the Proposal in relation to offsets were identified by the EPA in the ESD as:

- Potential impacts on vegetation, flora, habitat and fauna species of State and National Significance.

Potential impacts for vegetation, flora, habitat and fauna species of State and National Significance are addressed in the following sections:

- Section 14 - Flora and vegetation; and
- Section 15 - Terrestrial fauna and habitat.

18.3 Residual impact evaluation for vegetation, flora, habitat and fauna species of State significance

Taking into account measures to avoid, minimise and rehabilitate impacts (**Table 43**), the following significant residual impact arising from the Proposal has been identified:

- Clearing of up to 1,731 ha of native vegetation in Good to Excellent condition within the Proposal Area, including fauna habitat (excluding riparian zone vegetation[9]).
- Clearing of up to 69 ha of native riparian zone vegetation[9] within the Proposal Area, including fauna habitat.

While 1,327 ha of vegetation is currently proposed to be cleared within the Proposal Area as part of the current mine layout (1,277 ha in Good to Excellent condition, which includes 2.9 ha of riparian zone vegetation), approval for clearing of up for 1,800 ha of the Proposal Area is being requested as part of the Proposal, to allow for flexibility with mine planning and development. As the location of up to 457 ha (excludes 16 ha of riparian zone vegetation) of this vegetation clearing is unconfirmed (and thus the condition of this vegetation is also unknown), it has been assumed this vegetation is in Good to Excellent condition; thus 1,731 ha of vegetation in Good to Excellent condition is proposed to be offset. A total of 69 ha of riparian zone vegetation is also proposed to be offset as good to excellent condition due to its local significance, irrespective of its actual condition.

The EPA has raised concerns regarding cumulative impacts on terrestrial biodiversity values in the Pilbara IBRA region (Government of Western Australia 2014). A number of recommendations have been made to improve management and monitoring of issues in the area, including the establishment of a strategic conservation initiative to coordinate delivery of offsets in the Pilbara.

Consistent with the WA Environmental Offsets Guidelines (Government of Western Australia 2014), it is considered that the residual impact of disturbance of vegetation in Good to Excellent condition is significant and will therefore require compensation via an offset. A standard offset approach has been developed by the EPA in regard to this residual impact and it has been applied consistently to projects in the Pilbara. As such, the Proponent is proposing to contribute funding of $1,500 (excluding GST) per hectare of native vegetation, and funding of $3,000 (excluding GST) per hectare of riparian

[9] For the purposes of the offset calculation, riparian zone vegetation is classified as vegetation units within the riparian zone comprising C-coded and F2 coded vegetation located within the RCA.

vegetation cleared to a government-established conservation offset fund or an alternative offset arrangement providing an equivalent outcome as determined by the Minister.

Table 43: Quantification of significant residual impacts and proposed offsets

Existing environment /Impact	Mitigation			Significant Residual Impact	Offset Calculation Methodology				
	Avoid and minimise	Rehabilitation Type	Likely rehabilitation success		Type	Risk	Likely offset success	Time Lag	Offset Quantification
EPA objective: *To counterbalance any significant residual environmental impacts and/or uncertainty through the application of offsets.*									
Up to 1,800 ha of clearing of native vegetation, including fauna habitat, considered to be in Good to Excellent condition, including 69 ha of riparian zone vegetation	The Proposal has been designed to minimise the required amount of clearing; being an extension of an existing mine site enables utilisation of many existing facilities and reduces the footprint that would otherwise have been required.	Areas will be progressively rehabilitated with local native vegetation. The Yandicoogina Closure Plan will be implemented to ensure that the Proposal can be closed in an ecologically sustainable manner, consistent with agreed outcomes and land uses.	Can the environmental values be rehabilitated/ Evidence? Operator experience in undertaking rehabilitation? Yes – Rio Tinto has completed several areas of successful rehabilitation including examples within the Yandicoogina operation. What is the type of vegetation being rehabilitated? Assorted vegetation assemblages associated with plains, hills, flow lines and terminal basin habitat types. Time lag? Progressive rehabilitation where practicable; with mining of Proposal pit currently expected to be complete in 2032 (this timing may change). Credibility of the rehabilitation proposed (evidence of	Extent: 1,800 ha (1,731 ha Good to Excellent vegetation and 69 ha riparian zone vegetation) Quality: Vegetation is in Good to Excellent condition; provides fauna habitat. Riparian zone vegetation is in Very Poor to Excellent condition; provides fauna habitat. Conservation Significance: Local conservation significance for riparian vegetation Land Tenure: N/A Time Scale: N/A	Provision of funds to a government-established conservation offset fund or an alternative offset arrangement providing an equivalent outcome as determined by the Minister. 			demonstrated success) See previous rehabilitation from Rio Tinto.						
DRF - *Lepidium catapycnon*	Reconfigured waste dumps to avoid all recorded *L. catapycnon* populations (as well as applying a 50 m buffer) within the Proposal Area; all populations identified as 'areas of special protection from ground disturbance'.	Rehabilitation of areas surrounding DRF locations will occur in accordance with the Yandicoogina Closure Plan.	Rio Tinto has completed several areas of successful rehabilitation including examples within the Yandicoogina operation.	No.	N/A	N/A	N/A	N/A	N/A
Priority flora – Four populations (37 individuals) of *Goodenia nuda* (P4) will be impacted	Impact on individuals within Proposal Area represents less than 1% of Rio Tinto records for the species within the Pilbara.	Rehabilitation of Proposal Area will occur in accordance with the Yandicoogina Closure Plan.	Rio Tinto has completed several areas of successful rehabilitation including examples within the Yandicoogina operation.	No.	N/A	N/A	N/A	N/A	N/A

Recorded Threatened fauna species: - Pilbara Olive Python (*Liasis olivaceus barroni*); Schedule 1, Vulnerable Recorded Migratory fauna species: - Eastern Great Egret (*Ardea modesta*); Schedule 3, Migratory - Fork-tailed Swift (*Apus pacificus*); Schedule 3, Migratory - Rainbow Bee-eater (*Merops ornatus*); Schedule 3, Migratory Recorded Priority fauna species: - Western Pebble-mound Mouse (*Pseudomys chapmani*); Priority 4	Approximately 90% of the core habitat identified for the Pilbara Olive Python within the Proposal Area will be retained; with the species recorded in the broader Yandicoogina area and throughout the Pilbara bioregion. Implementation of the Yandicoogina EMP will further reduce any impacts to the species from car collisions or feral animals. The recorded Migratory fauna species are considered transient, highly mobile, common and/or widespread in the Pilbara bioregion and are unlikely to be reliant on habitats within the Proposal Area. Eleven known mounds of the Western Pebble-mound Mouse will be removed as a result of the Proposal, however, the species is considered to be broadly distributed throughout the Pilbara bioregion.	Rehabilitation of Proposal Area will occur in accordance with the Yandicoogina Closure Plan.	Rio Tinto has completed several areas of successful rehabilitation including examples within the Yandicoogina operation.	No.	N/A	N/A	N/A	N/A	N/A

19. Other environmental factors

19.1 Aboriginal heritage

19.1.1 Assessment of potential impacts

The major risks to Aboriginal heritage are related to the disturbance of archaeological or ethnographic sites and impacts on the heritage values of sites and places. Aboriginal heritage sites could potentially be disturbed by proposed activities such as clearing, dewatering, excavation and surface water discharge, although it is Rio Tinto's policy to avoid heritage sites, wherever practicable. Aboriginal archaeological and ethnographic surveys have been completed for the majority of the Revised Proposal Development Envelope. Numerous Aboriginal archaeological sites have been recorded in the locality ranging from low to high in archaeological and cultural significance (Rio Tinto 2014b). A number of ethnographic sites have been identified in the Yandicoogina region in connection to the Marillana Creek and Weeli Wolli Creek. The creeks are recognised to have important links with camping activities, ceremonial activities and other cultural activities (Rio Tinto 2014b).

Section 18 approvals under the *Aboriginal Heritage Act 1972* will be required where disturbance to heritage sites cannot be avoided. All potential indirect impacts to heritage sites and cultural values are also considered prior to any works approvals being granted (e.g. relating to dust, blasting, dewatering, discharge and subsidence). These are often site and works specific, and as such mitigation measures may vary.

A heritage zone is currently delineated around Weeli Wolli Creek, due to the association of this site with camping activities, ceremonial activities and other cultural activities. However, it is noted that part of the proposed mining activities occur within this exclusion zone. Proposed mining activities include the clearing of up to 69 ha of riparian zone vegetation within the proposed Restricted Clearing Area, locating some infrastructure within the heritage zone, and alteration to the creek system by groundwater drawdown from the mine and surplus water discharge. Any long term alteration to the regional water regime is also considered to likely be of high cultural significance (Rio Tinto 2014b). Rio Tinto is required to consult with Traditional Owners prior to any disturbance within this exclusion zone and engage them in the approvals process. Consultations to date have been on both a broader level and a detailed level with the main concerns raised by Traditional Owners being in relation to cultural landscape changes as a whole. While there will be some disturbance to Weeli Wolli Creek, it has been identified that the pit lakes proposed to be present at closure do have the potential to provide for alternate land use (Rio Tinto 2014b).

19.1.2 Proposed mitigation and management measures

Management strategies to address the potential impacts identified are briefly summarised below. These strategies are in place to ensure identified significant areas are protected as much as possible, in accordance with the following Rio Tinto practices and procedures for protecting Aboriginal heritage sites:

- Rio Tinto Cultural Heritage Management Procedure.
- Rio Tinto Heritage Policy.

Rio Tinto also adheres to environmental legislation with relevance for managing potential impacts on heritage values (such as dust control), together with Rio Tinto's internal environmental and health compliance policies and procedures.

Specific strategies for mitigating impacts to heritage values include:

- Complying with the *Aboriginal Heritage Act 1972.*

- Seeking statutory heritage approvals.
- Continuing consultation with the Traditional Owners likely to be affected by the Proposal. Previous comments received from Traditional Owners during consultation are summarised in Section 3.
- Implementing the Aboriginal Heritage Management Guidelines, in conjunction with the Cultural Heritage Management Plan.
- Avoiding Aboriginal heritage sites whenever reasonably practicable in accordance with internal Rio Tinto guidelines and policies.
- Creation and implementation of a heritage drill and blast management plan, where applicable.
- Appropriately fencing/signposting or barricading key heritage sites outside the footprint area (where approval to disturb is not being sought under the *Aboriginal Heritage Act 1972)* to prevent inadvertent impacts to these sites, or alternative suitable approaches agreed with Traditional Owners.
- Stopping work immediately if human remains or archaeological material are accidentally uncovered during any ground-disturbing activity, and contacting the DAA and Rio Tinto's Heritage team.
- Requiring all personnel working in the Proposal Area to attend inductions for the area covering Health, Safety and Environmental requirements, of which Cultural Heritage Awareness is one component.
- Cultural heritage values associated with the Proposal Area to be maintained post-closure as per Yandicoogina Closure Plan.

19.1.3 Predicted environmental outcome

After mitigation and management measures have been applied, the Proposal is expected to have some effect on the ethnographic cultural values of Weeli Wolli Creek. Any disturbance within the Weeli Wolli Creek heritage zone or of other archaeological/ethnographic sites will be in accordance with the provisions of the *Aboriginal Heritage Act 1972* and will have the consent of the relevant Traditional Owners. Rio Tinto will maintain ongoing consultation with Aboriginal stakeholders over the life of the Proposal, in accordance with processes established for the existing Yandi Operations.

19.2 Air quality

19.2.1 Assessment of potential impacts

Air quality has the potential to be negatively impacted by dust created by the Proposal. Dust will be generated by construction and mining activities such as vegetation clearing, earthworks and mining (including blasting), vehicle movements and dry ore processing, stockpiling, reclaiming and transport. The potential impact of dust on native vegetation is discussed in Section 14.3.5.

As the majority of the Iron Ore at the Proposal is below watertable ore, the moisture content of the ore will reduce the likelihood of dust-related impacts from materials handling. Additionally, the Proposal is remote from sensitive air quality receptors, with other mining operations being the nearest premise. There have never been any complaints received in regard to dust emissions from the existing Yandi Operations, with existing mitigation measures to be implemented for the Proposal. Dust emissions are also an occupational health and safety risk for employees at the mine site, and as such are managed appropriately.

19.2.2 Proposed mitigation and management measures

Dust management procedures successfully employed at existing Rio Tinto mines will be used to control dust emissions. Potential dust emissions from processing facilities that are currently operational at the Yandi Operations, and will be utilised for processing of ore from the Proposal, may also be subject to controls imposed through an environmental licence required for such prescribed premises, in accordance with Part V of the EP Act. The strategies for minimising impacts from dust include:

- Clearing work areas only as they are required.
- Minimising exposed surfaces by progressively rehabilitating disturbed and available areas no longer in use.
- Applying water, or appropriate suppressants to haul roads, working surfaces and stockpiles as required.
- Implementing speed limits to minimise dust generation from roads.

19.2.3 Predicted environmental outcome

There is not expected to be a significant air quality impact as a result of the Proposal. Existing Rio Tinto procedures and practices used at the existing Yandi Operations to effectively prevent significant dust emissions will be applied to the Proposal and the ore is predominantly below the water table so presents a lower dust risk.

19.3 Amenity

19.3.1 Assessment of potential impacts

The Proposal is located within the south east corner of the Revised Proposal Development Envelope. The Revised Proposal Development Envelope is not located near any major population centres, with the closest town of Newman being located approximately 90 km to the south east. Tourism in the vicinity is very limited, with the only significant feature being the Weeli Wolli Spring, located approximately 7 km south of the Proposal Area.

The topography of the area around the Proposal range from hilly terrain to the northwest and southeast of the deposit, which descends into the Weeli Wolli Creek floodplain, where the Proposal pit lie. Through the life of the Proposal there will be changes in the immediate vicinity of the mine. Excavation of the mine pit will result in the creation of temporary waste dumps that will be approximately 80 m high, which may be higher in areas than the surrounding landscape which ranges from 50 – 80 m in height above the broader floodplain. These waste dumps will be utilised to backfill part of the mine pit during closure, so the predominantly flat floodplain landscape will be reinstated. There will be a range of other infrastructure and facilities constructed for the Proposal, however, these are not considered to be particularly prominent in the landscape given the proximity to the existing Yandi Operations. The Weeli Wolli Creek crossing will be a culvert bridge arrangement, and hence not an imposing feature on the landscape.

Drawdown of the groundwater associated with dewatering of the mine pit will reduce water available to riparian vegetation along Weeli Wolli Creek, resulting in the death of some native vegetation. Discharge of surplus water to Marillana Creek will also increase the current water available to riparian vegetation in this location, which is likely to cause waterlogging and death of some native vegetation. It is expected that the riparian vegetation will be returned to baseline conditions (i.e. pre-impact from dewatering or surplus water discharge) whereby the system is returned to an ephemeral system.

During mine closure, the maintenance of aesthetic values for cultural and amenity purposes are an important consideration. Creating suitable final landforms and maintaining ecological processes (such as water requirements for vegetation) are significant factors. It is expected that there will be two pit lakes established at the time of closure. These will be located adjacent to Weeli Wolli Creek and form part of the creek system in the long term.

19.3.2 Proposed mitigation and management measures

Proposal implementation will result in a change to visual amenity of the Yandicoogina area, particularly in regard to reduced riparian vegetation and the creation of pit lakes, and it should be considered during the life of the Proposal when possible.

The post-mining landform will affect the accessibility of heritage sites and the ability of the Traditional Owners to use the area for cultural and amenity purposes. These uses require safe and stable landforms that are suitably integrated with the wider landscape and environment. For example, when constructing waste dumps, in pit disposal of waste is preferable. The planned closure will use the waste dumps for infill to the pit. However, there will not be sufficient material to completely backfill the pit void, resulting in two pit lakes being formed in the northern and southern ends of the pit. This will allow for new ecosystems to develop. The measures implemented to maintain amenity upon mine closure are addressed in the Yandicoogina Closure Plan.

19.3.3 Predicted environmental outcome

There will be some temporary and permanent changes to the landforms and general landscape of the Proposal Area. There will be the temporary visual effects in the immediate region around the mine pit with the use of waste dumps and infrastructure/facilities. The extent and condition of riparian vegetation is also expected to be reduced in the long term as the creeks are ultimately returned to an ephemeral system. Through mine closure the visual amenity will be returned as much as possible to the original pre-disturbance landscape. However, two pit lakes will be created within the Proposal Area, which have the potential to create new ecosystems. Amenity will be considered where possible during the life of the Proposal, and the management measures outlined in the Yandicoogina Closure Plan should ensure the key amenity values are maintained after mine closure.

Part 6 – Summary of cumulative impacts

This part provides a summary of the cumulative impacts associated with hydrological processes; flora and vegetation; and terrestrial fauna.

The following factors were considered in regard to cumulative impacts as a key issue for the Proposal:

- Hydrological processes and Inland waters environmental quality:
  - Marillana and Weeli Wolli Creeks.
- Flora and vegetation:
  - Riparian vegetation.
- Terrestrial fauna:
  - Pilbara Olive Python.
  - Chocolate Wattled Bat.
  - Four mygalomorph SRE spiders.

20. Hydrological processes cumulative impacts

The key hydrological receptors near the Proposal are Marillana Creek, Weeli Wolli Creek and Fortescue Marsh. Of these, an assessment of potential cumulative impacts was conducted for Marillana and Weeli Wolli Creeks. Fortescue Marsh will not be affected by the Proposal and therefore was excluded from the CIA.

A preliminary assessment of cumulative impacts to surface water hydrology in the Marillana-Weeli Wolli Creek system was conducted based on a review of the potential impacts of the Proposal, the existing Yandi Operations and six other projects identified as being potentially relevant based on their location in the Weeli Wolli Creek or Marillana Creek sub-catchments of the Upper Fortescue River Catchment.

The average of existing discharge to the Marillana - Weeli Wolli Creek system is approximately 46 GL/y, with a peak of approximately 70 GL/y. Average discharge is expected to increase to approximately 111 GL/y and may reach a peak of approximately 144 GL/y. The existing Yandi Operations, including the Proposal (this assessment), is predicted to account for an average of 55 GL/y (approximately 50% of the total average discharge), with a peak of approximately 83 GL/y (approximately 57% of the total peak discharge).

21. Flora and vegetation cumulative impacts

A preliminary assessment of cumulative impacts to potentially groundwater dependent riparian vegetation (herein defined as vegetation supporting *Eucalyptus camaldulensis* and/or *E. victrix* and/or *Melaleuca argentea*) was conducted based on a review of the potential impacts of the Proposal (Rio Tinto), the existing Yandi Operations and 19 other projects identified as being potentially relevant based on their location in the Upper Fortescue River Catchment (three Rio Tinto and 17 third party projects).

Of the approximately 14,946 ha of potentially groundwater dependent riparian vegetation mapped for the projects considered (including the Proposal), up to 1,800 ha will be disturbed (including areas cleared and areas subject to potentially significant impacts due to groundwater drawdown), which represents approximately 14% of the mapped extent.

22. Terrestrial fauna cumulative impacts

A preliminary assessment of cumulative impacts to the Chocolate Wattled Bat, Pilbara Olive Python and four potential SRE invertebrate taxa was conducted based on a review of the potential impacts of the Proposal, the existing Yandi Operations and other projects identified as being potentially relevant.

Of the approximately 859 ha of potential habitat for the Chocolate Wattled Bat occurring in the Proposal Area, up to 85.9 ha will be cleared for the Proposal. This represents approximately 10% of the extent of this habitat in the Proposal Area. Taken together with the remaining projects for which habitat has been quantified, the cumulative impact is a loss of up to 1,463 ha of potential Chocolate Wattled Bat habitat, which represents approximately 5.6% of the 2,902 ha of habitat mapped across the four projects.

Of the approximately 873 ha of potential habitat for the Pilbara Olive Python occurring in the Proposal Area, up to 87 ha will be cleared for the Proposal. This represents approximately 10% of the extent of this habitat in the Proposal Area. Taken together with the remaining projects for which habitat has been quantified, the cumulative impact is a loss of up to 5,447 ha of potential Pilbara Olive Python habitat, which represents approximately 15% of the 37,376 ha of habitat mapped across the seven projects.

For the four potential SRE invertebrate taxa:

- Approximately 1,439 ha (13%) of the currently known distribution of Nemesiidae sp. N42 (11,300 ha) is located in the Revised Proposal Development Envelope, including less than 1 ha (<1%) in the Proposal Area.
- Approximately 1,638 ha (63%) of the currently known distribution of Nemesiidae sp. N44 (2,600 ha) is located in the Revised Proposal Development Envelope, all of which (63%) is in the Proposal Area.
- Approximately 18,606 ha (7%) of the currently known distribution of Idiopidae sp. I1 (255,900 ha) is located in the Revised Proposal Development Envelope, including approximately 4,231 ha (2%) in the Proposal Area.
- Approximately 157 ha (2%) of the currently known distribution of Idiopidae sp. I9 (6,500 ha) is located in the Revised Proposal Development Envelope, including approximately 50 ha (<1) in the Proposal Area.

Part 7 – Proposed environmental management program and environmental commitments

This part describes the environmental management framework for the Proposal, including management measures identified in Part 5, to prevent and mitigate potential impacts. This part also provides measures to offset significant residual impacts and proposes draft conditions to further ensure the environmental acceptability of the Proposal.

23. Environmental management framework

23.1 Overview

The Proponent is a member of the Rio Tinto Group, which has extensive experience in managing the development, operation and environmental compliance of iron ore mining projects similar to the Proposal. This experience, along with stakeholder consultation, has been used to define the potential environmental impacts from the Proposal, and the proposed mitigation and management measures. The Proponent aims to conduct its business in an efficient and environmentally responsible manner that is compatible with the expectations of stakeholders. A systematic process of environmental management has been adopted, which improves the likelihood that significant environmental impacts have been identified, investigated and mitigated, as far as practicable. As a result, there is greater certainty in achieving desirable environmental outcomes.

At a high level, the Proponent will manage environmental impacts through:

- Complying with environmental approval conditions.
- Maintaining an EMS and supporting business systems.
- Preparing and implementing the management plans for the Proposal as outlined in Section 12, and regularly reviewing the performance of the management plans that address specific environmental factors.
- Measuring energy use and calculating greenhouse gas emissions, and continually seeking opportunities to reduce emissions.
- Improving the efficiency of using natural resources.
- Regularly updating plans for ground disturbance and closure, progressively rehabilitating disturbed land and measuring success.
- Training staff and contractors in environmental requirements and considerations of their work.
- Seeking stakeholder views and ensuring they are respected and considered.
- Reporting regularly to stakeholders on performance.
- Aligning with the Proponent's Health, Safety, Environment, Community and Quality Policy (HSECQ Policy).

23.2 Environmental policies and codes

The Proponent operates under a HSECQ Policy, as all members of the Rio Tinto Group are required to do. The HSECQ Policy is the guiding document for environmental management and provides context and specific direction for continuous improvement.

Rio Tinto has also developed a set of environment standards which establishes Group wide expectations for environmental performance. These standards act to consolidate Group wide principles and guidelines, formalise external voluntary agreements and strengthen Rio Tinto's assurance processes. Operational sites are audited against the standards on a bi-annual basis by Rio Tinto.

Existing environment standards cover:

- Air quality control.
- Hazardous materials and contamination control.
- Mineral waste management (including acid rock drainage).
- Land use and rehabilitation.
- Water use and quality control.

23.3 Environmental Management System

Rio Tinto requires its operations to implement and maintain an EMS that provides a model for continuous improvement, the key elements of which include assessing environmental risk and legal requirements, developing objectives and targets for improvement, training, operational control, communication, emergency response, corrective actions, audits and reviews.

23.4 Sustainability

The Proponent will consider the Rio Tinto Sustainable Development Principles. These principles are applied to all proposals to ensure the sustainable development outcomes align with the sustainability principles stated in the WA State Sustainability Strategy and in the Rio Tinto 'The Way We Work' statement of business practice.

Policies detailed in 'The Way We Work' state that Rio Tinto businesses, projects, operations and products should contribute constructively to the global transition to sustainable development. This will be achieved by helping satisfy global and community needs and aspirations, whether economic, social or environmental. Sustainable development considerations have been made an integral part of business planning, decision making processes and operations.

The Rio Tinto Sustainable Development Principles cover the interrelated streams of environmental stewardship, social wellbeing, economic prosperity, governance and integrity systems. The ten principles are:

- Deliver economic value from our assets and resources.
- Ensure our communities benefit from the value generated by our operations.
- Contribute to the creation of resilient communities.
- Protect the health, safety and wellbeing of our employees, contractors, customers and host communities.
- Attract, develop and retain diverse people with diverse backgrounds and skills.
- Respect the cultures, customs, beliefs and values of our employees, contractors, customers and host communities.
- Demonstrate responsible biodiversity stewardship in the regions in which as operate.

- Improve energy efficiency and contribute to a reduction in greenhouse gas intensity over our product life cycle.
- Responsibly manage our water resources.
- Minimise all forms of environmental harm.

23.5 Summary of likely environmental control instruments

The Proponent has identified the regulatory controls that will ensure that environmental values are protected during implementation of the Proposal. The key controls include, but are not limited to:

- Environmental conditions in any Statement issued by the WA Minister for the Environment allowing the Proposal to be implemented.
- Environmental conditions in any approval conditions issued by the Australian Government Minister for the Environment allowing the Proposal to be implemented.
- Conditions of DER Native Vegetation Clearing Permits, if applicable.
- Conditions of DER Works Approval(s) (under Part V of the EP Act) for construction of works on prescribed premises.
- Conditions of DER Licence(s) (under Part V of the EP Act) for the operation of activities on prescribed premises.
- Conditions of the Licences and Permits for activities relating to the abstraction of groundwater and disturbance to river bed and banks (under the RIWI Act 1914).
- Conditions of any DMP Program of Works or Mining Proposal approvals, if applicable.
- As part of the Proposal, management controls will be implemented to ensure key environmental factors are managed. Other relevant measures and/or actions are also contained in the management plans outlined in Section 11.
-

Table 44: Principles of environmental protection

Principles of Environmental Protection	Relevant (yes/no)	If yes, consideration	Relevant sections of PER
The precautionary principle Where there are threats of serious or irreversible damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation. In application of this precautionary principle, decisions should be guided by: (a) careful evaluation to avoid, where practicable, serious or irreversible damage to the environment; and (b) an assessment of the risk – weighted consequences of various options	Yes	The Proponent uses a risk assessment process in the development of new projects to identify potential issues and management actions early in the study phase. Part of this process includes undertaking site investigations of the biological and physical environments to identify existing conditions and significance as part of a detailed environmental assessment of the Proposal. The risk assessment process used throughout the scoping process identified the environmental factors at risk from the Proposal. These factors and the potential environmental impact on these factors are addressed in this PER document. Scoping of relevant environmental factors was undertaken through the ESD process for the Proposal. The EPA prepared and issued the ESD in consultation with relevant decision making authorities and the Proponent. The EPA, in its development of the ESD, consulted with the Proponent on the details of the Proposal, its environmental setting and the environmental surveys and investigations required and expected outcomes.	Section 9
The principle of intergenerational equity The present generation should ensure that the health, diversity and productivity of the environment is maintained and enhanced for the benefit of future generations	Yes	The Proposal has been developed to align with the Proponent's sustainable development principles which seek to ensure that a balance is achieved between economic, environmental and social aspects of the Proposal activities. These principles are consistent with the intent of the WA State Sustainability Strategy and Rio Tinto's 'The Way We Work' statement of business practice. The Proposal incorporates progressive rehabilitation of disturbed areas through the Yandicoogina Closure Plan. The aim of closure and rehabilitation is to ensure that post-mining land uses are enabled to ensure that relevant areas of the Proposal Area retain enduring value for future generations.	Section 17
The principle of the conservation of biological diversity and ecological integrity Conservation of biological diversity and ecological integrity should be a fundamental consideration	Yes	Environmental studies have been conducted in the Proposal Area to identify environmental values and the risks of impact associated with proposed operations. The requirement and scope of the environmental studies was defined through preliminary risk assessment, stakeholder consultation and scoping of the Proposal as part of the ESD process. Results from these studies have been used in the Environmental Impact Assessment presented in this PER document. A number of biodiversity management measures have been developed. These will be put in place in accordance with the EMS, MMP, SSMP, Yandi SSMP addendum and Yandicoogina Closure Plan to prevent and mitigate potential impacts to local and regional biological diversity and ecological integrity.	Sections 11, 13, 14, 15 and 1
***Principles relating to improved valuation, pricing and incentive mechanisms*:** (a) Environmental factors should be included in the valuation of assets and services (b) The polluter pays principle – those who generate pollution and waste should bear the cost of	Yes	The Proponent conducted a pre-feasibility study of the Proposal, accounting for environmental, economic and social considerations. The full life cycle costs of the Proposal, including costs associated with decommissioning and closure will be re-estimated for internal purposes at various stages of the Proposal life. The importance of improved valuation, pricing and incentive mechanisms is recognised. The Proponent has committed significant human and financial resources to ensure that an environmental management program for the Proposal is well developed and implemented.	Appendix 4 (Yandi MMP)

Principles of Environmental Protection	Relevant (yes/no)	If yes, consideration	Relevant sections of PER
containment, avoidance and abatement (c) The users of goods and services should pay prices based on the full life cycle costs of providing goods and services, including the use of natural resources and assets and the ultimate disposal of any waste (d) Environmental goals, having been established, should be pursued in the most cost-effective way, by establishing incentive structure, including market mechanisms, which enable those best placed to maximise benefits and/or minimise costs to develop their own solution and responses to environmental problems		The Proponent recognises the polluter pays principle, and has designed the Proposal to ensure that pollution impacts are avoided. The potential pollution impacts of the Proposal have been identified and management measures to minimise these impacts developed. Pollution will largely be addressed through a combination of minimisation and on-site treatment, resulting in minimal export of pollutants off-site. Environmental goals will be pursued in the most cost-effective manner, using a combination of internal resources and external expertise where appropriate. A comprehensive approach for mine rehabilitation and closure has been developed in the Yandicoogina Closure Plan.	
The principle of waste minimisation All reasonable and practicable measures should be taken to minimise the generation of waste and its discharge into the environment	Yes	Waste production will be minimised through the implementation of waste management approaches that apply the hierarchy of avoid, reduce, reuse, recycle and recover waste. The Proposal includes measures to minimise the generation of waste and reuse and recycle waste materials, wherever possible.	Appendix 4 (Yandi MMP)

24. Revised Proposal and proposed environmental conditions

The Revised Proposal will be implemented such that the resultant environmental effects will be as anticipated and assessed in this PER document, or as approved for the existing Yandi Operations based on MS 914.

The environmental footprint and other key characteristics of the Revised Proposal have been developed based on the description of the Proposal (Section 4) and MS 914 for the existing Yandi Operations (**Table 46**). A summary of the existing Yandi Operations and Proposal key characteristics, which together comprise the Yandicoogina Iron Ore Project – Revised Proposal, is outlined in **Table 1**, Section 1.4.1.

As the Proponent will be bound to implementing the Revised Proposal in accordance with technical specifications detailed in this PER document and as prescribed in any approval conditions (i.e. Schedule 1 of WA Ministerial Statement), only those elements of the Proposal that are significant from the point of view of environmental protection have been proposed as key characteristics.

The Proponent has also proposed environmental conditions for consideration by the State Minister (**Table 47**). These conditions are based on those outlined in MS 914, which would be superseded by a new Ministerial Statement pursuant to approval of the Revised Proposal. The changes made to MS 914 and the proposed new environmental conditions are also listed in **Appendix 6**.

The proposed Key Proposal Characteristics (**Table 46**) and Environmental Conditions (**Table 47**) have been developed to avoid duplication with other regulatory controls that can be applied under other existing legislation (Section 23.5). A condition relating to the management of a specific environmental factor has not been proposed if environmental impact can be, or is, adequately addressed by other environmental controls.

Table 46: Key Proposal Characteristics

Summary of the Proposal		
Proposal title	Yandicoogina Iron Ore Project – Revised Proposal	
Proponent name	Hamersley Iron – Yandi Pty Limited	
Short description	The proposal is to develop Iron Ore deposits Junction Central, Junction South East, Junction South West, Oxbow and Pocket and Billiard South, located in the central Pilbara region of Western Australia, on mining lease 274SA. Key aspects of the proposal include: • Ore transport and storage infrastructure (including rail link) –overland conveyors, stockyards, ore stackers and ore reclaimers, and storage infrastructure, rail loops. • Rail corridor allowing for rail lines and associated infrastructure. • Construction and operations support infrastructure. • 220kv power network including switchyard, back-up diesel power and transmission lines. • Dry and wet processing plants (including in pit waste fines storage facilities). • Flood protection structures and creek crossings. • Accommodation camps. • Access roads.	
Physical elements	**Location**	**Proposed Extent**
2. Mine and associated infrastructure	Figure 4 and Figure 79	Vegetation clearing up to 7,400 ha within Revised Proposal Development Envelope. Vegetation clearing up to 129 ha within the

		proposed Restricted Clearing Area.
Operational elements	**Location**	**Proposed Extent**
3. Dewatering	Figure 34	No more than 83 GL/year for entire Revised Proposal.
4. Surface water discharge	Figure 34	Up to 78 GL/year for entire Revised Proposal. No water flow or pooling further than 17 km downstream from the Marillana Creek and Weeli Wolli Creek system confluence.

Table 47: Proposed environmental conditions for the Yandicoogina Iron Ore Project – Revised Proposal

Condition No.	Proposed condition
Proposal implementation	
1-1	When implementing the proposal, the proponent shall not exceed the authorised extent of the proposal as defined in Schedule 1, unless amendments to the proposal and the authorised extent of the Proposal have been approved under the EP Act.
Contact details	
2-1	The proponent shall notify the CEO of any change of its name, physical address or postal address for the serving of notices or other correspondence within 28 days of such change. Where the proponent is a corporation or an association of persons, whether incorporated or not, the postal address is that of the principal place of business or of the principal office in the State.
Compliance reporting	
3-1	The proponent shall prepare and maintain a compliance assessment plan to the satisfaction of the CEO at least six (6) months prior to the first compliance assessment report required by condition 3-6.
3-2	The compliance assessment plan shall indicate: (1) the frequency of compliance reporting; (2) the approach and timing of compliance assessments; (3) the retention of compliance assessments; (4) the method of reporting of potential non-compliances and corrective actions taken; (5) the table of contents of compliance assessment reports; and (6) public availability of compliance assessment reports.
3-3	After receiving notice in writing from the CEO that the compliance assessment plan satisfies the requirements of condition 3-2 the proponent shall assess compliance with conditions in accordance with the compliance assessment plan required by condition 3-1.
3-4	The proponent shall retain reports of all compliance assessments described in the compliance assessment plan required by condition 3-1 and shall make those reports available when requested by the CEO.
3-5	The proponent shall advise the CEO of any potential non-compliance within seven days of that non-compliance being known.
3-6	The proponent shall submit to the CEO a compliance assessment report by the end of April each year addressing compliance in the previous calendar year. The compliance assessment report must address compliance for the period from the date of issue of this statement, notwithstanding that the first report may cover a period less or more than 12 months. The compliance assessment report shall: (1) be endorsed by the proponent's Managing Director / General Manager / Chief Executive Officer or a person delegated to sign on the Managing Director's / General Manager's / Chief Executive Officer's behalf; (2) include a statement as to whether the proponent has complied with the conditions; (3) identify all potential non-compliances and describe corrective and preventative actions taken; (4) be made publicly available in accordance with the approved compliance assessment plan; and (5) indicate any proposed changes to the compliance assessment plan required by condition 3-1.
Public availability of data	
4-1	Subject to condition 4-2, within six months of the issue of this statement and for the remainder of the life of the proposal the proponent shall make publically available, in a manner approved by the CEO, all validated environmental data (including sampling

Condition No.	Proposed condition
	design, sampling methodologies, empirical data and derived information products [e.g. maps]) relevant to the assessment of this proposal and implementation of this statement.
4-2	If any data referred to in condition 4-1 contains particulars of: (1) a secret formula or process; or (2) confidential commercially sensitive information The proponent may submit a request for approval from the CEO to not make this data publically available. In making such a request the Proponent shall provide the CEO with an explanation and reasons why the data should not be made publically available.
Surface water discharge (protection of Weeli Wolli Creek)	
5-1	The proponent shall ensure that the discharge of excess water from the Yandicoogina Iron Ore Project – Revised Proposal as a result of mining does not cause long term impacts to environmental values of the Weeli Wolli Creek system.
5-2	To verify that condition 5-1 is being met, the proponent shall maintain an Environmental Values Statement for the Weeli Wolli Creek system that defines the environmental values of the Weeli Wolli Creek system to the satisfaction of the CEO in consultation with Parks and Wildlife.
5-3	The proponent shall ensure that dewatering discharge from the Yandicoogina Iron Ore Project – Revised Proposal does not cause water flow or pooling downstream from the Marillana Creek and Weeli Wolli Creek system Confluence further than the extent identified in Schedule 1 (under natural no flow conditions).
5-4	The proponent shall submit a revised Water Discharge Monitoring and Management Plan in consultation with the DoW, to the satisfaction of the CEO, to ensure that identified environmental values associated with the Weeli Wolli Creek system and any downstream ecosystems, including the Fortescue Marsh, are maintained. This plan shall: (1) describe the water discharge and monitoring program; (2) when implemented, demonstrate by monitoring, whether conditions 5-1 and 5-3 are being met; (3) when implemented, require the proponent to manage the implementation of the proposal to meet the requirements of conditions 5-1 and 5-3; and (4) detail management actions and strategies to be implemented should the monitoring required by condition 5-4 (2) indicate that condition 5-1 or 5-3 may not be met.
5-5	The proponent shall implement the approved Water Discharge Monitoring and Management Plan required by condition 5-4, and any subsequent approved revisions.
Riparian vegetation	
6-1	The proponent shall ensure that surplus water discharge does not cause long term impacts on the health or cover of riparian vegetation or groundwater dependent ecosystems outside the management zones as shown in Figure 80.
6-2	The proponent shall ensure that dewatering discharge does not cause long term impacts on the health or cover of riparian vegetation or groundwater dependent ecosystems outside the management zones as shown in Figure 80.
6-3	The proponent shall manage the proposal in a manner that ensures there is no irreversible impact to riparian vegetation or groundwater dependent ecosystems across the catchment as measured within the management zones shown in Figure 80.
6-4	The proponent shall submit a revised Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan to the satisfaction of the CEO.
6-5	The Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan required pursuant to condition 6-4 shall: (1) when implemented, require the proponent to manage the implementation of the proposal to meet the requirements of conditions 6-1, 6-2, and 6-3; (2) when implemented, require the proponent to monitor to substantiate whether conditions 6-1, 6-2 and 6-3 are being met; (3) identify monitoring and control sites; (4) require the proponent to design a survey to acquire baseline biotic data, including health and abundance parameters and environmental data; (5) define health and cover parameters; (6) define monitoring frequency and timing; (7) identify criteria to measure any decline in health; (8) define critical correlative environmental parameters, including groundwater

Condition No.	Proposed condition
	drawdown; (9) define trigger and threshold levels for 'no irreversible impact'; (10) provide details of management actions and strategies to be implemented should trigger and threshold levels defined pursuant to condition 6-5(9) be exceeded within the management zones.
6-6	The proponent shall implement the approved Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan.
6-7	The proponent shall review and revise the approved Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan at intervals not exceeding five years, to the approval of the CEO.
6-8	Commencing on the date of this statement and until it commences implementation of the revised Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan in accordance with condition 6-6, the proponent shall continue to implement the existing approved Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan.
6-9	In the event that monitoring, undertaken pursuant to condition 6-6, identifies that trigger and threshold levels for no irreversible impact, defined pursuant to condition 6-5(9), have been or are being exceeded within the management zones, the proponent shall implement management actions and strategies defined in condition 6-5(10) to the satisfaction of the CEO.
Weeds	
7-1	The proponent shall ensure: (1) no increase in the species of weeds (including both declared weeds and environmental weeds) in the Proposal Area as a result of the implementation of the proposal; (2) the cover of weeds (including both declared weeds and environmental weeds) within the Proposal Area does not increase as a result of implementation of the proposal; and (3) identification and establishment of reference sites on nearby land outside the impact area shall be undertaken in consultation with the OEPA, on advice from Parks and Wildlife, to the satisfaction of the CEO. The reference sites are to be monitored biennially to determine whether changes in weed cover and type are as a result of proposal implementation or broader regional changes.
Decommissioning and rehabilitation	
8-1	The proponent shall ensure that the proposal is decommissioned and rehabilitated in an ecologically sustainable manner, consistent with agreed outcomes and land uses, and without unacceptable liability to the State of Western Australia, through the implementation of the Mine Closure Plan required by condition 8-2.
8-2	The proponent shall prepare the Yandicoogina Mine Closure Plan in accordance with the *Guidelines for Preparing Mine Closure Plans*, *June 2015* and any updates, to the requirements of the CEO on advice of the Department of Mines and Petroleum.
8-3	The proponent shall review and revise the Yandicoogina Mine Closure Plan required by condition 8-2 at intervals not exceeding three years, or as otherwise specified by the CEO.
8-4	The proponent shall implement the latest revision of the Yandicoogina Mine Closure Plan, which the CEO has confirmed by notice in writing, satisfies the requirements of condition 8-2.
Residual impact and risk management measures	
9-1	The 5,600 ha of clearing of native vegetation previously approved under Ministerial Statement 914 is exempt from the requirement to offset under condition 9-3.
9-2	In view of the significant residual impacts and risks as a result of implementation of the additional clearing for the Yandi PBS Proposal, the proponent shall contribute funds to offset the clearing of 'Good to Excellent' condition native vegetation, and calculated pursuant to condition 9-3. This funding shall be provided to a government-established conservation offset fund or an alternative offset arrangement providing an equivalent outcome as determined by the Minister.

Condition No.	Proposed condition
9-3	The proponent's contribution to the initiative identified in condition 9-3 shall be paid biennially, the first payment due two years after commencement of the additional ground disturbance defined in Schedule 1. The amount of funding will be $1,500 AUD (excluding GST) per hectare of 'Good to Excellent' condition native vegetation and $3,000 AUD (excluding GST) per hectare of riparian zone vegetation cleared within the Development Envelope (delineated in Figure 1 and defined by the geographic coordinates in Schedule 2), within the Hamersley IBRA subregion.

25. Conclusions

This PER provides:

- A description of the key components of the Revised Proposal.
- A summary of the important physical, biological and social factors of the existing environment.
- A discussion of the extent of stakeholder consultation.
- An evaluation of potential impacts of the Proposal to environmental factors, including cumulative impacts.
- Strategies and measures to ensure environmental factors and values are protected and managed to an appropriate level.

The PER has been prepared in accordance with the ESD developed by the EPA (**Appendix 2** and **Appendix 2**).

This PER document and all supporting biological survey reports have been prepared in line with the guidelines presented in the EPA checklist for documents submitted for Environmental Impact Assessment on marine and terrestrial biodiversity (**Appendix 5**).

25.1 Environmental impacts and mitigation

The key environmental factors identified by the EPA in the ESD for the Proposal were:

- Flora and vegetation.
- Terrestrial fauna.
- Subterranean fauna.
- Hydrological processes and Inland waters environmental quality.
- Rehabilitation and closure.
- Residual risk management (offsets).

Other environmental factors identified by the EPA in the ESD to be relevant to the Proposal were:

- Aboriginal heritage.
- Air quality.
- Amenity.

After mitigation and management measures have been applied, it is expected that the Proposal will result in the following residual outcomes in relation to the environmental factors identified by the EPA:

Hydrological processes and Inland waters environmental quality

- Natural surface water systems and flows – potential impacts likely to be minor and can be managed through typical stormwater management measures such as levees around the pit, diversion drains around waste dumps, and culverts under roads.

- Surface water resources including Weeli Wolli Creek due to surface discharge of surplus mine dewater – wetting front will be within existing approved limits, and therefore there will be negligible additional impacts on the downstream hydrological system of Weeli Wolli Creek.
- Altered flow regime to the Fortescue Marsh – surface water wetting front associated with the additional discharge from the Proposal is predicted to remain within existing approved limits of MS 914.
- Potential contamination of surface water and groundwater – acid rock drainage risk at the Revised Proposal has been assessed as low due to the geology of the area. Site drainage will be designed to minimise or eliminate surface runoff into areas where activities with a potential risk of hydrocarbon contamination occur. Management of waste dumps will ensure that risks of contamination of surface and groundwater are minimised.

Flora and vegetation

- Clearing of up to 1,800 ha flora and vegetation (including 69 ha riparian zone vegetation).
- Loss of some riparian vegetation associated with dewatering activities, with the vegetation expected to return to a more 'natural' state (i.e. pre-mining).
- Loss of some riparian vegetation associated with surplus water discharge, particularly waterlogging affects, though overall impacts will be limited to the currently approved limits of MS 914 (17 km downstream from confluence of Marillana and Weeli Wolli Creeks).
- No loss of known and recorded individuals of *Lepidium catapycnon* (Hamersley Lepidium); redesign of the waste dumps has avoided recorded individuals and they have been designated 'areas of special protection from ground disturbance' and therefore excluded from the ground disturbance footprint.
- Removal of some individuals of Priority 4 flora species (*Goodenia nuda*), though it is recorded throughout the Pilbara and it is considered that this will not alter the species' conservation status.
- Rehabilitation of areas disturbed by the Proposal, consistent with the Yandicoogina Closure Plan.

Terrestrial fauna

- Clearing of up to 1,800 ha of terrestrial fauna habitat over the life of the Proposal and habitat degradation due to the altered groundwater regime (some tree deaths within the riparian zone), which may lead to local reductions in fauna populations in the Proposal Area. The habitat types present in the Proposal Area are considered to be well represented in the local and regional area. It is considered likely that individuals will continue to forage in the remaining habitats within and adjacent to the Proposal Area.
- Clearing will result in the direct removal of up to 1,800 ha of potential SRE habitat within Proposal Area; this habitat is considered widespread locally and regionally.
- Risk of alteration to aquatic fauna habitat in Weeli Wolli Creek (surface water flows); additional habitat is available to north and south of the Proposal Area.

- Fragmentation of fauna habitat caused by the pit, waste dumps and association infrastructure; the mine footprint may also cause a barrier to dispersion for non-aerial species.
- Direct loss of some individual fauna through impact with machinery and vehicles, particularly during vegetation clearing.
- Progressive rehabilitation, with consideration given to restoring fauna habitat values where practicable.

Subterranean fauna

- Direct mortality and reduction in available subterranean habitats as a result of pit excavation and groundwater drawdown.
- Potential impacts will be localised to the proposed pit area and the groundwater drawdown zone during mining operations. However, it is not expected to significantly impact subterranean fauna assemblages and species persistence.
- The risk of pollutants being transported into the subterranean habitats is likely to be low and restricted to localised areas.
- The continuous nature of the alluvium, colluvium and calcrete units in which the subterranean fauna were predominately recorded indicates that geology is not a limiting factor in the distribution of the taxa currently known from the proposed pit area and the groundwater drawdown zone within the Proposal Area.

Rehabilitation and closure

- Pit walls of the final mine void that are adjacent to Weeli Wolli Creek are stabilised in a way that prevents the creek from collapsing into the mine voids post-closure, ensuring continued function of Weeli Wolli Creek.
- All areas disturbed for mining (with the exception of pit walls) and infrastructure that are not required by the State (under conditions of applicable State Agreements) are rehabilitated to a condition compatible with the post-mining land use following decommissioning.
- Creation of a dynamic wetland environment within the mine void, including two pit lakes and associated lake fringe, with water levels that will rise and fall in accordance with flooding of the creek systems.
- Regional hydrogeological impacts are minimised and adequately managed.
- Outside of the mining disturbance areas and more than 2 km from the Proposal mine voids, water levels are largely predicted to return to pre-disturbance levels.
- No impacts to the hydrological regime of the Fortescue Marsh as a result of closure of the site.

Offsets

Taking into account measures to avoid, minimise and rehabilitate impacts, the following significant residual impact arising from the Proposal has been identified:

- Clearing of up to 1,731 ha of native vegetation in Good to Excellent condition within the Proposal Area, including fauna habitat (excluding riparian zone vegetation[10]).
- Clearing of up to 69 ha of native riparian zone vegetation[10] within the Proposal Area, including fauna habitat.

The EPA has raised concerns regarding cumulative impacts on terrestrial biodiversity values in the Pilbara IBRA region. Consistent with the WA Environmental Offsets Guidelines, it is considered that the residual impact of disturbance of vegetation in Good to Excellent condition or riparian zone vegetation is significant and will therefore require compensation via an offset. As such, the Proponent is proposing to contribute funding of $1,500 (excluding GST) per hectare of native vegetation, and funding of $3,000 (excluding GST) per hectare of riparian zone vegetation cleared to a government-established conservation offset fund or an alternative offset arrangement providing an equivalent outcome as determined by the Minister.

Aboriginal heritage

- Any disturbance within the Weeli Wolli Creek heritage zone or of other archaeological/ethnographic sites will be in accordance with the provisions of the *Aboriginal Heritage Act 1972* (WA) and will have the consent of the relevant Traditional Owners.

Air quality

- Existing Proponent procedures and practices used at Yandi Operations to effectively prevent significant dust emissions will be applied to the Proposal.

Amenity

- Through mine closure the visual amenity will be returned as much as possible to the original pre-disturbance landscape. However, two pit lakes will be created within the Proposal Area, which have the potential to create new ecosystems. Amenity will be considered where possible during the life of the Proposal, and the management measures outlined in the Yandicoogina Closure Plan should ensure the key amenity values are maintained after mine closure.

25.2 Environmental management framework

The Proposal will be subject to the Proponent's HSECQ Policy and operated under the company EMS.

Management controls to be implemented as part of the Proposal to ensure key environmental factors are managed as described in the PER include measures and/or actions contained within the following key documents:

[10] For the purposes of the offset calculation, riparian vegetation is classified as vegetation units within the riparian zone comprising C-coded and F2 coded vegetation located within the RCA.

- Yandicoogina MMP, which includes:
    - Yandicoogina Vegetation and Groundwater Dependant Ecosystems Monitoring and Management Plan.
    - Yandicoogina Surface Water Discharge Monitoring and Management Plan.
- Yandicoogina Weed Action Plan:
- SSMP, including Yandi Operations site specific addendum.
- Yandicoogina Closure Plan.

25.3 Environmental offsets

The Proponent recognises that an environmental offset will be required for significant residual impacts that remain after mitigation measures have been exhausted. An offset is proposed in regard to significant residual impacts on 'Good to Excellent' condition vegetation (Sections 18 and 24).

25.4 Environmental acceptability of the Proposal

The approach taken in this PER has been based on a risk assessment approach to characterise the environmental factors, determine potential impacts and develop mitigation measures.

The Proponent has extensive experience in managing the development, operation and environmental compliance of similar projects, particularly including the existing Yandi Operations. The knowledge and experience gained from the Yandi Operations to date is considered to have provided rigour to additional studies undertaken for the Proposal and is anticipated to lead to a greater certainty in achieving stated environmental outcomes.

The Proponent has consulted with key stakeholders to scope the potential impacts of the Proposal and to determine the significance of environmental issues and the acceptability of mitigation. This process substantially improves the likelihood that all significant environmental issues have been identified, investigated and mitigated as far as practicable.

On the basis of the findings of this PER, the Proposal is considered to be environmentally acceptable if implemented in accordance with the proposed management and mitigation measures, including proposed Ministerial Statement implementation conditions (which are based on the existing conditions in MS 914 for the Yandi Operations).

EIA	Environmental impact assessment
EMS	Environmental Management System
EPA	Environmental Protection Authority
EP Act	*Environmental Protection Act 1986*
EPBC Act	*Environment Protection and Biodiversity Conservation Act 1999*
ESD	Environmental Scoping Document
EVS	Environmental Values Statement
FIFO	Fly In-Fly Out
GIS	Geographic information system
GL	Gigalitre/s
GL/y	Gigalitre/s per year
ha	Hectare/s
Hamersley Iron	Hamersley Iron – Yandi Pty Limited
HSECQ	Health, Safety, Environment, Community and Quality Policy
IBRA	Interim Biogeographic Regionalisation for Australia
JAMBA	Japan-Australia Migratory Bird Agreements
JC	Junction Central
JSE	Junction South East
JSW	Junction South West (-A & C pits)
km	Kilometre/s
km^2	Square kilometre/s
kV	Kilovolt/s
m	Metre/s

Abbreviation	Definition
m^3	Cubic metre/s
Matters of NES	Matters of National Environmental Significance
mg/L	Milligrams per litre
mm	Millimetre/s
MMP	Monitoring and Management Plan
MS 914	Ministerial Statement No. 914
Mt	Million tonnes
Mtpa	Million tonnes per annum
MW	Megawatt/s
OEPA	Office of the Environmental Protection Authority
Parks and Wildlife	Department of Parks and Wildlife
PER	Public Environmental Review
Pilbara Iron	Pilbara Iron Company (Services) Pty Limited
RCA	Restricted Clearing Area
Revised Proposal	Yandicoogina Iron Ore Project – Revised Proposal; comprised of the existing Yandi Operations and Yandi PBS Proposal
RIWI Act	*Rights in Water and Irrigation Act 1914*
ROKAMBA	Republic of Korea-Australia Migratory Bird Agreements
SRE	Short Range Endemic
SSMP	Significant Species Management Plan
TDS	Total Dissolved Solids
TEC	Threatened Ecological Community
Existing Yandi Operations	Existing Yandicoogina Operations
Proposal	Yandicoogina Pocket and Billiard South Iron Ore Development
YLUA	Yandicoogina Land Use Agreement
WA	Western Australia
WAM	Western Australian Museum

Abbreviation	Definition
WC Act	*Wildlife Conservation Act 1950*
WFSFs	Waste fines storage facilities

Appendix 1: Yandicoogina Iron Ore Project – Revised Proposal Environmental Scoping Document

(Yandicoogina Iron Ore Project – Revised Proposal Environmental Scoping Document is contained on CD inside the back cover of the PER)

Appendix 2: Compliance checklist

Compliance checklist of work requirements for preliminary key environmental factors (and other environmental factors) stated in the ESD. For the EPA objective, relevant aspects and potential impacts, please see Appendix 1 (ESD).

Environmental factor	Work required	PER reference
Flora and Vegetation	1. Provide information on the current status and outcomes of the riparian vegetation management actions required by Ministerial Statement 914 Condition 7 - Riparian Vegetation, and Condition 8 - Weeds.	Section 14.5.1
	2. Provide a detailed description of the cumulative impacts associated with the proposal, including direct impacts from clearing, and indirect impacts such as groundwater drawdown, surface discharge of excess groundwater, altered drainage, changes in water quality, dust emissions and fragmentation of vegetation.	Section 14.4
	3. Provide figures showing the extent of clearing and indirect impact to vegetation and conservation significant flora species, including but not limited to threatened and/or Priority ecological communities, Declared Rare Flora, Priority flora and new flora species.	Figures 44 to 56
	4. Consolidate vegetation and flora reports incorporating information from all relevant previous and new studies, particularly for the Declared Rare Flora species *Lepidium catapycnon*.	Section 14.2.1; Appendix 3; Biota (2015a)
	5. Describe the environmental values and rational of the Clearing Avoidance Area identified in Ministerial Statement 914. Quantify the disturbance to this area as a result of implementing the proposal and describe how the environmental values of the Clearing Avoidance Area and Weeli Wolli Creek will be maintained.	Section 6.2.1.2 and 14.3.1
	6. Carry out Level 2 flora and vegetation surveys in areas that are likely to be directly or indirectly disturbed. Surveys are to be undertaken in accordance with Guidance Statement 51. Details of the scope, timing (survey season/s) and methodology for surveys used must be provided. Follow up targeted surveys may be required based on the results of the baseline survey for conservation significant flora and vegetation.	Section 14.2.1; Appendix 3; Biota (2015a)
	7. Analyse the extent of clearing and indirect impacts to assist in the determination of the significance of impacts, including impacts on: • vegetation units; • threatened and Priority ecological communities; • threatened and Priority flora; • species identified as significant consistent with Guidance Statement 51;	Section 14.3

Environmental factor	Work required	PER reference
	• vegetation units identified as significant consistent with Guidance Statement 51; and • groundwater dependent vegetation.	
	8. Undertake baseline mapping of weed affected areas in any area likely to be directly or indirectly impacted by the proposal.	Section 14.2.1; Appendix 3; Biota (2015a)
	9. Discuss potential direct/indirect (including downstream) and cumulative impacts to flora and vegetation as a result of the proposal, and provide quantitative data on impacts of the proposal to species of conservation significance.	Section 14.3
	10. Discuss proposed management, monitoring and mitigation methods to be implemented. Also, discuss engineering solutions that could be implemented to redesign the waste rock dump locations to avoid impacts to *Lepidium catapycnon*.	Sections 14.3 and 14.5
	11. Demonstrate that all practicable measures have been taken to reduce both the area of the proposed disturbance footprint and the Development Envelope based on progress in the proposal design and understanding of the environmental impacts.	Sections 14.3 and 14.5
	12. Demonstrate that the mitigation hierarchy of avoid, minimise, rehabilitate and offset has been applied effectively during the mine planning and design stages of the project.	Sections 14.3 to 14.6, Section 17 and Section18
Terrestrial Fauna	1. Conduct desktop study of information available to provide a comprehensive listing of vertebrate fauna and SRE invertebrate fauna known or likely to occur in the habitats present, and identification of conservation significant fauna species likely to occur in the area. Consideration of species listed under both the WA *Wildlife Conservation Act 1950* and the *Environment Protection & Biodiversity Conservation Act 1999 (*EPBC Act), and species listed by the Department of Parks and Wildlife as Priority Fauna to include, but not necessarily be limited to, the following species of conservation significance have been recorded in the Yandicoogina PBS surveys: • Brush-tailed Mulgara (*Dasycercus blythi*) • Star Swift (*Neochmia ruficaudo*) • Fork-tailed Swift (*Apus pacificus)* • Western Pebble-mound Mouse (*Pseudomys chapman*) • Olive Python (Pilbara subspecies) (*Liasis olivaceus barroni*) • Rainbow Bee-eater (*Merops arnatus*) • Any other Priority fauna species identified in a Level 1 survey as likely to occur in the Proposal Area.	Sections 15.2 to 15.4; Appendix 3; Biota (2015b)
	2. For each relevant conservation significant species, provide baseline information on their abundance (including known occurrences), distribution, ecology, and habitat preferences at both the site and regional levels.	Sections 15.2 to 15.4; Appendix 3; Biota (2015b)
	3. Conduct a Level 1 reconnaissance vertebrate and SRE invertebrate fauna survey and mapping of habitats including specialised	Sections 15.2 to 15.4; Appendix 3; Biota

Environmental factor		Work required	PER reference
		habitats within the development envelopes, identification and mapping of important, rare or unusual habitat types within areas to be impacted, in accordance with Guidance Statements 56 and 20. This should also consider other areas outside the proposed disturbance footprint to determine whether the most suitable areas have been chosen for location of infrastructure.	(2015b)
	4.	Consider habitat types that provide important ecological function e.g. riparian vegetation, protected area buffer zones, refugia, important habitat corridors, wetlands, areas of conservation significance or geological features which may support unique ecosystems. Analyse the extent of clearing, including percentages of habitat types to be cleared or otherwise impacted, to assist in determination of significance of impacts. Information, including maps, must also differentiate habitat on the basis of use e.g. breeding habitat, migration pathways, feeding habitat. Consider whether the remaining habitat has adequate carrying capacity.	Sections 15.2 to 15.6
	5.	Conduct Level 2 fauna surveys in areas that are likely to be directly or indirectly impacted as a result of the proposal. Surveys are to be undertaken in accordance with Guidance Statements 20 and 56. Additional targeted surveys for conservation significant fauna that are known to or likely to occupy habitats in the Project area may be required based on the results of the survey.	Sections 15.2 to 15.4; Appendix 3; Biota (2015b)
	6.	For each relevant conservation significant species, provide: • information on the conservation value of each habitat type from a local and regional perspective, including the percentage representation of each habitat type on-site in relation to its local and regional extent; and • if a population of a conservation significant species is present on the site, its size and the importance of that population from a local and regional perspective and potential percentage loss of the conservation significant species locally due to loss of habitat.	Sections 15.2 to 15.6
	7.	Discuss known existing threats to the species, whether or not attributable to the proposed action with reference to relevant impacts from the proposed action (including taking into consideration any relevant guidelines, policies, plans and statutory provisions).	Sections 15.2 to 15.4
	8.	Discuss potential direct/indirect (including downstream) and cumulative impacts to fauna as a result of the proposal, and provide quantitative data on impacts of the proposal to species of conservation significance.	Sections 15.5 and 15.6
	9.	Discuss proposed management, monitoring and mitigation methods to be implemented including an assessment of the effectiveness of the methods, any statutory or policy basis for the methods.	Section 15.7
Subterranean Fauna	1.	Conduct surveys within areas to be impacted and in surrounding areas in accordance with Guidance Statement 54a.	Sections 16.2 and 16.3; Appendix 3; Biota (2015c, 2015d)
	2.	Present the results of the subterranean fauna surveys and discuss the potential for direct and indirect impacts to subterranean fauna including consideration of altered water regimes and nutrient flows.	Sections 16.2 to 16.4
	3.	Assess any impacts to subterranean fauna in accordance with EAG 12. For species which are likely to be impacted, provide	Sections 16.2 to 16.4

Environmental factor		Work required	PER reference
		information, including detailed geological maps on habitat continuity and an appropriate explanation of the likely distribution of species within those habitats.	
	4.	Discuss proposed management, monitoring and mitigation methods to be implemented.	Section 16.5
Hydrological Processes and Inland Waters Environmental Quality	1.	Provide information on the current status and outcomes of surface water discharge management actions required by Ministerial Statement 914 Condition 6 - Surface Water Discharge (Protection of Weeli Wolli Creek).	Section 13.2.4
	2.	Provide a detailed description of the design and location of the proposal with the potential to impact surface water or groundwater.	Sections 13.2 and 13.3
	3.	Characterise baseline hydrological and hydrogeological regimes.	Section 13.2
	4.	Develop a conceptual model of the surface and groundwater systems, incorporating the extent of connectivity between surface and ground water systems.	Section 13.2; Appendix 3; URS (2015)
	5.	Discuss the effectiveness of the current water management scheme and provide a comparison of its actual operation versus what was predicted including discussion of accuracy. Also detail any problems with how the system has operated and what management measures have been taken when it is not operating as expected.	Section 13.2
	6.	Present information on predicted annual dewatering requirements and surplus water quantities over the life of the operations.	Sections 13.2 and 13.3
	7.	Provide a conceptual mine water balance over the life of the proposal to discuss the capacity to reuse surplus mine dewater.	Section 13.2.4
	8.	Discuss the potential environmental impacts and benefits of identified surplus water management options (i.e. reuse on-site, local water supply, aquifer recharge etc.) and discuss the most appropriate water management strategy for the proposal.	Sections 13.3 and 13.5
	9.	Discuss the impacts to Weeli Wolli Creek and the potential impacts on Fortescue Marsh considering worst case conditions, including natural flow conditions and maximum anthropogenic inputs. Describe methods used to minimise the impacts to Weeli Wolli Creek, including minimising the period of surface discharge. Quantify the period of surface discharge required, as well as the extent of surplus mine dewater release (wetting front) and changes to flows within Weeli Wolli Creek.	Section13.3
	10.	Model the impact of different flooding scenarios during operations and post- closure on infrastructure and final landforms. Note the for any storm water infrastructure on-site and provide an explanation, including reference to standards and guideline documents, for the chosen criteria.	Section13.3
	11.	Detail and assess the geotechnical criteria of the bund or levee that will be located next to Weeli Wolli Creek. Discuss the permanency of the bund or levee in the catchment. Identify the likely source of the material that will be used to build the bund or levee, and describe how the design and structural integrity will withstand large storm events. If the bund or levee is part of a closure strategy assess the Iona term integrity of the bund taking into consideration different flooding scenarios or a worst case	Section 4.2.8 and 13.3

Environmental factor	Work required	PER reference
	scenario.	
	12. Investigate groundwater drawdown due to ground water abstraction associated with the proposal. Analyse and discuss any impacts to groundwater levels and flows taking into consideration the cumulative impacts with other proposals.	Section13.3
	13. Develop a conceptual model of the surface and groundwater systems, incorporating groundwater quality and the extent of connectivity between surface and ground water systems and Fortescue Marsh.	Sections 13.2 and 13.3
	14. Have the surface and groundwater modelling for this assessment independently peer reviewed. Determine the scope, timing and the selection of the peer review in consultation with the Department of Water. The groundwater modelling should be consistent with Australian Government National Water Commission's Australian Groundwater Modelling Guidelines (2012). The surface water modelling should be in accordance with the Australian Rainfall and Runoff Guidelines.	Section 3; Appendix 3; WorleyParsons (2015) and Hydrogeologic (2015)
	15. Analyse, discuss and assess surface water and groundwater impacts, including changes in groundwater levels and changes to surface water flows associated with the proposal together with cumulative impacts with other projects and referred proposals (including the BHPBIO strategic proposal) for which relevant information is publicly available.	Sections 13.3 and 13.4
	16. Discuss the proposed management, monitoring and mitigation to prevent groundwater and surface water impacts as a result of implementing the proposal.	Section 13.5
	17. Characterise baseline water quality, including the analysis of groundwater quality that is proposed to be discharged into the surrounding environment.	Sections 13.2 and 13.3
	18. Develop a conceptual model of the surface and groundwater systems, incorporating groundwater quality and the extent of connectivity between surface and ground water systems and Fortescue Marsh (same requirement for hydrological processes).	Sections 13.2 and 13.3
	19. Undertake a hydrological investigation to determine what effect groundwater abstraction, and modified drainage will have on the surface water and groundwater quality and quantity of the area, including interactions between surface and groundwater.	Sections 13.2 and 13.3; Appendix 3; URS (2015)
	20. Have the surface and groundwater modelling for this assessment independently peer reviewed. Determine the scope, timing and the selection of the peer review in consultation with the Department of Water. The modelling should be consistent with Australian Government National Water Commission's Australian Groundwater Modelling Guidelines (2012) (same requirement for hydrological processes).	Section 3; Appendix 3; WorleyParsons (2015) and Hydrogeologic (2015)
	21. Undertake a comprehensive review of surface water and groundwater quality collected from the existing mining operation at the site. Identify any adverse changes caused by the mining operation and outline avoidance, minimisation and management methods to be used to prevent further impacts.	Sections 13.2 and 13.5
	22. Undertake waste characterisation studies of waste rock and other materials and carry out an acid and metalliferous drainage risk	Sections 13.3.7 and 17.2.2

Environmental factor	Work required	PER reference
	assessment. Detail where Potentially Acid Forming (PAF) material will be located and discuss stored and containment options, including sub-aqueous storage.	
	23. Provide a description of the design, location and extent of discharges of the proposed waste facilities, and any other elements of the proposal with the potential to impact surface water or groundwater quality.	Sections 13.3 and 13.5
	24. Model cumulative impacts with other mines in the catchment (currently operating and referred proposed mines, including the BHPBIO strategic proposal, where information is publicly available). Develop strategies and controls to minimise the impacts.	Sections 13.3 to 13.6
	25. Confirm whether or not pit lakes may form and provide details of potential backfill options. If pit lakes may form, provide an assessment of the long term contamination of any pit lakes and the potential impact on groundwater and surface water quality with particular attention to possible impacts on Fortescue Marsh. In addition, undertake a risk assessment in accordance with the most recent version of the joint DMP/EPA Mine Closure Guidelines and provide details of mitigation measures undertaken to reduce the risk of any pit lakes.	Section 17
	26. Discuss proposed management , monitoring and mitigation methods, including the identification of water quality trigger levels, to be implemented during construction, operation and following closure to ensure that the EPA's objective for this factor is met.	Section 13.5.
Rehabilitation and Closure	1. Provide information on the current status of Yandicoogina Decommissioning and Rehabilitation Plan required by Ministerial Statement 914 Condition 9 - Decommissioning and Rehabilitation.	Section 17.2.1
	2. Undertake a desktop study of successful and unsuccessful rehabilitation strategies and outcomes in similar geologies and vegetation types in the Pilbara, including any rehabilitation that has been conducted to date within the Development Envelope. Including a discussion of the different methodology and success rates for the various proposed disturbance types including: • created landforms (e.g. waste rock dump, tailings storage facility); • short term disturbances (e.g. borrow pits and access tracks); • long term disturbances (e.g. construction camp, permanent accommodation village and administration buildings); and • linear and/or fragmentation disturbances (e.g. roads, power lines, bore fields).	Appendix 4; Rio Tinto (2015c)
	3. Provide waste characterisation work including static, short term leaching and kinetic test results, and water quality monitoring results for drainage from existing waste storage facilities to enable a thorough assessment of acid and metalliferous drainage risk posed by the project. If PAF material is identified, provide mine scheduling detail to demonstrate that PAF material is not disturbed during mining and/or that effective strategies will be in place to ensure PAF material is adequately managed should it be exposed and/or disturbed.	Sections 13.3.7 and 17.2.2
	4. Provide the physical characteristics of the waste materials and proposed locations and geotechnical design detail (including slope	Section 17.2.3

Environmental factor	Work required	PER reference
	stability) for the waste landforms, including the WFSFs. Identify proposed management and monitoring for the waste landforms. Describe contingencies to make landforms secure and non-polluting in the event of unexpected or temporary closure.	
	5. Prepare a Rehabilitation and Mine Closure Plan consistent with the current version of the Department of Mines and Petroleum (DMP) and EPA Guidelines for Preparing Mine Closure Plans. Include completion criteria and closure objectives addressing native vegetation and habitat for significant flora and fauna and base the conclusions on the availability of suitable substrates and landform design. Establish and measure vegetation and fauna reference sites to inform completion criteria. Determine requirements for, and sources of, soil and seed for rehabilitation. A conclusive discussion on backfill options (including 'worst case scenario') is also required.	Appendix 4; Rio Tinto (2015c)
	6. Discuss proposed management, monitoring and mitigation methods to be implemented including post-mining land use and areas to be rehabilitated.	Section 17.4
	7. Discuss proposed monitoring of linkages of specialised habitats to demonstrate that rehabilitated areas function as ecological corridors for conservation significant fauna.	Section 17.4; Appendix 4; Rio Tinto (2015c)
Offsets (Residual Risk Management)	1. Examine residual impacts and, if required, develop a draft program of environmental offsets that adheres to the relevant policy/guidance document listed below.	Section 18
	2. Include the completed Environmental Offsets Reporting Form and any offsets required and proposed in the PER.	Section 18
Heritage (Indigenous)	Not stated (other environmental factor)	NA
Air Quality	Not stated (other environmental factor)	NA
Amenity	Not stated (other environmental factor)	NA

Appendix 4: Environmental management documents

The following environmental management documents are contained on CD inside the back cover of the PER:

- Yandicoogina Monitoring and Management Plan (MMP) (October 2015), which includes:
  - Yandicoogina Vegetation and Groundwater Dependant Ecosystems Monitoring and Management Plan; and
  - Yandicoogina Surface Water Discharge Monitoring and Management Plan;
- Yandicoogina Weed Action Plan (July 2012); and
- Rio Tinto Significant Species Management Plan (including Yandicoogina Significant Species Management Plan addendum) (September 2014).
- Yandicoogina Closure Plan (August 2015).

Appendix 5: EPA checklist for documents submitted for EIA on marine and terrestrial biodiversity

Checklist Item	Completed	PER reference
PART 1 – GENERAL QUALITY OF DOCUMENTS		
Ensure that the following standard elements are present in all documentation (including appendices):		
A clear and concise title that outlines basic information about the proposal and purpose of the document.	✓	Cover page
Date and document revision number.	✓	Cover page
Information identifying the document's author and publishing entity.	✓	Cover page
All issues identified in a scoping guideline or scoping document have been addressed and covered in the report.	✓	**Appendix 2**
Complete and correct tables of contents, maps, tables and figures.	✓	Table of Contents; Figure 1 to **Figure 80**; **Table 1** to **Table 47**
Suitably-sized scale maps placing the proposal into both a regional and local context.	✓	Figure 1 and **Figure 2**
Figures, plates, maps, technical drawings or similar including scale bar, legend, informative caption, labels identifying important or relevant locations/features referred to in the document text.	✓	Figure 1 to **Figure 80**
All survey site locations and derived data products (e.g. benthic habitat maps, vegetation maps) have been provided in map and appropriate GIS-based electronic database forms.	✓	GIS-based electronic data contained on CD inside back cover of PER
All survey data from terrestrial biological surveys have been provided in electronic database form (Access/Excel).	✓	Contained on CD inside back cover of PER

Checklist Item	Completed	PER reference
Proposed infrastructure is shown on scale maps and associated spatial data and are provided in an appropriate GIS-based electronic database form.	✓	**Figure 4**; GIS-based electronic data contained on CD inside back cover of PER
A list of references that have been cross-checked to ensure that all references in the Reference list are cited in the text (and vice versa).	✓	Section 27
All information based on 'expert' opinion/judgement are explicitly attributed, by name and qualification, to a person/s or organisation.	✓	Entire document
Where relevant, appendices are attached to the main EIA document that describe the details of technical work undertaken to underpin the content of the main document, and explicitly attributed by name to the author/s and (if applicable) their organisation.	✓	**Appendix 3**
Description(s) of the proposal are internally consistent throughout all documentation and are couched to allow potential environmental impacts to be placed in local and regional contexts, including cumulative impacts of existing and approved developments.	✓	Section 4
Descriptions of the local and regional environmental features most likely to be directly or indirectly affected by the proposal.	✓	Sections 5 to 7
PART 3 – TERRESTRIAL BIODIVERSITY ISSUES		
For proposals likely to impact on native flora and vegetation/plant communities, the EIA document describes how potential impacts have been addressed in the context of EPA Guidance Statement No. 51, *Terrestrial Flora and Vegetation Surveys for Environmental Impact Assessment* (June 2004), including:		
Determining the level of flora and vegetation survey consistent with that expected in Table 3 of Guidance Statement No. 51 (Appendix 2);	✓	**Appendix 3**; Biota (2015a)
Describing the survey area and methodologies, including reference to timing, duration, survey effort, any survey limitations, and the nomenclature used (WA Herbarium);	✓	**Appendix 3**; Biota (2015a)
Maps and text describing the survey area/plot sites, location of significant species, vegetation mapping, vegetation condition assessment and predicted extent of impact on the vegetation;	✓	**Figure 43** to **Figure 56**; Sections 14.2 and 14.3
A comprehensive list of flora species identified and assessment of threatened, Priority or other significant flora / Ecological Communities (TECs, PECs) known or reasonably expected to occur in the area (as defined in Guidance Statement 51);	✓	Sections 14.2 and 14.3; further detail provided in **Appendix 3**, Biota (2015a)
Evaluating the impact of the proposal on the species/communities, including reference to the extent of regional clearing of the vegetation complex/type and ecological linkage; and	✓	Sections 14.3 and 0

Checklist Item	Completed	PER reference
All quadrat data used in reporting provided as electronic database in raw form, in addition to hardcopy reports.	✓	Contained on CD inside back cover of PER
For proposals likely to impact on vertebrate fauna or fauna habitat, the EIA document describes how potential impacts have been addressed in the context of EPA Guidance Statement No. 56, *Terrestrial Fauna Surveys for Environmental Impact Assessment* (June 2004) and *Technical Guide Terrestrial Fauna Surveys for Environmental Impact Assessment* (EPA and Department of Environment and Conservation 2010), including		
Determining the level of fauna survey consistent with that expected in Table 3 (Appendix 2) of Guidance Statement No. 56;	✓	**Appendix 3**; Biota (2015b)
Describing the survey methodologies in the context of EPA and DEC (2010), including reference to timing, duration and survey effort used to sample each of the fauna groups sampled, any survey limitations and the nomenclature used (WA Museum checklist except for birds which should follow Christidis and Boles 2008);	✓	**Appendix 3**; Biota (2015b)
Maps and text describing the survey area, sampling locations and fauna habitats; and	✓	**Figure 57** to **Figure 61**, **Figure 64** and **Figure 65**; Sections 15.2 and 15.4; further detail available in **Appendix 3**, Biota (2015b)
A comprehensive list and assessment of fauna known or reasonably expected to occur in the area, including Specially Protected and other significant fauna (as defined in Guidance Statement No. 56), and an evaluation of the impact of the proposal on the species and key habitat/s.	✓	Sections 15.2, 15.4 and 15.5; further detail available in **Appendix 3**, Biota (2015b)
For proposals with the potential to impact on short range endemic (SRE) invertebrate fauna or SRE habitat, the EIA document describes how potential impacts have been addressed in the context of EPA Guidance Statement No. 20, *Sampling of Short Range Invertebrate Fauna for Environmental Impact Assessment in Western Australia* (May 2009), including:		
Early initial assessment for restricted habitat types that have potential to support SRE fauna, including advice from the WA Museum and the DEC/OEPA.	✓	**Appendix 3**; Biota (2015b)
Maps and text describing the survey area, potential SRE habitats and regional context and extent of predicted impact on the habitat.	✓	**Figure 62** and **Figure 63**; Sections 15.3, 15.5.2.2 and 1.1.1; further detail available in Appendix 3, Biota (2015b)
Describing the survey methodologies, including reference to timing, duration and survey effort used to sample each of the SRE groups sampled, and any survey limitations.	✓	**Appendix 3**; Biota (2015b)
A survey report with assessment of SRE fauna found or reasonably expected to occur in the area, including any Specially Protected and other significant fauna, their known occurrence/habitats locally and their wider status if known, and an evaluation of the risk of the proposal to long term survival of the species and community.	✓	**Appendix 3**; Biota (2015b)

Checklist Item	Completed	PER reference
For proposals with the potential to impact on subterranean (stygofauna and troglofauna) fauna, the EIA document describes how potential impacts have been addressed in the context of EPA Guidance Statement No. 54 *Consideration of Subterranean Fauna in Groundwater and Caves during Environmental Impact Assessment in Western Australia* (2003) and 54a, *Sampling Methods and Survey Considerations for Subterranean Fauna in Western Australia* (Draft 2007), including:		
Early initial desktop review to determine if the site has potentially suitable geology /substrate habitat that could support subterranean fauna, including advice from the WA Museum and the DEC/OEPA and a pilot study, if appropriate;	✓	**Appendix 3**; Biota (2015c,d)
A subterranean fauna survey report, if the site has a very high or high likelihood of supporting subterranean fauna, or a pilot study indicated that the site supports a significant subterranean fauna;	✓	**Appendix 3**; Biota (2015c,d)
Maps and text identifying and describing the survey sites/area, and the geology/ habitat supporting subterranean fauna, and extent of predicted impacts on the habitat (Note the survey area should extend beyond the predicted impact zone);	✓	further detail available **Appendix 3** Biota (2015c,d)
Describing the survey methodologies (see Guidance Statement No. 54a), including reference to timing, duration and survey effort used to sample each of the fauna groups sampled, species identification, and any survey limitations; and	✓	**Figure 66** to **Figure 76;** Sections **16.2** and **16.4;** further detail available **Appendix 3**; Biota (2015c,d)
A comprehensive list and assessment of subterranean fauna recorded or reasonably expected to occur in the area, including any Specially Protected and other significant fauna and their known occurrence/habitats locally and their wider status if known, and an evaluation of the risk of the proposal to long term survival of the species and community.	✓	Section 16.2, further detail available **Appendix 3**; Biota (2015c,d)

Appendix 6: Existing Ministerial Statement 914 environmental conditions and proposed environmental conditions for the Yandicoogina Iron Ore Project – Revised Proposal

Condition No.	Existing Condition	Proposed Condition	Reason for change
Proposal implementation			
1-1	When implementing the proposal, the proponent shall not exceed the authorised extent of the proposal as defined in Column 3 of Table 2 in Schedule 1, unless amendments to the proposal and the authorised extent of the Proposal has been approved under the EP Act.	When implementing the proposal, the proponent shall not exceed the authorised extent of the proposal as defined in Schedule 1, unless amendments to the proposal and the authorised extent of the Proposal **have** been approved under the EP Act.	Removal of Column 3 of Table 2. Update based on new Schedule 1
Contact details			
2-1	The proponent shall notify the CEO of any change of its name, physical address or postal address for the serving of notices or other correspondence within 28 days of such change. Where the proponent is a corporation or an association of persons, whether incorporated or not, the postal address is that of the principal place of business or of the principal office in the State.	The proponent shall notify the CEO of any change of its name, physical address or postal address for the serving of notices or other correspondence within 28 days of such change. Where the proponent is a corporation or an association of persons, whether incorporated or not, the postal address is that of the principal place of business or of the principal office in the State.	No Change
Time limit for proposal implementation			
3-1	The proponent shall not commence implementation of the proposal after the expiration of five years from the date of this statement, and any commencement, within this five year period, must be substantial.	**Remove**	Yandicoogina Operations is currently a brownfields site and substantially commenced operations in 1996. Consistent with other Brownfields operations contemporised Ministerial Statements (e.g. MS 1000).

3-2	Any commencement of implementation of the proposal, within five years from the date of this statement, must be demonstrated as substantial by providing the CEO with written evidence, on or before the expiration of five years from the date of this statement.		
Compliance reporting			
4-1	The proponent shall prepare and maintain a compliance assessment plan to the satisfaction of the CEO.	The proponent shall prepare and maintain a compliance assessment plan to the satisfaction of the CEO at least six (6) months prior to the first compliance assessment report required by condition 4-6. ~~**or prior to implementation, whichever is sooner.**~~	Condition contemporised between split of 4-1 and 4-2. The proposal is already implemented and hence the prior to implementation (of the proposal) is not possible.
4-2	The proponent shall submit to the CEO the compliance assessment plan required by condition 4-1 at least six months prior to the first compliance report required by condition 4-6, or prior to implementation, whichever is sooner. The compliance assessment plan shall indicate: (1) the frequency of compliance reporting; (2) the approach and timing of compliance assessments; (3) the retention of compliance assessments; (4) the method of reporting of potential non-compliances and corrective actions taken; (5) the table of contents of compliance assessment reports; and (6) public availability of compliance assessment reports.	The compliance assessment plan shall indicate: (1) the frequency of compliance reporting; (2) the approach and timing of compliance assessments; (3) the retention of compliance assessments; (4) the method of reporting of potential non-compliances and corrective actions taken; (5) the table of contents of compliance assessment reports; and (6) public availability of compliance assessment reports.	
4-3	The proponent shall assess compliance with conditions in accordance with the compliance assessment plan required by condition 4-1.	**After receiving notice in writing from the CEO that the compliance assessment plan satisfies the requirements of condition 4-2** the proponent shall assess compliance with conditions in accordance with the compliance assessment plan required by condition 4-1.	Condition contemporised to reflect more recent Ministerial Statements.
4-4	The proponent shall retain reports of all compliance assessments described in the	The proponent shall retain reports of all compliance assessments described in the	No Change

	compliance assessment plan required by condition 4-1 and shall make those reports available when requested by the CEO.	compliance assessment plan required by condition 4-1 and shall make those reports available when requested by the CEO.	
4-5	The proponent shall advise the CEO of any potential non-compliance within seven days of that non-compliance being known.	The proponent shall advise the CEO of any potential non-compliance within seven days of that non-compliance being known.	No Change
4-6	The proponent shall submit to the CEO a compliance assessment report by the end of April each year addressing compliance in the previous calendar year. The first compliance assessment report must be submitted by 30 April 2013 addressing compliance for the period from the date of issue of this statement, notwithstanding that the first reporting may be less than 12 months. The compliance assessment report shall: (1) be endorsed by the proponent's Managing Director / General Manager / Chief Executive Officer or a person delegated to sign on the Managing Director's / General Manager's / Chief Executive Officer's behalf; (2) include a statement as to whether the proponent has complied with the conditions; (3) identify all potential non-compliances and describe corrective and preventative actions taken; (4) be made publicly available in accordance with the approved compliance assessment plan; and (5) indicate any proposed changes to the compliance assessment plan required by condition 4-1.	The proponent shall submit to the CEO a compliance assessment report by the end of April each year addressing compliance in the previous calendar year. The compliance assessment report must address compliance for the period from the date of issue of this statement, notwithstanding that the first report may cover a period less or **more** than 12 months. The compliance assessment report shall: (1) be endorsed by the proponent's Managing Director / General Manager / Chief Executive Officer or a person delegated to sign on the Managing Director's / General Manager's / Chief Executive Officer's behalf; (2) include a statement as to whether the proponent has complied with the conditions; (3) identify all potential non-compliances and describe corrective and preventative actions taken; (4) be made publicly available in accordance with the approved compliance assessment plan; and (5) indicate any proposed changes to the compliance assessment plan required by condition 4-1.	Minor change if compliance assessment report covers 13 months if approval granted 1 month or less prior to compliance assessment reporting period.
Public availability of data			

5-1	Subject to condition 5-2, within six months of the issue of this statement and for the remainder of the life of the proposal the proponent shall make publicly available, in a manner approved by the CEO, all validated environmental data (including sampling design, sampling methodologies, empirical data and derived information products [e.g. maps]) relevant to the assessment of this proposal and implementation of this statement.	Subject to condition 5-2, within six months of the issue of this statement and for the remainder of the life of the proposal the proponent shall make publically available, in a manner approved by the CEO, all validated environmental data (including sampling design, sampling methodologies, empirical data and derived information products [e.g. maps]) relevant to the assessment of this proposal and implementation of this statement.	No Change
5-2	If any data referred to in condition 5-1 contains particulars of: (1) a secret formula or process; or (2) confidential commercially sensitive information The proponent may submit a request for approval from the CEO to not make this data publically available. In making such a request the Proponent shall provide the CEO with an explanation and reasons why the data should not be made publically available.	If any data referred to in condition 5-1 contains particulars of: (1) a secret formula or process; or (2) confidential commercially sensitive information The proponent may submit a request for approval from the CEO to not make this data publically available. In making such a request the Proponent shall provide the CEO with an explanation and reasons why the data should not be made publically available.	No Change
Surface water discharge (protection of Weeli Wolli Creek)			
6-1	The proponent shall ensure that the discharge of excess water from the Yandicoogina Iron Ore Project - Expansion to Include Junction South West and Oxbow Deposits as a result of mining does not cause long term impacts to environmental values of the Weeli Wolli Creek System.	The proponent shall ensure that the discharge of excess water from the Yandicoogina Iron Ore Project – **Revised Proposal** as a result of mining does not cause long term impacts to environmental values of the Weeli Wolli Creek system.	Change to reflect Revised Proposal name.
6-2	To verify that condition 6-1 is being met, the proponent shall develop an Environmental Values Statement for the Weeli Wolli Creek System that defines the environmental values of the Weeli Wolli Creek System to the satisfaction of the CEO in consultation with the DEC.	To verify that condition 6-1 is being met, the proponent shall **maintain** an Environmental Values Statement for the Weeli Wolli Creek system that defines the environmental values of the Weeli Wolli Creek system to the satisfaction of the CEO in consultation with **Parks and Wildlife**.	DEC changed to Parks and Wildlife.

6-3	The proponent shall ensure that dewatering discharge from the Yandicoogina Iron Ore Project - Expansion to Include Junction South West and Oxbow Deposits does not cause water flow or pooling further than 17 kilometres downstream from the Marillana Creek and Weeli Wolli Creek System Confluence.	The proponent shall ensure that dewatering discharge from the Yandicoogina Iron Ore Project – Revised Proposal does not cause water flow downstream from the Marillana Creek and Weeli Wolli Creek system Confluence further than the extent identified in Schedule 1 (under natural no flow conditions)	Contemporised condition in line with more recent Ministerial statements, with discharge extent included in proposed Schedule 1. Inclusion of 'under natural no flow conditions' to meet the intent of the condition and reflect the wording in Schedule 1. Removal of 'pooling' as localised natural pools can be created during rainfall events and can persist for extended periods due to variable basement geology.
6-4	The proponent shall ensure that any dewater discharged to the environment does not exceed whichever is greater of the following: (1) the default trigger for the protection of marine and freshwater ecosystems as per the Australian and New Zealand Environmental and Conservation Council and Agriculture and Resource Management Council of Australia and New Zealand (ANZECC/ARMCANZ (2000)) Australian Water Quality Guidelines for Fresh and Marine Waters and its updates; or (2) baseline levels identified pursuant to condition 6-6(3). (3) other criteria agreed by the CEO on the advice of the Department of Environment Regulation.	**Remove**	Condition contemporised to match more recent Ministerial Statements (e.g. MS 1000) and management under Part IV of the EP Act (by DER).
6-5	The proponent shall prepare a Water Discharge Monitoring and Management Plan.	**Remove**	Original condition is redundant as a Water Discharge Monitoring and Management Plan has been developed and implemented for the existing Yandicoogina Operations

6-6	The Water Discharge Monitoring and Management Plan required pursuant to condition 6-5 shall: (1) when implemented, require the proponent to monitor to substantiate whether condition 6-1, 6-3 and 6-4 are being met; (2) (when implemented, require the proponent to manage the implementation of the proposal to meet the requirements of condition 6-1, 6-3 and 6-4; (3) identify water quality baseline levels at the Western tenement boundary for the criteria measured under the Australian and New Zealand Environmental and Conservation Council and Agriculture and Resource Management Council of Australia and New Zealand (ANZECC/ARMCANZ (2000)) Australian Water Quality Guidelines for Fresh and Marine Waters and its updates; (4) require the proponent to monitor the hydrology, extent of discharges and ecology of the Weeli Wolli Creek System; (5) include provisions for remediating the Weeli Wolli Creek System to ensure that identified environmental values associated with the Weeli Wolli Creek System and any downstream ecosystems, including the Fortescue Marsh, are maintained.	**<u>New Condition 6-4</u>** **The proponent shall submit a revised** Water Discharge Monitoring and Management Plan **in consultation with the DoW, to the satisfaction of the CEO, to ensure that identified environmental values associated with the Weeli Wolli Creek system and any downstream ecosystems, including the Fortescue Marsh, are maintained. This plan shall:** **(1) describe the water discharge and monitoring program;** **(2) when implemented, demonstrate by monitoring, whether conditions 6-1 and 6-3 are being met;** **(3) when implemented, require the proponent to manage the implementation of the proposal to meet the requirements of conditions 6-1 and 6-3; and** **(4) detail management actions and strategies to be implemented should the monitoring required by condition 6-4 (2) indicate that condition 6-1 or 6-3 may not be met.**	Condition updated to reflect a revision of the existing approved and implemented Water Discharge Monitoring and Management Plan. Condition contemporised to match more recent Ministerial Statements.
6-7	Prior to commencing groundwater abstraction from or excavation below the water table at Junction South West A, Junction South West C and Oxbow and until advised otherwise by the CEO, the proponent shall implement the approved Water Discharge Monitoring and Management Plan.	**<u>New Condition 6-5</u>** The proponent shall implement the approved Water Discharge Monitoring and Management Plan **required by condition 6-4, and any subsequent approved revisions.**	Condition updated to reflect the updated Proposal and the existing approved and implemented Water Discharge Monitoring and Management Plan.

6-8	Commencing on the date of this statement and until it commences implementation of the approved Water Discharge Monitoring and Management Plan in accordance with condition 6-7, the proponent shall implement Section 1 Groundwater Management Plan and Section 2 Surface Water Management Plan of Part 3 - Management Plans of the *Yandicoogina Iron Ore Environmental Management Program (March 2011*).	**Remove**	Redundant as covered by the requirements of Condition 6-5.
6-9	The proponent shall annually submit the results of monitoring required by condition 6-6, in the compliance assessment report required by condition 4-6.	**Remove**	Redundant as covered by the requirements of Condition 4.
Riparian vegetation			
7-1	The proponent shall ensure that groundwater abstraction does not cause clearing or loss of vegetation or groundwater dependent ecosystems outside Zones 1, 2, 2a, 3, 3a, 4 and 5 as shown in Figure 1.	The proponent shall ensure that groundwater abstraction does not cause **long term impacts on the health or cover of riparian** vegetation or groundwater dependent ecosystems outside the **management** zones **as shown in Figure 80.**	Reference to clearing removed as condition relates to impacts of groundwater abstraction. Clearing of vegetation is managed under Schedule 1. Condition updated to reflect: • objectives in relation to riparian vegetation; • contemporised conditions. • the impacts recognised in the original MS914 approval (Report 1448) • impacts predicted to riparian vegetation (particularly artificially augmented vegetation); and • abundance changed to cover – to more accurately reflect measurable tree health monitoring parameters; and • new impact management zones.

7-2	The proponent shall ensure that dewatering discharge does not cause clearing or loss of vegetation or groundwater dependent ecosystems outside Zones 1, 2, 2a, 3, 3a, 4 and 5.	The proponent shall ensure that **surplus** water discharge does not cause **long term impacts on the health or cover of riparian** vegetation or groundwater dependent ecosystems outside the **management** zones **as shown in Figure 80**.	Reference to clearing removed as condition relates to impacts of surplus water discharge. Dewatering discharge changed to surplus water discharge as dewatering is a generic term covering both abstraction and discharge. Clearing of vegetation is managed under Schedule 1. Condition updated to reflect: • objectives in relation to riparian vegetation; • contemporised conditions; • the impacts recognised in the original MS914 approval (Report 1448); • impacts predicted to riparian vegetation (particularly artificially augmented vegetation); • abundance changed to cover – to more accurately reflect measurable tree health monitoring parameters; and • new impact management zones.
7-3	The proponent shall manage the proposal in a manner that ensures there is no irreversible impact to riparian vegetation or groundwater dependent ecosystems within Zones 1, 2, 2a, 3, 3a, 4 and 5.	The proponent shall manage the proposal in a manner that ensures there is no irreversible impact to riparian vegetation or groundwater dependent ecosystems **across the catchment as measured** within the **management** zones **as shown in Figure 80.**	Condition updated to reflect predicted localised impacts to riparian vegetation *within* the management zones, but no irreversible impact to the local catchment functioning (*across* the management zones).
7-4	The proponent shall prepare a Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan.	The proponent shall **submit a revised** Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan to the satisfaction of the CEO.	Revision only: the current Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan for Yandicoogina Operation has been approved and implemented.
7-5	The Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan required pursuant to condition 7-4 shall: (1) when implemented, require the proponent to manage the implementation of the proposal to meet the requirements of conditions 7-1, 7-2, and 7-3; (2) when implemented, require the proposal to monitor to substantiate whether conditions 7-	The Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan required pursuant to condition 7-4 shall: (1) when implemented, require the proponent to manage the implementation of the proposal to meet the requirements of conditions 7-1, 7-2, and 7-3; (2) when implemented, require the	Condition contemporised to match more recent Ministerial Statements. Clause (3) – (5) covered by conditions 7-1, 7-2, 7-3 and Condition 6. As per comments in Condition 7-1 & 7-2

1, 7-2 and 7-3 are being met;

(3) require the proponent to minimise impact to riparian Vegetation and Groundwater dependent ecosystems from groundwater abstraction and dewatering discharge;

(4) require the proponent to maintain the abundance, diversity, geographical distribution and productivity of vegetation communities through the avoidance or management of adverse impacts and improvement in knowledge;

(5) require the proponent to maintain the flow paths, quantity and quality of water within Marillana, Yandicoogina and Weeli Wolli Creeks and the underlying aquifers to protect the surface water and groundwater dependent ecological systems;

(6) identify potential impact monitoring and control sites between the Oxbow pit and the Fortescue Marsh;

(7) require the proponent to design a survey to acquire baseline biotic data, including health and abundance parameters and environmental data;

(8) define health and abundance parameters;

(9) define monitoring frequency and timing;

(10) identify criteria to measure any decline in health;

(11) define critical correlative environmental parameters, including groundwater drawdown;

(12) define trigger levels for no impact;

(13) define trigger levels for no irreversible impact;

(14) provide details of management actions and strategies to be implemented should trigger levels defined pursuant to condition 7 -5(12) be exceeded outside Zones 1, 2, 2a, 3, 3a, 4 and 5; and

(15) provide details of management actions and strategies to be implemented should trigger

proposal to monitor to substantiate whether conditions 7-1, 7-2 and 7-3 are being met;

(3) identify monitoring sites;

(4) require the proponent to design a survey to acquire baseline biotic data, including health and abundance parameters and environmental data;

(5) define health and cover parameters;

(6) define monitoring frequency and timing;

(7) identify criteria to measure any decline in health;

(8) define critical correlative environmental parameters, including groundwater drawdown;

(9) define trigger **and threshold** levels for 'no irreversible impact';

(10) provide details of management actions and strategies to be implemented should trigger **and threshold** levels defined pursuant to condition 7-5(9) be exceeded within the management zones.

	levels defined pursuant to condition 7-5(13) be exceeded within Zones 1, 2, 2a, 3, 3a, 4 or 5.		
7-6	Prior to commencing groundwater abstraction from or excavation below the water table at Junction South West A, Junction South West C and Oxbow and until advised otherwise by the CEO, the proponent shall implement the approved Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan.	The proponent shall implement the approved Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan.	Condition revised to reflect that an existing approved and implemented Groundwater Dependent Ecosystems Monitoring and Management Plan exists for the Yandicoogina Operations and that Yandicoogina Operations already implements dewatering activities.
7-7	The proponent shall review and revise the approved Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan at intervals not exceeding five years, to the approval of the CEO.	The proponent shall review and revise the approved Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan at intervals not exceeding five years, to the approval of the CEO.	No Change
7-8	Commencing on the date of this statement and until it commences implementation of the approved Vegetation and Groundwater. Dependent Ecosystems Monitoring and Management Plan in accordance with condition 7-6, the proponent shall implement Section 6 Riparian vegetation management Plan Part 3 - Management Plans of the Yandicoogina Iron Ore Environmental Management Program (March 2011).	Commencing on the date of this statement and until it commences implementation of the **revised** Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan in accordance with condition 7-6, the proponent shall **continue to** implement **the existing approved Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan.**	Condition revised to reflect that an existing approved and implemented Groundwater Dependent Ecosystems Monitoring and Management Plan exists for the Yandicoogina Operations and that Yandicoogina Operations already implements dewatering activities.
7-9	In the event that monitoring, undertaken pursuant to condition 7-6, identifies that trigger levels for no impact, defined pursuant to condition 7-5(12), have been or are being exceeded outside Zones 1, 2, 2a, 3, 3a, 4 and 5, the proponent shall implement management actions and strategies defined in condition 7-5(14) to the satisfaction of the CEO.	In the event that monitoring, undertaken pursuant to condition 7-6, identifies that trigger **and threshold** levels for no **irreversible impact,** defined pursuant to condition 7-5**(9)**, have been or are being exceeded **within the management** zones, the proponent shall implement management actions and strategies defined in condition 7-5**(10)** to the satisfaction of the CEO.	Condition is not feasible to measure outside of the management zones as monitoring extends only to the limit of conservative predicted impact extents. Impacts to riparian vegetation have been predicted in the original MS914 approval and the current approval. Intent of the condition is that there are no irreversible impacts.

7-10	In the event that monitoring, undertaken pursuant to condition 7-6, identifies that trigger levels for no irreversible impact, defined pursuant to condition 7-5(13), have been or are being exceeded within Zones 1, 2, 2a, 3, 3a, 4 or 5, the proponent shall implement management actions and strategies defined in condition 7-5(15) to the satisfaction of the CEO.	Remove	Captured in proposed Condition 7-9.
Weeds			
8-1	The proponent shall ensure: (1) no increase in the species of weeds (including both declared weeds and environmental weeds) in the Proposal Area as a result of the implementation of the proposal; (2) the cover of weeds (including both declared weeds and environmental weeds) within the Proposal Area does not exceed that on comparable, nearby land, determined by the CEO which has not been disturbed during implementation of the proposal; and (3) reference sites on nearby land are to be chosen in consultation with the OEPA, on advice from Parks and Wildlife and established within the Proposal Area and outside the impact area to the satisfaction of the CEO. The reference sites are to be monitored biennially to determine whether changes in weed cover and type are as a result of proposal implementation or broader regional changes.	The proponent shall ensure: (1) no increase in the species of weeds (including both declared weeds and environmental weeds) in the Proposal Area as a result of the implementation of the proposal; (2) the cover of weeds (including both declared weeds and environmental weeds) within the Proposal Area does **not increase as a result of** implementation of the proposal; and (3) **identification and establishment of** reference sites on nearby land **outside the impact area shall be undertaken** in consultation with the OEPA, on advice from Parks and Wildlife ~~and established within the Proposal Area and outside the impact area~~ to the satisfaction of the CEO. The reference sites are to be monitored biennially to determine whether changes in weed cover and type are as a result of proposal implementation or broader regional changes.	Condition revised to reflect the current weed baseline knowledge.
Decommissioning and rehabilitation			
9-1	Within 12 months following commissioning of the Junction South West or Oxbow pits, whichever is first, the proponent shall prepare and implement a Yandicoogina Decommissioning and Rehabilitation	**The proponent shall ensure that the proposal is decommissioned and rehabilitated in an ecologically sustainable manner, consistent with agreed outcomes**	Condition contemporised to match more recent Ministerial Statements (e.g. MS 1000)

	Plan in accordance with the *Guidelines for Preparing Mine Closure Plans, June 2011* and any updates to the requirements of the CEO on advice of the Department of Mines and Petroleum.	**and land uses, and without unacceptable liability to the State of Western Australia, through the implementation of the Mine Closure Plan required by condition 9-2.**	
9-2	The Yandicoogina Decommissioning and Rehabilitation Plan required pursuant to condition 9-1 shall ensure that closure planning and rehabilitation are carried out in a coordinated, progressive manner and are integrated with development planning, consistent with current best practice, and the agreed land uses.	**The proponent shall prepare the Yandicoogina Mine Closure Plan in accordance with the *Guidelines for Preparing Mine Closure Plans*, *June 2015* and any updates, to the requirements of the CEO on advice of the Department of Mines and Petroleum.**	Condition contemporised to match more recent Ministerial Statements (e.g. MS 1000)
9-3	The Yandicoogina Decommissioning and Rehabilitation Plan required pursuant to condition 9-1 shall set out procedures to: (1) manage long term hydrogeological impacts of mining the channel iron deposit; (2) model the long term hydrological impacts, particularly the water levels and quality both in the pit void and downstream of waste material landforms; (3) manage over the long term the surface water systems affected by the open pit; (4) progressively rehabilitate all disturbed areas to a standard suitable for the agreed end land use(s), with consideration and incorporation of: (a) the characteristics of the pre-mining ecosystems within the Project area (through research and baseline surveys); (b) the performance of previously rehabilitated areas within the mining lease; (c) the performance of rehabilitation areas at the proponent's other operations in the Pilbara; and (d) best practice rehabilitation techniques used elsewhere in the mining industry. (5) develop and identify completion criteria; (6) monitor rehabilitation to assess the performance of all rehabilitated areas against the completion criteria;	The proponent shall review and revise the Yandicoogina Mine Closure Plan required by condition 9-**2** at intervals not exceeding three years**, or as otherwise specified by the CEO.**	Condition modifies 9-4 and contemporised to match more recent Ministerial Statements (eg. MS 1000)

	(7) report on the rehabilitation and monitoring results; (8) remove all infrastructure; (9) develop management strategies and/or contingency measures in the event that operational experience and/or monitoring identify any significant environmental impact as a result of the proposal; (10) manage and monitor mineral waste including physical characteristics and acid or neutral metalliferous drainage using national and international standards and updates; and (11) develop a 'walk away' solution for the decommissioned mine site.		
9-4	The proponent shall review and revise the Yandicoogina Decommissioning and Rehabilitation Plan required by condition 9-1 at intervals not exceeding three years.	**The proponent shall implement the latest revision of the Yandicoogina Mine Closure Plan, which the CEO has confirmed by notice in writing, satisfies the requirements of condition 9-2.**	Condition contemporised to match more recent Ministerial Statements (eg. MS 1000)
9-5	The proponent shall make revisions of the Yandicoogina Decommissioning and Rehabilitation Plan required by condition 9-1 publicly available.	**Remove**	Addressed by Condition 4 and 5.
Residual impact and risk management measures			
10-1	In view of the significant residual impacts and risks (permanent and temporary) to native vegetation including riparian vegetation as a result of the implementation of the proposal, the proponent shall contribute three million dollars ($AUD) to a strategic regional conservation initiative for the Pilbara as determined by the Minister for Environment on advice of the Environmental Protection Authority and the DEC.	**The 5,600 ha of clearing of native vegetation previously approved under Ministerial Statement 914 is exempt from the requirement to offset under condition 10-3.**	The previous approval under MS914 was subject to an upfront contribution of $AUD 3 Million to a strategic regional conservation initiative as agreed by the CEO.
10-2	The contribution shall be paid in full by 31 December 2013, unless otherwise agreed by the CEO.	**Remove**	

10-3	**New Condition 10-2** **In view of the significant residual impacts and risks as a result of implementation of the additional clearing for the Yandi PBS Proposal, the proponent shall contribute funds to offset the clearing of 'Good to Excellent' condition native vegetation, and calculated pursuant to condition 10-3. This funding shall be provided to a government-established conservation offset fund or an alternative offset arrangement providing an equivalent outcome as determined by the Minister.**	Condition contemporised to match more recent Ministerial Statements (e.g. MS 1000)
10-4	**New Condition 10-3** **The proponent's contribution to the initiative identified in condition 10-3 shall be paid biennially, the first payment due two years after commencement of the additional ground disturbance defined in Schedule 1. The amount of funding will be $1,500 AUD (excluding GST) per hectare of 'Good to Excellent' condition native vegetation and $3,000 AUD (excluding GST) per hectare of riparian zone vegetation cleared within the Development Envelope (delineated in Figure 1 and defined by the geographic coordinates in Schedule 2), within the Hamersley IBRA subregion.**	Condition contemporised to match more recent Ministerial Statements (e.g. MS 1000)

Dear Ms Scott

YANDICOOGINA IRON ORE PROJECT – REVISED PROPOSAL - ENVIRONMENTAL SCOPING DOCUMENT (Assessment No. 2017)

As you are aware the Environmental Scoping Document (ESD) for the Yandicoogina Iron Ore Project – Revised Proposal was considered by the Environmental Protection Authority (EPA) at meeting number 1073 on 11 December 2014. The approved ESD is enclosed.

In considering the scoping document the EPA had some significant concerns about the potential environmental impacts associated with disturbing the riparian vegetation of Weeli Wolli Creek, which is the subject of a Clearing Avoidance Area delineated in Ministerial Statement 914 (MS 914). The EPA was also concerned about the potential for long term impacts that proposed infrastructure would have on the hydrology of Weeli Wolli Creek, as well as the aesthetic value of infrastructure left in perpetuity within the catchment.

In addition to the requirements outlined in the scoping document the EPA would like to draw your attention to the following points:

- **Clearing Avoidance Area** – The EPA is particularly concerned about the proposed disturbance within the Clearing Avoidance Area to accommodate a bridge/floodway and levee structure. Considering that this area has been delineated for protection in accordance with MS 914, and an Environmental Values Statement has been developed, Hamersley Iron will be required to demonstrate how the environmental values of Weeli Wolli Creek will be maintained and protected during the implementation of this proposal.

- **Hydrological Impacts** – The EPA has identified as a key issue cumulative impacts on Weeli Wolli Creek and potentially Fortescue Marsh considering this proposal together with other existing and proposed projects in the catchment. Considering this, the EPA will expect Hamersley Iron to

demonstrate that any potential impacts to the Fortescue Marsh are minimised and managed to ensure the protection of the Marsh and its environmental values.

- **EPA Board Meeting** – The EPA encourages Hamersley Iron to attend the February EPA Board Meeting to discuss these key concerns.

If you have any queries please contact Matt Spence on 9145 0816.

Yours sincerely

Dr Paul Vogel
CHAIRMAN

31 December 2014

Encl. Environmental Scoping Document

ENVIRONMENTAL SCOPING DOCUMENT

PROPOSAL NAME:	**YANDICOOGINA IRON ORE PROJECT – REVISED PROPOSAL**
ASSESSMENT NUMBER:	**2017**
LOCATION:	**APPROXIMATELY 90 KILOMETRES (KM) NORTH-WEST OF NEWMAN**
LOCAL GOVERNMENT AREA:	**SHIRE OF EAST PILBARA**
PROPONENT:	**HAMERSLEY IRON – YANDI PTY LIMITED**
PUBLIC REVIEW PERIOD:	**6 WEEKS**

1. Introduction

The above proposal is being assessed by the Environmental Protection Authority (EPA) under Part IV of the *Environmental Protection Act 1986* (EP Act) at the level of Public Environmental Review (PER). This Environmental Scoping Document (ESD) sets out the requirements for the environmental review of the proposal. The purpose of an ESD is to:

- provide proposal-specific guidelines to direct the proponent on the preliminary key environmental factors or issues that are to be addressed during the environmental review and preparation of the environmental review report;
- identify the required work that needs to be carried out; and
- timing of the environmental review.

The proponent must conduct the environmental review in accordance with this ESD and then report to the EPA in an environmental review report (PER document). As well as the proposal-specific requirements for the environmental review identified in this ESD, the PER document must also address the generic information requirements listed in section 10.2.4 of the EPA's *Environmental Impact Assessment (Part IV Divisions 1 and 2) Administrative Procedures 2012* (Administrative Procedures). When the EPA is satisfied that the PER document adequately addresses both of these requirements, the proponent will be required to release the document for a public review period of 6 weeks.

This ESD has been prepared by the EPA in consultation with the proponent, decision-making authorities and interested agencies consistent with EPA Environmental Assessment Guideline (EAG) 10 – *Scoping a proposal.* ESDs prepared by the EPA are not subject to public review. The ESD will be available on

the EPA website (www.epa.wa.gov.au) upon endorsement and must be appended to the PER document.

2. The proposal

The subject of this ESD is Hamersley Iron – Yandi Pty Limited's (Hamersley's) proposed Yandicoogina Pocket & Billiard South Iron Ore Mine. The proposal is located approximately 90 km north-west of the town of Newman. The regional location of the proposal is shown in Figure 1.

The revised proposal includes the development of the ore bodies known as Pocket and Billiard South which are located within the south-eastern corner of the development envelope of the existing Yandicoogina operations, approved under Ministerial Statement 914 (Figure 2). The revised proposal (including existing Yandicoogina operations and the Pocket and Billiard South deposits) is likely to have a combined total throughput of up to 70 Mtpa over a mine life of approximately 16 years.

The Pocket and Billiard South deposits occur at the eastern extents of an extensive 80 km long Channel Iron Deposit (CID) palaeochannel. This extension of the Yandicoogina operations is proposed to consist of a single below water table open-cut pit along the CID palaeochannel, temporary and permanent surface waste dumps and the following major infrastructure (Figure 3):

- **one flood protection levee** along the eastern bank of Weeli Wolli Creek;
- **Weeli Wolli creek crossing** - either a floodway or bridge-type structure;
- **ore-handling and processing infrastructure** including dry crushing and potentially future wet-processing facilities;
- **in-pit waste fines storage facilities** (WFSFs) when wet processing is undertaken; and
- **supporting mine infrastructure** including haul roads and ramps, mine access and internal road network, and conveyors.

In addition, a number of the Yandicoogina operation's existing facilities will be upgraded or integrated, including:

- **a land bridge** across Junction South East pit;
- **a levee** along the southern edge of Junction South East pit;
- **trucking or conveying ore** back to the existing Yandicoogina Plant;
- **a water management system** including on-site reuse of water abstracted from pit dewatering, and discharge of surplus volumes into creek systems. Discharge infrastructure servicing the existing Yandicoogina operations will be used; and
- **mine support facilities** (power supply infrastructure, communications infrastructure, offices, explosives storage, waste water treatment plants etc).

Waste rock material from the mine will be stored in waste dumps with some progressive backfilling once individual mine pits (including those from the approved Yandicoogina operations) are exhausted.

As this proposal is a sustaining extension of the existing Yandicoogina operations, the proponent has requested that this referral be treated as a revised proposal and a new statement be issued superseding the existing Ministerial Statement (MS914). Figure 2 shows the proposal area approved under Ministerial Statement 914.

The key characteristics of the proposal are set out in Table 1, in accordance with EAG 1 – *Defining the key characteristics of a proposal*. The development envelope encompassing the physical elements of the proposal is delineated in Figure 2.

It should be noted that the key proposal characteristics may change as a result of implementation of the mitigation hierarchy by the proponent on account of the findings of studies and investigations conducted as part of the environmental review.

Table 1 – Key Characteristics Table

Summary of the proposal			
Proposal Title	Yandicoogina Iron Ore Project – Revised Proposal		
Proponent Name	Hamersley Iron – Yandi Pty Limited		
Short Description	The proposal includes the existing Hamersley Yandicoogina iron ore project and proposed sustaining operations. The existing project includes open pit mining at the Junction Central, Junction South East, Junction South West and Oxbow operations and associated waste landforms, infrastructure, rail, dewatering activities and disposal activities. The proposed sustaining operations includes the development of new pits at Pocket and Billiard South and associated additional temporary and permanent waste landforms, infrastructure, additional dewatering activities and water disposal activities.		
Physical Elements			
Element	**Location**	**Existing Authorised Extent (Ministerial Statement 914)**	**Proposed Extent**
Mine and associated infrastructure	Figure 4	Up to 5,600 ha within Restricted Clearing Area 1. Up to 60 ha within Restricted Clearing Area 2.	Within the Mine Development Envelope of 19,351 ha: • Clearing no more than 8,400 ha within Clearing Area 1; • Clearing no more than 60 ha within Restricted Clearing Area 2; • Clearing no more than 60 ha within Restricted Clearing Area 3; and • No clearing (0 ha) within the Clearing Avoidance Area.

Railway and associated infrastructure	Figure 5		Clearing no more than 300 ha within the Infrastructure Development Envelope of 605 ha.

Operational Elements			
Element	**Location**	**Existing Authorised Extent** **(Ministerial Statement 914)**	**Proposed Extent**
Dewatering	Dewatering Zones	No more than 35 GL/a from Junction South East and Junction Central operations. Up to 18 GL/a from Junction South West A, Junction South West C and Oxbow operations.	Groundwater abstraction of no more than 83 GL/a for the entire Yandicoogina Operations.
Surplus dewater water	Weeli Wolli Creek		Controlled surface discharge of no more than 80 GL/a for the entire Yandicoogina Operations.

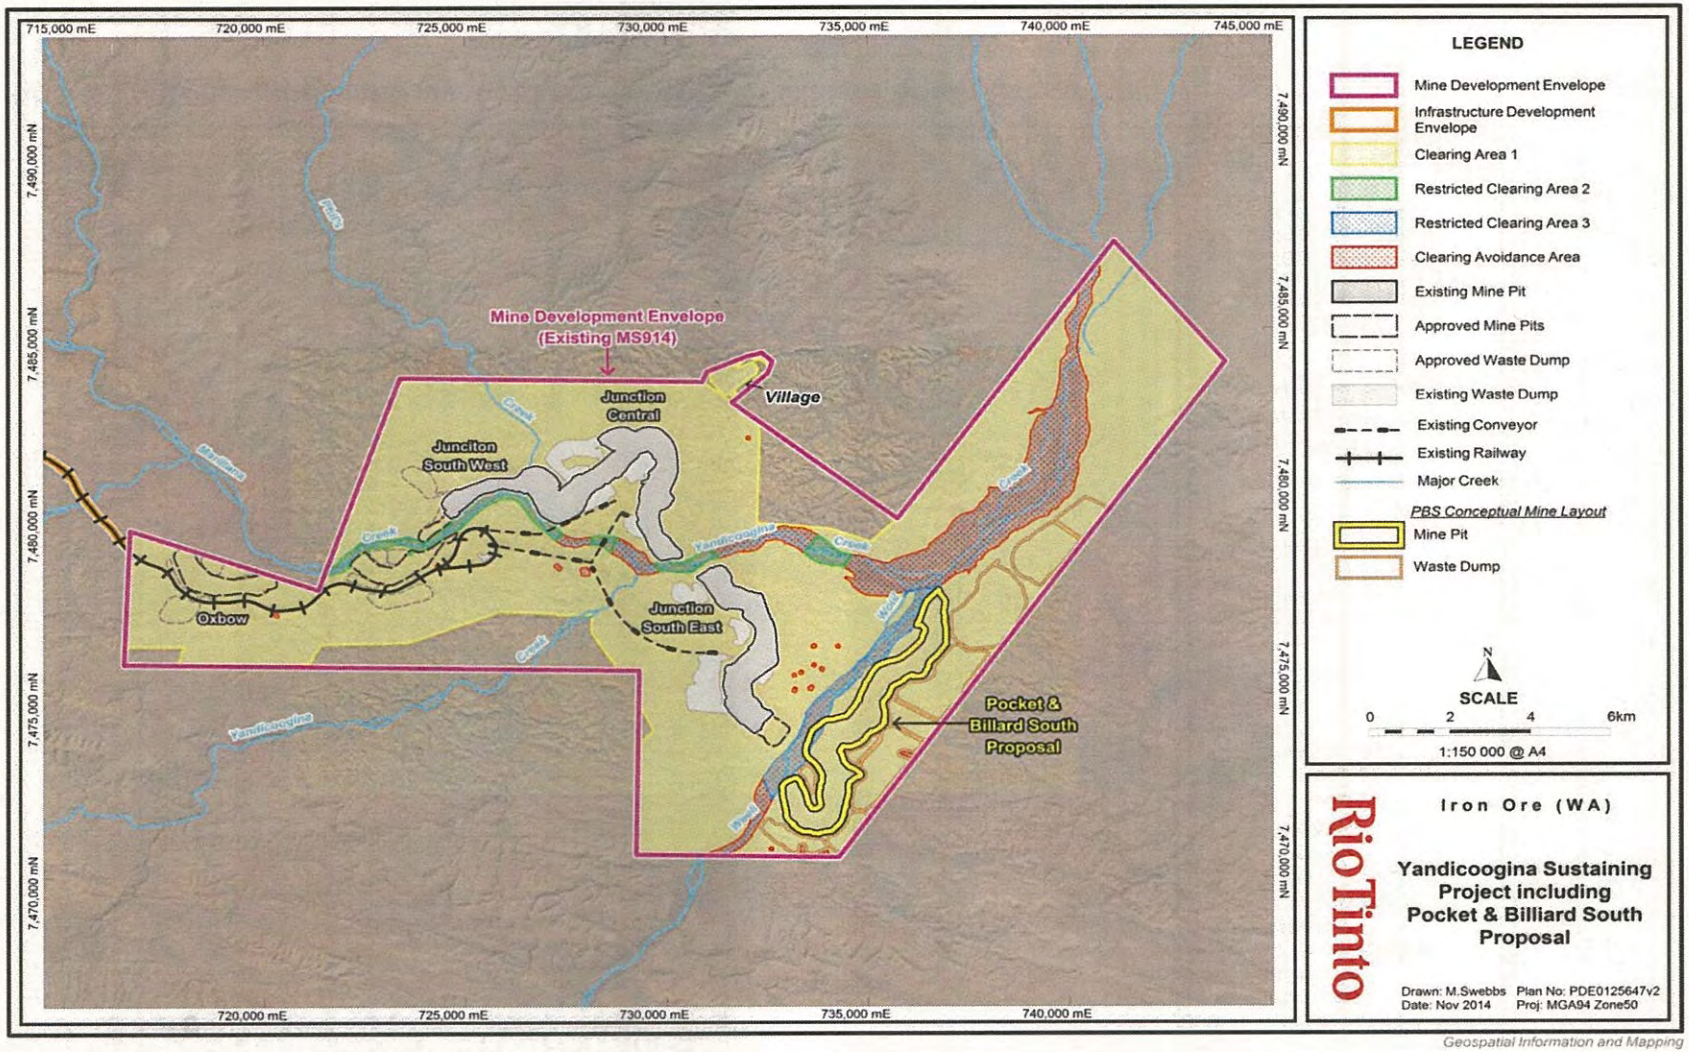

Figure 4 – Avoidance and clearing areas

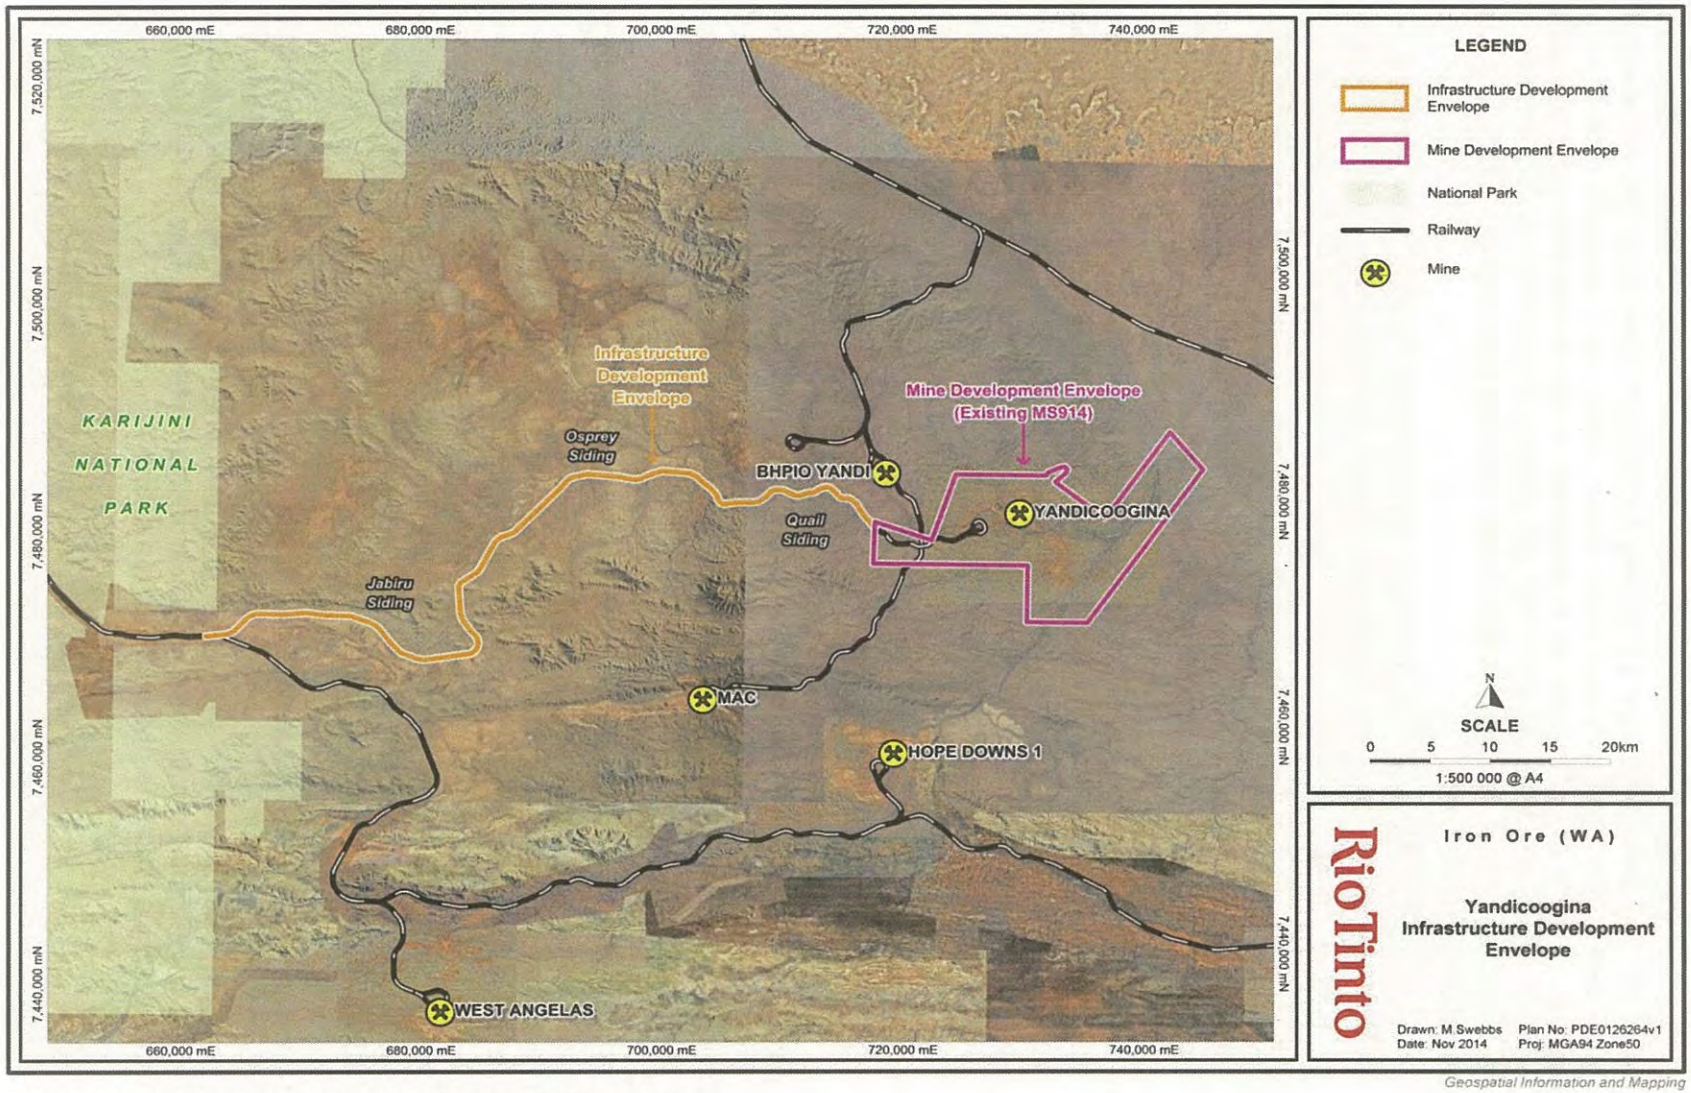

Figure 5 – Infrastructure Development Envelope

3. Assessment context

The current Yandicoogina Iron Ore Project was approved by the Minister for the Environment in October 2012 and currently operates under Ministerial Statement 914 (MS 914). MS 914 delineated a Clearing Avoidance Zone along the entire length of riparian vegetation zone of Weeli Wolli Creek within the proposal's development envelope to protect an area that is considered to be environmentally sensitive. Furthermore, Condition 6-2 required the proponent to develop an Environmental Values Statement (EVS) for Weeli Wolli Creek, defining the environmental values of the system, which included:

- **Value 1 - Hydrology:** the proposal area includes major creek systems that ultimately drain into the Fortescue Marsh Priority Ecological Community (PEC);

- **Value 2 - Flora and Vegetation:** the proposal area includes individuals of *Lepidium catapycnon* (Declared Rare Flora) and a riparian vegetation community of elevated conservation significance;

- **Value 3 - Fauna:** the project area contains a number of stygofauna species known only from the Marillana-Weeli Wolli Catchment. Riparian habitat provides a conduit for the movement of microbats and other fauna. In the wider catchment, the Weeli Wolli Spring (upstream from the proposal area) is known to support a significant microbat species assemblage; and

- **Value 4 - Heritage and Social:** the local creek systems have cultural significance for traditional owners.

The EVS was developed in consultation with the former Department of Environment and Conservation and approved by the CEO on 14 September 2012. The EVS confirmed that the riparian vegetation community of Weeli Wolli Creek was of elevated conservation significance and required protection.

The EPA understands that this revised proposal proposes changes to the Clearing Avoidance Area delineated in MS 914 (shown by the proposed Restricted Clearing Area 3 in Figure 4). The proponent proposes to clear 60 ha within this area to accommodate a bridge/floodway and levee structure that will traverse Weeli Wolli Creek. The EPA is particularly concerned about the disturbance within this area and will require the proponent to demonstrate how the above environmental values would be maintained and protected during the implementation of any revisions to the currently approved proposal.

Furthermore, the EPA has identified as a key issue cumulative impacts on Weeli Wolli Creek and potentially Fortescue Marsh considering this proposal together with other existing and proposed projects in the catchment. The EPA will expect the proponent to demonstrate that any impacts to the Fortescue Marsh are minimised and managed to ensure the protection of the wetland.

4. Preliminary key environmental factors and scope of work

The key proposal characteristics in Table 1 have informed the identification of the preliminary key environmental factors for the proposal, in accordance with EAG 8 – *Environmental factors and objectives*. The preliminary key environmental factors for this proposal and the EPA's objective for each of those factors are identified in Table 2.

To provide context to the preliminary key environmental factors, Table 2 also identifies the aspects of the proposal that cause the factors to be preliminary key factors, and the potential impacts and risks likely to be relevant to the assessment. All of this in turn has informed the work required to be conducted in the environmental review.

Finally, Table 2 identifies the policy documents that establish how the EPA expects the environmental factors to be addressed in the environmental review and the PER document that follows. Impacts associated with proposals are to be considered at a local and regional scale, including evaluation of cumulative impacts, and provide details of proposed management/mitigation measures. This includes whether environmental offsets are required by application of the mitigation hierarchy, consistent with the WA Environmental Offsets Guidelines.

Table 2 Preliminary key environmental factors and required work

Flora and Vegetation	
EPA objective	To maintain representation, diversity, viability and ecological function at the species, population and community level.
Relevant aspects	Clearing, dewatering, alterations to surface water flows and rehabilitation activities.
Potential Impacts	• The proposal involves additional clearing that will increase the disturbance footprint from 5,600 ha to 8,520 ha for the mine and supporting infrastructure. • The clearing includes up to 60 ha of riparian vegetation within Weeli Wolli Creek. There are potential for impacts on Priority Flora species and *Lepidium catapycnon,* which is Declared Rare Flora. • Groundwater drawdown from the mine has the potential to impact on the health of riparian vegetation along an 8 km stretch of Weeli Wolli Creek. • Discharge of surplus water from mine pit dewatering has the potential to impact on riparian vegetation along Marillana and Weeli Wolli creeks. • There is the potential for the introduction of weeds through vehicle movements and earthworks. • There is also the potential to impact on vegetation through the generation of dust from mining operations.
Work required	1. Provide information on the current status and outcomes of the riparian vegetation management actions required by Ministerial Statement 914 Condition 7 – Riparian Vegetation, and Condition 8 - Weeds. 2. Provide a detailed description of the cumulative impacts associated with the proposal, including direct impacts from clearing, and indirect impacts such as groundwater drawdown, surface discharge of excess groundwater, altered

	drainage, changes in water quality, dust emissions and fragmentation of vegetation. 3. Provide figures showing the extent of clearing and indirect impact to vegetation and conservation significant flora species, including but not limited to threatened and/or priority ecological communities, declared rare flora, priority flora and new flora species. 4. Consolidate vegetation and flora reports incorporating information from all relevant previous and new studies, particularly for the Declared Rare Flora species *Lepidium catapycnon*. 5. Describe the environmental values and rational of the Clearing Avoidance Area identified in Ministerial Statement 914. Quantify the disturbance to this area as a result of implementing the proposal and describe how the environmental values of the Clearing Avoidance Area and Weeli Wolli Creek will be maintained. 6. Carry out Level 2 flora and vegetation surveys in areas that are likely to be directly or indirectly disturbed. Surveys are to be undertaken in accordance with Guidance Statement 51. Details of the scope, timing (survey season/s) and methodology for surveys used must be provided. Follow up targeted surveys may be required based on the results of the baseline survey for conservation significant flora and vegetation. 7. Analyse the extent of clearing and indirect impacts to assist in the determination of the significance of impacts, including impacts on: - vegetation units; - threatened and priority ecological communities; - threatened and priority flora; - species identified as significant consistent with Guidance Statement 51; - vegetation units identified as significant consistent with Guidance Statement 51; and - groundwater dependent vegetation. 8. Undertake baseline mapping of weed affected areas in any area likely to be directly or indirectly impacted by the proposal. 9. Discuss potential direct/indirect (including downstream) and cumulative impacts to flora and vegetation as a result of the proposal, and provide quantitative data on impacts of the proposal to species of conservation significance. 10. Discuss proposed management, monitoring and mitigation methods to be implemented. Also, discuss engineering solutions that could be implemented to re-design the waste rock dump locations to avoid impacts to *Lepidium catapycnon*. 11. Demonstrate that all practicable measures have been taken to reduce both the area of the proposed disturbance footprint and the Development Envelope based on progress in the proposal design and understanding of the environmental impacts. 12. Demonstrate that the mitigation hierarchy of avoid, minimise, rehabilitate and offset has been applied effectively during the mine planning and design stages of the project.
Relevant policy/guidance documents	• Position Statement 2 *Environmental Protection of Native Vegetation in Western Australia*. • Position Statement 3 *Terrestrial Biological Surveys as an Element of Biodiversity Protection*.

	• Guidance Statement No. 51 *Terrestrial Flora and Vegetation Surveys for Environmental Impact Assessment in Western Australia* June 2004. • EPA (2013) *Environmental and water assessments relating to mining and mining-related activities in the Fortescue Marsh management area. Advice of the Environmental Protection Authority to the Minister for Environment under Section 16(e) of the Environmental Protection Act 1986*. EPA Report 1484. July 2013. • EPA (2014) *Cumulative environmental impacts of development in the Pilbara region. Advice of the Environmental Protection Authority to the Minister for Environment under Section 16(e) of the Environmental Protection Act 1986.* • Checklist for documents submitted for EIA on marine and terrestrial biodiversity.
Terrestrial Fauna	
EPA objective	To maintain representation, diversity, viability and ecological function at the species, population and assemblage level.
Relevant aspects	Clearing, dewatering, alterations and disruptions to surface water flows and pools, vehicle movement.
Potential impacts	• Habitat removal and fragmentation due to vegetation clearing. • Indirect impacts may occur through altered fire regimes, groundwater drawdown and discharge of surplus water, altered water regimes, changes to feral animal populations, the introduction or increase in spread of weed species, noise and light spill.
Work required	1. Conduct desktop study of information available to provide a comprehensive listing of vertebrate fauna and SRE invertebrate fauna known or likely to occur in the habitats present, and identification of conservation significant fauna species likely to occur in the area. Consideration of species listed under both the WA *Wildlife Conservation Act 1950* and the *Environment Protection & Biodiversity Conservation Act 1999 (*EPBC Act), and species listed by the Department of Parks and Wildlife as Priority Fauna to include, but not necessarily be limited to, the following species of conservation significance have been recorded in the Yandicoogina PBS surveys: - Brush-tailed Mulgara (*Dasycercus blythi*) - Star Swift (*Neochmia ruficaudo*) - Fork-tailed Swift (*Apus pacificus)* - Western Pebble-mound Mouse (*Pseudomys chapman*) - Olive Python (Pilbara subspecies) (*Liasis olivaceus barroni*) - Rainbow Bee-eater (*Merops arnatus*) - Any other priority fauna species identified in a Level 1 survey as likely to occur in the proposal area. 2. For each relevant conservation significant species, provide baseline information on their abundance (including known occurrences), distribution, ecology, and habitat preferences at both the site and regional levels. 3. Conduct a Level 1 reconnaissance vertebrate and SRE invertebrate fauna survey and mapping of habitats including specialised habitats identified within the development envelopes, identification and mapping of important, rare or unusual habitat types within areas to be impacted, in accordance with Guidance Statements 56 and 20. This should also consider other areas outside the proposed disturbance footprint to determine whether the most suitable areas have been chosen for location of infrastructure.

	4. Consider habitat types that provide important ecological function e.g. riparian vegetation, protected area buffer zones, refugia, important habitat corridors, wetlands, areas of conservation significance or geological features which may support unique ecosystems. Analyse the extent of clearing, including percentages of habitat types to be cleared or otherwise impacted, to assist in determination of significance of impacts. Information, including maps, must also differentiate habitat on the basis of use e.g. breeding habitat, migration pathways, feeding habitat. Consider whether the remaining habitat has adequate carrying capacity. 5. Conduct Level 2 fauna surveys in areas that are likely to be directly or indirectly impacted as a result of the proposal. Surveys are to be undertaken in accordance with Guidance Statements 20 and 56. Additional targeted surveys for conservation significant fauna that are known to or likely to occupy habitats in the project area may be required based on the results of the survey. 6. For each relevant conservation significant species, provide: - information on the conservation value of each habitat type from a local and regional perspective, including the percentage representation of each habitat type on site in relation to its local and regional extent; and - if a population of a conservation significant species is present on the site, its size and the importance of that population from a local and regional perspective and potential percentage loss of the conservation significant species locally due to loss of habitat. 7. Discuss known existing threats to the species, whether or not attributable to the proposed action with reference to relevant impacts from the proposed action (including taking into consideration any relevant guidelines, policies, plans and statutory provisions). 8. Discuss potential direct/indirect (including downstream) and cumulative impacts to fauna as a result of the proposal, and provide quantitative data on impacts of the proposal to species of conservation significance. 9. Discuss proposed management, monitoring and mitigation methods to be implemented including an assessment of the effectiveness of the methods, any statutory or policy basis for the methods.
Relevant policy/guidance documents	• Guidance Statement No. 20 *Sampling of Short Range Endemic Invertebrate Fauna for Environmental Impact Assessment* in Western Australia. • Guidance Statement No. 56 *Terrestrial Fauna Surveys for Environmental Impact Assessment in Western Australia* June 2004. • Position Statement 3 *Terrestrial Biological Surveys as an Element of Biodiversity Protection.* • Technical Guide – *Terrestrial Vertebrate Fauna Surveys for Environmental Impact Assessment* September 2010. • Department of Water (2009) Pilbara Water in Mining Guideline Report No.34 • EPA (2013) *Environmental and water assessments relating to mining and mining-related activities in the Fortescue Marsh management area. 	Environment under Section 16(e) of the Environmental Protection Act 1986. • Checklist for documents submitted for EIA on marine and terrestrial biodiversity.
Subterranean Fauna	
EPA objective	To maintain representation, diversity, viability and ecological function at the species, population and assemblage level.
Relevant aspects	Excavation for mining activities. Dewatering groundwater for mining activities.
Potential impacts	Direct mortality and loss of habitat through sub-surface disturbance and abstraction of groundwater for dewatering.
Work required	1. Conduct surveys within areas to be impacted and in surrounding areas in accordance with Guidance Statement 54a. 2. Present the results of the subterranean fauna surveys and discuss the potential for direct and indirect impacts to subterranean fauna including consideration of altered water regimes and nutrient flows. 3. Assess any impacts to subterranean fauna in accordance with EAG 12. For species which are likely to be impacted, provide information, including detailed geological maps on habitat continuity and an appropriate explanation of the likely distribution of species within those habitats. 4. Discuss proposed management, monitoring and mitigation methods to be implemented.
Relevant policy/guidance documents	• Environmental Assessment Guideline 12 Consideration of subterranean fauna in environmental impact assessment in Western Australia June 2013. • Guidance Statement No. 54a Sampling methods and survey considerations for subterranean fauna in Western Australia July 2007. • Department of Water (2009) Pilbara Water in Mining Guideline Report No.34 • EPA (2013) Environmental and water assessments relating to mining and mining-related activities in the Fortescue Marsh management area. Advice of the Environmental Protection Authority to the Minister for Environment under Section 16(e) of the Environmental Protection Act 1986. EPA Report 1484. July 2013. • EPA (2014) Cumulative environmental impacts of development in the Pilbara region. Advice of the Environmental Protection Authority to the Minister for Environment under Section 16(e) of the Environmental Protection Act 1986. • Checklist for documents submitted for EIA on marine and terrestrial biodiversity.
Hydrological processes	
EPA objective	To maintain the hydrological regimes of groundwater and surface water so that existing and potential uses, including ecosystem maintenance are protected.
Relevant aspects	Altered hydrological regimes. Dewatering groundwater for mining activities.
Potential impacts	• Impacts to natural surface water flows as a result of placement, design and operation of new mine and associated infrastructure.

	• Impacts to surface water resources including Weeli Wolli Creek due to surface discharge of surplus mine dewater. • Altered flow regime to the Fortescue Marsh due to groundwater drawdown and discharge of surplus water into Weeli Wolli and Marillana creeks. Cumulative impact due to similar activities of other mines operating in the area. • Impacts to any groundwater dependent ecosystems and subterranean fauna, as a result of groundwater drawdown.
Work required	1. Provide information on the current status and outcomes of surface water discharge management actions required by Ministerial Statement 914 Condition 6 – Surface Water Discharge (Protection of Weeli Wolli Creek). 2. Provide a detailed description of the design and location of the proposal with the potential to impact surface water or groundwater. 3. Characterise baseline hydrological and hydrogeological regimes. 4. Develop a conceptual model of the surface and groundwater systems, incorporating the extent of connectivity between surface and ground water systems. 5. Discuss the effectiveness of the current water management scheme and provide a comparison of its actual operation versus what was predicted including discussion of accuracy. Also detail any problems with how the system has operated and what management measures have been taken when it is not operating as expected. 6. Present information on predicted annual dewatering requirements and surplus water quantities over the life of the operations. 7. Provide a conceptual mine water balance over the life of the proposal to discuss the capacity to reuse surplus mine dewater. 8. Discuss the potential environmental impacts and benefits of identified surplus water management options (i.e. reuse on site, local water supply, aquifer recharge etc.) and discuss the most appropriate water management strategy for the proposal. 9. Discuss the impacts to Weeli Wolli Creek and the potential impacts on Fortescue Marsh considering worst case conditions, including natural flow conditions and maximum anthropogenic inputs. Describe methods used to minimise the impacts to Weeli Wolli Creek, including minimising the period of surface discharge. Quantify the period of surface discharge required, as well as the extent of surplus mine dewater release (wetting front) and changes to flows within Weeli Wolli Creek. 10. Model the impact of different flooding scenarios during operations and post-closure on infrastructure and final landforms. Note the design criteria for any storm water infrastructure on site and provide an explanation, including reference to standards and guideline documents, for the chosen criteria. 11. Detail and assess the geotechnical criteria of the bund or levee that will be located next to Weeli Wolli Creek. Discuss the permanency of the bund or levee in the catchment. Identify the likely source of the material that will be used to build the bund or levee, and describe how the design and structural integrity will withstand large storm events. If the bund or levee is part of a closure strategy assess the long term integrity of the bund taking into consideration different

	flooding scenarios or a worst case scenario. 12. Investigate groundwater drawdown due to ground water abstraction associated with the proposal. Analyse and discuss any impacts to groundwater levels and flows taking into consideration the cumulative impacts with other proposals. 13. Develop a conceptual model of the surface and groundwater systems, incorporating groundwater quality and the extent of connectivity between surface and ground water systems and Fortescue Marsh. 14. Have the surface and groundwater modelling for this assessment independently peer reviewed. Determine the scope, timing and the selection of the peer review in consultation with the Department of Water. The groundwater modelling should be consistent with Australian Government National Water Commission's Australian Groundwater Modelling Guidelines (2012). The surface water modelling should be in accordance with the Australian Rainfall and Runoff Guidelines. 15. Analyse, discuss and assess surface water and groundwater impacts, including changes in groundwater levels and changes to surface water flows associated with the proposal together with cumulative impacts with other projects and referred proposals (including the BHPBIO strategic proposal) for which relevant information is publicly available. 16. Discuss the proposed management, monitoring and mitigation to prevent groundwater and surface water impacts as a result of implementing the proposal.
Relevant policy/guidance documents	• Rights in Water and Irrigation Act (1914). • Department of Water (2009) Pilbara Water in Mining Guideline. Report No 55, October 2013. • EPA (2013) Environmental and water assessments relating to mining and mining-related activities in the Fortescue Marsh management area. Advice of the Environmental Protection Authority to the Minister for Environment under Section 16(e) of the Environmental Protection Act 1986. EPA Report 1484. July 2013. • EPA (2014) Cumulative environmental impacts of development in the Pilbara region. Advice of the Environmental Protection Authority to the Minister for Environment under Section 16(e) of the Environmental Protection Act 1986. • Australian Government National Water Commission's Australian Groundwater Modelling Guidelines (2012). • Australian Rainfall and Runoff Guideline.
Inland Waters Environmental Quality	
EPA objective	To maintain the quality of groundwater and surface water, sediment and/or biota so that the environmental values, both ecological and social, are protected.
Relevant aspects	Temporary stockpiling of waste material on the surface, storage and use of hazardous materials and hydrocarbons. Legacy of mine pit lakes.

Potential impacts	• Disruption of surface drainage systems in the Fortescue Marsh catchment by mine pits, surface waste dumps and stock piles, and drainage structures. • Potential changes to the ground water quality over time from pit lakes left by the proposal. • Potential contamination of surface water and groundwater, if management of waste dumps containing at-risk material (material with potential for acid or metalliferous drainage) is not appropriate.
Work required	1. Characterise baseline water quality, including the analysis of groundwater quality that is proposed to be discharged into the surrounding environment. 2. Develop a conceptual model of the surface and groundwater systems, incorporating groundwater quality and the extent of connectivity between surface and ground water systems and Fortescue Marsh (same requirement for Hydrological Processes). 3. Undertake a hydrological investigation to determine what effect groundwater abstraction, and modified drainage will have on the surface water and groundwater quality and quantity of the area, including interactions between surface and groundwater. 4. Have the surface and groundwater modelling for this assessment independently peer reviewed. Determine the scope, timing and the selection of the peer review in consultation with the Department of Water. The modelling should be consistent with Australian Government National Water Commission's *Australian Groundwater Modelling Guidelines (2012)* (same requirement for Hydrological Processes). 5. Undertake a comprehensive review of surface water and groundwater quality collected from the existing mining operation at the site. Identify any adverse changes caused by the mining operation and outline avoidance, minimisation and management methods to be used to prevent further impacts. 6. Undertake waste characterisation studies of waste rock and other materials and carry out an acid and metalliferous drainage risk assessment. Detail where Potentially Acid Forming (PAF) material will be located and discuss stored and containment options, including sub-aqueous storage. 7. Provide a description of the design, location and extent of discharges of the proposed waste facilities, and any other elements of the proposal with the potential to impact surface water or groundwater quality. 8. Model cumulative impacts with other mines in the catchment (currently operating and referred proposed mines, including the BHPBIO strategic proposal, where information is publicly available). Develop strategies and controls to minimise the impacts. 9. Confirm whether or not pit lakes may form and provide details of potential backfill options. If pit lakes may form, provide an assessment of the long term contamination of any pit lakes and the potential impact on groundwater and surface water quality with particular attention to possible impacts on Fortescue Marsh. In addition, undertake a risk assessment in accordance with the most recent version of the joint DMP/EPA Mine Closure Guidelines and provide details of mitigation measures undertaken to reduce the risk of any pit lakes. 10. Discuss proposed management, monitoring and mitigation methods, including the identification of water quality trigger levels, to be implemented during construction, operation and following closure to ensure that the EPA's objective

	for this factor is met.
Relevant policy/guidance documents	• ANZECC and ARMCANZ (2000) Implementation Framework for Western Australia for the Australian and New Zealand Guidelines for Fresh and Marine Water Quality and Water Quality Monitoring and Reporting. • Government of WA (2004) State Water Quality Management Strategy Document No. 6. • Department of Water (2009) Pilbara Water in Mining Guideline. Report No 34. • Department of Water (2013) Western Australian Water in Mining Guideline. Water licensing delivery report series. Report No. 12.EPA (2013) • EPA (2013) Environmental and water assessments relating to mining and mining-related activities in the Fortescue Marsh management area. Advice of the Environmental Protection Authority to the Minister for Environment under Section 16(e) of the Environmental Protection Act 1986. EPA Report 1484. July 2013.
Rehabilitation and Closure (Integrating factor)	
EPA objective	To ensure that premises can be closed, decommissioned and rehabilitated in an ecologically sustainable manner, consistent with agreed outcomes and land uses, and without unacceptable liability to the State.
Relevant aspects	Excavation and earthworks resulting in changed landforms, disposal of waste material and clearing of large areas requiring rehabilitation.
Potential impacts	• The proposal is under a State Agreement Act (Iron Ore (Yandicoogina) Agreement Act 1996) and as such rehabilitation and closure cannot be regulated and managed by the Department of Mines and Petroleum. • The proposal may impact on Fortescue Marsh Management Zones listed in the EPA's strategic advice on mining-related assessments in the Fortescue Marsh area (EPA, 2013). • Should there be poor rehabilitation and mine closure planning and management practices there could be a number of undesirable impacts to the receiving environment, such as: - unauthorised vegetation disturbance; - depletion of topsoil resources; - compacted soil layers with poor infiltration rates; - the formation of pit lakes which may attract and harm wildlife, birds or stock; - the introduction of weeds to rehabilitated areas; - landscape modification, altered hydrology and other ecosystem impacts; - unstable landforms and adverse dust impacts; - poor return of native vegetation and flora species; and - contamination.
Work required	1. Provide information on the current status of Yandicoogina Decommissioning and Rehabilitation Plan required by Ministerial Statement 914 Condition 9 –

	Decommissioning and Rehabilitation. 2. Undertake a desktop study of successful and unsuccessful rehabilitation strategies and outcomes in similar geologies and vegetation types in the Pilbara, including any rehabilitation that has been conducted to date within the development envelope. Including a discussion of the different methodology and success rates for the various proposed disturbance types including: - created landforms (e.g. waste rock dump, tailings storage facility); - short-term disturbances (e.g. borrow pits and access tracks); - long-term disturbances (e.g. construction camp, permanent accommodation village and administration buildings); and - linear and/or fragmentation disturbances (e.g. roads, power lines, bore fields). 3. Provide waste characterisation work including static, short term leaching and kinetic test results, and water quality monitoring results for drainage from existing waste storage facilities to enable a thorough assessment of Acid and Metalliferous Drainage risk posed by the project. If PAF material is identified, provide mine scheduling detail to demonstrate that PAF material is not disturbed during mining and/or that effective strategies will be in place to ensure PAF material is adequately managed should it be exposed and/or disturbed. 4. Provide the physical characteristics of the waste materials and proposed locations and geotechnical design detail (including slope stability) for the waste landforms, including the WFSFs. Identify proposed management and monitoring for the waste landforms. Describe contingencies to make landforms secure and non-polluting in the event of unexpected or temporary closure. 5. Prepare a Rehabilitation and Mine Closure Plan consistent with the current version of the Department of Mines and Petroleum (DMP) and EPA *Guidelines for Preparing Mine Closure Plans.* Include completion criteria and closure objectives addressing native vegetation and habitat for significant flora and fauna and base the conclusions on the availability of suitable substrates and landform design. Establish and measure vegetation and fauna reference sites to inform completion criteria. Determine requirements for, and sources of, soil and seed for rehabilitation. A conclusive discussion on backfill options (including 'worst case scenario') is also required. 6. Discuss proposed management, monitoring and mitigation methods to be implemented including post-mining land use and areas to be rehabilitated. 7. Discuss proposed monitoring of linkages of specialised habitats to demonstrate that rehabilitated areas function as ecological corridors for conservation significant fauna.
Relevant policy/guidance documents	• DMP and EPA (2011) Guidelines for Preparing Mine Closure Plans or its revisions. • EPA (2006) Guidance Statement No 6: Rehabilitation of Terrestrial Ecosystems. • EPA (2013) Environmental and water assessments relating to mining and mining-related activities in the Fortescue Marsh management area. July 2013. • EPA (2014) Cumulative environmental impacts of development in the Pilbara region. Advice of the Environmental Protection Authority to the Minister for Environment under Section 16(e) of the Environmental Protection Act 1986.

Offsets (Integrating factor)	
EPA objective	To counterbalance any significant residual environmental impacts and/or uncertainty through the application of offsets.
Relevant aspects	Clearing of native vegetation including conservation significant flora, 'good to excellent' condition vegetation, habitat for conservation significant fauna species.
Potential impacts	Potential impacts on vegetation, flora, habitat and fauna species of State and National significance.
Work required	1. Examine residual impacts and, if required, develop a draft program of environmental offsets that adheres to the relevant policy/guidance documents listed below. 2. Include the completed Environmental Offsets Reporting Form and any offsets required and proposed in the PER.
Relevant policy/guidance documents	• EPA (2008) *Environmental Protection Bulletin No 1 – Environmental Offsets – Biodiversity*. • Govt of WA (2011) *WA Environmental Offsets Policy*. • Govt of WA (2014) *WA Environmental Offsets Guidelines*. • EPA (2014) *Cumulative environmental impacts of development in the Pilbara region. Advice of the Environmental Protection Authority to the Minister for Environment under Section 16(e) of the Environmental Protection Act 1986*. • EPA Offsets Reporting Form.

5. Stakeholder consultation

The EPA expects that the proponent will consult with stakeholders who are interested in, or affected by, the proposal. This includes decision-making authorities (DMAs), other relevant State government departments and local government authorities, environmental non-government organisations and the local community.

The proponent must document the stakeholder consultation undertaken and the outcomes, including any adjustments to the proposal and any future plans for consultation. This is to be addressed in a specific section of the PER document and, in addition, key outcomes of consultation are to be reported against the preliminary key environmental factors as relevant.

It is expected that as a part of the consultation with DMAs there will be discussion around each agency's specific regulatory approvals, and a demonstration that other factors can be managed by another regulatory body.

6. Other factors or matters

During assessment of proposals, other factors or matters will be identified as relevant to the proposal, but not of significance to warrant further assessment by the EPA, or impacts can be regulated by other statutory processes to meet the EPA's objectives.

These factors do not require further work as part of the environmental review, or detailed discussion and evaluation in the PER document, although they must be

included in the PER document in a summarised, tabular format noting that the PER document will be subject to public review.

In some circumstances other factors, while not being considered as preliminary key environmental factors, may require greater emphasis in the PER document. This may be due to high public interest or at the request of another stakeholder, so that the potential impacts and management measures associated with the other factor are sufficiently articulated for the public review. For this assessment, the other factors that need to be concisely described and discussed in the PER document, are:

- Air quality;
- Amenity; and
- Heritage.

It is also important that the proponent be aware that other factors or matters may be identified during the course of the environmental review that were not apparent at the time that this ESD was prepared. If this situation arises, the proponent must consult with the EPA to determine whether these factors and/or matters are to be addressed in the PER document, and if so, to what extent.

7. Agreed assessment timeline

Table 3 sets out the timeline for the assessment of the proposal agreed between the EPA and the proponent. Proponents are expected to meet the agreed timeline, and in doing so, provide adequate, quality information to inform the assessment.

Table 3 Assessment Timeline

Key Stages of Assessment	Agreed Completion Date
EPA approval of ESD Document	December 2014
Proponent submits first adequate draft of PER Document	March 2015
OEPA provides comment on first draft PER Document	6 weeks Mid May 2015
Proponent submits adequate revised draft PER Document	4 weeks Mid June 2015
EPA authorises release of PER Document	2 weeks End June 2015
Proponent releases approved PER Document	1 Week Early July 2015
Public Review of PER Document	6 weeks Mid August 2015
EPA provides Summary of Submissions	3 Weeks

	Early September 2015
Proponent provides adequate Response to Public Submissions	4 Weeks Early October 2015
OEPA reviews Response to Submissions	4 weeks Early November 2014
OEPA assesses proposal for consideration by EPA	7 weeks End December 2015
Preparation and finalisation of EPA Report (including 2 weeks consultation on draft conditions with proponent and key Government agencies)	5 weeks (+2 weeks for Christmas) End February 2016

If any stage in the agreed timeline is not met or inadequate information is submitted by the proponent, the timing for the completion of subsequent stages of the process will be revised. Equally, where the EPA is unable to meet an agreed completion date in the timeline, the proponent will be advised and the timeline revised.

The proponent should refer to EPA's EAG 6 – *Timelines for environmental assessment of proposals* for information regarding the responsibilities of proponents and the EPA for achieving timely and effective assessment of proposals.

8. Decision-making authorities

At this stage, the EPA has identified the authorities listed in Table 4 as DMAs for the proposal. Additional DMAs may be identified during the course of the assessment.

Table 4 Decision-making authorities

Decision-making authority	Relevant legislation
Minister for Environment	*Wildlife Conservation Act 1950*
Minister for Water	*Rights in Water and Irrigation Act 1914*
Minister for State Development	*Iron Ore (Yandicoogina) Agreement Act 1996*
Minister for Aboriginal Affairs	*Aboriginal Heritage Act 1972*
Minister for Lands	*Lands Administration Act 1997*
Department of Environment Regulation	Part V of the *Environmental Protection Act 1986*
Department of Mines and Petroleum	*Mining Act 1978* <u>Dangerous Goods</u> *Dangerous Goods Safety Act 2004* Storage and handling of hazardous materials Chief Dangerous Goods Officer

	Mine Safety *Mines Safety and Inspection Act 1994* District Inspector, Resources Safety Branch

9. Parallel processing

The EP Act constrains DMAs from making any decision that could have the effect of causing or allowing the proposal to be implemented. However, the proponent is encouraged to pursue other approvals in parallel with the EPA's assessment noting that the constraint only relates to making an approval decision.

10. PER document

When the EPA is satisfied with the standard of the PER document (refer to section 4.4 of EAG 6) it will provide written authorisation for the release of the document for public review. The proponent must not release the PER document for public review until this authorisation is provided.

The proponent is responsible for advertising the release and availability of the PER document in accordance with instructions that will be issued to the proponent by the EPA. The EPA must be consulted on the timing and details for advertisement.

1. Overview

This report summarises the outcomes of an independent review of the Yandi Mine numerical groundwater flow model developed by the Water Resource Evaluation (Projects and Development) business unit of Rio Tinto (on behalf of Pilbara Iron). The review was conducted in accordance with the principles of the Australian Groundwater Modelling Guidelines issued by the National Water Commission (NWC) in June 2012 (Barnett et al., 2012), as well as the Murray Darling Basin Commission Groundwater Flow Modelling Guideline (Middlemis et al, 2001), which was the foundation for the 2012 guidelines. The 2012 guideline suggests a compliance checklist suitable for high-level appraisals, which can also be used to summarise the outcomes of a review. The completed summary checklist is presented at Table 1, and justifications for the opinions indicated are summarised in the comments field, with key elements explored/detailed further in later sections.

In summary, it is my professional opinion that the model has been developed in a manner that is broadly consistent with basic practice, but does not yet achieve best practice. The review confirmed good overall model calibration performance has been achieved, but also identified weaknesses in certain elements of the model design, surface and groundwater interaction features and parameter values. Such weaknesses/inconsistencies are not necessarily fatal flaws as such, but they could potentially form easy targets for unwarranted criticism, and many (if not all) could be readily addressed with refinements in the next modelling work program.

The main weakness is that the model design process has not thoroughly optimised all the issues of model functionality required to support a high model confidence classification in relation to the 2012 guideline (e.g. the layer structure is a little too complex and the calibration performance could be improved in the JSE Southern area). This does not mean that the model is technically flawed; simply that it is not a good example of best practice in its design and execution (i.e. the model could be described as somewhat over-designed). While the transient calibration performance is generally very good, it should be improved in the key area of the JSE Southern borefield and Weeli Wolli Creek intersection, which may require some additional data to validate the stream-aquifer interaction performance. The exploration of model uncertainty in structural and parameter value terms is basic and needs improvement under future work programs, notably in relation to stream-aquifer interaction.

This independent review finds that a Class 2 model confidence level classification (Barnett et al, 2012) has been achieved, meaning that this model is suitable for mining project impact prediction purposes.

Table 1 – Groundwater Model Compliance Checklist: 10-point essential summary

Question	Yes/No	Comments re Rio Tinto Yandi Mine groundwater model
1. Are the model objectives and model confidence level classification clearly stated?	**Yes**	• As part of the PFS, dewatering requirements and potential environmental impacts of dewatering are needed for the Public Environmental Review. • A numerical groundwater model was selected as the tool to predict the dewatering requirements to meet the A8 mine schedule released in August 2014 and demonstrate the potential cumulative impacts of increased dewatering.
2. Are the objectives satisfied?	**Yes**	The general aims are satisfied via a generally good model calibration performance, and the prediction results provide data on dewatering needs and related impacts that are basically suitable for the PER purpose.
3. Is the conceptual model consistent with objectives and confidence level classification?	**Yes**	The close-coupled aquifer and creek system involves many complexities but the conceptualisation appears to be sound, representing the key features in quite some detail. The 15-layer model design is arguably too complex, but that does allow for a detailed spatial distribution of aquifer properties.
4. Is the conceptual model based on all available data, presented clearly and reviewed by an appropriate reviewer?	**Yes**	Critical /fatal model flaws have not been identified during this review, but some weaknesses and minor inconsistencies identified have the potential to form easy targets for unwarranted criticism. Many (if not all) should be addressed in the next model work program. A multi-disciplinary team at Rio Tinto has clearly been involved in the hydrological and hydrogeological investigations and data analysis, with collaboration and review evidenced by acknowledgements in reports and papers, reinforced during discussions undertaken for this review.

5. Does the model design conform to best practice?	**Yes**	The model design, software, extent, cell size, boundaries and parameters are generally consistent with best practice (with some minor issues). The 15 layers are arguably too many (5 layers would be a bare minimum; perhaps 10 layers might be optimal?). The 15 layers do allow for a detailed representation of the spatial distribution of aquifer properties (especially helpful where the CID and alluvium are contiguous). However, this also results in a large model (>3 million cells) and thus long run times (around 2 days), which makes scenario modelling inefficient (e.g. the running of many scenarios to assess uncertainty, alternative mine plans, closure options, or climate variability would be ideal but not feasible in this case). This indicates that the model design process has not, in fact, optimised all the issues of model functionality required to support a high model confidence level classification. This does not mean that the model is technically flawed; simply that it is not a good example of best practice in its design and execution.
6. Is the model calibration satisfactory?	**Yes**	Model calibration performance is very good in terms of time series matches to measured groundwater levels at most bores (statistical measures are superfluous in this case). One area of relatively poor (but still adequate) performance is actually in a key area where good performance is required: near the JSE Southern borefield and where Weeli Wolli Creek crosses the CID for the first time, upstream from Billiard. Many processes are concentrated here: dewatering, reinjection, Discharge Outlet #6, creek interaction, and there is a complex distribution and wide range of parameter values. There are good matches pre-2006 to bores JSE31, JSE32, JSE39 and WB02, but then variable subsequent performance (model sometimes high and/or low at various times, with no obvious systematic trend). The next model refinement work program should focus on this area to improve calibration performance.
7. Are the calibrated parameter values and estimated fluxes plausible?	**Yes**	An appropriate level of complexity in parameter distributions has been applied to achieve overall good calibration performance. The parameter values and fluxes are plausible and generally consistent with site-specific testing and also literature values. Calibration uses measured data on groundwater levels, fluxes for bore extraction and injection, and stream flow volumes. There is an acknowledged level of uncertainty on some elements of the mine water balance volumes, which makes robust calibration performance difficult to achieve. Improved metering & monitoring will provide data for future model improvements. There is room for improvement on validation of stream-aquifer interactions, which form the major water balance volumes and thus strong performance is required. The review identified that the data available near discharge outlets 1 and 5 is not suitable for validating stream-aquifer interactions (i.e. these DO's are not active when groundwater monitoring was active). However, suitable data is available in the area of JSE Southern and DO6, an area where model validation is critical and must be demonstrated. The relatively poor (but still adequate) calibration performance here must be improved in the next work program.
8. Do the model predictions conform to best practice?	**Yes**	The methods applied were generally consistent with best practice. For example, the predictions conservatively accounted for the effects of BHP Billiton mining operations upstream, and scenarios were run to evaluate the effect of replacing DO9 by DO10 (demonstrating a reduction in dewatering). Other model predictions are adequate, but certain scenarios should be updated in the next work program; for example: • monthly creek flows over the quite dry 2009-2013 period were averaged and applied to the Marillana Ck and Weeli Wolli Ck boundary inputs for prediction scenarios; this approach should be improved to help evaluate climate variability effects, for example, a simple method would be to apply a repeated historical sequence of flows from wet/dry periods (e.g. 1998-2008) • the post-closure aquifer parameters are unchanged from in-situ values, which would over-estimate aquifer recovery rates & groundwater levels.
9. Is the uncertainty associated with the predictions reported?	**Yes**	Aquifer parameter sensitivity was analysed and the results used to evaluate related uncertainties in the model predictions, and this was executed very well. However, parameters relating to key processes including stream-aquifer interaction (streambed conductance) and evapotranspiration were not tested, and this should be a focus for the next work program to update the model.
10. Is the model fit for purpose?	**Yes**	My professional opinion is that the model has been developed in a manner consistent with basic practice, but not achieving best practice. The model design process has not optimised all the issues of model functionality required to support the PER purpose (e.g. the layer structure is too complex). This does not mean that the model is technically flawed; simply that it is not a good example of best practice in its design and execution. The transient calibration performance is generally very good, but is poor in the key area of the JSE Southern borefield and Weeli Wolli Creek traverse, where data is available to validate the stream-aquifer interaction performance.

2. Review Approach

For the record, the reviewer (Hugh Middlemis) is an independent groundwater modelling specialist with more than 25 years' experience in this field, including eight years based in Perth working mainly on mining projects, notably the Marillana Creek groundwater model for BHP (Middlemis et al, 1998). Hugh is principal author of the MDBA groundwater modelling guidelines (Middlemis et al, 2001) and was awarded a Churchill Fellowship in 2004 to benchmark groundwater modelling against international best practice.

The review was undertaken at Rio Tinto offices in Perth on Friday, January 23, 2015, when discussions were held with various staff, notably Eddy Lim (Senior Modeller), Keith Brown (Superintendent Hydrogeology) and Shawan Dogramaci (Principal Hydrogeologist). Mr Lim gave a presentation of various model details on that morning, and a brief question and answer session ensued regarding certain model specifics, with interrogation of some of the model data files facilitated by Eddy Lim. There was some subsequent provision of certain model information via email and discussion on certain model details via telephone. Dr Dogramaci provided copies of several published papers on research into stream-aquifer interactions and isotope analysis, and one Rio Tinto report for background purposes.

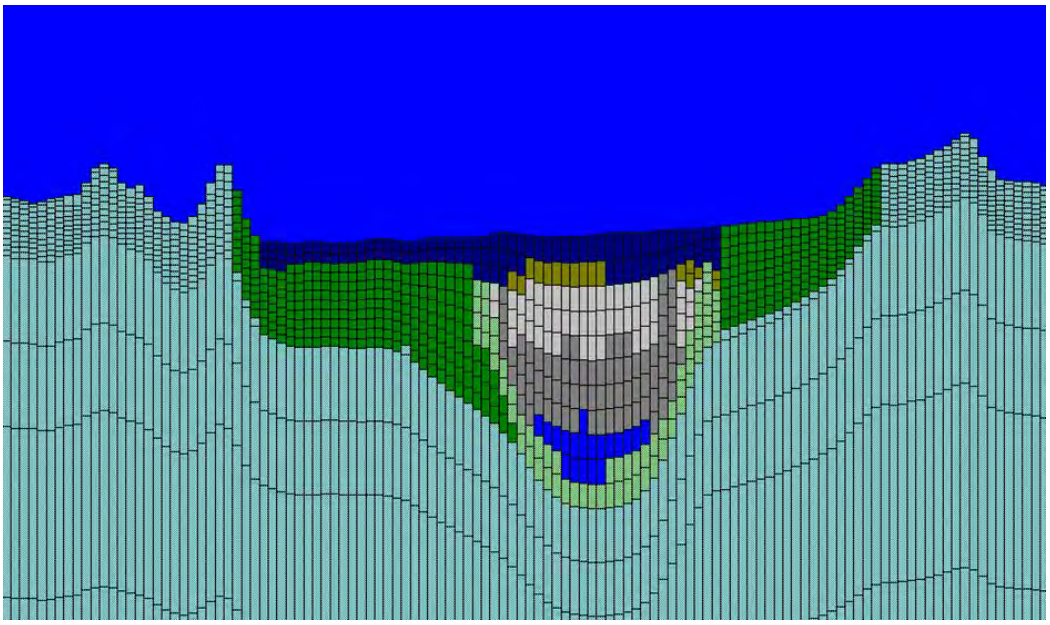
It was not possible to evaluate comprehensively the entire range of hydrogeological data nor every element of the gigabytes of model data files, nor indeed all the background reports and papers. While this review does not consider or address all uncertainties and risks, it aims to investigate any weaknesses relating to the model design and implementation, based on application of the review protocols in modelling guidelines.

Given the aim to identify weaknesses, this review process tends to focus on negative aspects. However, it is acknowledged that many elements of the technical modelling process have been very well executed.

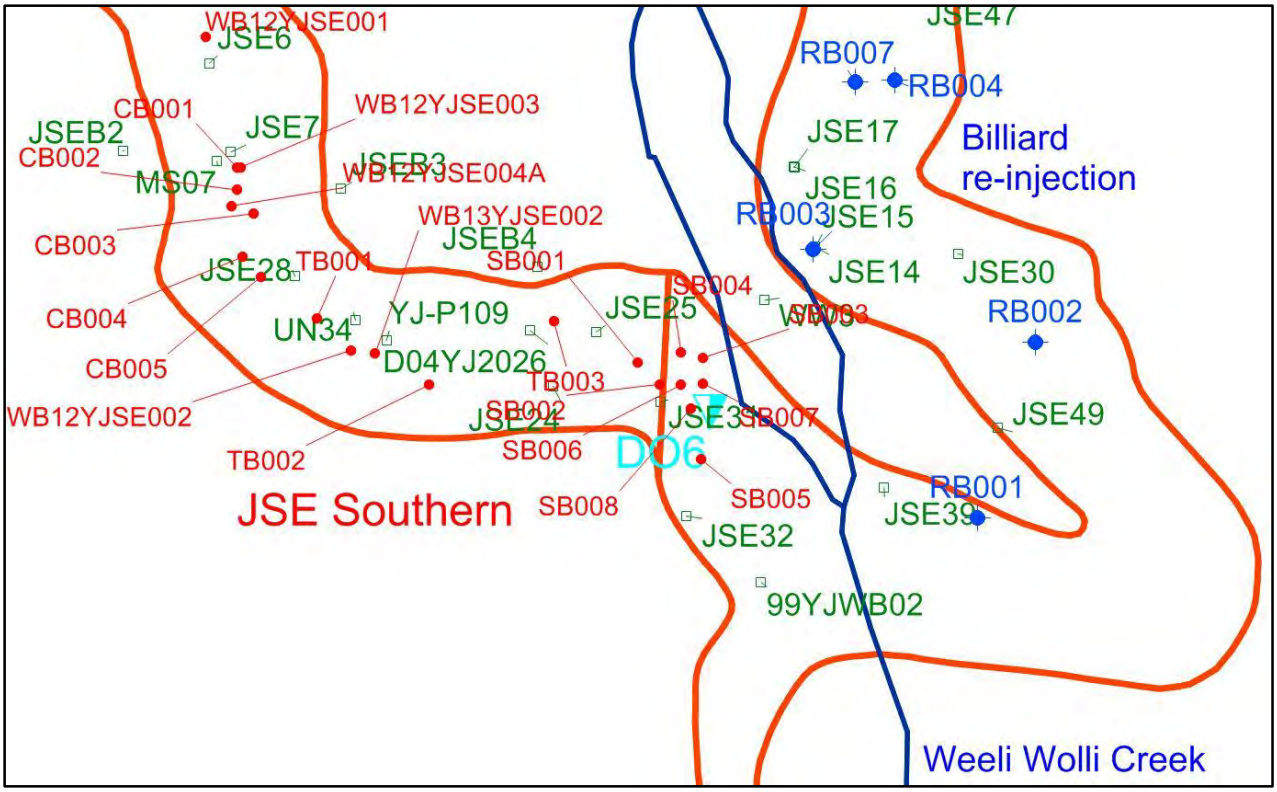
3. Impact Assessment Modelling Approach

The following points summarise the model design, calibration, sensitivity testing and prediction approach undertaken, with comments added to confirm where the work forms a sound basis for impact assessment, or to outline where/why it may be deficient:

- **conceptual model** is summarised adequately in geological terms and is based on substantial investigations over the many years that Rio Tinto has operated the Yandi mine;
- **25 x 30 km model extent** with maximum cell size of 509 x 750 m provides adequate regional extent (boundaries remote from mine area with intervening low permeability units); minimum cell size of 31 x 32 m provides adequate detail internally where needed;
- **15-layer regional model** with model layer elevations based on geological structure/mapping, validated against drill logs; 15 layers is arguably too many (5 layers would be a bare minimum; perhaps 10 layers might be optimal?); but the approach does allow for a detailed representation of the spatial distribution of aquifer properties (e.g. see screen grab of model cross section west-east at Billiard, showing aquifer parameter distribution consistent with hydrogeological understanding, including basal clay conglomerate forming lateral separation of thick alluvium from CID, validated by pumping test);



- **modelling software is Modflow-Surfact** (industry-leading and suitable); model comprises 3.3 million cells, or three times larger than what the industry regards as a large model of 1 million cells; long run times result (around 2 days), which make for inefficient scenario modelling; this indicates that the model design process has not, in fact, optimised all the issues of model functionality required to support the PER purpose; it does not mean that the model is technically flawed, simply that it is not a good example of best practice in its design and execution;
- **model boundaries**: western boundary is specified head plus stream discharge from BHPB discharge point (i.e. reasonable in principle, but conservatively assumes no groundwater level impact from BHPB dewatering, although ongoing BHPB stream discharge outlet volumes are applied); northern boundary is drain cells, whereas it would be expected that the same (fixed head) boundary type as for the western boundary would be adopted and another calibration parameter (drain conductance) would not be introduced without suitable justification (this is not a fatal flaw as such, simply an example of inelegant design); southern boundary is no flow (not unreasonable given lack of CID in this area) plus stream discharge based on Tarina gauging station flows, which includes the effects of dewatering discharge from mining operations south of Weeli Wolli Spring;
- **steady state calibration**: groundwater contours appear acceptable across almost all areas, but show some perturbations on the northern boundary, which the on-site review identified as being related to a localised active evapotranspiration process that may not be realistic due to the (low) topographical data in that area; this is not material to overall model performance (other than in this unimportant area on the northern model boundary), and should be addressed in the next model update;
- **transient calibration performance** is demonstrated by generally good time series matches at most bores; there is one area of relatively poor performance: near the JSE Southern borefield and Discharge Outlet 6, close to where Weeli Wolli Creek crosses the CID for the first time, and upstream from Billiard (see sketch below); many processes are concentrated here: dewatering, reinjection, Discharge Outlet #6, creek interaction, and there is a complex distribution and wide range of parameter values; there are good matches pre-2006 to bores JSE31, JSE32, JSE39 and WB02, but then variable performance (model high and/or low at various times, with no obvious systematic trend); further calibration effort at the next modelling work program is required to improve model performance in this key area;



- **stream-aquifer interactions** are a key element of the model design and execution and form the major water balance volumes, but more effort is required on the validation of this key process; this could be demonstrated by interrogating model output data to show that the persistence of stream flows downstream of discharge outlets matches the observable stream leakage characteristics, and is consistent with published information on stream aquifer interactions (e.g. Dogramaci et al, 2015); the Q&A review session identified that the data available at DO1 and DO5 is not suitable for such validation (i.e. DO's are not active when groundwater monitoring was active); however, it was identified that DO6 is a site where model validation could be demonstrated, including information from published papers;

- **transient prediction simulations of mine dewatering** are well executed; however, the climate variability effects of wet and dry periods were not comprehensively assessed, as the predictions used the averaged monthly creek flows 2009-2013 (a relatively dry period) to specify the Marillana Creek and Weeli Wolli Creek boundary inputs; this is an arguably conservative approach that is suited to mining project impact prediction purposes; a better approach (albeit very simple) that does consider climatic variability would be to apply a repeated historical sequence of flows from a period with wet and dry sequences (e.g. 1998-2008); future model updates should consider the need for assessment of the effects of climatic variability;
- **post-closure model scenarios** assumed in situ parameters, which would have the effect of over-estimating the rate of aquifer recovery, and the assumed climatic inputs have not considered variability effects.

4. Model Conceptualisation and Complexity

The overall modelling approach applied is reasonable for the mining project impact assessment purpose. In terms of the 2012 guideline (Barnett et al, 2012), this review has found that a model confidence level 2 classification would be justified for the Yandi model (or medium complexity in terms of the 2001 guideline).

1.0 Introduction

1.1 Project Background

Rio Tinto (Pty Ltd) (Rio Tinto) currently operates the Yandicoogina (Yandi) iron ore mine as part of its Pilbara Iron operations. Yandi is located approximately 90 km northwest of Newman in the Pilbara region of Western Australia. Rio Tinto is currently conducting a Pre-feasibility Study for development of two channel-iron deposits at Yandi Billiards, Pocket and Billiards South, located approximately 7 km east of the existing Yandi mine.

It is anticipated that the future development of Yandi Billiards will be formally assessed under both the State *Environmental Protection Act 1986* and the Federal *Environment Protection and Biodiversity Conservation (EPBC) Act 1999*. Any potential impacts on fauna species listed as Threatened under the *EPBC Act 1999* have potential to constitute a Matter of National Environmental Significance (MNES) and in cases where threatened fauna are recorded, would require referral to the Department of the Environment (DotE) under the Federal act. A key threatened fauna species that is likely to be relevant at both State and Federal levels is the Northern Quoll (*Dasyurus hallucatus*).

To address this, Biota Environmental Sciences (Biota) was commissioned to undertake a targeted Northern Quoll (*Dasyurus hallucatus*) survey at Yandi Billiards, an area approximately 8,640 ha in size. The polygon defining this Yandi Billiards survey extent is hereafter referred to as the 'study area' (see Figure 1.1)

1.2 Scope and Objectives of this Study

In preparation for forthcoming environmental assessment, Rio Tinto required a single-phase survey specifically targeting the Northern Quoll (*Dasyurus hallucatus*), in order to address anticipated MNES species requirements and demonstrate compliance with relevant Federal referral guidelines (DSEWPaC 2011).

The work also addresses the key gaps relating to Northern Quoll studies as identified by the Yandi Billiards desktop assessment (Biota 2013a), including a requirement for increased sampling effort and to further assess the likelihood of the Northern Quoll occurring within the study area.

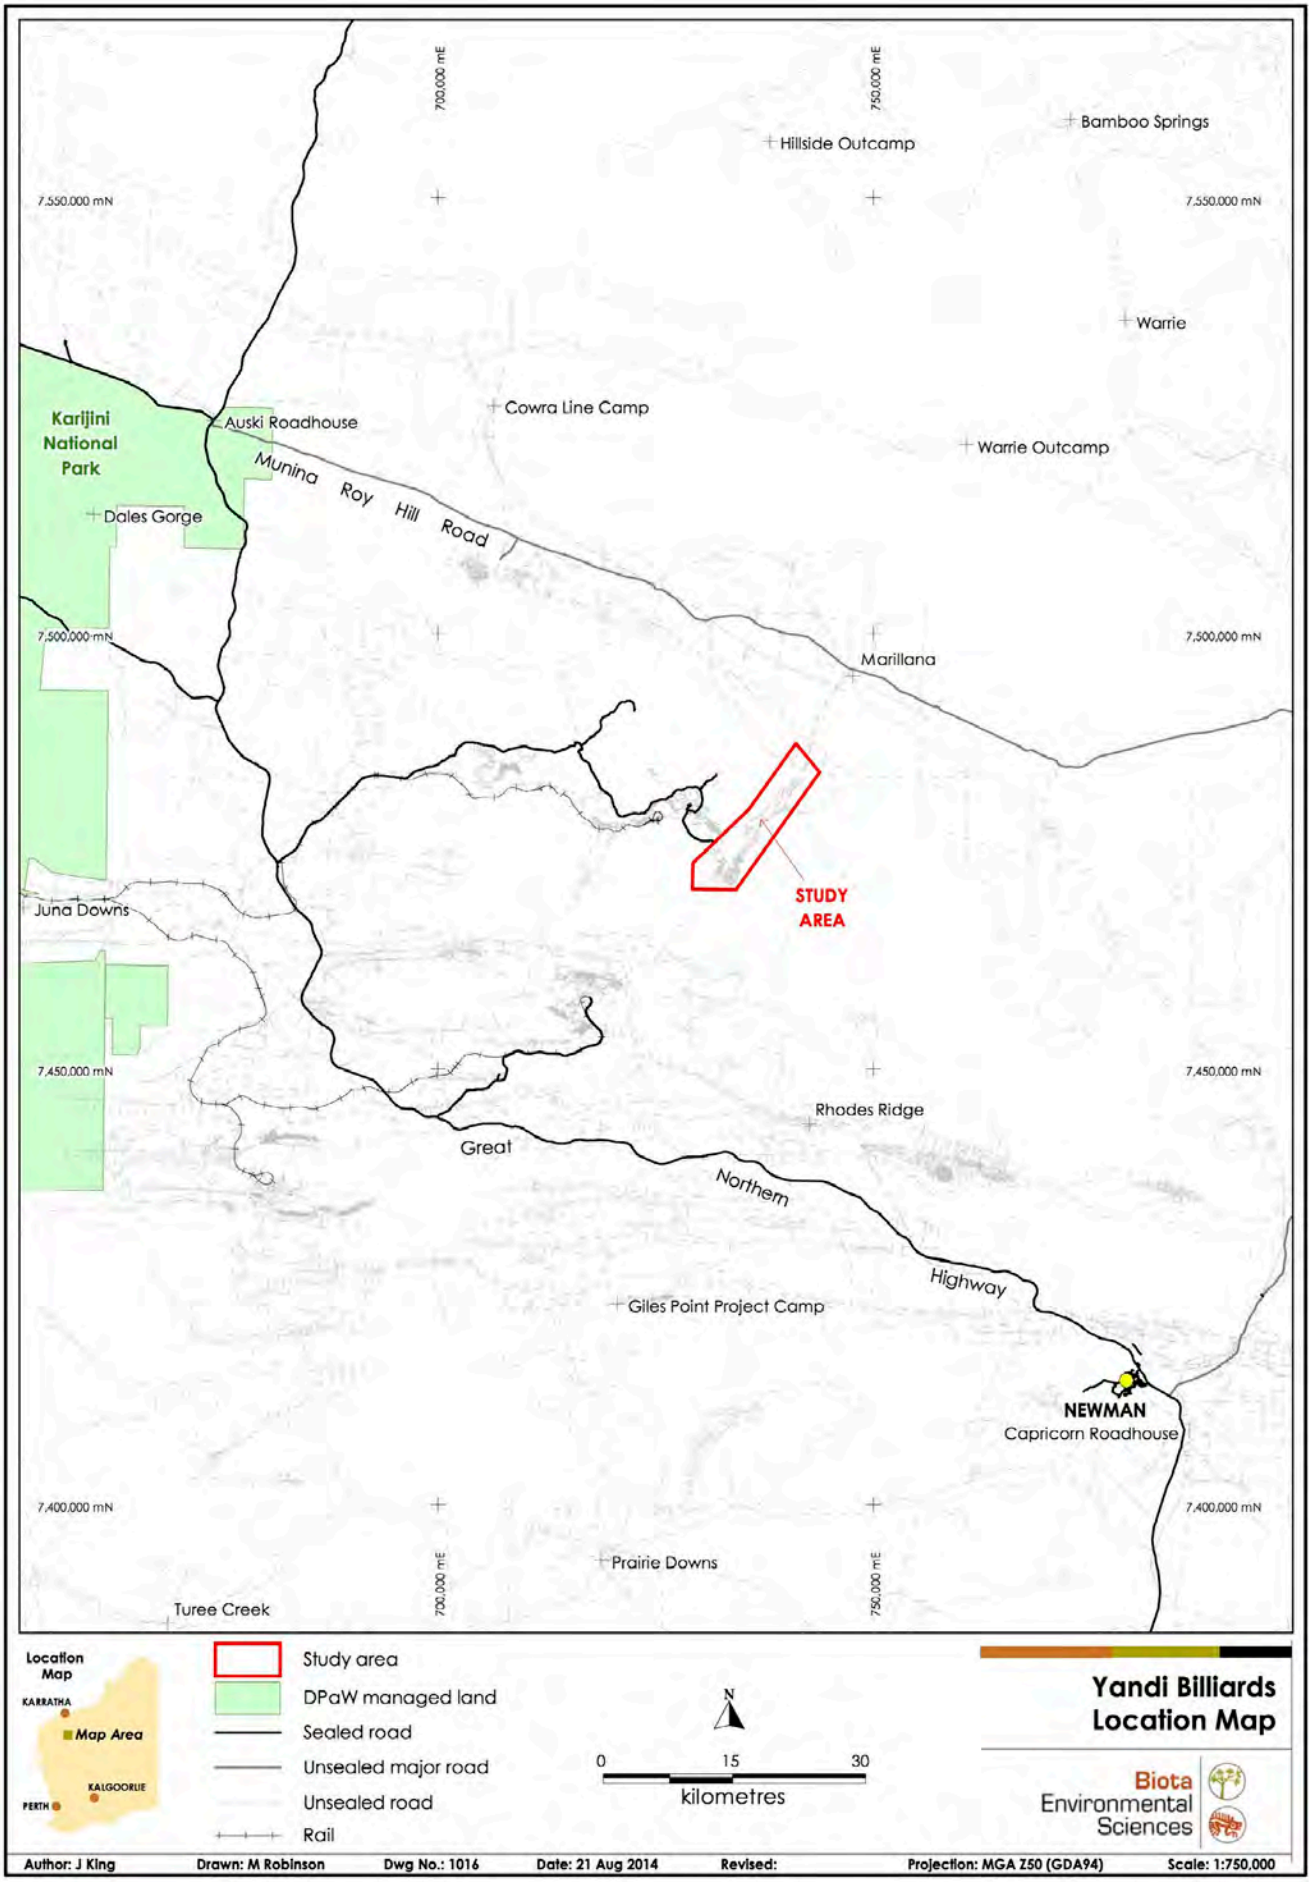

Figure 1.1: Location of the study area.

2.0 Background on the Northern Quoll

2.1 Ecology

The Northern Quoll is specially protected under both State and Federal legislation. It is listed as Schedule 1 ('Endangered') under the Western Australian *Wildlife Conservation Act 1950* and is listed as "Endangered" under the Federal *EPBC Act 1999.* It is a medium-sized dasyurid marsupial, with adult weight ranging from 300 to 1,200 g. It is considered a partially arboreal and aggressive carnivore, preying on a varied diet of small invertebrates and vertebrates, including lizards, birds, snakes, small mammals and frogs (Oakwood 1997), and is also known to feed on fleshy fruit and carrion. The Northern Quoll is mostly nocturnal, although crepuscular (dusk and dawn) activity also occurs.

The Northern Quoll formerly occurred across much of northern Australia but is now restricted to six main areas: the north and western top end of the Northern Territory, north of Cape York, the Atherton-Cairns area, the Carnarvon Range-Bowen area of Queensland (Menkhorst and Knight 2011), and the northwest Kimberley and Pilbara regions of Western Australia (Braithwaite and Griffiths 1994). The species is most abundant in open, rocky habitat and is also commonly found in gorges, rocky freefaces and hills, particularly for denning purposes (van Dyck and Strahan 2008, DEWHA 2010, DSEWPaC 2011). It also occurs near creek lines and drainage lines, where adjacent plains and vegetated areas provide habitats for foraging and dispersal of young (van Dyck and Strahan 2008).

Northern Quoll populations fluctuate on both annual and inter-annual cycles. This variability is driven by both the reproductive biology of individuals and longer-term cycles in response to regional stochastic processes such as rainfall, fire and related changes of prey populations (How et al. 2009). They are short-lived mammal, with both sexes maturing at 11 months. Females reproduce only once each year and almost all males die shortly after reproducing (Dickman and Braithwaite 1992, Oakwood 2000). The extent of this semelparity in the Pilbara is not well documented however, and there are suggestions that some males may survive more than one season (How et al. 2009).

The discrete male cohorts that arise within populations can make quolls more susceptible to local population extinctions. If no juvenile male quolls survive to adulthood, there will be no males available for mating the following year and the local population will rapidly decline (Braithwaite and Griffiths 1994, Oakwood 2000).

2.2 Desktop Assessment

A total of 105 land systems have been identified and mapped in the Pilbara bioregion[1], with 63 land systems occurring in the Hamersley subregion. Land systems mapping covering the study area has been prepared by van Vreeswyk et al. (2004).

Several recent studies have examined the regional relationship between Northern Quoll records and land systems in the Pilbara (Biota 2009a, 2010, 2013b). Compiled Northern Quoll records for the region show a wide distribution across the Pilbara, with records from locations across the extent of the bioregion (NatureMap database and Biota 2010), represented within a wide range of land systems.

In the Pilbara, more than half of all Northern Quoll records have come from within the Rocklea, Macroy, Robe and Newman land systems. These land systems contain rocky hills, gorges, rocky free faces, plateaus, drainages and granite tor fields, representing core Northern Quoll habitat (DEWHA 2010, DSEWPaC 2011). Northern Quolls have also been recorded relatively frequently

[1] This information was obtained by merging the Ashburton land system mapping (Payne et al. 1988) and Pilbara land system mapping (van Vreeswyk et al. 2004) and intersecting this with the Pilbara bioregion (Environment Australia 2000) in ArcView (v. 3.2).

from the Capricorn and River land systems, which also include incised terrain and major drainage habitats (Table 2.1). Together, these six land systems account for 77% of the Northern Quoll records from the region (Table 2.1).

Table 2.1: Relationship between Northern Quoll records and land systems in the Pilbara bioregion (land systems in grey contain core habitats for the Northern Quoll; Table modified from Biota (2010); six additional land systems with less than two records not shown).

Land System	No. of Records	Description
Rocklea	49	Basalt hills, plateaux, lower slopes and minor stony plains supporting hard spinifex (and occasionally soft spinifex) grasslands.
Macroy	42	Stony plains and occasional tor fields based on granite supporting hard and soft spinifex grasslands.
Robe	36	Low plateaux, mesas and buttes of limonites supporting soft spinifex (and occasionally hard spinifex) grasslands.
Newman	24	Rugged jaspilite plateaux, ridges and mountains supporting hard spinifex grasslands.
Capricorn	17	Hills and ridges of sandstone and dolomite supporting low shrublands or shrubby spinifex grasslands.
Wona	10	Basalt upland gilgai plains supporting tussock grasslands and minor hard spinifex grasslands.
River	8	Active flood plains, major rivers and banks supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands.
Horseflat	7	Gilgaied clay plains supporting tussock grasslands and minor grassy snakewood shrublands.
McKay	5	Hills, ridges, plateaux remnants and breakaways of meta sedimentary and sedimentary rocks supporting hard spinifex grasslands.
Boolgeeda	5	Stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands or mulga shrublands.
Calcrete	5	Low calcrete platforms and plains supporting shrubby hard spinifex grasslands.
Uaroo	5	Broad sandy plains supporting shrubby hard and soft spinifex grasslands.
Boolaloo	3	Granite hills, domes and tor fields and sandy plains with shrubby spinifex grasslands.
Taylor	3	Stony plains and isolated low hills of sedimentary rocks supporting hard and soft spinifex grasslands.
Urandy	3	Stony plains, alluvial plains and drainage lines supporting shrubby soft spinifex grasslands.

The Yandi Billiards study area intersects three land systems, Newman, River and McKay (Biota 2013a). Regional analysis indicates the Northern Quoll could occur in all these land systems, with the Newman land system most likely to provide habitat for the species.

In addition, there have been a small number of anecdotal sightings of Northern Quolls at the existing Yandi operations to the northwest (Biota 2009b, 2010) (M. Brand, Rio Tinto, pers. comm. 2014), and two individuals were recently trapped 10 km to the northwest in the Koodaideri project area (Biota 2013c). There are also three other records of the Northern Quoll within 15 km of the study area, which were recorded in 2010 (NatureMap database). Given the presence of Weeli Wolli Creek, riparian vegetation and rocky habitat along the study area periphery, it is possible that the Northern Quoll occurs in the study area. However, if present, it is likely to be at low density, as appears to be typical for the eastern Pilbara (Biota 2009b, 2010).

3.0 Methodology

3.1 Survey Design

The survey trapping locations were selected to sample the most prospective habitats for Northern Quolls available within the study area. These were determined based on examination of land systems data (Section 2.2), vegetation types (Biota 2014a) and aerial imagery. Consideration was also given to spatial distribution of trapping sites within the study area, with most effort apportioned to the south of the study area where the Pocket and Billiards South deposits are located. Five nominal trapping sites were selected within the study area prior to the field survey, with the exact locations being determined by confirmation of habitats on-site on commencement of the field work.

3.1.1 Timing and Personnel

The project was co-ordinated by Garth Humphreys of Biota. The field survey team consisted of Michael Greenham and Jacinta King, both from Biota. The survey ran from August 5th to 13th, 2014 with each sampling site being open for a minimum of seven nights, such that duration and seasonal timing were consistent with Federal referral guidelines (DSEWPaC 2011).

3.1.2 Climate and Weather

Minimum temperatures during the survey ranged from 5.3°C to 15.3°C and maximum temperatures ranged from 30.3°C to 22.2°C (Table 3.1). No rain was recorded for the duration of the sampling.

Table 3.1: Daily meteorological observations for Newman Airport during the survey period.

	5/08	6/08	7/08	8/08	9/08	10/08	11/08	12/08	13/08
Minimum Temperature (°C)	8.0	6.1	5.3	7.7	9.8	15.3	9.5	10.2	12.0
Maximum Temperature (°C)	23.5	23.5	26.0	27.6	30.3	29.4	28.2	26.6	22.2
Daily Rainfall (mm)	0	0	0	0	0	0	0	0	0

Data obtained from Bureau of Meteorology Newman Airport, BOM (station 007176)

Long-term climatic data for Newman Airport indicate that the mean minimum and maximum temperatures for the six months leading up to the survey were close to the long term average (Figure 3.1). Monthly rainfall for the six months leading up to the survey was below average, wuth the exception of May and July (Figure 3.1).

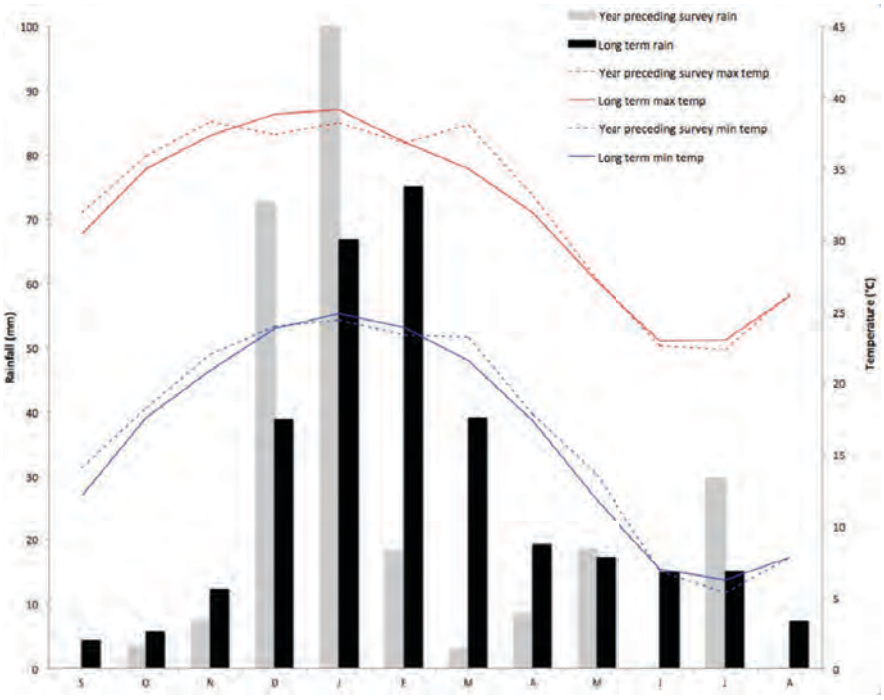

Figure 3.1: Long-term and recent climatological averages recorded at Newman Airport. Data supplied by BOM: long-term rainfall data (1996-2014); long-term temperature data (1971-2014); year preceding the survey (September 2013-August 2014).

3.2 Sampling Techniques and Effort

3.2.1 Systematic Northern Quoll Sampling

Targeted trapping for the Northern Quoll was carried out in accordance with the Federal referral guidelines (DSEWPaC 2011). The survey consisted of a combination of systematic fauna sampling and targeted searches. Systematic sampling was centred on five main trapping sites, each consisting of four cage traps and 20 large Elliott traps (see Figure 3.2). Individual traps were placed in specifically targeted microhabitats and were suitably spaced to maximise the likelihood of encountering Northern Quolls. Traps were baited with a mixture of peanut butter, rolled oats, bacon and sardines, which was placed at the back of each trap, with rebaiting with fresh bait conducted every second day. Each trapping site was open for seven consecutive nights, translating to a total of 840 trap nights (Table 3.2).

Table 3.2: Trapping site locations and effort (coordinates in zone 50, GDA94).

Site Name	Easting (mE)	Northing (mN)	Date Opened	Date Closed	Number of Traps		Nights Open	Trap Nights
					Elliott	Cage		
YBQ01	731811	7472976	5/08/14	12/08/14	20	4	7	168

				Total large Elliott trapping effort				700
				Total cage trapping effort				140
				Total trapping effort				840

Automatic infrared motion cameras were deployed in rocky overhangs between boulders and within other habitat that Northern Quolls might be expected to utilise. The majority of the cameras were placed in areas close to the Elliott/cage trapping sites (Figure 3.2). However, other suitable locations within the study area were also utilised. Bait was placed on the ground in order to attract animals to within the camera's field of view. Each motion camera was deployed for a minimum of three nights, comprising a combined total of 22 camera-trap nights (Table 3.3).

Table 3.3: Automatic camera locations and effort (coordinates in zone 50, GDA94).

				Total Trap Nights		22

3.2.2 Non-systematic Sampling

Non-systematic observations of vertebrate fauna were also recorded during the survey. This included observations made during routine trap checks and timed, targeted searches in various other suitable parts of the Yandi Billiards study area (Figure 3.2). Targeted searches focussed on the detection of trace records such as tracks and scats.

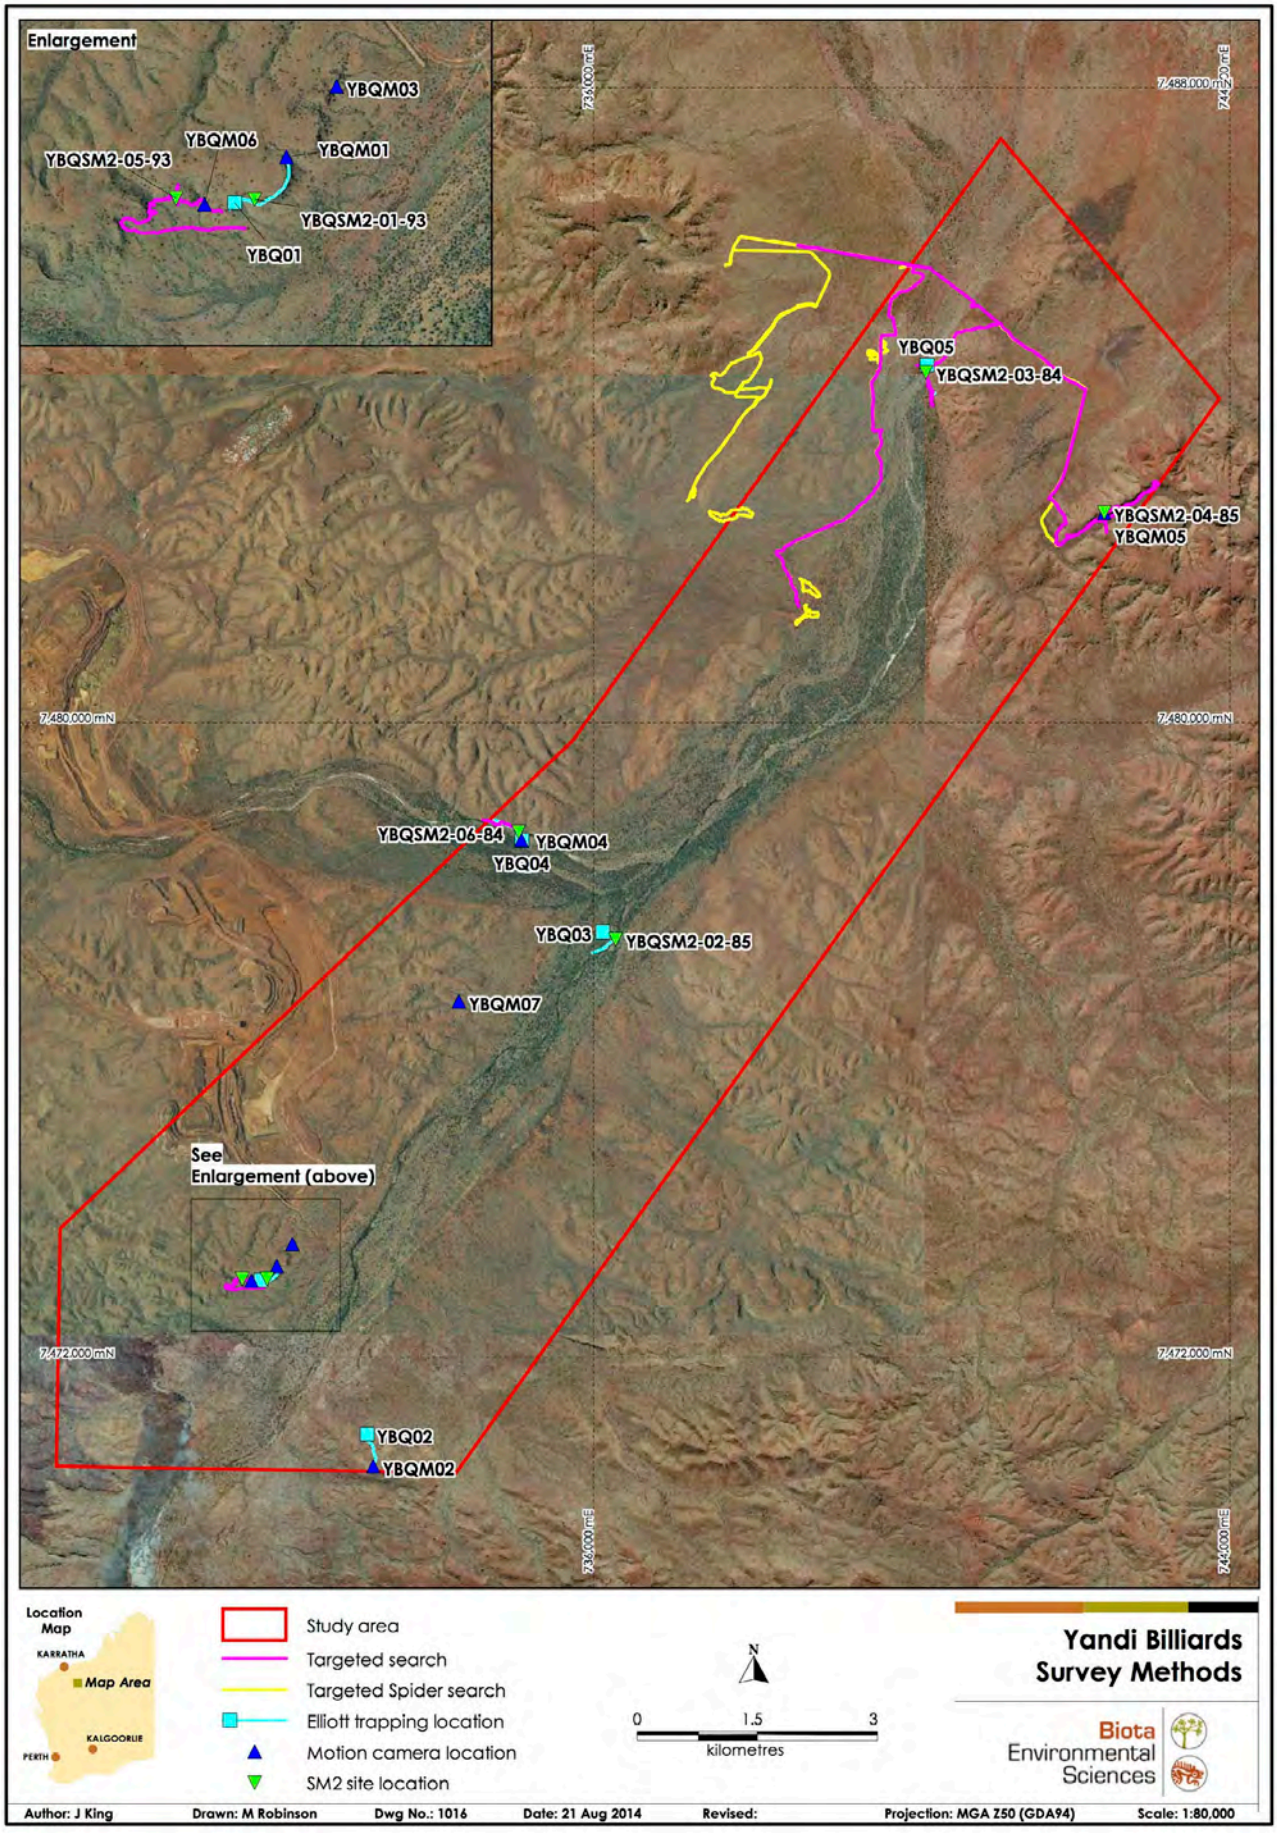

Figure 3.2: Targeted sampling effort in study area.

4.0 Results

4.1 Habitats

The study area comprised three, well defined landscapes, each containing specific landforms (Table 5.1). Within each functional landform, habitats were identified on the basis of geomorphology, geology, vegetation and ecological niches relevant to fauna (see Table 4.1 and Table 4.2). Much of the Newman land system present in the study area contained hillslope land units rather than gorges suitable for Northern Quoll. Sampling effort was deployed in the optimal habitats available in the study area based on field confirmations (Table 4.1 and Table 4.2).

Table 4.1: Landscapes and landforms present in the study area.

4.2 Trapping and Targeted Search Results

No specimens of Northern Quoll were collected during the survey. A single potential *Dasyurus hallucatus* scat was collected during a targeted search, close to site YBQ01 (Plate 4.1; Figure 3.2). However, molecular sequencing was unable to confirm its origin.

Plate 4.1: Typical cylindrical shaped scat typical of Northern Quolls (reference image from Biota (2014b)).

Three other fauna species were recorded during the survey (Table 4.4). The Common Rock-Rat, *Zyzomys argurus* was frequently caught at the two rocky freeface sites (YBQ01 and YBQ02). The Sandy Inland Mouse, *Pseudomys hermansburgensis* was frequently captured at two of the grass-dominated riverine locations (YBQ03 and YBQ04). A single individual of Woolley's False Antechinus, *Pseudantechinus woolleyae*, was captured on four occasions at YBQ02. None of these species are of elevated conservation significance.

4.3 Automatic Motion Camera Results

The automatic cameras did not record the presence of Northern Quolls during the survey period. However, four native mammal species, one introduced mammal and one bird species were recorded at the various automatic camera locations (Table 4.4).

Table 4.4: Fauna recorded during the survey.

5.0 Discussion and Conclusions

The targeted survey of the Billiards study area recorded no evidence of *Dasyurus hallucatus* from any of the 120 traps or seven automatic cameras deployed. The only potential evidence of the species presence was a single possible scat belonging to the species located during a traverse, but confirmation of this is currently pending (Section 4.2).

These findings are generally consistent with the outcomes of past biological survey effort in the vicinity of the study area. Numerous targeted and general terrestrial fauna surveys have been undertaken in the wider Yandi locality over many years and seasons with a combined total trap effort of over 10,000 Elliott traps (Biota 2010). Past work in similar landscapes to the current study area has also specifically targeted *Dasyurus hallucatus* with cage and Elliott traps, without any record of the species' presence (Biota 2009b). While the species' life history also plays a role, with significant natural population fluctuations influencing the ability to detect individuals in an area (Biota 2009a, 2010), it is unlikely that a significant Northern Quoll population occurs within the study area. This is also consistent with the small proportion of the study area mapped as potential NES species habitat by the field zoological interpretation of Biota (2014c).

The only evidence of *D. hallucatus* from the Yandi locality in the past 15 years remains the anecdotal observations of individuals around the warehouse and camp of the existing Yandi operations. This may be partially attributable to the lack of good quality suitable habitat for the species within the generally lower elevation habitats of the study area, and that better quality habitat for the species occurs further northwest where the camp is sited (G. Humphreys, Biota, pers. obs. 2014). Individual Northern Quoll may be foraging from core habitat in gorges further north of the camp and warehouse and becoming habituated to human activity in the area. This and other past studies, however, show no evidence that a population of the species currently occurs as far southwest as Yandi Billiards.

Context and Purpose

This document provides the information to address the following requirement of the Yandicoogina PER.

Undertake a desktop study of successful and unsuccessful rehabilitation strategies and outcomes in similar geologies and vegetation types in the Pilbara, including a discussion of the different methodology and success rates for the various proposed disturbance types including:

- created landforms (e.g. waste rock dump, tailings storage facility)
- short-term disturbances (e.g. borrow pits and access tracks)
- long-term disturbances (e.g. construction camp, permanent accommodation village and administration buildings); and
- linear and/or fragmentation disturbances (e.g. roads, power lines, bore fields)

The Yandicoogina ore body is a specific type of paleochannel[1] known as a Channel Iron Deposit (CID). The CID mined at Yandicoogina consists of three main layers the overburden material (a mixture of lateritic pisolite, poorly sorted angular to sub-rounded BIF, chert and dolomite gravels in a sandy matrix), the iron deposit and the basement rocks and altered basement rocks.

The key waste types that will result from mining at Yandicoogina are referred to as Channel Iron Deposit (CID) waste and Alluvials. The erodibility potential of these waste types at Yandicoogina has been assessed with the majority of waste classified as high erodibility when utilised in final landform design at Yandicoogina.

Rio Tinto Iron Ore aims to create landforms that are safe and stable, considered aesthetically compatible with the surrounding landscape, supportive of native vegetation, and are non-polluting

[1] Paleochannels are remnants of ancient streams cut into old rocks and filled with sediments from younger rocks; such that they reflect historical drainage lines. The contemporary equivalent is called an alluvial channel.

Assessment of Rehabilitation Strategies

To enable a discussion of the "success" or otherwise of past rehabilitation strategies and outcomes a review of rehabilitation monitoring results that compares rehabilitation areas to "similar" reference or control sites has been undertaken. Reference sites can be described as an unmined site, usually representative of the 'natural' landscape surrounding the mine site or rehabilitated area. The reference site generally consists of the target vegetation community, soil type and terrain and provides an example of what the rehabilitated area should achieve. For example to determine the success of waste dump slope rehabilitation it has been compared to a reference site that has been established on an undisturbed slope in the surrounding environment. Similarly rehabilitation of flat areas has been compared to reference sites established in an area of flat undisturbed vegetation, with the vegetation being typical of the surrounding area. By comparing rehabilitated areas to undisturbed reference areas (with similar terrain and topography) effectively it is answering the question as to whether the rehabilitated areas have similar biodiversity to surrounding communities. This aligns with the overall closure and rehabilitation strategy outlined in the Yandicoogina Closure Plan (2013) that is to establish ecosystems with similar biodiversity and cultural heritage values as surrounding reference sites.

Whilst this is a high level approach, it is suitable for getting a general understanding of the success of a rehabilitation area (regardless of site specific completion criteria which might apply). As rehabilitation (and related closure strategies and outcomes might differ between sites depending on the site based risks and environmental values) comparing rehabilitation to similar reference sites also allows us to understand how the rehabilitation is performing against the general objective of creating a stable, non-polluting landform, that comprises local native vegetation that is self-sustaining and compatible with the surrounding environment.

It is acknowledged that Yandicoogina has specific objectives and completion criteria proposed in its current Closure Plan including those listed relating to stability and biodiversity in ***Table 1***.

Table 1: Yandicoogina objectives and completion criteria relating to biodiversity and landform stability.

Function	Objective	Indicative Completion Criteria
Landform Stability	Rehabilitated landforms are stable and designed to manage floodwater appropriately.	Erosion does not threaten the long term stability of the landform.
Biodiversity	Final landforms are rehabilitated to be compatible with post-mining land use.	Vegetation on rehabilitated land is native and self-sustaining. Habitat for native fauna is provided in appropriate rehabilitated areas. The prevalence of invasive species (weeds, feral animals) is similar to that in nearby reference site.

By reviewing previously completed rehabilitation areas on similar geologies in Pilbara ecosystems (against adjacent similar reference/control sites), we can get an understanding of what rehabilitation methods might be transferable and utilised at Yandicoogina to help Yandicoogina achieve its objectives and completion criteria.

As the rehabilitated areas assessed in this discussion are located at numerous locations and terrains across the Pilbara, a range of vegetation types will be assessed (by default). It is acknowledged that some of the vegetation communities proposed to exist following rehabilitation and closure at Yandicoogina are considered new types of rehabilitation for RTIO such as wetland habitat within mine voids. As a result, examples of this disturbance type and proposed rehabilitation are not included in this discussion. Whilst general methodologies are likely to be transferable to implement this type of new rehabilitation (such as waste characterisation and resulting landform design and shaping, topsoil application, ripping and seeding) there is a recognised knowledge gap as to the details for the rehabilitation methods such as topsoil application rates, surface water controls required and species mix to utilise.

Created Landforms (Waste Rock Dumps, Tailings Storage Facilities)

The proposed final landform at Yandicoogina on closure will not result in any external waste dumps. There will however be rehabilitated slopes external to the pit areas, such as where current infrastructure has been decommissioned and removed. In addition the edge of the backfilled waste within the pit areas that will slope down into what will eventually be pit lakes will also be rehabilitated. It is therefore important to review successful and unsuccessful rehabilitation strategies of slopes built of similar materials to what is predicted to be encountered at Yandicoogina. This rehabilitation type (built slopes) may be present in the rehabilitated land and wetland habitats that are likely to be introduced at Yandicoogina at closure.

At present, as there are no rehabilitated slopes at Yandicoogina with sufficient monitoring data to enable a review and discussion of rehabilitation success, rehabilitated slopes at Pannawonica Operations and Brockman Two Operations have been reviewed. The Pannawonica Operations in the Robe Valley are situated in a similar geology to Yandicoogina, with the mining of Iron Ore from a channel iron style deposit. In addition Brockman 2 Pit 2 deposit was mined in the late 1990's and involved the mining of ore and waste from a detrital iron ore deposit. The resultant single waste dump from the mining of ore from Brockman 2 Pit 2 deposit is comprised primarily of a erodible waste type considered similar (in terms of physical characteristics and erodibility) to the CID and alluvial wastes that are encountered as a result of mining ore at Yandicoogina from the Channel Iron Deposit.

This section will therefore focus on different strategies utilised for rehabilitated slopes at the Pannawonica Operations by reviewing rehabilitation success at Mesa J Waste Dump S and Mesa J Waste Dump T and Brockman 2 pit 2 Waste Dump 1. The strategy utilised to rehabilitate a tailings storage facility located at Pannawonica's Mesa J operation and early monitoring results will also be discussed.

Successful and Unsuccessful Rehabilitation Strategies

Mesa J Operations Waste Dump S

Waste Dump S at Mesa J Operations had rehabilitation of its slopes completed between 2002-2004 and these have a monitoring transect located on them. The same dump had further slopes rehabilitated in 2007 and has a monitoring transect located on it. Both areas were battered to 15 degrees slopes, comprise of a 12-15m lift height and had 150mm of topsoil applied and ripped into the surface and seed was applied. Approximately 90% of the single lift dump was rehabilitated as at 2007 (~40Ha). The monitoring transects on the slope of Waste Dump S are positioned where the lift height is approximately 8-10m.

The most recent monitoring of these areas, completed in in 2013 showed both areas had good perennial species diversity with 13 species present (higher than the slope control sites that had seven species present). The 2002-2004 rehabilitation, lower storey vegetation was absent until 2013, and then only represented a very small proportion of the total cover. The lower storey vegetation at this site was primarily made up of a mixture of *Triodia* and small or juvenile shrubs and the upper storey dominated by *Acacia* shrubs. The 2007 rehabilitation dominant stratum was the upper storey of *Acacia* shrubs, including *Acacia bivenosa* and *Acacia ancistrocarpa.*

Landscape function indices for stability were 61% for the slope reference sites while the rehabilitate sites were 59% (in 2013). The nutrient cycling and infiltration values for the

rehabilitation sites were also higher than the values measured in the slope reference site in 2013. All three indices compared favourably to the average scores achieved by the sloping reference sites. Due to the mature stage of ecosystem development these scores are not expected to change substantially in the future until *Acacia* senescence, or a disturbance event occurs, such as fire.

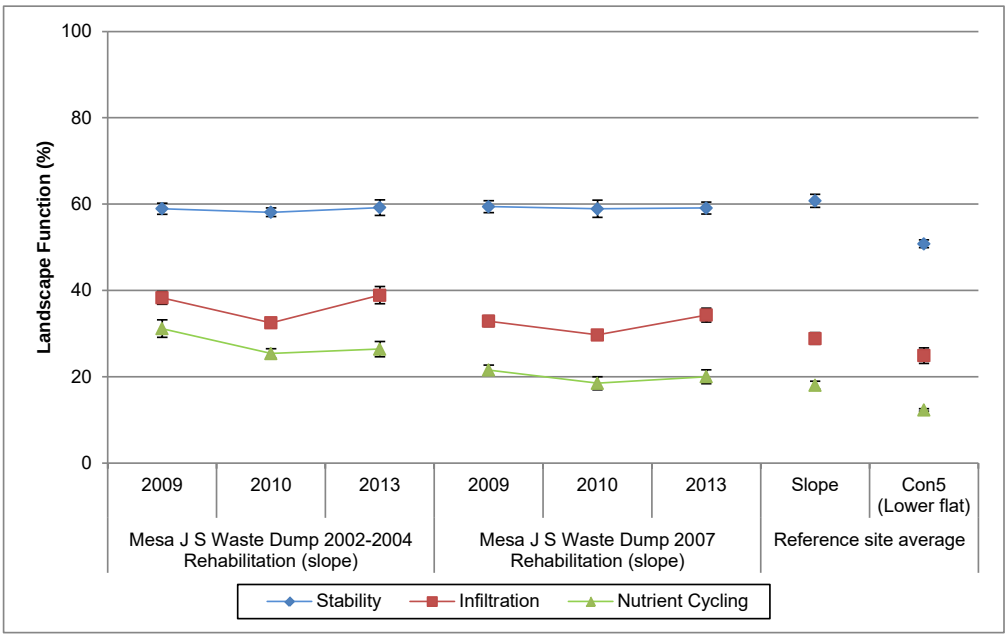

Figure 1: Changes in landscape function of the 2002-2004 and 2007 rehabilitation on the Mesa J S Waste dump (slope), in comparison with the sloping reference sites (Con7 and Con10) average, and Con5.

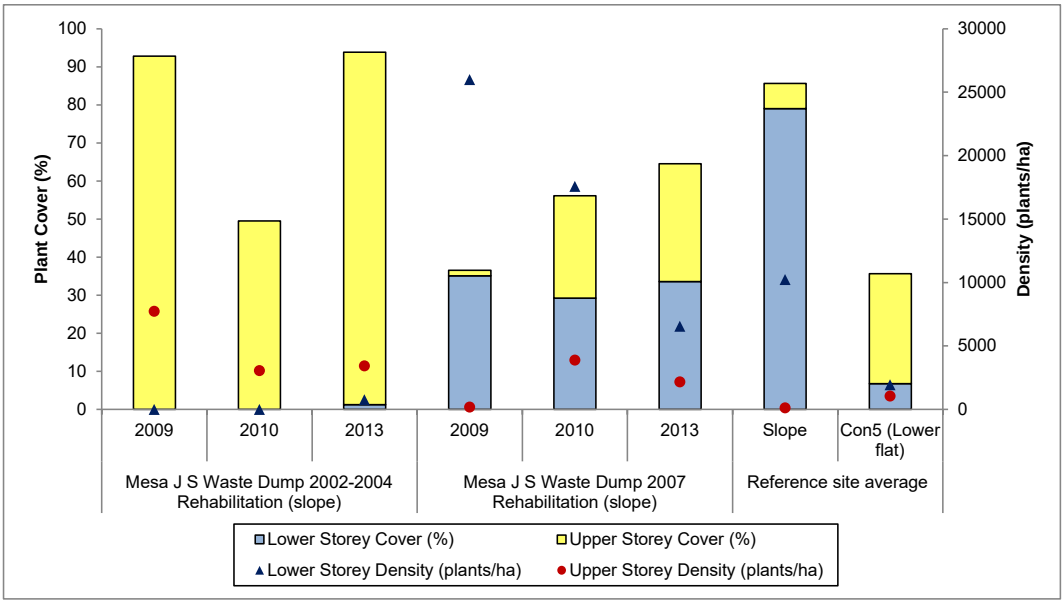

Figure 2: Changes in the plant cover index and density (lower and upper storey) of the 2002-2004 and 2007 rehabilitation on the Mesa J S Waste dump (slope), in comparison with the sloping reference sites (Con7 and Con10) average, and Con5.

The plant cover percentage was 63% and 93% for the two rehabilitation areas which was both higher and lower than the slope reference site which had 85% vegetation cover. The density of the cover was dominated by upper storey plants in both rehabilitation sites whilst the reference site was dominated by a lower story (refer to ***Figure 1*** and ***Figure 2***).

In terms of habitat complexity (which is used as an indicator of suitability of habitat for fauna) of the Waste Dump S rehabilitation areas several faunal niches were available such as litter, logs and rocks. Kangaroo scats were observed at both transects providing evidence that native fauna were utilising the rehabilitation area.

Since this site was first monitored in 2009, the proportion of the slope eroded has decreased on the 2002-2004 rehabilitation area from 14% to less than 9% in 2013. On the 2007 rehabilitation area, erosion increased slightly but the overall proportion of slope eroded was low. The vast majority of the erosion that was present was on the lower slope of the transect; erosion present on the upper slopes of both transects was minor.

Rehabilitation monitoring data to date suggests that the rehabilitation on Waste Dump S at Mesa J Operations is on track to achieving a stable, self-sustaining native vegetation community similar to the control sites. Whilst total plant cover percentages and density values are within or above the range of the combined slope and flat reference sites the composition/breakdown of this cover is different to the reference sites at the older (2002-2004) Mesa J S Waste Dump rehabilitation. A large proportion of the vegetation on the rehabilitation comprises of upper story cover (*Acacia's*) as opposed to lower story cover (*Spinifex sp*.) which is the dominant strata in the reference sites. The importance of this composition of species and how it may affect the achievement of completion criteria will be further clarified and refined as the site progresses towards closure and site specific completion criteria are established. Whilst erosion is present it appears to be either stabilising over time or only on a small proportion of the slope that was assessed.

Overall the few indicators of rehabilitation monitoring discussed here suggest that the right species are present (albeit in different proportions to the reference sites), the cover is adequate, and a number of landscape function indices are within the range of (or above) the reference sites indicating that this rehabilitation is heading in the direction of being considered stable, native and self-sustaining with habitat for native fauna present.

Brockman 2 Pit 2 Waste Dump 1

Pit 2 Waste Dump 1 at Brockman 2 Operations is comprised of waste that came from the adjacent Pit 2 deposit (detrital iron ore deposit) and is considered a similar waste type (in terms of physical characteristics and erodibility) to the alluvial and CID wastes that are encountered as a result of mining ore at Yandicoogina from the Channel Iron Deposit. The Pit 2 Waste Dump 1 is built with a single lift with the total dump height ranging from 8-20m and 15-20 degree outer slopes and was rehabilitated in 1999. It is assumed the dump had topsoil applied and was ripped and seeded (no records have been found to confirm this although evidence of cross ripping can be seen on aerial photos). The last monitoring of this rehabilitation was completed in 2012 (via a transect established on the waste dump slope where the lift height is ~8m) and the results are discussed below.

The total species number recorded in the rehabilitation was six which was within the range of values recorded in the three reference sites (six to nine species). *Spinifex, Acacias* and several other native perennial species were identified in the rehabilitation as well as the reference sites. The density of the S*pinifex* and native perennial plants was lower in the rehabilitation at 2.7 plants per quadrant than the range of the reference sites which were 5.8 – 19.4 plants per quadrant. Despite this the percentage perennial cover of the rehabilitation (53%) was within the range of the reference sites (38-70%).

In terms of habitat complexity *Spinifex species*, grass, shrub and litter cover were all comparable to or higher than values recorded in the reference sites, and good numbers of logs and rocks were present. Overall, the fauna habitat could be considered good, with the range of vegetation strata present suggesting that the site is likely to support a diversity of small mammal, reptile, bird and invertebrate species. Erosion monitoring of Pit 2 Waste Dump 1 described the site as very stable, with minimal erosion and no measurements provided for gullies (suggesting they were too small for measurement or that no gullies were located along the monitoring transect). No landscape function measures were completed during this monitoring.

Overall monitoring in 2012 showed that relatively good rehabilitation has developed after 14 years with species diversity and cover similar to reference sites, fauna habitat considered good and the rehabilitated slope in a stable condition. It was noted that the density of the *Spinifex* was lower than in reference sites although this is likely to improve in time (given that the species are present in the rehabilitation area).

Mesa J Operations Waste Dump T

A different rehabilitation strategy was applied at Mesa J operations in 2007 that involved a single lift waste dump having subsoil applied (as opposed to topsoil). The T Waste Landform was reworked in 2007, the slopes were battered to 15 degrees and stockpiled subsoil (less than five years old) was applied, prior to the area being ripped and seeded. The total lift height of the waste dump is 22-25m whilst at the area of monitoring the lift height is 20m. Due to the sloping gradient of the rehabilitation, monitoring results for the rehabilitation slopes were compared to the average achieved by the sloping reference sites.

Rehabilitation monitoring of the T waste landform in 2013 found there were seven species recorded, the same number as both sloping reference sites. Despite the similar number of species present native perennial plants have established poorly and between 2010 and 2013, plant cover and density only slightly improved (***Figure 3***). The rehabilitation had minimal vegetation compared to the average of the sloping reference sites. The lower storey contributed two thirds of the cover with *Triodia pungens* the most frequently sampled species. The upper storey contributed less than 1% cover with only four *Acacia* individuals sampled.

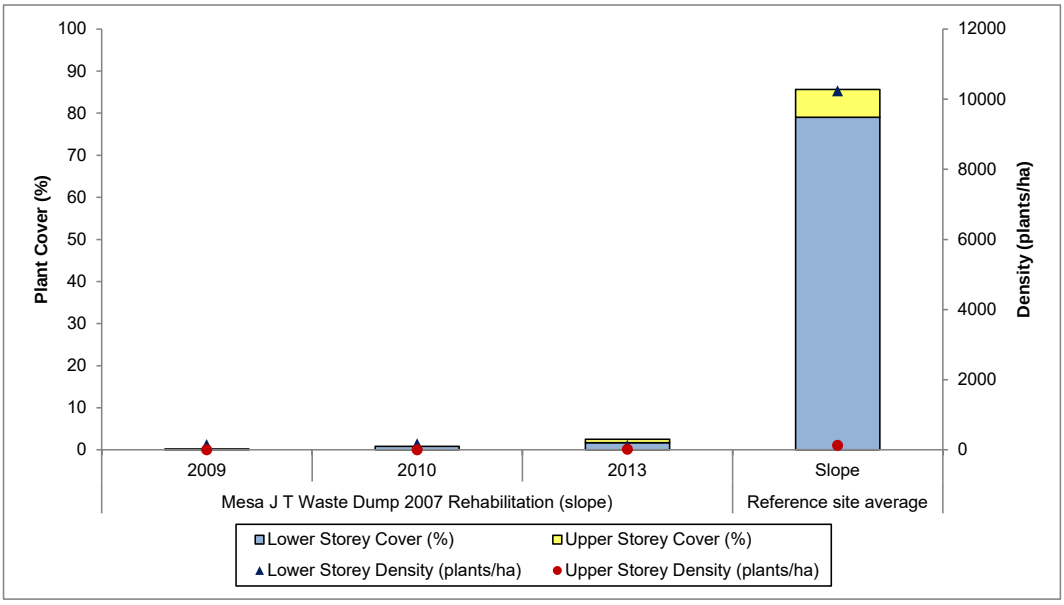

Figure 3: Changes in the plant cover index and density of the 2007 rehabilitation on the Mesa J T Waste Landform (slope), in comparison with sloping reference site (Con7 and Con10) average

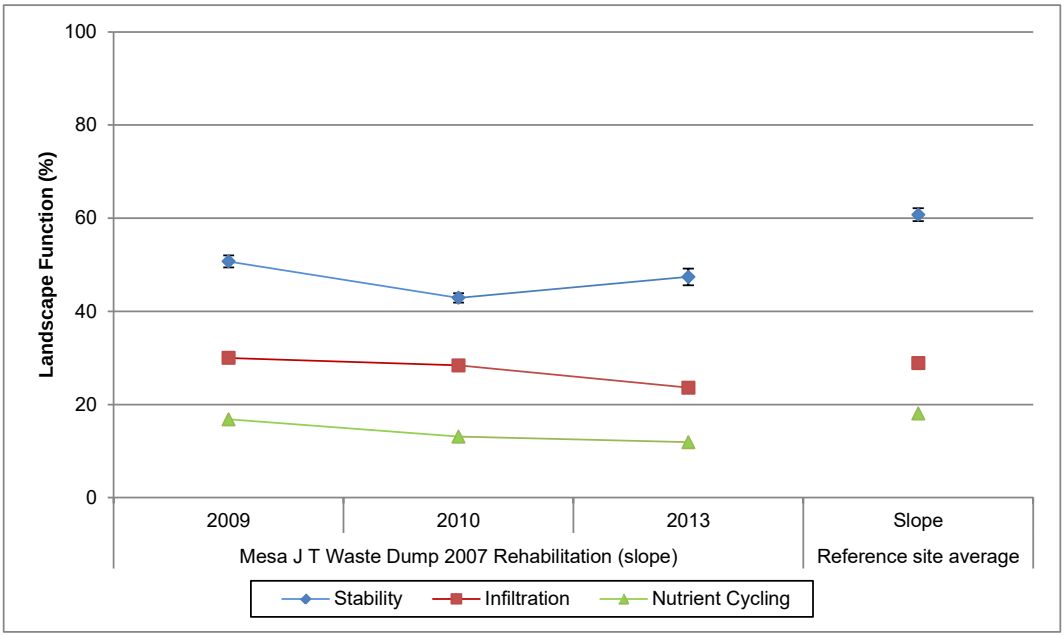

Figure 4: Changes in landscape function of the 2007 rehabilitation on the Mesa J T Waste Landform (slope), in comparison with sloping reference site (Con7 and Con10) average

In terms of landscape function all three indices achieved scores substantially lower than the average scores achieved by the sloping reference sites (refer to ***Figure 4***). The low scores can be attributed to a lack of rocky material on the soil surface and poor vegetation establishment.

A moderate degree of habitat complexity was present with numerous vegetation strata present from grasses to a few shrubs taller than three metres. Faunal habitat was available in the form of grass litter and rocks.

Erosion was a significant issue affecting the performance of the rehabilitation on the T Waste Landform. Since 2009 monitoring the proportion of the slope eroded doubled to 30%. Both the upper and lower slope was substantially eroded, indicating substantial loss of water resources and therefore reduced potential productivity of the ecosystem.

At the same time as the T waste landform slope rehabilitation was completed, a flat section (on the top of the dump) was also completed. The rehabilitation involved flattening the area, applying subsoil then ripping and seeding. The landscape function scores of this flat area of rehabilitation compare favourably with those achieved by similar flat reference sites. Despite this the vegetation has not established well on the flat rehabilitation with total native perennial cover and density substantially lower than that of the reference sites and the habitat complexity was considered moderate (similar to the slope rehabilitation). There was no erosion (as expected as the area was flat).

The monitoring results to date of the T waste landform slope rehabilitation suggest that while the utilisation of subsoil may assist rehabilitation in achieving some of the rehabilitation indices considered important, in this example it is unlikely to lead to successful rehabilitation. The utilisation of the subsoil on the flat area and slope and resultant low vegetation cover and density suggest the application of subsoil may have contributed to these low values (and not the values being a result of rehabilitation being on a slope versus on a flat area).

The evidence of extensive erosion also suggests that the subsoil used (and underlying waste type) may not be suitable for use in lift heights of 20m even when battered to 15 degrees.

Mesa J Operations Tailings Storage Facility 1 (Mesa J TSF1)

RTIO has only rehabilitated one tailings storage facility which was completed in 2014 at Mesa J Operations. The Mesa J TSF1 operated as a tailings storage facility between 1999 and 2004. It was decommissioned in 2004 and upon rehabilitation consisted of two low-lying areas that covered ~20% of the surface and an upper, dryer area that covered the remaining 80%. The tailings on the surface of TSF1 had been investigated in 2009 and it was determined it was suitable for plant growth with few potentially restrictive properties; in addition the TSF already supported regrowth of native vegetation. As a result no topsoil was added during the rehabilitation process to trial whether successful rehabilitation could be achieved on the surface of tailings storage facilities without the utilisation of capping and topsoil.

The TSF rehabilitation commenced in December 2013 and was finished in February 2014 and involved the rehabilitation of the northern two thirds of the facility (~45Ha).

Rehabilitation involved ripping and seeding the surface of the TSF and trees that were present prior to rehabilitation works were retained (and worked around). Contour ripping was conducted to a depth of 600 to 800mm in all areas. Two seed mixes were utilised (with seed collected the year prior to rehabilitation) with one seed mix used for the lower lying potentially wet areas and a second seed mix for the remainder of the TSF. Species were selected specifically to be able to germinate and grow in "wet" inundated clays or water logged soils such as *Cyperus vaginatus.*

Monitoring of Mesa J TSF1 conducted mid 2014 showed that whilst the number of species present in the rehabilitation was within the range of the reference sites the density of lower storey plants (which represents germination) in the rehabilitation was very low. There was less than 1% cover of lower storey perennial vegetation at the time of the 2014 assessment of the dryer areas, whilst the pre-existing upper story contributed up to 10% cover in some areas. Whilst it is expected the density and cover would be lower than reference sites given the young age of the rehabilitation these are particularly low numbers. The landscape function indices and habitat complexity measures were also lower than references sites, which was to be expected given the young age of the rehabilitation. There was a large amount of the weed species *Acetosa vesicaria* (ruby Dock) and cattle present at the time of monitoring. Ruby Dock had been noted on the tailings dam prior to the rehabilitation commencing.

In regards to stability and erosion while no rill or gully formations were present at the three low-lying monitoring transects, some low lying areas at TSF1 were showing signs of subsidence and erosion. A small but deep cavity (sinkhole) and other cavities were present adjacent to one of the monitoring transects and contoured rip-lines appeared to be deepening into gully-like flow lines in some areas.

Initial monitoring results of the rehabilitation suggest that the rehabilitation was showing signs of developing an ecosystem comprising of local native species although the rehabilitated area was threatened by the spread of ruby dock and disturbance by cattle. In addition early signs of erosion suggest that this needs to be monitored to determine if it will result in long term stability concerns.

It is too early to determine if tailings storage facilities similar to the Mesa J TSF1 can be successfully rehabilitated without the use of capping and topsoil. Continued monitoring of this rehabilitation will be undertaken to assess the ongoing development of the vegetation and rehabilitation success.

Early learnings from the rehabilitation methodology used for the TSF1 indicate that for future areas with Ruby Dock infestations it is worth considering completely eradicating Ruby Dock prior to commencing rehabilitation works. This could be achieved through an aggressive and long term spraying program. RTIO has examples of borrow pits along the Tom Price Rail Line located in a national park that are undergoing such a program and have almost eradicated the Ruby Dock.

The other critical learning from the TSF1 rehabilitation that is critical for rehabilitation success related to the post rehabilitation management of cattle (as opposed to rehabilitation methodology). Stray cattle accessed the rehabilitated TSF1 and during monitoring negative impacts on the vegetation and surface of the TSF1 from the cattle were evident. This highlights the need to exclude cattle (and potentially other grazing animals as far as possible such as goats) from rehabilitated areas to assist in the initial establishment of vegetation and long-term success of the areas. Grazing of historically rehabilitated areas can be seen across the Pilbara and anecdotally it appears the vegetation and ecosystems continue to survive. However areas of young rehabilitation (that have not yet become a self-sustaining ecosystem) appear to require protection from grazing animals during the early years of vegetation establishment. This is an important consideration for closure and particularly rehabilitation planning and implementation at Yandicoogina where areas of the operations co-exist with pastoral leases and areas of rehabilitation may be utilised post closure for grazing purposes.

Methodology and Success Rate

Based on the above examples at Mesa J and Brockman of rehabilitation of created landforms comprising of erodible material, the success rates to date indicate the use of topsoil enhances rehabilitation success. Whilst the use of subsoil may assist in improving certain parameters of rehabilitation success (such as habitat complexity and functional indices and does enable some native species germination) it has proven less effective and in some places (such as on slopes) problematic for use in rehabilitation. Whilst this is a limited review of only a few rehabilitated slopes it confirms that topsoil management and the ultimate use of topsoil in rehabilitation greatly enhances rehabilitation success (when compared to subsoil). It also indicates that subsoil may assist in rehabilitation success but should be prioritized for use in flat areas and would require a review of the subsoil properties and seed mixes utilized (to try and improve germination success and ultimately vegetation establishment).

A review of the three sloped rehabilitation areas comprised of CID or similar waste types Waste Dump S, Pit 2 Waste Dump 1 and T waste landform has indicated that it is possible to achieve a stable, non-polluting landform, that comprises local native vegetation that is self-sustaining and compatible with the surrounding environment containing these waste types if appropriate landform design is utilised and topsoil and seed are applied.

The performance of the rehabilitation area that utilized subsoil suggests that any subsoil proposed for utilization in rehabilitation should have material testing (physical and chemical properties relevant to plant growth) completed to determine its applicability as a growth medium and that if subsoil is to be used it may be better placed on flat areas (as opposed to slopes).

The fact that significant erosion was evident on the slopes utilised in a 20m lift, only minor erosion was noted on the lower slopes of the 8-10m lift and no erosion was noted on the 8m lift suggest that CID and alluvial waste if utilising a 15 degree slope should be built with a maximum 8-10m lift height.

The slope stability results seen in the three rehabilitation examples is further supported by testing on CID waste and alluvial materials completed in more recent years that indicate the appropriate maximum lift heights (when using a 15 to 20 degree slope) is from 0m to 10m (depending on the location of the site and associated climate). By 0m lift height testing of some waste type and climate combinations suggest that some wastes will not be stable enough for use in final outer slopes.

The single review of a tailings storage facility highlights that whilst rehabilitation can be completed and germination can be achieved on a tailings storage facility surface without capping and topsoil application, the success of this is yet to be proven. The need for the exclusion of cattle in the immediate years post rehabilitation is also highlighted as a recommendation for at Yandicoogina and the control and eradication of Ruby Dock prior to rehabilitation should be considered.

Short-term disturbances and Linear and/or fragmentation disturbances

In addition to created landforms such as built slopes the proposed final landform at Yandicoogina on closure will also have rehabilitation that was completed on short term disturbances. Examples of short term disturbances include borrow pits, access tracks, clearing for power line and railway construction and are assumed as any disturbance that is rehabilitated within a short time frame following disturbance.

This disturbance can also regularly encompass disturbance described as linear and or fragmentation disturbances such as rehabilitation completed for the construction or removal of pipelines, roads, power lines and bore fields. Whilst a majority of this disturbance is often narrow long areas of disturbance adjacent to undisturbed vegetation with minor earthworks, it can also include significant earthworks and is likely to range from short term to longer term disturbance timeframes.

The short-term disturbance type often occurs on the surface of the landscape and often involves only minor earthworks. Minor earthworks may include clearing topsoil and using an area as a laydown, or following topsoil removal excavating a shallow pit and utilising the material as borrow resulting in a borrow pit that requires rehabilitation. As a result of this disturbance type occurring often at the surface of the landscape, the material types intersected are usually restricted to the first few metres from surface. This material (first few metres from surface) is generally comprised primarily of topsoil and subsoil (as opposed to alluvial and CID materials). Therefore in discussing rehabilitation methodologies and successful completion of this type of rehabilitation a range of examples from across the Pilbara of different ages have been reviewed and not just examples from Yandicoogina and Pannawonica Operations.

Rio Tinto regularly complete this type of rehabilitation and have refined methodologies over many years of learning and generally achieve rehabilitation success for this type of rehabilitation. In addition the ability to utilise relatively fresh (young) topsoil, these disturbance areas are usually small or narrow and adjacent to undisturbed vegetation, which greatly enhances the ability to achieve successful rehabilitation.

Successful and Unsuccessful Rehabilitation Strategies

Yandicoogina Borrow Pits

Borrow pits associated with the railway at Yandicoogina were rehabilitated in the second half of 1998 and rehabilitation monitoring commenced in 1999. Monitoring of these borrow pits completed in 2013 suggest that vegetation communities, in general, are similar to that of reference sites and differences appear to be a result of some reference sites being burnt during the monitoring period.

The rehabilitation methodology for these borrow pits is consistent with methodology used in current borrow pit rehabilitation and includes battering of all slopes, ensuring the borrow pits are free draining and pulling back salvaged vegetation and topsoil across the disturbed area at completion of the rehabilitation, no seed was applied. All borrow pits reviewed appear to have had topsoil replaced and were ripped. There is no evidence of erosion in any of the borrow pits. Monitoring results from three of the borrow pits are shown in ***Table 2*** below to give an indication of rehabilitation success as at 2013.

Table 2: Selected monitoring results of the Borrow Pit rehabilitation areas and reference site values (shown in brackets).

Borrow Pit	Age of Rehabilitation (years)	No Species (Rehab)	Plants/ Quadrant	% Perennial Cover	Summary (sourced from the rehabilitation monitoring report)
BP363	14	7 (8)	4.3 (4.2)	45 (64)	The rehabilitated site continues to compare favorably with the reference site
BP374	14	7 (13)	5.6 (20.3)	55 (53)	The 2007 burn in the reference site significantly changed a number of key parameters, making comparison of the two sites difficult, overall, the rehabilitation appears to be developing well
BP417	14	7 (7)	3.3 (13.3)	49 (31)	Results in 2003 indicated that the vegetation communities of the reference and rehabilitated sites had become similar in most regards, a fire in 2010 has since altered this trend.

In addition to the above results all borrow pits were found to have an abundance of *Spinifex* species and *Acacia* species, which were the species dominant in the reference sites they were being compared to.

Figure 5 below show as an example BP374 monitoring transect at the start and end of the transect and the reference site it is being compared to.

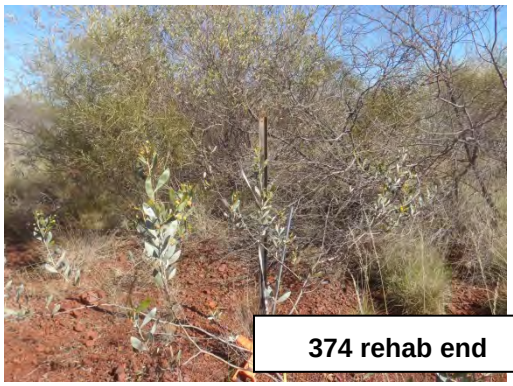

Figure 5: The start and end of the monitoring transect on borrow pit 374 at Yandicoogina and the start and end of the relative reference site transect (in undisturbed vegetation).

Hope Downs 4 Haul Roads, Borrow Pits, Power Line and Railway Rehabilitation

To further review rehabilitation strategies and success relating to short term disturbances the 2014 rehabilitation monitoring conducted across Hope Downs 4 is discussed. The monitoring completed at Hope Downs 4 involved assessing 35 locations across a range of rehabilitated disturbance types and associated reference sites. These included the mine access road (1 site), disturbance for power line construction (4 sites), borrow pits (11 sites), camps (4 sites), railway construction (15 sites) and mine disturbance (5 sites). All of this rehabilitation was completed during 2013 and resulted from disturbance to enable the establishment of the new Hope Downs 4 Mine. The rehabilitation methods utilised included reprofiling areas, replacing topsoil and salvaged vegetation and shallow or deep ripping of areas (dependent on compaction), no seed was applied.

The executive summary from the Hope Downs 4 2014 Rehabilitation Monitoring Final Report (Environmental Management and Research Consultants, 2014) states that *"Vegetation in most of the Railway sites has established well, with good species establishment, species/q and density comparable to that of the reference sites. Spinifex was present in all sites."* The summary goes on to state *"All Railway and Powerline rehabilitated sites appeared to be stable. Weeds were only present in four of the 19 Railway and Powerline sites, with weed abundance (mostly Buffel Grass) low in all apart from 2014_HD4_Powerline_T2 where Spiked Malvastrum was abundant across the whole transect"*. The report stated that the *"Vegetation in many of the Mine Access Road, Camp and Mine rehabilitated sites has also established well, with total species numbers, species/q and native plant density comparing favourably with the reference sites. Spinifex was establishing in most rehabilitated sites".* Results are shown in ***Table 3*** and ***Table 4***.

Table 3: Rehabilitation monitoring results of the Railway line sites, with green shading indicating values within or above the reference site range which indicate rehabilitation heading in the right direction given its young age.

In terms of Fauna habitat the report states that fauna habitat assessment showed that fauna habitat is beginning to develop well in many sites, though more time is needed to assess this.

Methodology and Success Rate

The methodology utilised for rehabilitating short term disturbances in general appears to be working to achieve successful rehabilitation (stable, non-polluting landform, that comprises local native vegetation that is self-sustaining and compatible with the surrounding environment) and is proposed for use to rehabilitate similar types of disturbance at Yandicoogina. This methodology involves salvaging and stockpiling vegetation and salvaging and stockpiling topsoil prior to disturbance, then reprofiling areas, returning the stockpiled topsoil and vegetation and deep or shallow ripping along the contour as appropriate. With regard to borrow pits the initial placement of them on the landscape and resultant excavation is critical to enabling the borrow pits to be free draining following rehabilitation.

Long-term disturbances (e.g. construction camp, permanent accommodation village and administration buildings)

In addition to created landforms and short term disturbances the proposed landform at Yandicoogina on closure will also have rehabilitation that was completed on long-term disturbances. Examples of long- term disturbances include construction camps, landfill sites, accommodation villages and are considered in this discussion as any generally flat disturbance that is rehabilitated within a medium to longer time frame following disturbance. The discussion of rehabilitation strategies and success rates for long-term disturbance will involve a review of monitoring results for a rehabilitated landfill at Yandi and fixed plant rehabilitation completed at Mesa A.

Landfill Sites at Yandicoogina

Two landfill sites (adjacent to each other) that were rehabilitated in 2009 after being disturbed (active) at Yandicoogina for three and a half years and last monitored in 2014 are considered examples of longer term disturbance and discussed below.

The decommissioned landfill had clean fill imported to cover the pits, then it had topsoil applied, was ripped and seeded and monitored for the first time in 2013, then again in 2014.

Numbers of total species in the two landfill sites were nine and 11 which was similar to those in the two reference sites (11 and 12 species), with a range of *Acacia species* as well as *Spinifex species*, native grasses, and various other native shrub and herb species identified at the rehabilitated site. Species per quadrant values showed no clear separation between the reference site and the Landfill sites. Native plant density in the two landfill sites had changed very little since 2013, and was comparable to or higher than those in the reference sites. Mean bare areas values (which provides an indication of cover values) in the two landfill sites and the reference sites were similar to each other, with no significant differences.

Results for the two landfill sites show that rehabilitation has established and developed well, with most measured and calculated parameters similar to values recorded in the two reference sites and in some cases higher. No weeds were recorded in either landfill site, and both sites are stable, with no erosion recorded. Field notes for both sites describe the rehabilitation as excellent. Fauna habitat of the two sites is likely to be good for any small reptiles, mammals, birds and invertebrates that utilise spinifex and shrubs, but less suitable for ground dwelling species that utilise litter and logs.

Mesa A Fixed Plant Rehabilitation

A nine hectare area previously utilised as a laydown area for approximately three years by the fixed plant personnel at Mesa A operations was rehabilitated in 2012. The area had topsoil applied, was ripped and seeded. Monitoring of the area in 2013 showed the total numbers of species in the two rehabilitated sites were comparable to or greater than those recorded in the reference sites, species present in the rehabilitation included a number of *Acacia species* and other shrub, herb and grass species as well as *Spinifex species*. The plant density values were lower in the rehabilitated site at 2.3 and 2.3 plants per quadrant as compared to the reference sites (5.3 and 6.4 plants per quadrant), which is expected given the young age of the rehabilitation. The percentage of perennial cover was also very low in the rehabilitated sites (1% and 4%) as compared to the reference sites (43% and 51%).

There were no signs of erosion in the rehabilitated sites and it was too early to do an assessment of habitat diversity (to determine appropriate habitat for fauna). It is too early to determine if the rehabilitation is on track to be successful. The early indicators of the rehabilitation certainly show it is not doing as well as some other shorter term rehabilitated areas such as the areas reviewed at Hope Downs 4. This may be a result of weather and rainfall received at the two sites or as a result of the disturbance being longer term (which may lead to reduced quality of topsoil). The other factor that may be contributing to the rehabilitation success at the Mesa A Fixed plant area is that it is surrounded by disturbed areas (and not immediately adjacent to undisturbed native vegetation).

Methodology and Success Rate

The two examples for longer term disturbance reviewed suggest that it may be more difficult to achieve rehabilitation success in areas of longer term disturbance (than short term disturbance areas). In both cases the rehabilitation methodology has shown that the areas are stable and have native species present, with the landfill indicating density and cover is similar to the reference sites whilst further monitoring of the Mesa A rehabilitation will determine if cover values will be achieved in time. Whilst only a review of two areas the rehabilitation methodology of landform shaping, topsoil application, ripping and seeding appears to support the development of successful rehabilitation in longer term disturbance. An important step of the rehabilitation of the longer term disturbance (as opposed to short term disturbance) is the addition of seed. The addition of seed in the rehabilitation process should be considered regardless of the disturbance type but based on the likely viability of the seed bank with the topsoil utilised in the rehabilitation. In addition the germination of seed in rehabilitation areas may also assist if the proposed rehabilitation habitat being established is different to the habitat from which the topsoil was sourced, which may be the case in Yandicoogina where some wetland habitats will be developed as a part of the closure of the site.

1. BACKGROUND

An acid and metalliferous drainage (**AMD**) risk assessment for the Billiard deposits at Yandicoogina has been undertaken and takes into account: total sulfur concentrations within rock types; the sample location with respect to the proposed pit shell; and geochemical data to identify enriched elemental concentrations which may pose an environmental risk. This data, along with site specific baseline information can be used to generate a conceptual site model to describe mechanisms by which acid and metals/metalloids may mobilise and interact with environmental receptors.

The Yandicoogina Billiard deposits are located approximately 100 km north-west of Newman and approximately 3 km south-east of the existing JSE crusher at Yandicoogina (Figure 1-1). Yandicoogina is a large pisolitic iron deposit that follows a winding palaeochannel approximately 80 km long. Much of the area is covered by alluvial gravels overlying a lateritic clay unit known as the Eastern Clay. The Channel Iron Deposit (**CID**) palaeochannel is saucer-shaped with a simple structure exhibiting no folds or faults, with the main ore zone approximately 40 – 50 m thick in the centre and thins towards the channel margins. The current production from Yandicoogina is 53 Million tonnes per annum (**Mt/a**) with the Billiard deposits being the last developed to sustain this rate.

The Yandicoogina area is a semi-arid to arid environment, characterised by hot summers and warm winters. The region experiences climate extremes, where severe droughts and major floods can follow in close succession. The Billiard deposits runs parallel to the Weeli Wolli Creek, and encroach into the floodplain.

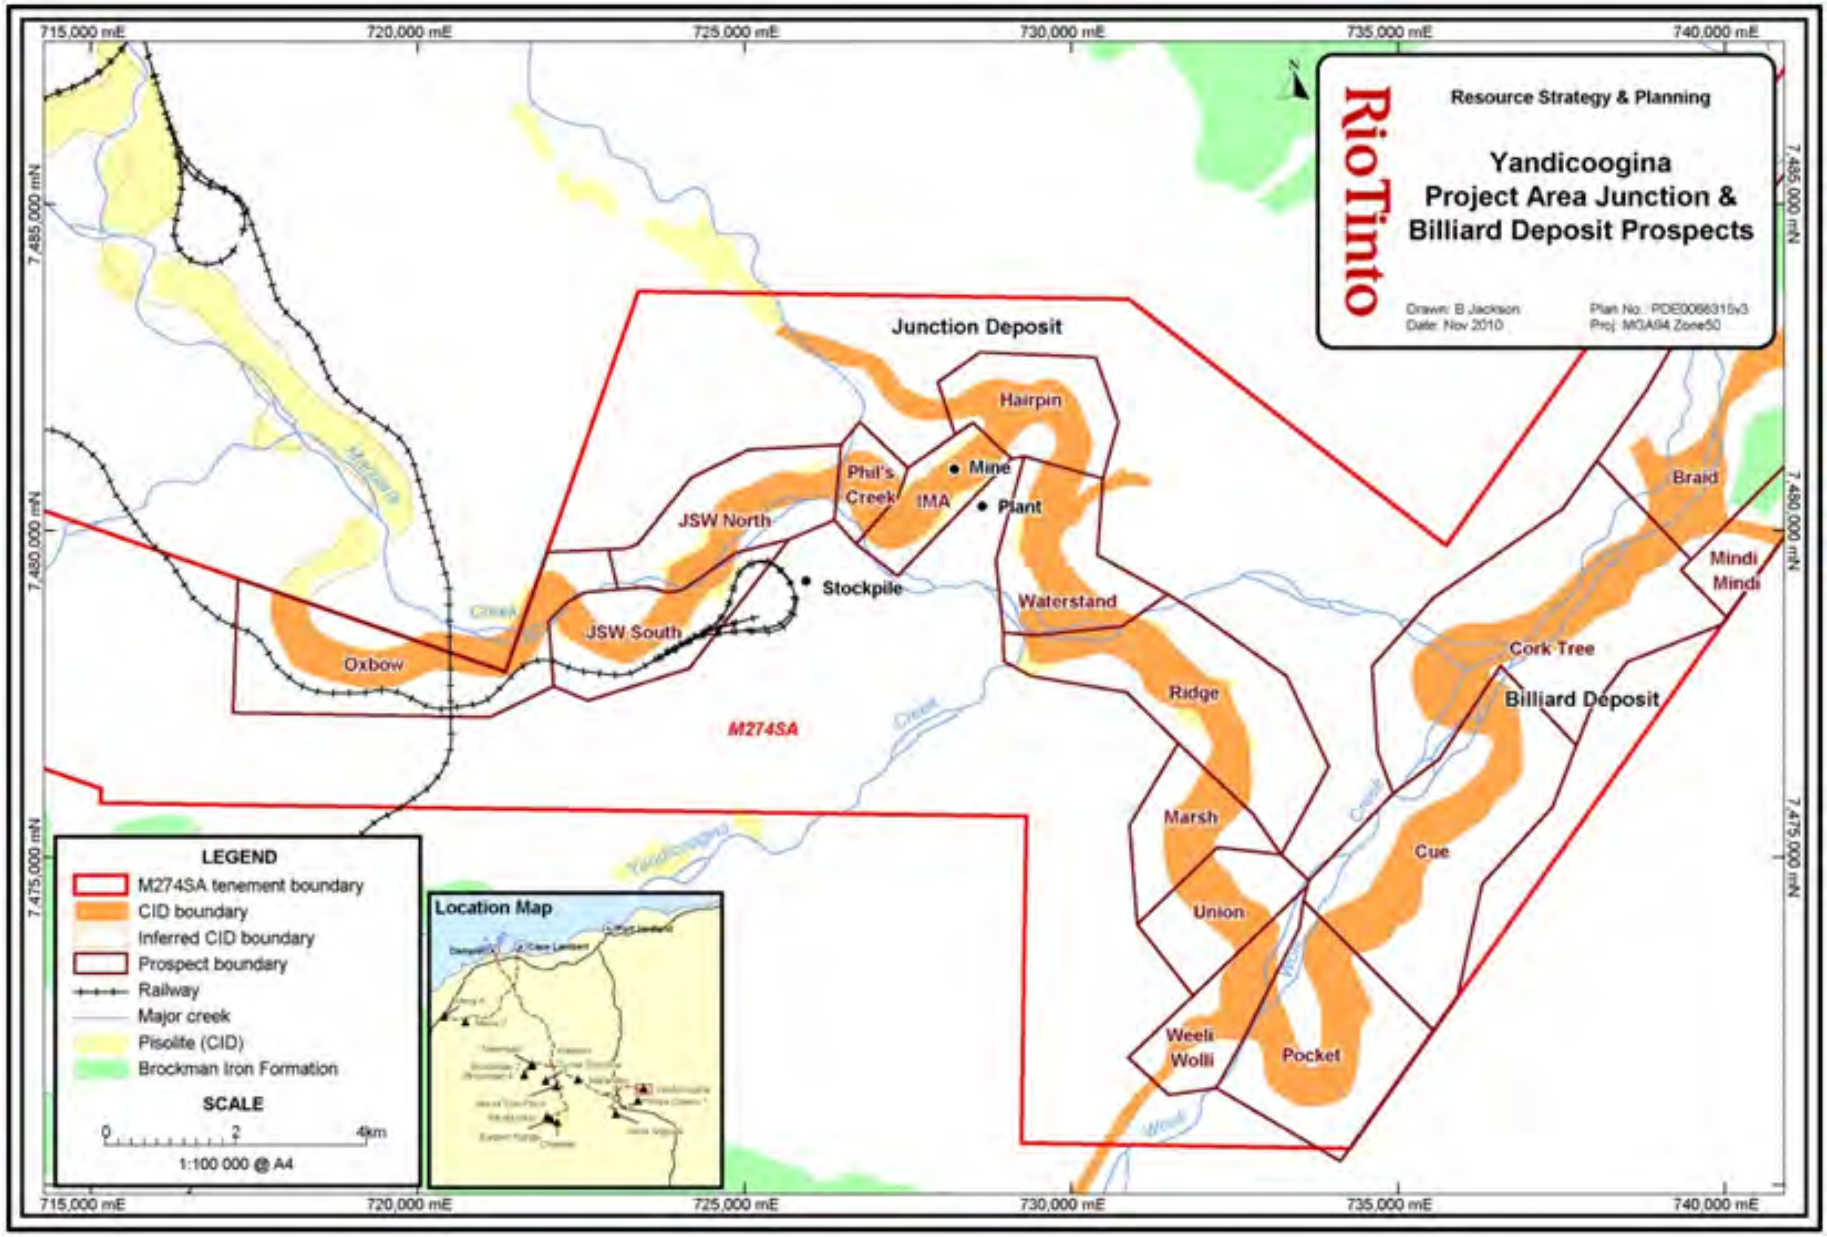

Figure 1-1: Yandicoogina Project Area Junction and Billiard Deposit Prospects

2. SULFUR ANALYSIS

A summary of the risk assessment process followed here is detailed in *Geochemical Risk Assessment Process for Rio Tinto's Pilbara Iron Ore Mines* (Green and Borden 2011) and in *Mineral Waste Management in the Pilbara: A Position Statement* (Brown 2012).

The Proponent has undertaken static acid base accounting (**ABA**) and kinetic characterisation on different lithologies to identify the potential for these rock types to generate acidity. ABA data for sulfidic black shale confirms a value of 0.1% total sulfur can be adopted as the boundary to delineate potentially acid forming (**PAF**) material from inert/non-acid forming (**NAF**) material. For other lithologies such as banded iron formation (**BIF**) and detrital rock types, a value of 0.3% total sulfur concentration is the most appropriate boundary. In oxidised material it has been shown that sulfur may be in the form of the hydroxysulfate mineral alunite (KAl3(SO4)2(OH)6) (RTIO 2011). There is the potential for relatively low levels of acid generation from elevated-sulfur samples that contain alunite (when compared against acid generation from sulfide minerals), since the low solubility of alunite may result in a low flux of acid release (and contaminant release). A sulfur cut-off of both 0.1% and 0.3% are considered for the purpose of this assessment.

It is recognised that sulfur-related AMD includes acid drainage and neutral drainage, with both potentially containing elevated concentrations of contaminants (INAP 2010; DITR 2007). Brown (2012) has summarised geochemical data from the Proponents drillhole database showing that contaminants predominately become soluble when associated with material containing elevated sulfur (i.e. pyrite and alunite). If there is sufficient neutralising capacity in the acid-generated rock then any acid generated at the microscopic scale is subsequently neutralised; however as a result, concentrations of some contaminants which do not precipitate at circumneutral pH, may remain in solution and result in poor-quality drainage (DITR 2007). For this reason, analysis of total sulfur in rock types will identify those with the propensity to generate acid and lead to poor quality drainage characterised at both low-pH and circumneutral pH conditions.

Poor quality drainage may also result from contaminants soluble at neutral pH (and not related to sulfur). Many minerals are unstable when exposed to the atmosphere after disturbance; elevated concentrations of dissolved minor and trace elements in surface water runoff may result from the dissolution of readily soluble salts (being a source of such elements). The potential for this risk is assessed by considering the oxidation state of minerals characterising the rock types likely to be exposed, and by also considering the average concentration of elements relative to the average crustal abundance for that element, as well as ecological toxicity trigger values.

3. ACID BASE ACCOUNTING AND GEOCHEMICAL CHARACTERISATION

Although no geochemical characterisation has been undertaken on Billiard samples, it is expected that the Billiard material will be similar to other Yandicoogina materials. A total of 90 samples from the Junction Central, Junction SE and Junction SW deposits and 13 tailings samples were submitted for ABA and geochemical characterisation. All samples were classified as either NAF or Uncertain-NAF (**UC-NAF**). The samples were enriched (when compared to the average crustal abundance) in As, Au, B, Bi, Sb, Se, Tl and Hg; however the static leach testing indicated that these elements were not readily leached.

To determine how the elements are distributed among mineral hosts, a multi stepped leach regime using different leachants, each more aggressive than the last were selected to target different mineral components of the samples. The tests indicated that Sr, Mn and Ba were either labile

(loosely bound), adsorbed, exchangeable or associated with carbonates. Lead was found to be associated with crystalline iron oxyhydroxides. The bulk of the elements were not leached until the final steps indicating that they are strongly bound and unlikely to be leached under the expected geochemical conditions.

The Proponent has also commissioned studies into leaching under saline conditions. Leaching was undertaken at two different levels to represent saline groundwater and possible brines that develop in pit voids due to evapoconcentration. Overall, the results indicate the mass of Ca, Mg, K, Sr, Cu, Ba, Mn and Zn leached increased as salinity increased. These increases can be explained by cation exchange processes, desorption or increased formation of aqueous complexes. For all other elements there appeared to be no increase or decrease in leached concentration as a function of the differing salinity levels.

4. TOTAL DRILLHOLE SULFUR ANALYSIS

An analysis of sulfur values in drillhole data (to the end of April 2014) was undertaken to identify those rock types that require further investigation relating to acid-forming potential (and any related metalliferous drainage). An outcome of this analysis includes the likelihood that a particular rock type will pose an acid drainage risk. For the purpose of this assessment, the rock types, or "strand-tag groups" comprise like-material assigned the same "geozone" code based upon their sub-divided stratigraphies (strands) and further differentiated based on dominant material type (tag).

It should be noted that the following factors may also influence the interpretations within this assessment:

- Negative assay results represent concentrations below the detection limit. The assay value for the element or oxide was taken to be the absolute value (i.e. the detection limit). This approach is conservative, as the true values for these assays may be below the detection limit value.
- Total sulfur was measured using the XRF method rather than the LECO method. The XRF method may underestimate the total sulfur concentration when sulfur values are high.
- The logging code pyrite (**PYT**) can be used where it is readily identifiable. However logging codes either do not exist or are not readily used for the sulfate minerals gypsum and alunite as these minerals are less identifiable.
- The drillhole data for the ore body is extensive with less data collected for waste rock types.
- Assay values of "-99" or "zero" indicate that the element was not assayed and were deleted and not considered in this assessment.
- Some intervals had incomplete stratigraphy, strand or tag information. These samples were grouped into and UNKNOWN strand-tag category.
- Limited information exists related to the neutralising potential of the rock type; the presumed risk of acid drainage may be over-stated if the available neutralising capacity of that rock type is unaccounted for.
- The drillhole spacing varies across the deposit.

Table 4-1 shows a summary of the total sulfur analysis performed using the drillhole sample assays extracted from the acQuire database in April 2014, and filtered by the "YBIL" "PROJECTCODE". The average sulfur value for those samples with elevated-sulfur (i.e. sulfur values greater than 0.1%) is

also tabulated and considered in the analysis. Drillhole samples represent rock types associated with the Billiard deposits, and that not all rock types drilled and listed in the table are expected to be mined.

Three samples from the Billiard deposits had pyrite visibly identified. The samples were from the Pocket and Braid areas with one sample being located in the Weeli Wolli (**WW**) and the two others located in the basal clay conglomerate (**BCC**). The sulfur levels for the samples were 0.075% for the WW sample and 3.15% and 1.89% for the BCC samples. These three samples were logged as having lignite.

For the Billiard deposits approximately 0.25% of more than 61,000 samples have sulfur levels greater than 0.1%. Approximately 0.7% of all the waste samples have sulfur levels greater than 0.1%. When a 0.3% sulfur filter is applied, 0.07% of all samples have sulfur levels greater than 0.3%, and 0.23% of waste samples have sulfur values greater than 0.3%. The elevated sulfur samples come from the detrital ore (**DET ORE**), Joffre Member Hydrated (**JOF HYD**) and the Mount McRae Shale (**MCS WASTE**). The maximum sulfur content measured from the Billiard deposit is from a Weeli Wolli sample with a measured sulfur content of 3.65%. The sample is associated with lignite and clay; however no pyrite was identified in the core sample.

Almost 5.9% of DET ORE samples have sulfur levels greater than 0.1%; however none of these samples have sulfur levels greater than 0.3%. These elevated sulfur samples are located in one drillhole, and are associated with samples with Fe values greater than 56%. Based on the low sulfur values associated with the elevated-sulfur samples (i.e. average of 0.19%) and that these samples are located in one drillhole, **DET ORE is expected to pose a low acid drainage risk**.

Almost 24% of JOF HYD samples have sulfur levels greater than 0.1%, with 6.9% with sulfur levels greater than 0.3%. The 48 elevated-sulfur samples are located within two drillholes; 47 were from one drillhole. Although there was no pyrite visibly identified in the elevated sulfur-samples, the majority of samples were identified as having siderite which has been known to be associated with pyrite at other Proponent deposits. Based on the high number of elevated-sulfur samples, the moderate sulfur values associated with these samples (i.e. average of 0.29%), **JOF HYD is expected to pose a moderate acid drainage risk**. The distribution of this material with respect to the pit shell should be investigated further.

A total of five or 10.4% of MCS WASTE samples have sulfur levels greater than 0.3%. All five samples were from the same drillhole and consecutive intervals. Given the relatively high sulfur values associated with these samples (i.e. average of 0.92%), **MCS WASTE is expected to pose a moderate acid drainage risk**, and further analysis of the MCS material with respect to the pit shell should be undertaken.

5. TOTAL SULFUR ANALYSIS CONSIDERING THE PROPOSED FINAL PIT SHELLS

The proposed final pit design (bill_pkt_cf_v05.00t) was used to filter the drillhole data according to which samples are located within the final pit shell. A summary is provided in Table 5-1. Approximately 0.25% of all in-pit samples (including all waste samples) have sulfur levels greater than 0.1%. Approximately 0.07% of all in-pit samples have sulfur levels greater than 0.3%. The DET ORE, JOF HYD and MCS WASTE rock-types identified as having greater than 3% of samples greater than 0.1%, are not present within the pit shell. It is unlikely that acid drainage will be an issue in material mined from the Billiard pit.

Table 5-1: Total Sulfur Analysis for Drillholes Located within the Billiard Pit Shell

6. TOTAL SULFUR ANALYSIS IN THE MINING MODEL

The mining model for Billiard was used to predict the amount of material with elevated sulfur likely to be encountered during the life of the deposit. This is undertaken by looking at the sulfide_risk variable and the block sulfur grade. Sulfur grades are estimated into the blocks using the available surrounding data (i.e. assay values of nearby drillhole samples). The method used includes Ordinary Kriging for ore blocks and is more reliable than the inverse distance method used for the estimation of waste blocks. It should be noted that the sulfur grades may be over- or under-estimated; and this exercise identifies the presence of mining blocks in proximity to elevated-sulfur drillhole samples that may have the potential to generate acidity.

Blocks have been assigned to the rock type air. This is due to the sub-blocked model being regularised (aggregating data for the selected mining unit size). The dominant rock type in the sub-blocked model is assigned as the rock type in the regularised mining model. Therefore where blocks are close to the surface such that air is the dominant rock type it will be assigned as air in the regularised model.

Based on the mining model yndapr_bil_20130821_003, the estimated tonnes of elevated-sulfur material is given in Table 6-1, and summarised below.

All material within the Billiard pit shells have been assigned a sulfide_risk variable of 0 (no risk, material classified as non-acid forming). When the mining model is filtered by the s_bin variable it

can be seen that the bulk of the material is expected to have sulfur levels less than 0.1%, and is consistent with the inpit drillhole analysis. The only material that is expected to have sulfur levels greater than 0.1% is waste material and in particular the ALL and WW. Approximately 94,000 t of elevated-sulfur material is expected, however none of this material is expected to have sulfur levels greater than 0.3%. From this it can be seen that elevated-sulfur material comprises a very small part of the material to be encountered at Billiard and therefore it is unlikely that acid drainage will be a problem.

Table 6-1: Breakdown of Quantities of Material by mp_dest and sulfur bin

Grand Total (Mt)	1,455	0.07	0.01	0.01	1,456

7. GEOCHEMICAL ENRICHMENT

Understanding the geochemistry of rock types can assist with more environmentally sound management of waste rock and low-grade stock piles. Drillholes are regularly analysed for the main chemical element suite of Fe, Si, Al, P, Ti, Ca, Mg, S and Mn. Occasionally there have been full chemical suite analyses of As, Ba, Bi, Cl, Co, Cr, Cu, K, Na, Ni, Pb, Sn, Sr, V, Zn, and Zr. The assay results are determined using XRF and it is now common practice to analyse for the full chemical suite as part of ore body evaluation.

The extent of enrichment of a drillhole sample can be reported as the Geochemical Abundance Index (**GAI**), which relates the actual concentration with average crustal abundance on an adjusted log 2 scale (Bowen 1979). The GAI is expressed in integer increments where a GAI of zero indicates the element is present at a concentration similar to, or less than, median crustal abundance, and a GAI of 6 indicates approximately a 100 fold enrichment above median crustal abundance. The main purpose of the GAI is to provide an indication of any elemental enrichment. As a general rule, a GAI of 3 or greater (more than 12-times the average crustal abundance) signifies enrichment that warrants further examination, while a GAI of 1 or 2 indicates that the element may be elevated.

The GAI values from the drillhole samples were contrasted with Ecological Investigation Levels (EILs) and Health Investigation Levels (**HILs**) provided in the Contaminated Sites Management Series Assessment Levels for Soil, Sediment and Water (DEC 2010), as well as US EPA Ecological Soil Screening Levels (Eco-SSLs) (US EPA 2005, 2010). These various screening levels identify contaminants of potential concern in soils and sediments, which can then be evaluated through site specific assessments. The comparison of the GAI trigger concentrations used in this assessment are

lower than the EILs, HILs and Eco-SSL values with the exception of Ba, Cd, Co, Cr, Cu, Mn, Ni, P, Pb, S, Sb, V and Zn. The GAI trigger is generally higher than the Eco-SSLs in the US EPA report with the exception of As and Se, for which the crustal abundance values are lower than the most conservative Eco-SSL values.

The most conservative Eco-SSLs were considered for the purpose of this comparison, however these values may not be the most appropriate for Pilbara-specific receptors.

Some potential issues are that:

- Material mined on the Proponents mine sites is mostly rock and not soil, and therefore whilst EILs, HILs and Eco-SSLs are useful for screening, they may not be the most appropriate to use as management triggers; and
- Concentrations of some trace elements of environmental concern (e.g. As) may be enriched in some of the sampled material, but these elements may not necessarily mobilise into groundwater.

8. ANALYSIS OF DRILLHOLE SAMPLES FOR THE BILLIARDS DEPOSITS

The multi-element analysis of all drillhole assay data (derived from the full chemical suite) for the Billiard deposits and the corresponding GAI values are summarised in Table 8-1, with the full details given in Appendix 1. The same factors outlined earlier may also influence the interpretations. Most rock types are either enriched or elevated in Fe, as correlated with the iron mineralisation associated with the ore body. Arsenic (**As**) is enriched in most rock types while tin (**Sn**), Th and U are generally elevated. MCS also had elevated levels of Mn and S, while JOF HYD had elevated levels of S and Cl.

Table 8-1: Geochemical Enrichment Summary for the Billiards Deposits

Yandi Rock Type	Enriched (GAI >=3)				Elevated
	Fe	As	Sn	U	(GAI = 1 or 2)
ALLUVIUM		3		3	Fe, Sn, Th
DET WASTE		3			Fe, Sn, Th, U

WW ORE	3	3			Fe, Sn, Th
YS WASTE		4			Fe, Sn, Th, U
YS ORE	3	3			Sn, U
JOF WASTE		3			Fe, Sn, Th, U
JOF ORE	3	3			Sn, U
JOF HYD	3	3			S, Cl, Th, U
WS WASTE		3			Fe, Th, U
WS ORE	3	3			Sn, U
DG WASTE		3			Fe, Sn, U
DG ORE	3	3			Fe, Sn, U
FWZ WASTE	3	4			
MCS WASTE		3		3	Fe, S, Mn, Sn, Th

For the standard suite of element suite including Ba, Co, Cr, Cu, Mn, Ni, P, Pb, S, V and Zn the GAI triggers are higher than the standard DEC/US EPAA EILs, HILs and Eco-SSL triggers (see Green 2011). An analysis comparing the lower triggers against the average concentration of those elements in each rock type (Table 8-2) indicates that:

- the majority of rock types have values lower than the DEC/EPA triggers for Ba, Cu, Ni, P, S and Zn;
- most rock types have relatively high concentrations of Mn, V and Pb; and
- generally the dominant rock types to be encountered in the Billiard pit have relatively high levels of Co, Mn, Pb and V.

In general, whilst concentrations of some trace elements of potential environmental concern (e.g. As, Pb) were enriched in some of the sampled ore and waste materials, these elements will not necessarily mobilise into groundwater. Arsenic in particular is commonly enriched in ore and waste for many Hamersley Group deposits. Iron oxy-hydroxides such as hematite and magnetite have high sorption capacities for As (e.g. Zhang *et. al*. 2004), and consequently these materials have been used around the world for treating water enriched in arsenic.

In summary, the following elements have been identified as being enriched in the Billiard deposits: **Fe, As, Sn, Th and U (based on GAI triggers) and Mn, V, Pb and Co (based on DEC/EPA triggers)**. Although these elements were found to be enriched, the results of static and sequential leach extractions indicated that elements other than Mn and Pb are unlikely to leach at appreciable levels; however these enriched elements should be monitored in groundwater to ensure that geochemical conditions do not change.

Table 8-2: Analysis of Billiard Drillhole Mean Concentrations Compared to the Lowest DEC/EPA Trigger Values

	Ba (mg/kg)	Co (mg/kg)	Cr (mg/kg)	Cu (mg/kg)	Mn (%)	Ni (mg/kg)	P (%)	Pb (mg/kg)	S (%)	V (mg/kg)	Zn (mg/kg)

9. AMD RISK ASSESSMENT AND CONCLUSION

The risk associated with AMD for the Billiard deposits has been investigated and takes into account: total sulfur concentrations within rock types; the sample location with respect to the proposed pit shell; the estimated tonnes expected during mining; and geochemical data to identify enriched elemental concentrations which may pose an environmental risk. The results of this assessment, taking into account background information related to mining of the deposit, as well as environmental factors which may be impacted are presented in the AMD Hazard Scorecard.

The Billiard deposit is expected to pose a low AMD risk based on the current pit design. Approximately 0.12% of all in-pit samples have sulfur levels greater than 0.1%, with 0.03% with sulfur levels greater than 0.3%. From the mining model it can be seen that elevated sulfur (i.e. S greater than 0.1%) material makes up a very small proportion of material to be encountered during mining, with this material likely to be sulfate minerals.

The following elements were found to be enriched in samples from the Billiard samples and should be monitored in groundwater: Fe, As, Sn, Th, U, Mn, V, Pb and Co, though these elements are not expected to leach from waste material in appreciable levels.

Introduction

1. Overview

Surplus water discharge into Weeli Wolli Creek is one of the water disposal options currently in place at Hope Downs 1 (HD1) and Yandicoogina mine sites, and is subject to condition 6-3 of Ministerial Statement 914, which limits the wetting front to 17 km downstream from the confluence of Marillana and Weeli Wolli Creek. To ensure compliance, Mine Operations at Yandicoogina are required to monitor the extent of surplus discharge on a regular basis and recent measurements suggest that the wetting front has travelled 7 km downstream from the confluence.

A baseline hydrologic assessment was completed in 2010 to evaluate the response of Weeli Wolli Creek to increased artificial discharge associated with the development of the JSW and Oxbow deposits within the Yandicoogina mine (RTIO, 2010). The assessment has since been updated to incorporate the potential increase in surplus water generation as a result of dewatering at Pocket and Billiard South (RTIO, 2013).

The main uncertainty associated with the current approach of estimating creek response and subsequently the extent of surplus water discharge is the channel loss rate[1], which is influenced by the alluvial characteristics, the underlying geology, the depth to groundwater table, and the seasonal variation in evaporation and transpiration. Previous modelling attempts utilised regional values for the channel loss rates due to the lack of localised information for the catchment. These values do not sufficiently capture the variations in losses along the creek, due to changes in catchment characteristics, which are considered important in assessing the reaction and impact of dewatering discharge in a creek system in a local scale. In order to improve the estimation of the discharge footprint along Weeli Wolli Creek, more representative values of channel loss rates are required in the model simulations.

Discharge measurements were carried out at various locations along Weeli Wolli Creek to quantify the channel loss rates in reaches of the creek system. These measurements were complemented by infiltration testing to better understand the rates of infiltration, in particular along the section downstream of the current discharge extent. Channel loss rates were estimated based on these field measurements (RTIO, 2014a), and were subsequently incorporated into the discharge extent modelling for Weeli Wolli Creek. Specific objectives of this assessment were:

- To calibrate the existing steady state discharge extent model using the field-derived channel loss rates for Weeli Wolli Creek.
- To predict the response of Weeli Wolli Creek, using the calibrated loss parameters, from the potential increase in surplus water discharge associated with the development of the Pocket and Billiard South deposits.
- To assess the sensitivity of the loss rates on the predicted wetting front along Weeli Wolli Creek.

2. Model Calibration

Detailed description of the rationale behind the development of the discharge extent model is provided in the Yandicoogina discharge baseline hydrology report (RTIO-PDE-0074001/RTIO, 2013). In brief, the wetting front of the artificial discharge is estimated based on a water balance approach, which calculates the length of the creek over which the discharge is lost to the environment. A short section of Marillana Creek was modelled

[1] The channel loss rate is the rate of total loss/gain of discharge to the environment via evaporation, infiltration, recharge and transpiration from riparian vegetation.

from DO8 to the catchment outlet and a 51 km section of Weeli Wolli Creek was modelled from the HD1 outlet to the BHP rail that runs across the Weeli Wolli Creek alluvial plain. Both creeks were divided into reaches based on creek morphology, vegetation type/pattern and the field-derived channel loss rates.

2.1.1 Existing discharge regime

The existing regime of surplus water discharge from the Yandicoogina and HD1 mine operations between 2007 and September 2014 is shown in Figure 1. This is compared with the movement of the wetting front for the same period downstream from the confluence of Marillana and Weeli Wolli Creek. The period saw a steady increase in total discharge, predominantly from water released from the HD1 operation. A sudden increase in discharge was observed in February 2009, which was associated with the activation of DO8 at Marillana Creek. This resulted in a dramatic response in the creek, where the wetting front migrated 6 km downstream from the confluence. The footprint receded quickly following the peak, which mirrored the sudden drop in total discharge in mid-2009 and early 2010. The wetting front remained fairly consistent at 5 km downstream from the confluence in 2012 where HD1 discharge stabilised at approximately 100 ML/day (37 GL/year). However, an increase in footprint distance was observed from 2013, which coincided with the activation of DO9 in April of the same year. DO9 was to replace all discharge outlets along Marillana Creek as the main point of discharge at Yandicoogina. Its location, downstream from the current mine operations, was chosen to prevent re-circulation from dewatering, thus water released from this outlet has the tendency to travel further down the creek. The maximum recorded wetting front was 7.7 km downstream from the confluence in June/July 2014.

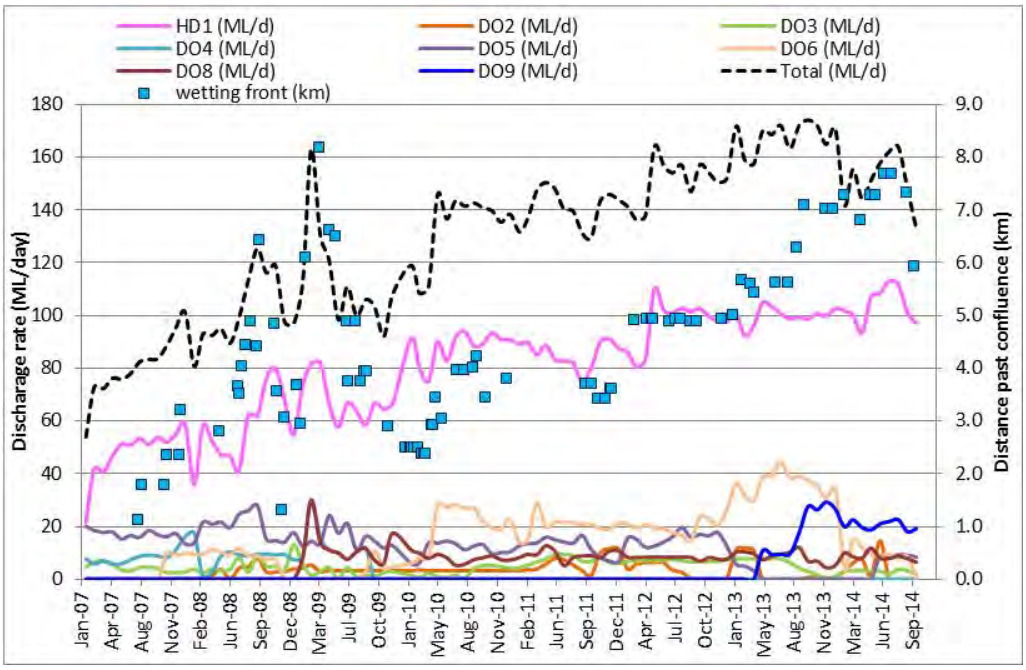

Figure 1: Existing discharge regime from Yandicoogina and Hope Downs 1 between 2007 and September 2014.

2.1.2 Calibration results

The most recent measurements of the wetting front from January to September 2014 were used to calibrate the discharge extent model. This was achieved by adjusting the channel loss rates to match the model results of the observed footprints along Weeli Wolli Creek. A comparison of the observed and estimated wetting front is provided in Table 1,

and the calibrated loss rates for each of the modelled reaches, together with the field-derived loss rates, are presented in Figure 2.

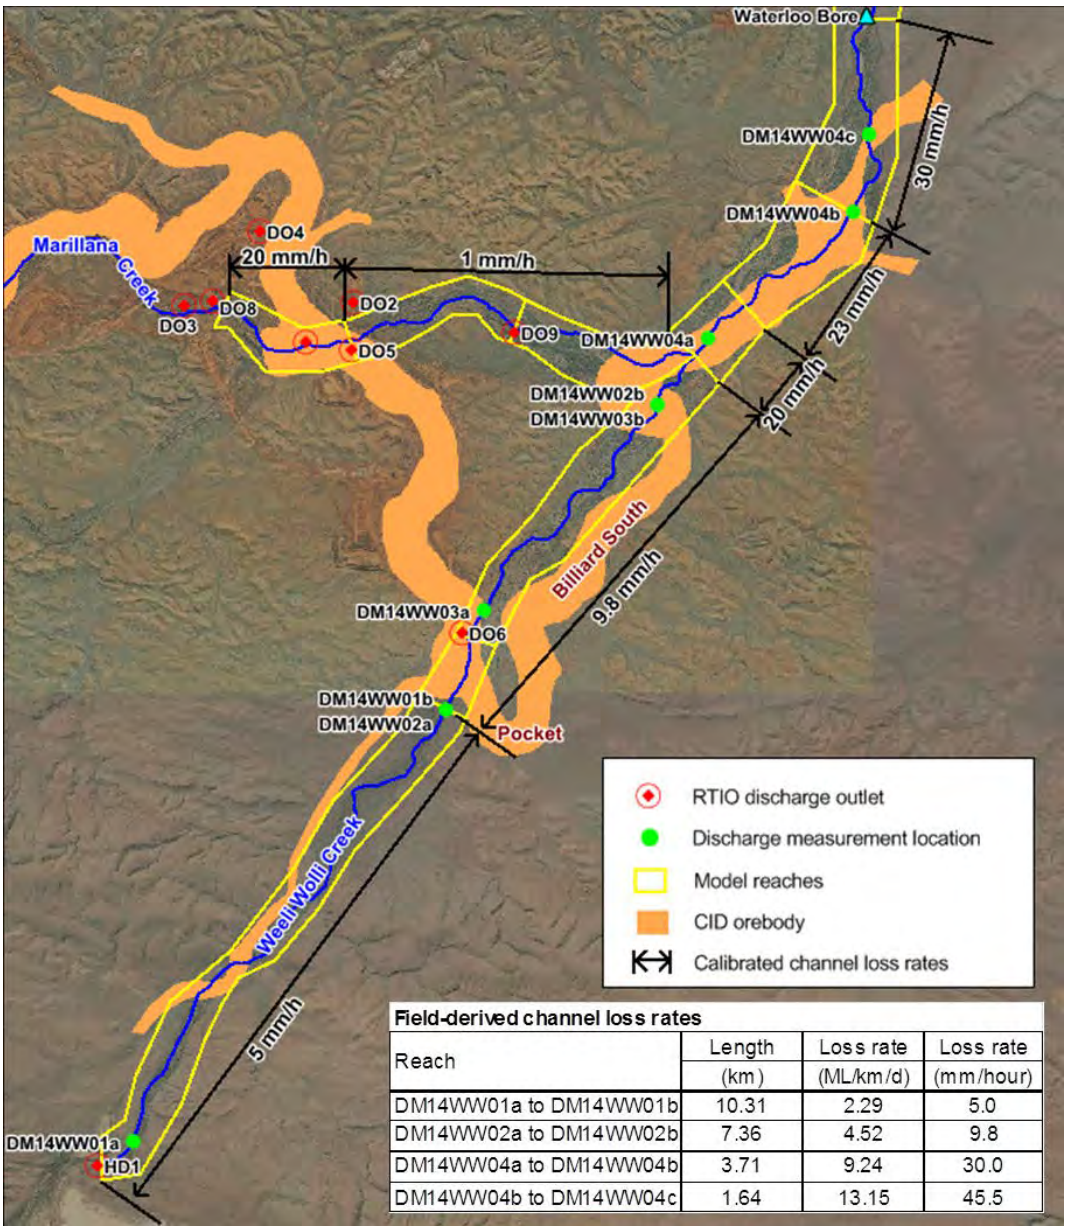
Minimal adjustments were made to the field-derived loss rates for Weeli Wolli Creek reaches upstream of the confluence, which range from approximately 5 to 10 mm/hour. A significant increase in losses is observed downstream from the confluence, where the rates increase from 20 mm/hour to approximately 30 mm/hour towards Waterloo Bore[2]. These findings are consistent with those of the study conducted by Dogramaci et al, who identifies Weeli Wolli Creek as a groundwater-connected system, with minimal losses, upstream of the confluence, and a disconnected creek downstream as the unsaturated zone increases. This transition also coincides with where the creek is underlain by the CID orebody, which has a high hydraulic conductivity (K) of approximately 10 m/day (Dogramaci et al., 2014). This change in understanding of the hydrogeological properties has resulted in the substantial increase in channel loss rates, predominately via infiltration, in the disconnected section of the creek.

Greater uncertainty is associated with the channel loss rates for Marillana Creek, but model calibration indicates a very small value of 1 mm/hour for reaches underlain by the impermeable Weeli Wolli Formation, which has the potential to restrict water loss via infiltration and/or recharge. On the other hand, due to the presence of the CID orebody, a high loss rate of 20 mm/hour was used for the first reach of Marillana Creek.

Table 1: Comparison of the observed and estimated wetting front distances along Weeli Wolli Creek downstream from the Marillana and Weeli Wolli Creek confluence.

Date	Discharge (GL/year)	Wetting front past the confluence (km)		Error (%)
		Observed	Estimated	
30/01/2014	52	7.3	6.6	-9.3
19/02/2014	57	7.3	7.5	2.3
24/03/2014	53	6.8	6.8	-0.2
29/04/2014	55	7.3	7.1	-2.9
14/05/2014	58	7.3	7.6	4.9
11/06/2014	59	7.7	7.8	1.1
9/07/2014	60	7.7	7.8	1.5
26/08/2014	54	7.3	7.0	-5.0
20/09/2014	48	6.0	6.3	5.4

[2] Waterloo Bore is a Department of Water (DoW) rainfall and streamflow gauging site.



Field-derived channel loss rates

Reach	Length (km)	Loss rate (ML/km/d)	Loss rate (mm/hour)
DM14WW01a to DM14WW01b	10.31	2.29	5.0
DM14WW02a to DM14WW02b	7.36	4.52	9.8
DM14WW04a to DM14WW04b	3.71	9.24	30.0
DM14WW04b to DM14WW04c	1.64	13.15	45.5

Figure 2: Calibrated and field-derived channel loss rates for Marillana and Weeli Wolli Creek.

2.2 Model prediction

With future expansion and development of the Pocket and Billiard South deposits, the total groundwater abstraction and the rate of surplus water discharge will increase for the Yandicoogina operation. Due to the close proximity of the deposits to Weeli Wolli Creek, discharge from HD1 will be re-circulated through the CID and back to the surface when dewatering begins. Results from the latest groundwater modelling indicates that all potential discharge from HD1 will be abstracted by dewatering, hence surface water flow will likely be terminated along the section of the creek parallel to Pocket and Billiard South. The abstracted water will be pumped to DO9 and released into Marillana Creek and subsequently into Weeli Wolli Creek downstream of the confluence.

Results from the water balance and groundwater modelling suggest that the total volume of water likely to be released from DO9 between 2017 and 2032 will range from 46 GL/year to maximum 84 GL/year (RTIO, 2014b). These predicted rates include abstraction from JSE, JSW, Pocket/Billiard South, as well as HD1 discharge re-circulation. This assessment investigates the response of the wetting front through

continual discharge of 46 GL/year, 58 GL/year and 84 GL/year at DO9, the minimum, average and maximum rate of discharge predicted for the outlet from 2017 to 2032, respectively. Discharge footprints were determined based on the assumption that steady state conditions were established.

The channel loss rates for Weeli Wolli Creek, down gradient from the current observed wetting front (down gradient from Waterloo Bore), cannot be definitively estimated in the field (RTIO, 2014a). However, the extensive layer of unsaturated surficial alluvium (> 40 m in thickness) that characterises the very downstream of Weeli Wolli Creek is highly conductive, K= ~ 1000 m/day, which allows rapid recharge to occur during creek flows; the underlying Brockman Iron Formation is also relatively permeable with a K value of approximately 5 m/day (Dogramaci et al., 2014). Based on these hydrogeological properties, it is expected that the channel loss rates for the downstream reaches will be as high as 30 mm/hour (the calibrated value of the last reach where the wetting front was observed) if not greater due to the increasing thickness of the unsaturated creek alluvium. However, to be conservative in the model predictions, the channel loss rate of 30 mm/hour was adopted for all reaches downstream of Waterloo Bore.

2.2.1 Model results

Model results for the proposed discharge rates and the associated contiguous surface water footprint distances, measured from the confluence of Marillana and Weeli Wolli Creek, are detailed in Table 2 and Figure 3, respectively.

Table 2: Estimated footprints for Weeli Wolli Creek for different discharge rates at DO9

Discharge rate at DO9 (GL/year)	**Footprint distance (km)**	
	From DO9	From confluence
46	13.6	10.7
58	15.3	12.3
84	18.5	15.5

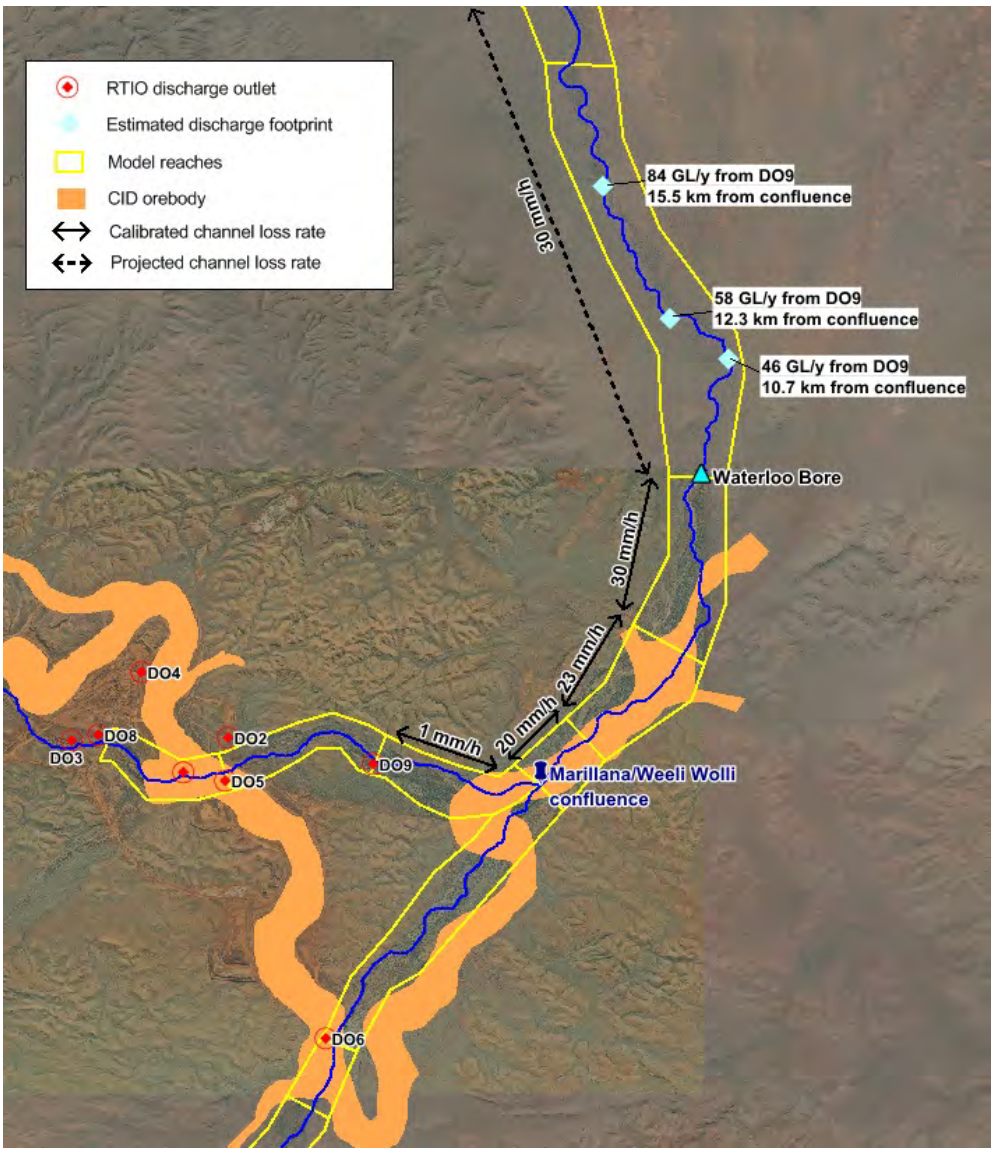


Figure 3: Estimated discharge footprints for Weeli Wolli Creek and the channel loss rates used in the model simulations.

Based on a constant loss rate of 30 mm/hour for the creek section downstream of Waterloo Bore, the modelled footprint for discharge rates 46 GL/year to 84 GL/year at DO9 would extend approximately 11 km to 16 km downstream from the confluence of Marillana and Weeli Wolli Creek. However, due to the lack of actual measurements, the level of uncertainty associated with the channel loss rate for the downstream reaches is high. Hence sensitivity analysis was undertaken to assess the response of Weeli Wolli Creek, beyond Waterloo Bore, to varying channel loss rate (± 20%).

Table 3 illustrates the results of the sensitivity analysis. It can be seen that modifying the channel loss rate by 20%, in general, resulted in less than 10% change in the discharge extent. Of exception is the 84 GL/year (- 20% loss rate) case where the modelled footprint was increased by 12%. The sensitivity analysis also shows that the creek is less responsive to the increase in channel loss rate than the decrease in rate for reaches downstream of Waterloo Bore, which suggests the nonlinearity of the relationship between footprint distance and channel loss rate for the Weeli Wolli Creek system.

The results of this assessment indicate that Weeli Wolli Creek could potentially accommodate the maximum predicted discharge rate of 84 GL/year at DO9, which incorporates surplus water generated from both HD1 and Yandicoogina mine operations, without breaching condition 6-3 of the existing Ministerial Statement 914. Continuous monitoring and discharge measurements are required and recommended to ensure compliance.

Table 3: Results of the sensitivity analysis of the channel loss rate for Weeli Wolli Creek downstream of Waterloo Bore

Discharge rate at DO9 (GL/year)	**Channel loss rate beyond Waterloo Bore (mm/hour)**	**Footprint distance from confluence (km)**
46	30 (base case)	10.7
58		12.3
84		15.5
46	24 (- 20 %)	11.4 *(6 %)*
58		13.4 *(9 %)*
84		17.4 *(12 %)*
46	36 (+ 20 %)	10.2 *(- 4 %)*
58		11.6 *(- 6 %)*
84		14.3 *(- 8 %)*
(x %) is the percentage difference in footprint distance compared with the base case.		

3. Conclusion

The existing discharge extent model for Weeli Wolli Creek has been reviewed and calibrated, based on field-derived channel loss rates, to improve the estimation of the wetting front associated with the potential increase in surplus water discharge from dewatering at Pocket and Billiard South. It can be concluded that:

- The channel loss rate for Weeli Wolli Creek increases from approximately 5 mm/hour at the HD1 discharge outlet to 30 mm/hour at Waterloo Bore, in association with the changes in hydrogeological properties of the creek as it transitions from a groundwater-connected system upstream of the confluence with Marillana Creek to a disconnected system downstream.

- The calibrated channel loss rates for the last two reaches of Marillana Creek are very small, which may be related to the impermeable Weeli Wolli Formation that underlays the creek alluvium restricting water loss via infiltration.

- The modelled footprint for discharge rates 46 GL/year to 84 GL/year (maximum predicted based on recent water balance and groundwater modelling) at DO9 would extend approximately 11 km to 16 km downstream from the confluence of Marillana and Weeli Wolli Creek, based on a constant loss rate of 30 mm/hour for the creek section downstream of Waterloo Bore.

- Varying the channel loss rate by ± 20% for Weeli Wolli Creek, downstream of Waterloo Bore, would result in less than 10% change in the footprint distance.

- Weeli Wolli Creek could potentially accommodate the maximum predicted discharge rate of 84 GL/year at DO9 without breaching condition 6-3, which limits the wetting front to 17 km downstream from the Marillana and Weeli Wolli Creek confluence, of the existing Ministerial Statement 914.

1.0 Summary

1.1 Background

The Yandicoogina iron ore mine is located approximately 75 km north-west of Newman, in the Pilbara region of Western Australia (Figure 2.1). This mine site is owned and operated by Rio Tinto Iron Ore (RTIO).

Rio Tinto is seeking to expand their current mining operations at Yandicoogina. This involves a development site at Billiard, located to the east of the existing mine. A further two expansion sites, Junction South West and Oxbow are located to the west of the existing Yandicoogina operation. These two sites are the subject of a related, but separate, report.

Biota Environmental Sciences (Biota) was commissioned to complete a fauna survey of the proposed the Billiard project area, which is currently intended for use as a dewatering site. The survey was planned and implemented in accordance with the EPA Position Statement No. 3 "Terrestrial Biological Surveys as an Element of Biodiversity Protection" (EPA 2002) and Guidance Statement No. 56 "Terrestrial Fauna Surveys for Environmental Impact Assessment in Western Australia" (EPA 2004).

The scope of the study was to:

- identify the fauna habitats, particularly those with conservation significance, within the study area;
- document the vertebrate and SRE invertebrate fauna assemblage within the study area; and
- identify fauna (particularly Schedule and Priority listed fauna as well as potential short-range endemic taxa) of particular conservation significance occurring within the area.

1.2 Methods

The initial survey took place during a single phase conducted in July 2008. This was followed in March 2010 by a four-day survey phase specifically targeting invertebrate SRE (Short-range endemic) fauna.

Systematic censusing of terrestrial fauna assemblages, including avifauna, mammals and herpetofauna, was carried out at nine sites, each located within defined habitats. The central component of the censusing consisted of trapping grids at six sites comprising 10 pit-fall traps (alternating 20 litre buckets and 20 cm diameter PVC tubes) spaced at 10 m intervals and connected by a single length (90 m) of 30 cm high flywire fence. One further sampling site exclusively comprised 50 Elliott traps, while two funnel trap sites were also utilised.

Seventeen avifauna censuses were conducted during the surveys across eight sites. Censuses were conducted between approximately 7:10 am and 12:00 pm, and were supplemented by opportunistic sightings of birds while traversing the study area.

Invertebrates were collected from both systematic sampling sites and opportunistic sampling sites. Groups targeted during these activities included:

- mygalomorph (trap-door) spiders;
- pseudoscorpions;
- scorpions;
- millipedes; and
- terrestrial snails.

Additional non-systematic collection techniques were undertaken by the survey team to supplement trapping efforts, and to investigate habitats not sampled using systematic methods.

1.3 Fauna

The single phase survey of vertebrate taxa in the Billiard study area yielded a total of 62 species, comprising 44 avifauna species, 18 mammals and 10 herpetofauna species: two frogs and eight reptiles (Table 1.1; Section 5.0).

Table 1.1: Number of vertebrate fauna species recorded during the fauna survey of the study area.

Fauna Group	Number of Species	Number of Individuals
Avifauna	44	860
Non-volant mammals	5	15
Bats	3	-
Amphibians	2	2
Reptiles	8	29
Total	62	906

One Priority 4 listed species was recorded by Biota from the survey area (Table 1.2). A further seven Schedule and six Priority listed species have either previously been recorded or may occur in the region (as determined by a search of the DEC Threatened Fauna Database and the WAM FaunaBase; Appendix 1 and Appendix 2). The Northern Quoll and the Night Parrot are listed as Endangered at the Federal level, while the Bilby, Pilbara Orange Leaf-nosed Bat and Pilbara Olive Python are listed as Vulnerable under the *Environment Protection and Biodiversity Conservation (EPBC) Act 1999*. The Rainbow Bee-eater was also recorded during the survey and is listed as Migratory under the *EPBC Act 1999*. These species are discussed further in Section 6.4.

Table 1.2: Fauna of conservation significance recorded during the fauna survey, or with the potential to occur within the study area (* denotes recorded during the survey).

Threatened Fauna Species	Status	
	State	Federal
Pezoporus occidentalis Night Parrot	Schedule 1	Endangered
Dasyurus hallucatus Northern Quoll	Schedule 1	Endangered
Macrotis lagotis Bilby	Schedule 1	Vulnerable
Rhinonicteris aurantius Pilbara Orange Leaf-nosed Bat	Schedule 1	Vulnerable
Lerista olivaceus barroni Pilbara Olive Python	Schedule 1	Vulnerable
Falco peregrinus Peregrine Falcon	Schedule 4	
Ramphotyphlops ganei	Priority 1	
Neochmia ruficauda subclarescens Star Finch	Priority 4	
Falco hypoleucos Grey Falcon	Priority 4	
Ardeotis australis Australian Bustard	Priority 4	
Burhinus grallarius Bush Stone-curlew	Priority 4	
**Pseudomys chapmani* Western Pebble-mound Mouse	Priority 4	
Leggadina lakedownensis Short-tailed Mouse	Priority 4	
Macroderma gigas Ghost Bat	Priority 4	

Only one Priority 4 species, the Western Pebble-mound Mouse, was confirmed from the study area (Table 1.2). This species is not restricted to the study area and is well represented in similar habitats across the Pilbara bioregion. The conservation status of this species is not expected to change as result of the Billiard development.

Searches for invertebrates during the initial survey phase, as well as during the targeted effort in 2010, yielded no taxa considered likely to represent potentially SREs

2.0 Introduction

2.1 Project Background and Study Area

The Yandicoogina iron ore mine is located approximately 75 km north-west of Newman, in the Pilbara region of Western Australia (Figure 2.1). This mine site is owned and operated by Rio Tinto Iron Ore (RTIO).

A further two expansion sites; Junction South West (JSW) and Oxbow are located to the west of the existing Yandicoogina operation. These two sites are the subject of a related, but separate, report.

Rio Tinto is seeking to expand their current mining operations at Yandicoogina. This involves a development site at Billiard, located to the east of the existing mine. The site at Billiard is intended for use as a dewatering area. The other two study areas, JSW and Oxbow, are located to the west of the existing Yandicoogina operation. These two study areas are the subject of a related, but separate report.

The project footprint was altered subsequent to the field survey and reduced in extent (see Section 4.0). For the purposes of this report, the original extent has been referred to as the 2007 survey boundary and the modified footprint the 2009 survey boundary.

2.2 Study Objectives and Scope

Biota Environmental Sciences (Biota) was commissioned to complete a fauna survey of the proposed Billiard project area. The survey was planned and implemented in accordance with the EPA Position Statement No. 3 "Terrestrial Biological Surveys as an Element of Biodiversity Protection" (EPA 2002) and Guidance Statement No. 56 "Terrestrial Fauna Surveys for Environmental Impact Assessment in Western Australia" (EPA 2004).

The scope of the study was to:

- identify the fauna habitats, particularly those with conservation significance, within the study area;
- document the vertebrate and SRE invertebrate[1] fauna assemblage within the study area; and
- identify fauna (particularly Schedule and Priority listed fauna as well as potential short-range endemic taxa) of particular conservation significance occurring within the area.

2.3 Purpose of this Report

This report describes the methodology employed for the fauna survey of the Billiard project area. It documents the methods and results of the survey and identifies potential fauna of conservation significance occurring within the project area. Its intended use is as a supporting document for the environmental assessment of the project. Both the survey and report are subject to specific limitations that are discussed in detail in Section 4.5.

[1] Note that the survey referred to here was completed prior to publication of SRE survey guidelines (EPA 2009).

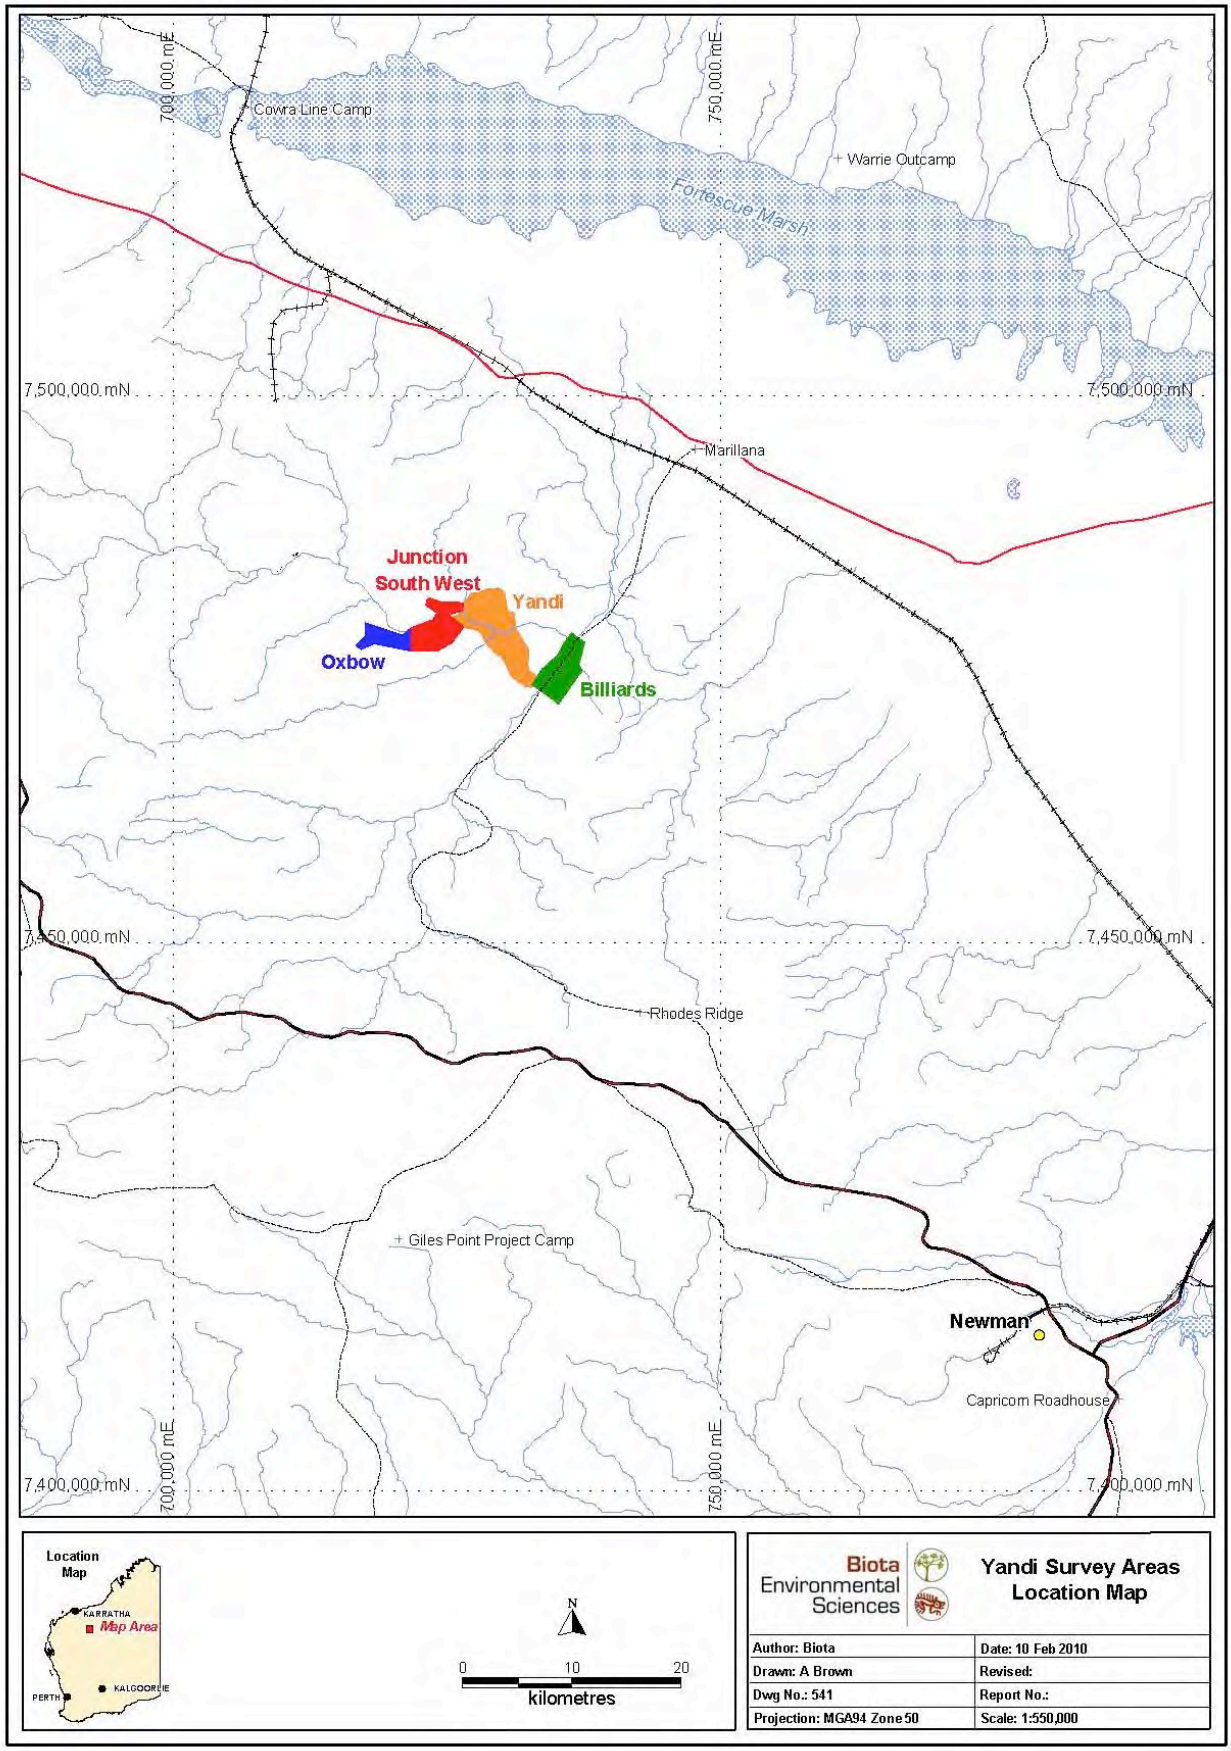

Figure 2.1: Location Map for the Yandicoogina Expansion fauna survey.

3.0 Existing Environment

3.1 Geological and Physiographic Context of the Study Are

3.1.1 Geology

Thorne and Trendall (2001) surveyed the geological units present within the proposed Yandicoogina Expansion study area, as part of a wider Pilbara project. There are six of their geological units present within the study area (Table 3.1; Figure 3.1).

Table 3.1: Geological units present in the study area.

Unit	Description
Czk	Calcrete - sheet carbonate, found along major drainage lines
Qw	Alluvium and colluvium - red-brown sandy and clayey soil; on low slope and sheetwash areas
PLHj	Weeli Wolli Formation: banded iron-formation (commonly jaspilitic), pelite, and numerous metadolerite sills
Czc	Colluvium - partly consolidated quartz and rock fragments in silt and sand matris; old valley-fill deposits, locally derived
Qa	Alluvium - unconsolidated silt, sand, and gravel; in drainage channels and adjacent floodplains
PLHb	Brockman Iron Formation: banded iron-formation, chert, and pelite

3.1.2 Land Systems

Land Systems (Rangelands) mapping covering the study area has been prepared to a draft stage by the Western Australian Department of Agriculture (van Vreeswyk et al. 2004). Land Systems are comprised of repeating patterns of topography, soils, and vegetation (Christian and Stewart 1953) (i.e. a series of "land units" that occur on characteristic physiographic types within the Land System).

A total of 107 Land Systems occur in the Pilbara bioregion. [This information was obtained by combining the Land System mapping for the Pilbara (van Vreeswyk et al. 2004) and Ashburton (Payne et al. 1988), and intersecting this with the Pilbara bioregion in ArcView 3.2.]

Land Systems mapped by the Department of Agriculture (van Vreeswyk et al. 2004) for the region including the Billiard study area are shown in Figure 4.3. Descriptions for each Land System within the project area are provided in Table 3.2.

Table 3.2: Land systems present in the study area (based on the 2009 survey boundary).

Land System	Description	Extent within bioregion (ha)	Extent within study area (ha)	% of total within bioregion
Boolgeeda (RGEBGD)	Stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands.	961,635	587	0.06
McKay (RGEMCK)	Hills, ridges, plateaux remnants and breakaways of meta sedimentary and sedimentary rocks supporting hard spinifex grasslands.	426,142	29	0.007
Newman (RGENEW)	Rugged jaspilite plateaux, ridges and mountains supporting hard spinifex grasslands.	1,993,742	390	0.02
River (RGERIV)	Active flood plains and major rivers supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands.	482,176	506	0.1
		3,863,695	1,512	

3.2 Biological Context of the Study Area

3.2.1 IBRA Bioregions and Subregions

The Interim Biogeographic Regionalisation for Australia (IBRA) recognises 85 bioregions (Environment Australia 2000). The Billiard study area lies entirely within the Pilbara bioregion.

The Pilbara bioregion is divided into four subregions, described in Environment Australia (2000) as the four major components of the Pilbara Craton. The Billiard study area is located within a crossover section between the east of the Hamersley subregion and the Fortescue subregion (Figure 4.3):

- Fortescue Plains (PIL2): alluvial plains and river frontages with salt marsh, Mulga-bunch grass and short grass communities on alluvial plains and River Gum (*Eucalyptus camaldulensis*) woodlands fringing drainage lines; and
- Hamersley (PIL3): mountainous area of Proterozoic ranges and plateaux with low Mulga (*Acacia aneura*) woodland over bunch grasses on fine textured soils, and Snappy Gum (*Eucalyptus leucophloia*) over *Triodia brizoides* on the skeletal sandy soils of the ranges.

3.2.2 Previous Fauna Surveys

Numerous surveys have been undertaken adjacent to the proposed project area, or are otherwise relevant because they have been undertaken nearby in the same sub-region of the Pilbara Craton. These include:

- Yandi (HI) biological survey (Ninox Wildlife Consulting 1995);
- BHPIO Yandi Stage II biological survey (Ecologia 1995);
- Mining Area C biological survey (see Woodward-Clyde 1997);
- Seasonal survey of the Hope Downs mine area (Ecologia 1997);
- Weeli Wolli Springs biological survey (Ecologia 1998a);
- West Angelas biological survey (Ecologia 1998b);
- BHPIO Marillana Creek biological surveys (summarised in Halpern Glick Maunsell 1999);
- BHPIO Marillana Creek rare fauna survey (Bamford and Associates 2003);
- Western Rail Corridor survey from the Hope Downs mine to the vicinity of Coondewanna Flats (Halpern Glick Maunsell 2000);
- Eastern Rail Corridor survey from the Hope Downs mine to Weeli Wolli siding (Halpern Glick Maunsell 2000);
- Vertebrate fauna survey of the proposed Hope Downs rail corridor from Weeli Wolli Siding to Port Hedland (Biota 2002a);
- Mulgara *Dasycercus cristicauda* and Bilby *Macrotis lagotis* surveys completed in late October 2001 (Biota 2002b);
- Vertebrate fauna survey of a proposed extension to the Hope Downs rail corridor through the Hamersley Range (Biota 2004a);
- Vertebrate fauna survey of a proposed addition to the Hope Downs rail corridor through the Chichester Range (Biota 2004b);
- An assessment of the fauna habitats and fauna assemblage of the proposed Fortescue Metals Group (FMG) Stage A rail corridor (Biota 2004c);
- An assessment of the fauna habitats and fauna assemblage of the proposed FMG Stage B rail corridor and mine areas (Biota 2004d);

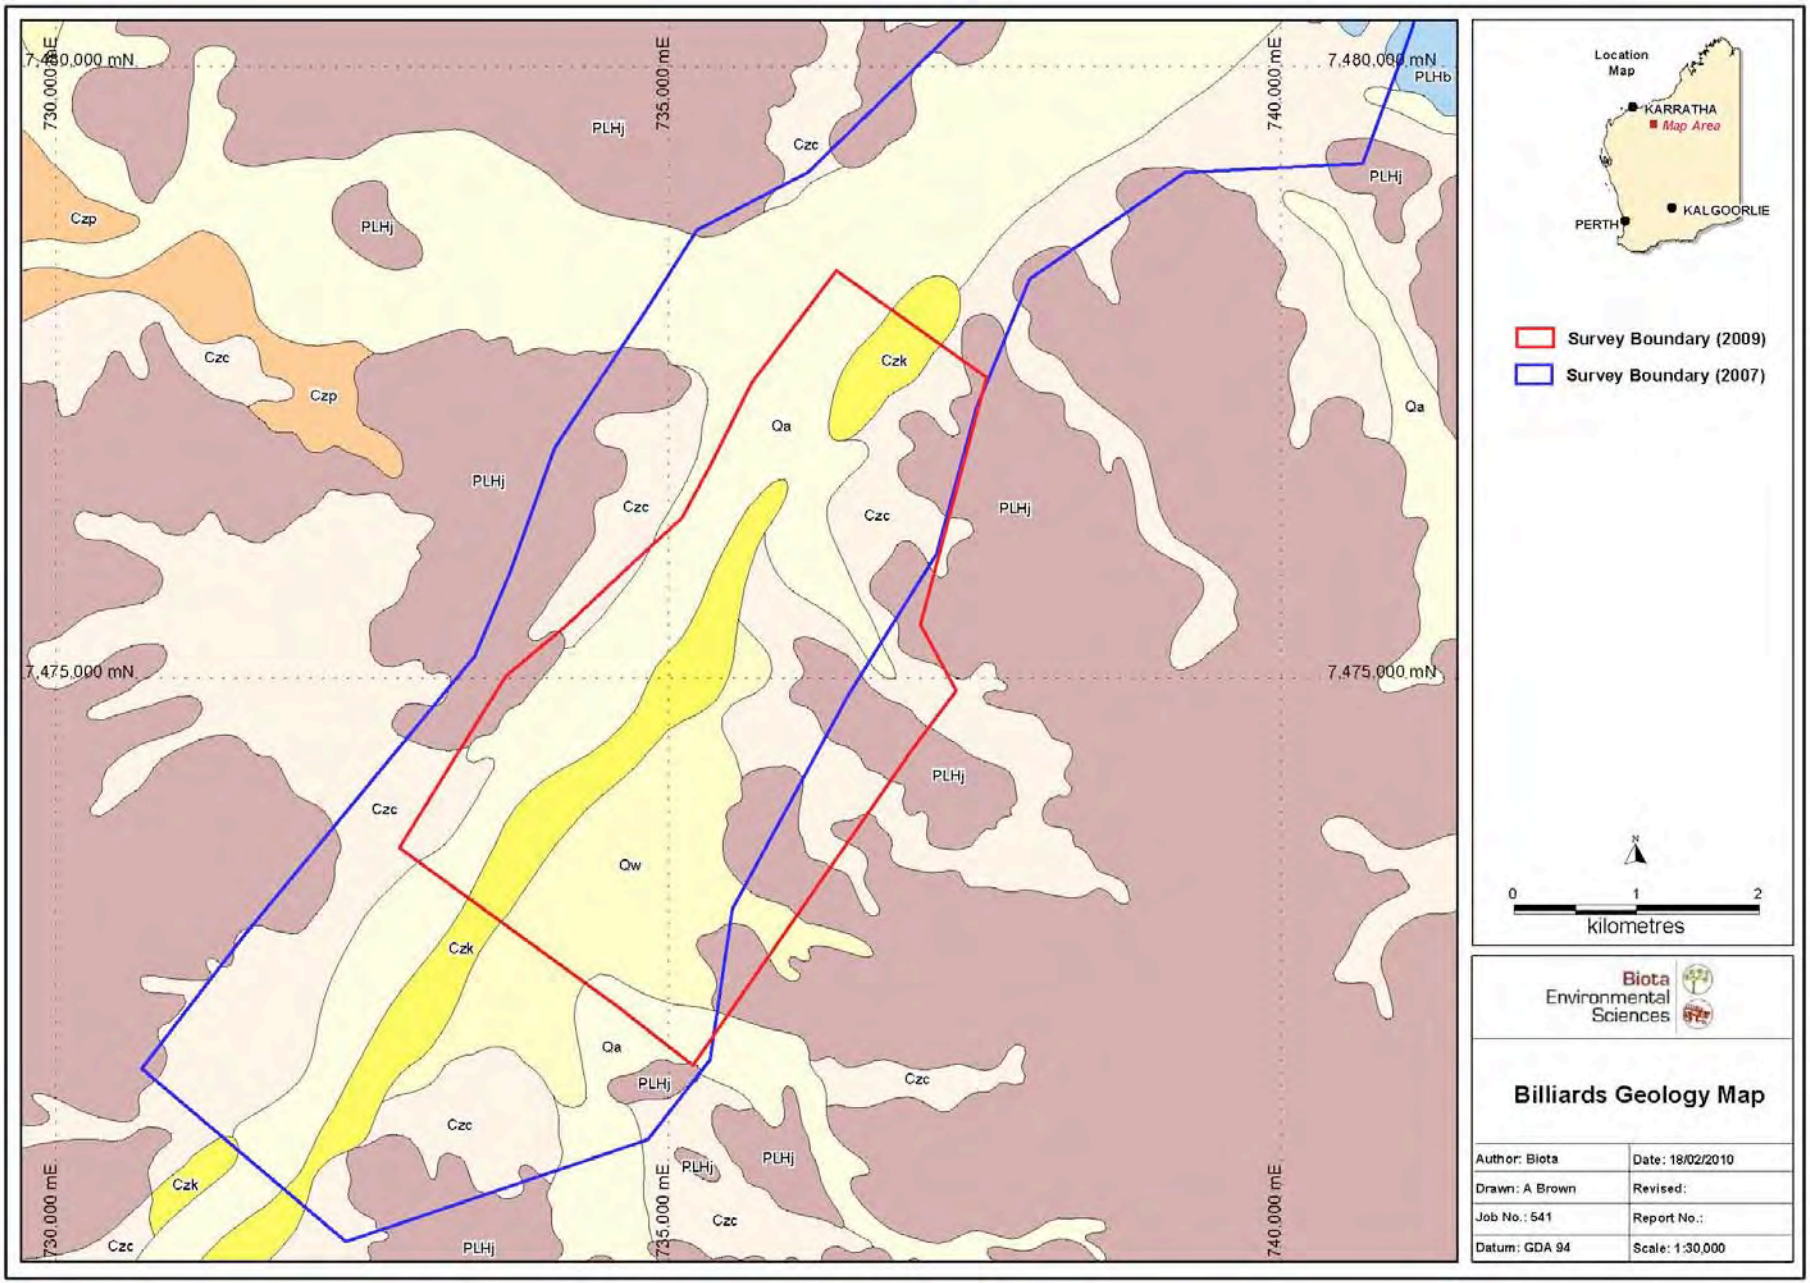

Figure 3.1: Geology mapping for the Billiard study area.

- A desktop fauna assessment and targeted invertebrate survey of the Yandi Expansion (Biota 2004e); and
- Yandicoogina Targeted Northern Quoll Survey (Biota 2009).

3.2.3 Conservation Reserves in the Locality

The main conservation reserve in the locality is the A-class Karijini National Park, approximately 100 km to the west-northwest of the study area.

While not listed as a conservation reserve the area known as Fortescue Marshes, approximately 45 km northeast of the study area, is listed as a Wetland of National Significance (Figure 2.1).

The Pilbara bioregion is listed as a medium priority for funding for land purchased under the National Reserves System Co-operative Program due to the limited representation of the area in conservation reserves. Portions of various pastoral leases in the region have been nominated for exclusion for public purposes in 2015, when the leases come up for renewal. Many of the submissions are from the Department of Environment and Conservation (DEC), with the intention of adding these areas to the existing conservation estate in order to provide a comprehensive, adequate and representative reserve system. None of these proposed exclusions are located in the vicinity of the expansion areas.

4.0 Study Methodology

4.1 Database Searches

Database searches were conducted of the DEC Threatened Fauna database (Appendix 1), the WA Museum FaunaBase (Appendix 2), and the *EPBC Act 1999* Protected Matters database (Appendix 3). These were completed using a point search utilising a 50 km buffer on the study area. The central coordinates for this search were:

- 22º47'5.61"S and 119º13'18.62"E

4.2 Survey Timing and Weather

The initial survey was conducted over a 7-day period between 5th July and 12th July 2008. Minimum temperatures during the survey ranged from 2.3°C to 11.5°C and maximum temperatures ranged from 20.4°C to 26.6°C (Table 4.1). No rainfall was recorded in Newman during the survey (Table 4.1).

The weather experienced during the fauna survey was comparable to the long-term climatic averages for Newman (Figure 4.1). The long-term averages for July include a maximum temperature of 22.3°C and a minimum temperature of 8.1°C. While the average rainfall for the month is 12.6 mm, rainfall events are typically only recorded sporadically at this time of year.

An additional survey phase targeting only invertebrate SRE taxa was completed between March 4th and 7th 2010.

Table 4.1: Daily meteorological observations at Newman Airport for July 2008 during the fauna survey (data provided by the Western Australian Bureau of Meteorology).

	5/07	6/07	7/07	8/07	9/07	10/07	11/07	12/07	Average

Rainfall (mm)	0	0	0	0	0	0	0	0	

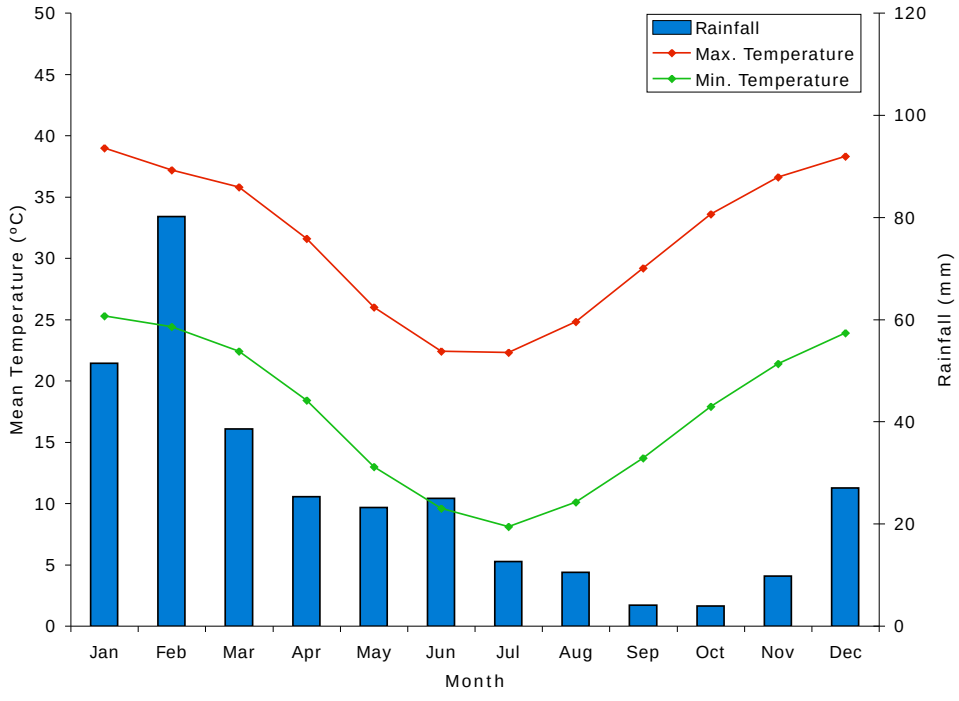

Figure 4.1: Long-term climatic averages for Newman (data provided by the Bureau of Meteorology).

4.3 Fauna Survey Team

The vertebrate fauna sampling for the field survey component of this study in 2008 was conducted under "Licence to Take Fauna for Scientific Purposes" No. SF006426 issued to Dr Phil Runham (Appendix 4). The fauna survey team comprised Dr Phil Runham, Mr Dan Kamien, Ms Erin Harris and Ms Jessica Cairnes (all of Biota Environmental Sciences). Mr Michael Greenham and Mr Ashley Johnsen participated in the set-up process for the fauna survey. The targeted SRE survey phase in 2010 was completed by Dr Phil Runham and Ms Erin Harris.

4.4 Systematic Censusing

4.4.1 Selection and Location of the Survey Sites

The principal component of the field survey consisted of systematic fauna sampling centred on a total of nine trapping sites, including six grids of 10 pit-traps in environments considered to represent the range of habitats available within the study area. Two funnel trap sites, each with 20 traps, and one site of 50 Elliott traps were also utilised.

Each survey site was installed within a defined habitat and was selected such that equal weight was given to accessibility of the sites in terms of regular inspection of traps (Plate 5.1 - Plate 5.9). Locations of trapping sites are presented in Table 4.2 and Figure 4.3.

4.4.2 Trapping Effort and Layout of the Trapping Grids

The trapping effort at each of the systematic trapping sites is detailed in Table 4.2. The locations of the trapping sites are shown in Figure 4.3.

During the fauna survey, pit-traps at six sites were arranged in a single row of ten traps, alternating between 20 litre buckets (~40 cm diameter) and PVC tubes (~20 cm diameter). Pit-traps were spaced at ~10 m intervals and connected with a single length of 30 cm tall flywire fence (Figure 4.2). Funnel traps were placed in a layout similar to that used for pit-traps, whilst Elliott traps were spaced at 5 - 10 m intervals along the base of breakaways or other suitable landscape features.

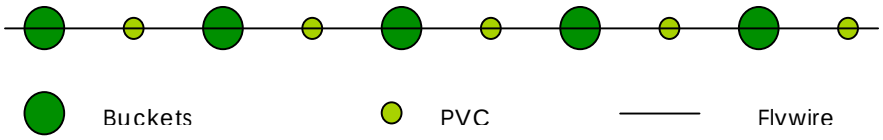

Figure 4.2: Indicative layout of trapping grids for the fauna survey.

Table 4.2: Trapping effort and trap location (WGS84, Zone 50) for the fauna survey.

Site	Location	Trap Type	Date Opened	Date Closed	Nights Open	No. of Traps	Total Trapping Effort

					Pit-trapping Nights		360
					Funnel Trap Nights		240
					Elliott Trap Nights		250
					Total Trap Nights		850

4.4.3 Avifauna Sampling

The avifauna of the project area was sampled using a combination of techniques, which included:

- unbounded area searches conducted at the systematic sampling grids (Table 4.3);
- unbounded area searches conducted at opportunistic locations containing habitats or microhabitats likely to support previously unrecorded species; and
- opportunistic observation of birds while driving around the study area.

A total of 17 avifauna censuses were completed across eight sites during the survey period (Table 4.3). Avifauna were sampled using 30 or 40-minute censuses comprising a total of 10 hours of dedicated avifauna sampling.

Censuses were supplemented by recording avifauna species observed opportunistically within the study area.

Table 4.3: Timing of avifauna censuses during the fauna survey.

Site	7/7/08	8/7/08	9/7/08	10/7/08	11/7/08	Total (min)

BIL13F & BIL14E			0725 - 0805	0910 - 0950	0947 - 1027	110
					Total	600 min

4.4.4 Bat Sampling

Bats were sampled at one site using an Anabat echolocation call detector (Table 4.4 and Figure 4.3; Plate 4.1).

Table 4.4: Location of bat sampling during the Billiard fauna survey.

Site	Location	Structure	Type	Date Opened	Date Closed	No. of Nights

					Total Bat Sampling Nights	4

Plate 4.1: Site BILANA01.

4.4.5 Non-systematic Sampling of Vertebrate Fauna

A range of non-systematic fauna survey activities was also undertaken by the Biota survey team to supplement the trapping and investigate additional habitats identified during the course of the survey. These included:

- habitat-specific searches for Schedule and Priority listed fauna species;
- searching of microhabitats for reptile, frog and small mammal species;
- opportunistic sightings and records;
- identification of road kills and other animal remains; and
- recording and identification of secondary signs including tracks, scats and diggings.

4.4.6 Invertebrate Sampling

Hand foraging was undertaken for pseudoscorpions, involving peeling bark and lifting rocks. The latter technique was also used to search for scorpions, with additional specimens collected from pit traps. Millipedes were searched for whilst raking leaf litter and other debris and whilst searching for land snails. Representative samples of other invertebrates from pit traps were collected, sorted to morphotype, placed in 70% ethanol and lodged with the WA Museum."

Groups targeted during these activities included:

- mygalomorph (trap-door) spiders;
- pseudoscorpions;
- scorpions;
- millipedes; and
- terrestrial snails.

Invertebrates were collected from systematic sampling sites in the course of removing vertebrates from traps, as well as searches being conducted in these habitats. Additional non-systematic sampling for invertebrate groups supporting potential short-range endemic (SRE) taxa was also conducted across four sites (Table 4.5) through bulk sampling of leaf litter under vegetation.

Table 4.5: SRE sampling sites within the Billiard study area.

Site	Easting (mE)	Northing (mN)
BIL SRE03	739 019	7 479 322
BIL SRE04	732 777	7 472 371
BIL SRE05	736 627	7 477 820
BIL SRE08	736 422	7 475 639

4.5 Survey Limitations

The following limitations should be recognised by the reader of this report:

- The Billiard fauna survey represents a single phase of sampling with an additional phase targeting SRE taxa. It is probable that a broad seasonal survey would augment the number of species recorded from the study area.
- Not all sections of the study area were ground-truthed or equally sampled for fauna. Parts of the study area were inaccessible by vehicle hence regular checking of fauna traps in these areas would not have been possible. However, systematic fauna sampling was completed on the basis of trapping grid installation in habitats considered to be representative of the range of units present within the development area.
- It should be noted that nightspotting was not undertaken during the survey in accordance with site operational and safety procedures.

- Terrestrial invertebrate sampling was targeted at a small number of specific groups that are known to potentially harbour SRE taxa. Whilst the survey guidelines for SRE sampling were not published prior to completion of the survey, retrospective analysis has demonstrated that the sampling techniques utilised are in accordance with the EPA Guidelines for this type of work (EPA 2009).

5.0 Results

5.1 Fauna Habitats

Six separate fauna habitat units were identified during the Billiard fauna survey (Table 5.1). The fauna habitats were distinguished primarily on the basis of landforms, but also on their associated vegetation and soil types.

Table 5.1: Fauna habitats utilised during the Billiard fauna survey, distinguished by landform.

5.2 Overview

The fauna survey of the Billiard project area yielded a total of 62 vertebrate fauna species representing 33 families (Table 5.2). Forty-four species of avifauna, eight species of mammals and 10 species of herpetofauna were recorded during the survey (Table 5.2).

Table 5.2: Vertebrate Fauna Groups recorded during the fauna survey.

Fauna Group	Number of Species	Number of Individuals
Avifauna	44	860
Non-volant mammals	5	15
Bats	3	-
Amphibians	2	2
Reptiles	8	29
Total	62	906

5.3 Avifauna

5.3.1 The Assemblage

A total of 44 species of birds was recorded during the Billiard fauna survey, comprising 23 families. This included 14 non-passerine species and 30 passerine species (Table 5.3).

The most commonly recorded species was the Zebra Finch *Taeniopygia guttata* with a total of 176 records, representing 20.5% of all avifauna records. The Masked Woodswallow *Artamus personatus* was also relatively common, with 14.0% of the total of all avifauna records for the survey. The most abundant family was the Estrildidae (finches) with 176 records accounting for 20.5% of all records (it should be noted these are all Zebra Finch records). The Meliphagidae (honeyeaters) was also an abundant family with 158 records representing 18.4% of the total avifauna records. The Meliphagidae was also the most speciose family with six species recorded (Table 5.3).

The most species rich sites were BILF13 with 28 species, followed by BILF10 (both situated on major drainage lines) with 27 species (Table 5.3).

5.3.2 Avifauna of Conservation Significance

One Migratory species, the Rainbow Bee-eater *Merops ornatus* was recorded during the Billiard fauna survey (Table 5.3).

A further five avifauna species of elevated conservation significance may occur within the study area.

Further information on these species of elevated conservation significance can be found in Section 6.4.

5.4 Mammals

5.4.1 The Assemblage – Non-volant mammals

A total of five species of non-volant mammals was recorded during the survey, comprising four families. This total includes four native mammal species and one non-native species (a total of 46.7% of all non-volant mammal records for the survey). The most commonly recorded native species was the Red Kangaroo Macropus rufus, with a total of four records, representing 26.7% of all non-volant mammal records.

Table 5.3: Avifauna species recorded during the Billiard fauna survey.

The most abundant family was the Macropodidae, with six records accounting for 40.0% of all records. The most speciose family observed was also the Macropodidae, which comprised two species (Table 5.4).

The most speciose site during the fauna survey was BIL07 (low stony hill slope), recording three species.

5.4.2 The Assemblage – Bats

Three species of bats were identified on the basis of ultrasonic call analysis from one site within the Billiard project area (Appendix 5). These comprised one Emballonuridae and two Vespertilionidae (Table 5.5).

5.4.3 Mammals of Conservation Significance

One mammal species of elevated conservation significance was recorded during the fauna survey; this was the Western Pebble-mound Mouse *Pseudomys chapmani* (see Section 6.4).

A further five mammal species of elevated conservation significance may occur within the study area, but were not recorded during the survey (see Section 6.4).

5.5 Herpetofauna

5.5.1 The Assemblage

A total of 10 species of herpetofauna were recorded during the fauna survey, comprising four families (Table 5.6). This total comprised two tree frogs (Hylidae), two dragons (Agamidae), five skinks (Scincidae) and two front-fanged snakes (Elapidae).

The most commonly recorded species was the dragon *Amphibolurus longirostris* with a total of 13 records, representing 42.0% of all herpetofauna records. The most abundant herpetofauna families were the Agamidae and the Scincidae; each with 14 records each accounting for 45.2% of all herpetofauna records. The most speciose family observed was the Scincidae, which comprised five species.

The most speciose site was BILF10 (major drainage line) with five species recorded (Table 5.6).

5.5.2 Herpetofauna of Conservation Significance

Two herpetofauna species of elevated conservation significance may occur within the study area, but were not recorded during the survey (see Section 6.4).

Table 5.6: Herpetofauna species recorded during the Billiard fauna survey.

5.6 Short-range Endemic (SRE) Taxa

A total of only three invertebrate taxa were collected from one site during the survey phases. None of these represented taxa considered to contain potential SRE fauna (Section 4.4.6). A further three sites (see Section 4.4.6) from which leaf litter samples were taken yielded no invertebrates at all. This result was probably attributable to the general lack of suitable microhabitats in the study area.

6.0 Discussion

The discussion following provides a synopsis of the significance of the fauna habitats and assemblages documented in the Billiard study area in the context of both the Pilbara Bioregion and the local area. The fauna assemblage is discussed predominantly in terms of the vertebrate families recorded and later in terms of fauna of elevated conservation significance.

6.1 Fauna Habitats

The survey of the Billiard study area identified six primary habitat types on the basis of landform, substrate types and vegetation assemblages (see Section 5.1). These six habitat types can be simplified into four habitat types based solely on landform:

- Major Drainage Line;
- Minor Drainage Line;
- Plain; and
- Low Stony Hill Slope.

This compares favourably with the previously available data, which indicate the potential for six habitat types (Biota 2004e). The four habitat types identified within the Billiard study area broadly comprise spinifex hummock grasslands on low stony hills, with open Eucalypt woodlands and *Acacia* shrublands over spinifex on valley floors, and Eucalypt woodlands along creeks. Creeklines were divided into the major creek habitat of Weeli Wolli and Marillana Creeks, and smaller secondary creeklines. The two habitat types not represented within the Billiard study area were low stony hills comprising areas of Mulga on hillcrests and rocky ridges / breakaways.

These habitats represent a small subset of the available habitats within the Pilbara and are largely considered to be ubiquitous throughout the Bioregion.

It should be noted here also that the habitats identified in the Billiard study area were characterised by high levels of degradation due to the presence of cattle and the frequency of fires. Relatively small, regenerating plants dominated much of the Triodia hummock grassland habitat, while the open areas between plants were frequently disturbed by cattle tracks. The dominant trees present in the *Acacia* groves close to the drainage line appeared largely intact, but understoreys were significantly impacted by cattle and / or the native vegetation replaced with *Cenchrus ciliaris*.

6.2 Fauna Assemblage

The fauna assemblage recorded during the survey of the Billiard study area comprised a total of 62 species, representing 33 families. This assemblage is considered to represent a subset of the vertebrate taxa that might be expected to occur in the study area, which has previously been estimated at 147 species across 51 families (Biota 2004e). For the greater part, the absence from the current study of families included in the earlier list can be attributed to factors including disturbed or unsuitable habitats, seasonality or the vagaries of species biologies.

Comparison of the avifauna assemblage with that compiled earlier (Biota 2004e) reveals the absence of nine families from the assemblage documented during this study. The absence of many of these species can be related to the state and/or availability of suitable habitat.

For instance, it is likely that members of avifauna families such as the Casuariidae (Emu), Otididae (Australian Bustard) and Turnicidae (Little Button-quail) were absent due to the extent of habitat that were highly degraded due to the presence of cattle. These areas were vegetated with only very small *Triodia* in most places and would have offered little foraging for frugivorous or

insectivorous species, and little protection for taxa reliant on *Triodia* respectively (Johnstone and Storr 1998). Portions of Weeli Wolli Creek influenced by existing dewatering activity (Figure 2.1) provide standing water within the study area, which accounts for the presence of the Ardeidae and Charadriidae (Table 5.3), however other water dependant taxa that may have been expected (Anatidae, Phalacrocoracidae, Threskiornithidae etc.) were not observed. Night birds (Tytonidae, Strigidae etc.) were not observed during the survey, this is likely due to nightspotting not occurring in accord with site operational procedures (see Section 4.5).

Amongst the mammals, there were only minor differences in the families recorded during the survey and those appearing in the earlier list (Biota 2004e). The sole native mammal family appearing in other documents (Biota 2004e) not documented by the current survey was the Molossidae. The one species representing this family in the vicinity of Billiard is the Northern Free-tail Bat *Chaerephon jobensis*. While this species may forage within the study area, it requires a core habitat that includes caves, this habitat is not available within the Billiard study area.

Although the herpetofauna documented during the current survey comprised representatives of four of the families, represented by 31 individuals, expected to occur in the Billiard study area, the numbers of both species and individuals were significantly below what might be expected for the area. However, this result is unsurprising given the low temperatures (both minima and maxima) experienced during the survey.

6.3 Fauna of Conservation Significance

6.3.1 Threatened Fauna Statutory Framework

Native fauna species that are rare, threatened with extinction, or have high conservation value are specially protected by law under the Western Australian *Wildlife Conservation Act 1950-1979*. In addition, many of these species are listed under the Federal *EPBC Act 1999*.

6.3.1.1 *EPBC Act 1999*

Fauna species of national conservation significance are listed under the *EPBC Act 1999*, and may be classified as 'critically endangered', 'endangered', 'vulnerable' or 'conservation dependent' (consistent with IUCN categories: http://www.iucn.org/themes/ssc/redlist2006/categories.htm).

Migratory wader species are also protected under the *EPBC Act 1999*. The national List of Migratory Species consists of those species listed under the following International Conventions:

- Japan-Australia Migratory Bird Agreement (JAMBA);
- China-Australia Migratory Bird Agreement (CAMBA); and
- Convention on the Conservation of Migratory Species of Wild Animals (Bonn Convention).

6.3.1.2 *Wildlife Conservation Act 1950-1979*

Classification of rare and endangered fauna under the *Wildlife Conservation (Specially Protected Fauna) Notice 2010* recognises four distinct schedules of taxa:

1. Schedule 1 taxa are fauna which are rare or likely to become extinct and are declared to be fauna in need of special protection;
2. Schedule 2 taxa are fauna which are presumed to be extinct and are declared to be fauna in need of special protection;
3. Schedule 3 taxa are birds which are subject to an agreement between the governments of Australia and Japan relating to the protection of migratory birds and birds in danger of extinction, which are declared to be fauna in need of special protection; and
4. Schedule 4 taxa are fauna that are in need of special protection, otherwise than for the reasons mentioned in paragraphs (1), (2) and (3).

In addition to the above, fauna are also classified under five different Priority codes:

Priority One Taxa with few, poorly known populations on threatened lands.
Taxa which are known from a few specimens or sight records from one or a few localities on lands not managed for conservation. The taxon needs urgent survey and evaluation of conservation status before consideration can be given to declaration as threatened fauna.

Priority Two Taxa with few, poorly known populations on conservation lands, or taxa with several, poorly known populations not on conservation lands.
Taxa which are known from few specimens or sight records from one or a few localities on lands not under immediate threat of habitat destruction or degradation. The taxon needs urgent survey and evaluation of conservation status before consideration can be given to declaration as threatened fauna.

Priority Three Taxa with several, poorly known populations, some on conservation lands.
Taxa which are known from few specimens or sight records from several localities, some of which are on lands not under immediate threat of habitat destruction or degradation. The taxon needs urgent survey and evaluation of conservation status before consideration can be given to declaration as threatened fauna.

Priority Four Taxa in need of monitoring.
Taxa which are considered to have been adequately surveyed or for which sufficient knowledge is available and which are considered not currently threatened or in need of special protection, but could be if present circumstances change. These taxa are usually represented on conservation lands. Taxa which are declining significantly but are not yet threatened.

Priority Five Taxa in need of monitoring.
Taxa which are not considered threatened but are subject to a specific conservation program, the cessation of which would result in the species becoming threatened within five years.

6.4 Threatened Fauna Species from the Study Area

Two species of elevated conservation significance were recorded during the Billiard fauna survey during (Table 6.1). The Western Pebble-mound Mouse *Pseudomys chapmani* is listed as Priority 4 species under State legislation. The Rainbow Bee-eater *Merops ornatus* is listed under Federal legislation as Migratory.

A further five species listed under Federal legislation as either Endangered or Vulnerable (and as Schedule 1 under State legislation) may also occur in the study area (Table 6.1). One Schedule 4 State-listed species may be present. A further seven Priority listed species under State legislation may also be present within the study area.

Table 6.1: Threatened Fauna Species possibly occurring within the Yandicoogina vicinity (* denotes species recorded during the Billiard fauna survey).

Threatened Fauna Species	Status	
	State	Federal

**Pseudomys chapmani* Western Pebble-mound Mouse	Priority 4	
Leggadina lakedownensis Short-tailed Mouse	Priority 4	
Macroderma gigas Ghost Bat	Priority 4	

6.4.1 Schedule Fauna Species

Pezoporus occidentalis Night Parrot
State: Schedule 1 'Critically Endangered'
Federal: Endangered

Distribution: Night Parrots have been reported from every state on the Australia mainland. Suitable habitat occurs, or has occurred, across most of the inland, covering at least half of the continent. Records are sparsely distributed through this area, however there do appear to be concentrations of records in western Queensland and the eastern Pilbara (Higgins 1999). There is a confirmed record from Minga Well north of the Fortescue Marsh (approx. 100 km north of Newman, and 250 km east of Brockman) and an unconfirmed sighting from near Yandicoogina on the edge of the Marshes (Mr Roy Teale, Biota, pers. obs.).

Ecology: Night Parrots inhabit areas where there is dense, low vegetation, which provides them shelter during the day. Most records come from hummock grasslands with spinifex (*Triodia*), from areas dominated by samphire, or particularly, where these two habitats are juxtaposed. It has been suggested that birds move into the grasslands when *Triodia* is seeding. They have also been reported in low chenopod shrublands with saltbush and bluebush, and from areas of Mitchell grass (*Astrebla*) with scattered chenopods.

Many records have come from waterholes, and almost all reports from areas of *Triodia* have noted the presence of nearby water. The species is secretive and almost all confirmed sightings of feeding or drinking birds have come after dark. Sightings during the day have almost always been of birds flushed from hiding places by herds of stock, dogs or fire. Birds typically sit very tight, flushing only if the disturbance is very close, actually affecting the clump of vegetation in which they are hiding. Early observers stressed the dependence of the parrot upon dense spinifex or samphire for daytime roosting spots and for nesting.

The Night Parrot is presumably like other arid zone birds in being markedly nomadic. The extent of the movements and the possibility of some seasonality in any part of the range are unknown. Several possible reasons have been proposed for the decline of this species in recent years, including (1) habitat loss through clearing, (2) changes in habitat from burning practices, (3) changes in habitat caused by or competition from stock, (4) reduced availability of water holes or surrounding suitable food plants and (5) predation from feral animals, particularly cats and foxes (cats were mentioned as a major problem by several early observers).

Likelihood of occurrence: While the proposed expansion areas contain areas of dense *Triodia*, this habitat is not restricted to these areas. Additionally, there are no areas vegetated with samphire in the vicinity of the study area.

Potential Impacts: As a Schedule 1 and federally listed species the Night Parrot is considered fauna in need of special protection. However the Night Parrot is considered unlikely to occur within the study area, and therefore the conservation status of this species would not be altered by the current proposal.

Dasyurus hallucatus Northern Quoll
State: Schedule 1 'Endangered'
Federal: Endangered

Distribution: The Northern Quoll was originally recorded across Northern Australia from the Northwest Cape, Western Australia to south-east Queensland but has declined in recent years. Its distribution is now restricted to six main areas: the north and western top end of the Northern Territory, north of Cape York, the Atherton-Cairns area, the Carnarvon Range-Bowen area of Queensland (Menkhorst and Knight 2001), and the northwest Kimberley and Pilbara regions of Western Australia (Braithwaite and Griffiths 1994). It also occurs on numerous islands off the Australian coast (Abbott and Burbidge 1995, Burbidge and McKenzie 1978).

Ecology: The Northern Quoll, *Dasyurus hallucatus*, is classed as a medium-sized marsupial, with adult weight ranging from 300 g up to 1,200 g. It is considered a partially arboreal and aggressive carnivore, preying on a varied diet of small invertebrates and vertebrates, including lizards, birds, snakes, small mammals and frogs (Oakwood 1997).

The Northern Quoll is a short-lived mammal with both sexes maturing at 11 months. Females reproduce only once each year, and all males die shortly after reproducing (Dickman and Braithwaite 1992, Oakwood 2000). The discrete male cohorts that arise within populations make quolls vulnerable to extinction. If no juvenile male quolls survive to adulthood, there will be no males for females to mate with the following year, and the local population will rapidly become extinct (Braithwaite and Griffiths 1994, Oakwood 2000). Therefore, any factor that results in significant increases in mortality rates of female and juvenile quolls could cause local extinction of quoll populations. This species is most abundant near major creek lines and rivers and in open, rocky habitat and is also commonly found in gorges, where breeding is successful (Oakwood 2008).

Likelihood of Occurrence: The Northern Quoll may occur in the rocky gorge located in the nearby Oxbow study area (OXB06E), as suitable habitat is available. However it is unlikely to occur within the Billiard project area due to a lack of suitable habitat.

Potential Impacts: Under the *EPBC Act 1999*, an action requires referral to the Federal Environment Minister if it is deemed likely to have a significant impact on a matter of national environmental significance (eg. a listed threatened species such as the Northern Quoll *Dasyurus hallucatus*). Given the apparently broad distribution of the Northern Quoll in the Pilbara bioregion, the relatively small scale of clearing required for the current proposal, and the lack of suitable habitat for this species in the current study area, it is considered that the action will not result in a significant impact to the Northern Quoll.

Macrotis lagotis Bilby
State: Schedule 1 'Vulnerable'
Federal: Vulnerable

Distribution: The former range of the Bilby included most of the semi-arid areas of mainland Australia, however, it is now confined to *Triodia* hummock grassland and *Acacia* scrub across parts of northern Australia. It has been reintroduced to parts of the south-west of Western Australia (eg. Dryandra Woodlands).

Ecology: The Bilby *Macrotis lagotis* is a medium sized ground mammal, ranging in weight from 1.0 - 2.5 kg. The species is apparently strictly nocturnal and constructs a substantial burrow system, which may be up to 3 m in length (Flannery 1990; Strahan 1995). Similar to the Mulgara, the species has been documented as holding temporary home ranges and showing relatively rapid changes in distribution in response to variation in habitat resources (Johnson 1995).

Likelihood of Occurrence: This species is considered unlikely to occur within the study area due to a lack of suitable habitat. It has never been recorded during any previous surveys in the vicinity of the Yandicoogina operations (see Section 3.2.2).

Potential Impacts: As a Schedule 1 and federally listed species the Bilby is considered fauna in need of special protection. However, the proposed development is not considered likely to have a significant impact upon this species.

Rhinonicteris aurantius Pilbara Orange Leaf-nosed Bat
State: Schedule 1 'Vulnerable'
Federal: Vulnerable

Distribution: The Pilbara Orange Leaf-nosed Bat is a relictual monotypic genus of the family Hipposideridae. It occurs in the Pilbara region of Western Australia, through the Kimberley and across the Top End into north-western Queensland (Churchill 1991).

Ecology: Occurrence of this species is influenced by the availability of suitable roost caves (Churchill 1998). That is, deep caves offering suitable humidity and a stable temperature. In the Pilbara, they are thought to be restricted to caves where at least semi-permanent water is nearby (Dr Kyle Armstrong, Kyoto University Museum, pers. comm. 2005).

Likelihood of Occurrence: The gorge located in the nearby Oxbow study area (OXB06E) may provide foraging opportunities for this species, but does not contain core roosting habitat. The Billiard study area does not contain suitable habitat for this species, and it is considered unlikely to occur.

Potential Impacts: As a Schedule 1 and federally listed species the Pilbara Orange Leaf-nosed Bat is considered fauna in need of special protection. However, the proposed development is not considered likely to have a significant impact upon this species.

Liasis olivaceus barroni Pilbara Olive Python
State: Schedule 1 'Vulnerable'
Federal: Vulnerable

Distribution: Regarded as a Pilbara endemic, this subspecies has a known distribution that coincides roughly with the Pilbara bioregion (Environment Australia 2000).

Ecology: The Pilbara Olive Python occurs in rocky areas within the Pilbara, showing a preference for rocky habitats near water, particularly rock pools.

Likelihood of Occurrence: This species may occur within the study area, as suitable habitat is available along the drainage lines.

Potential Impacts: As a Schedule 1 and federally listed species the Pilbara Olive Python is considered fauna in need of special protection. However, while the proposed development may impact on individuals it is not considered likely to have a significant impact upon this species.

Falco peregrinus Peregrine Falcon
State: Schedule 4

Distribution: The Peregrine Falcon has an almost cosmopolitan distribution, but is absent from most deserts and the Nullarbor Plain (Johnstone and Storr 1998). The only subspecies in Australia, *F. p. macropus*, is widespread throughout Australia and Tasmania (Marchant and Higgins 1993). The Australian population has been estimated at 3,000 to 5,000 pairs (Cade 1982). Whilst its status is difficult to determine in the Pilbara, it is certainly more common than its Priority 4 listed cogener *Falco hypoleucos*.

Ecology: This species inhabits a wide range of habitats including forest, woodlands, wetlands and open country (Pizzey and Knight 1997). The availability of prey is apparently more important than habitat in determining its distribution. Home ranges are probably defended year round and are variable in size, though typically not less than 480 ha (Marchant and Higgins 1993).

This species typically nests on cliffs (81% of nests Australia-wide) but also on stick nests (11%) and in tree hollows (8%). Breeding typically occurs from August to November (Johnstone and Storr 1998). Food is almost exclusively birds such as pigeons, parrots and passerines, which are captured in flight (Johnstone and Storr 1998). Mammals such as possums and rabbits have been recorded as rare prey items (Marchant and Higgins 1993).

Likelihood of Occurrence: This species may occur within the study area, as suitable habitat is available.

Potential Impacts: Loss of potential nesting and foraging habitat. With its cosmopolitan distribution, the conservation status of this species is unlikely to be affected by the proposal. The reason for initially listing this species was a global decline associated with the use of DDT.

6.4.2 Priority Fauna Species

Ramphotyphlops ganei
State: Priority 1

Distribution: This blind snake is poorly collected, being represented by just 15 specimens in the WA Museum collection. This distribution places them across the Pilbara Bioregion from Pannawonica in the west, to Millstream in the north, to Newman in the east.

Ecology: This species is poorly known, but as for most blind snakes, individuals are likely to mostly inhabit the topsoil, termitaria and ant nests. Blind snake diet typically consists of the eggs, larvae and pupae of ants (Storr et al. 2002). A single specimen (R151749) of this species was recorded from a pitfall trap in *Triodia epactia* hummock grassland on a scree slope of the Chichester Range near Redmont Camp (22°01'02"E, 118°58'57"E; Biota database).

Likelihood of Occurrence: There is insufficient data known about the ecology of this species to determine whether it may occur within the habitats available within the study area.

Potential Impacts: Some potential habitat loss and possible direct mortality associated with construction of mines and infrastructure. The conservation status of this species is difficult to ascertain from the small number of known records. However, the records of the species suggest that it does not have a restricted distribution, and therefore its conservation status is unlikely to be affected by the proposal.

Neochmia ruficauda subclarescens Star Finch
State: Priority 4

Distribution: This species is endemic to Australia where it is found from the Pilbara to south-eastern Australia. It remains most common in the tropics. Its population has not been estimated but the species is typically patchy and highly variable in abundance.

Ecology: This species is typically confined to reedbeds and adjacent vegetation communities along permanent waterways in the Pilbara. It is considered to be resident in most of its range but, as with all finches, the species can wander widely. Its ecology in the Pilbara is not well known but it has been observed feeding on the seed of sedges (*Cyperus* spp.) and Buffel Grass (*Cenchrus ciliaris*) (Dr Mike Craig, pers. obs.). In other parts of its range it feeds mainly on seeds, but insects are a common part of the diet during the breeding season. It typically nests in March and April, as seeds are maturing after summer cyclones, and its domed nest is usually built in reeds up to several metres from the ground. The clutch is between three and six and the young usually fledge after about 16 days. In captivity, Star Finches may produce as many as three broods per year.

The main threat to the species is considered to be overgrazing by stock along waterways, which destroys the riparian vegetation on which they depend (Garnett and Crowley 2000).

Likelihood of occurrence: This species was recorded during the Yandicoogina Expansion survey, at the nearby Junction South-West project area (Biota Internal Database). This species is likely to be found throughout the study area where suitable habitat is available.

Potential Impacts: Impacts would include loss of habitat and deaths of individuals, but are unlikely to make an impact on the conservation status of this species.

Falco hypoleucos Grey Falcon
State: Priority 4

Distribution: The Grey Falcon is endemic to Australia, where it is widespread but rare throughout the arid zone. Occurs in the northern half of Western Australia (Johnstone and Storr 1998). The Grey Falcon is a resident or nomadic visitor to inland parts of Australia (Pizzey and Knight 1997), but its movements are poorly understood. Its population has been estimated at 1,000 pairs, with about 5,000 individuals present post-breeding (Marchant and Higgins 1993).

Ecology: This species inhabits a wide range of habitats in the arid zone but appears to be least rare in lightly wooded coastal and riverine plains (Johnstone and Storr 1998). In the Pilbara, the Grey Falcon is mostly recorded from the coastal plain between the de Grey and Ashburton Rivers (Storr 1984). Little is known of the ecology of the species but it appears to feed primarily on birds, with mammals and insects forming variably important parts of the diet depending on season and location (Marchant and Higgins 1993; Johnstone and Storr 1998). It breeds in trees, such as *Eucalyptus* spp., typically in the abandoned nests of crows and butcherbirds (Marchant and Higgins 1993; Johnstone and Storr 1998). Eggs have been recorded in July and August but its breeding season is not certain.

Likelihood of Occurrence: This species may occur within the study area, as suitable habitat is available.

Potential Impacts: Potential impacts are likely to be similar to that of the Peregrine Falcon, such as loss of potential nesting and foraging habitat. The conservation status of this species, if present in the study area, is unlikely to be affected by the proposal.

Ardeotis australis Australian Bustard
State: Priority 4

Distribution: The Australian Bustard occurs over much of Western Australia, with the exception of the more heavily wooded southern portions of the state (Johnstone and Storr 1998). Its wider distribution includes eastern Australia and New Guinea. This species is classified as Near Threatened by Garnett and Crowley (2000).

Ecology: This species prefers open or lightly wooded grassland including Triodia sandplains (Johnstone and Storr 1998) and is considered scarce to common depending on season and habitat. It has an omnivorous diet and occurs in a relatively broad range of habitats, but appears to have some preference for grasshoppers and is often attracted to recently burnt areas (Marchant and Higgins 1993). This species is typically nomadic and has a large home range (Marchant and Higgins 1993). This species breeds from March to September and the eggs are laid on bare, preferably stony, ground (Johnstone and Storr 1998), which makes the eggs and young vulnerable to predation by foxes and cats.

Likelihood of Occurrence: This species has previously been recorded in the vicinity of the study area (Ecologia 1995 and Ecologia 1998a), and is likely to occur periodically within the study area as suitable habitat is available.

Potential Impacts: Impacts would include loss of habitat and deaths of individuals, but are unlikely to make an impact on the conservation status of this species.

Burhinus grallarius Bush Stone-curlew
State: Priority 4

Distribution: This species is widespread in Australia and southern New Guinea. It remains common in tropical Australia, but has declined alarmingly in temperate Australia and has disappeared from many regions (Marchant and Higgins 1993). It is found in the Kimberley and western portion of the remainder of the state west of a line joining Port Hedland, Leonora and Albany.

Populations are apparently secure in the Pilbara (Ron Johnstone, WA Museum, pers. comm. 2003). The Australian population has been estimated at c. 15,000 individuals.

Ecology: The nocturnal Bush Stone-curlews inhabit sparsely grassed, lightly timbered forest or woodland. In southern Australia, they persist most often where there is a well-structured litter layer and fallen timber debris. Individuals have an estimated home range of about 250 ha (Johnson and Baker-Gabb 1993). Foxes are usually considered to be the primary cause for their decline, hence their relative abundance in the tropics, but habitat clearance has also been identified as a threatening process (Garnett and Crowley 2000).

Likelihood of Occurrence: This species may occur within the study area, as suitable habitat is available.

Potential Impacts: Impacts would include loss of habitat and deaths of individuals, but are unlikely to make an impact on the conservation status of this species.

Pseudomys chapmani Western Pebble-mound Mouse
State: Priority 4

Distribution: *Pseudomys chapmani* is confined to the central and eastern Pilbara including Karijini National Park (Menkhorst and Knight 2001). This species is found on stony hillsides with hummock grasslands (Menkhorst and Knight 2001) and is common to very common in suitable habitat within the Hamersley and Chichester subregions of the Pilbara bioregion.

Ecology: The Western Pebble-mound Mouse is well known for its behaviour of constructing extensive mounds of small stones covering areas from 0.5 to 9.0 square meters (Start 2008). This mound formation is most common on spurs and gentle slopes with suitable size class stones.

Likelihood of Occurrence: This species was recorded during the Billiard fauna survey. This species is likely to be found throughout the study area where suitable habitat is available.

Potential Impacts: Impacts would include loss of habitat and deaths of individuals, however given the broad distribution of the Western Pebble-mound Mouse and the habitats occupied by the species in the Pilbara, it is unlikely that the conservation status of this species will be affected by the current proposal.

Leggadina lakedownensis Short-tailed Mouse
State: Priority 4

Distribution: Since 1997, the number of records of this species has increased substantially, such that it has now been recorded from over 20 locations (Armstrong et al. in prep). In Western Australia the distribution includes the Pilbara and Kimberley regions (Menkhorst and Knight 2001). We have recorded this species on cracking clay communities from Cape Preston (60 km west of Dampier) in the west to the northern flanks of the Fortescue Marshes in the east (Halpern Glick Maunsell and Biota 2000).

A recent taxonomic revision of *Leggadina* (Cooper et al. 2003) found that despite morphological variation, *L. lakedownensis* are genetically similar across their range and the variation is insufficient to warrant subspecific status for any regional populations.

Ecology: Regional records suggest that the primary mainland habitat comprises areas of cracking clay and adjacent habitats, although this species has also been recorded from hill tops (Dr Peter Kendrick, DEC Karratha, pers. comm. 2003) and sandy coastal areas near Onslow (Mr Garth Humphreys, Biota, pers. obs.). At Cape Preston this species was recorded from *Acacia xiphophylla* open shrubland over a mosaic of *Triodia wiseana* and *Eragrostis xerophila* mixed hummock and tussock grassland (Halpern Glick Maunsell and Biota 2000). At the Southern Plains study site (near Tom Price), numerous individuals were recorded from *Acacia xiphophylla* shrubland over *Triodia longiceps* and annual grasses (Biota 2002a). Along the proposed Hope Downs rail alignment, this species was recorded from *Astrebla pectinata* tussock grassland (Biota 2002b). During the FMG Stage A rail corridor survey (Biota 2004), this species was recorded from

Astrebla pectinata, *Aristida latifolia* tussock grassland on the self-mulching clays at a similar location in the Chichester Range.

Likelihood of occurrence: Not recorded to date and considered unlikely to occur within the study area due to a lack of suitable habitat.

Potential Impacts: The conservation status of this species is unlikely to be affected by the proposal.

Macroderma gigas Ghost Bat
State: Priority 4

Distribution: Previously distributed across most of inland and northern Australia, but now restricted to the tropical north of the continent (Churchill 1998). Occurs in a broad range of habitats, with their distribution being influenced by the availability of suitable caves and mines for roost sites (Churchill 1998). The distribution of Ghost Bats is fragmented, with each population showing some genetic differentiation (Armstrong and Wilmer 2004; Biota 2004f; and Dr. Kyle Armstrong, pers. comm. 2004). Populations in the Pilbara bioregion appear to be isolated from those in the Kimberley and Northern Territory.

Ecology: Ghost Bats are efficient predators of small birds, mammals and reptiles, and large insects, and they have highly developed echolocation, visual and hearing systems (Churchill 1998). Vocalisations audible to humans are used in their complex social interactions (Churchill 1998). Bats forage over large distances (ranges of ~ 60 ha; Churchill 1998), and the size of their foraging area is probably inversely related to the productivity of their landscape. Bats are known to have overlapping ranges (Churchill 1998).

Scat material from *M. gigas* is quite distinctive and can be used to identify temporary roosts or feeding sites. Fairy Martin (*Hirundo ariel*) nests within culverts provide a roosting substrate for *M. gigas* and culverts may function either as a night or feeding roost or (probably less commonly) as a temporary day roost. This is an example of where man-made habitat has benefited bats (Biota 2002c).

Likelihood of Occurrence: As for the Pilbara Orange Leaf-nosed Bat, the gorge located in the Oxbow study area (OXB06E) may provide foraging opportunities for this species, but does not contain core roosting habitat. This species is unlikely to occur within the Billiard study area as suitable habitat is not available.

Potential Impacts: Possible loss or disturbance of roosting sites and foraging habitat. No effect on the conservation status of the species is expected.

6.4.3 Migratory and Marine Avifauna Species

Avifauna species can be listed as migratory and/or marine species under the *EPBC Act 1999*. Database searches completed for this study indicate the following species listed as Migratory under the act could occur in the study area: Rainbow Bee-eater, Night Parrot, Great Egret and Cattle Egret. The following species listed as Marine could also be present: Fork-tailed Swift, Great Egret, Cattle Egret, Oriental Plover and Rainbow Bee-eater. Of these taxa, only the Rainbow Bee-eater has been confirmed as occurring in the study area.

The proposed Yandicoogina Expansion is unlikely to adversely affect the conservation status of any of these species. Therefore they would not require further specific consideration as part of the assessment process.

6.5 Short-range Endemic (SRE) Fauna

The small number of invertebrate taxa collected during the survey may be considered indicative of the suitability of the available microhabitats for potential SRE taxa. A large proportion of the

study area comprising loamy substrates adjacent to the drainage line exhibited the detrimental effects of cattle.

The lack of ground level vegetation due to grazing or trampling by cows corresponds with low levels of leaf litter, which may otherwise provide habitat for such groups as millipedes (Diplopoda) and some trapdoor spiders (Mygalomorphae). Additionally, the high quantity of disturbance to open ground, and to vegetation by frequent burning, reduce the faunal values of the available habitats for target groups.

6.6 Conclusions

The fauna habitats and assemblages recorded for the Billiard study area during this fauna survey represent a subset of those that might be expected to occur across the Pilbara Bioregion. The fauna habitats in particular are considered to be widespread and common throughout the local area and within the wider region. Additionally, the relatively poor quality of the available habitats due to the presence of cattle and the frequency of fires reduces the value of the habitats for fauna that might typically be adversely affected by the proposed expansion.

On this basis, the expansion of existing operations at Yandicoogina is unlikely to adversely affect the conservation value of the fauna habitats and assemblages in the local area or wider Bioregion. Similarly, the development is not considered likely to detrimentally alter the conservation significance of those fauna species having elevated conservation significance, including Schedule and Priority listed fauna as well as SRE invertebrate fauna.

#	Date	Certainty	Seen	Location Name	Method

Schedule 1 - Fauna that is rare or is likely to become extinct

Dasyurus hallucatus **Northern Quoll** *1 records*

This carnivorous marsupial occurs across much of northern Australia with a disjunct population in the Pilbara. Occurs in a wide range of habitats but most suitable habitat appear to be rocky areas.

1980	1		NULLAGINE	

Liasis olivaceus barroni **Pilbara Olive Python** *1 records*

2004	1	1	Newman	Caught or trapped

Priority Two: Taxa with few, poorly known populations on conservation lands

Ctenotus uber johnstonei *1 records*

This species of skink is associated with small rock outcrops on open sandy and stony plains.

2001	1	2	Fortescue Valley	Caught or trapped

Priority Four: Taxa in need of monitoring

Macroderma gigas **Ghost Bat** *2 records*

This species is Australia's only carnivorous bat and has a patchy distribution across northern Australia. It shelters in caves, mine shafts and deep rock fissures and is sensitive to disturbance.

1998	1	1	West Angela Hill	Caught or trapped
2007	1	1	Newman	Caught or trapped

Pseudomys chapmani **Western Pebble-mound Mouse, Ngadji** *30 records*

This species is well-known for the characteristic pebble-mounds which it constructs over underground burrow systems. These mounds are most common on spurs and lower slopes of rocky hills.

1979	1	2	West Angela Hill	Caught or trapped
1979	1	2	West Angela Hill	Caught or trapped

Ardeotis australis **Australian Bustard** *3 records*

This species is uncommon and may occur in open or lightly wooded grasslands.

	2007	1	1	Newman	Day sighting
	2007	0	1	Newman	Day sighting
	2008	1	1	Newman	Day sighting

Burhinus grallarius **Bush Stonecurlew** *1 records*

A well camouflaged, ground nesting bird which prefers to 'freeze' rather than fly when disturbed. It inhabits lightly timbered open woodlands.

	2007	1	2	Newman	Day sighting

Neochima ruficauda subclarescens **Star Finch (western)** *1 records*

A nomadic species inhabiting grasslands and eucalypt woodlands near water.

	2008	1	1	Newman	Day sighting

Leiopotherapon aheneus **Fortescue Grunter** *1 records*

A species of freshwater fish restricted to the Prince Regent and Roe River systems of the Kimberley region of Western Australia. Inhabits open rocky pools with minimal aquatic vegetation.

WILDLIFE CONSERVATION ACT 1950
REGULATION 17

LICENCE TO TAKE FAUNA FOR SCIENTIFIC PURPOSES

THE UNDERMENTIONED PERSON MAY TAKE FAUNA FOR RESEARCH OR OTHER SCIENTIFIC PURPOSES AND WHERE AUTHORISED, KEEP IT IN CAPTIVITY, SUBJECT TO THE FOLLOWING AND ATTACHED CONDITIONS, WHICH MAY BE ADDED TO, SUSPENDED OR OTHERWISE VARIED AS CONSIDERED FIT.

DIRECTOR GENERAL

CONDITIONS

1 THE LICENSEE SHALL COMPLY WITH THE PROVISIONS OF THE WILDLIFE CONSERVATION ACT AND REGULATIONS AND ANY NOTICES IN FORCE UNDER THIS ACT AND REGULATIONS.

2 UNLESS SPECIFICALLY AUTHORISED IN THE CONDITIONS OF THIS LICENCE OR OTHERWISE IN WRITING BY THE DIRECTOR GENERAL, SPECIES OF FAUNA DECLARED AS LIKELY TO BECOME EXTINCT, RARE OR OTHERWISE IN NEED OF SPECIAL PROTECTION SHALL NOT BE CAPTURED OR OTHERWISE TAKEN.

3 NO FAUNA SHALL BE TAKEN FROM ANY NATURE RESERVE, WILDLIFE SANCTUARY, NATIONAL PARK, MARINE PARK, TIMBER RESERVE OR STATE FOREST WITHOUT PRIOR WRITTEN APPROVAL OF THE DIRECTOR GENERAL. NO FAUNA SHALL BE TAKEN FROM ANY OTHER PUBLIC LAND WITHOUT THE WRITTEN APPROVAL OF THE GOVERNMENT AUTHORITY MANAGING THAT LAND.

4 NO ENTRY OR COLLECTION OF FAUNA TO BE UNDERTAKEN ON ANY PRIVATE PROPERTY OR PASTORAL LEASE WITHOUT THE CONSENT IN WRITING OF THE OWNER OR OCCUPIER, OR FROM ANY ABORIGINAL RESERVE WITHOUT THE WRITTEN APPROVAL OF THE DEPARTMENT OF INDIGENOUS AFFAIRS.

5 NO FAUNA OR THEIR PROGENY SHALL BE RELEASED IN ANY AREA WHERE IT DOES NOT NATURALLY OCCUR, NOR HANDED OVER TO ANY OTHER PERSON OR AUTHORITY UNLESS APPROVED BY THE DIRECTORGENERAL, NOR SHALL THE REMAINS OF SUCH FAUNA BE DISPOSED OF IN SUCH MANNER AS TO CONFUSE THE NATURAL OR PRESENT DAY DISTRIBUTION OF THE SPECIES.

6 THIS LICENCE AND THE WRITTEN PERMISSION REFERRED TO AT CONDITIONS 3 & 4 MUST BE CARRIED BY THE LICENSEE OR AUTHORISED AGENT AT ALL TIMES FOR THE PURPOSE OF PROVING THEIR AUTHORITY TO TAKE FAUNA WHEN QUESTIONED AS TO THEIR RIGHT TO DO SO BY A WILDLIFE OFFICER, ANY OTHER STATE OR LOCAL GOVERNMENT EMPLOYEE OR ANY MEMBER OF THE PUBLIC.

**********ANY INTERACTION INVOLVING GAZETTED THREATENED FAUNA THAT MAY BE HARMFUL AND/OR INVASIVE MAY REQUIRE APPROVAL FROM THE COMMONWEALTH DEPT OF THE ENVIRONMENT AND WATER RESOURCES, PHONE 02 6274 1900. INTERACTION WITH SUCH SPECIES IS CONTROLLED BY THE COMMONWEALTH GOVERNMENT'S "ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION ACT 1999" & "ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION REGULATIONS 2000" AS WELL AS DEC'S WILDLIFE CONSERVATION ACT & REGULATIONS.**********

8 NO BIOPROSPECTING INVOLVING THE REMOVAL OF SAMPLE AQUATIC AND TERRESTRIAL ORGANISMS (BOTH FLORA AND FAUNA) FOR CHEMICAL EXTRACTION AND BIOACTIVITY SCREENING IS PERMITTED TO BE CONDUCTED WITHOUT SPECIFIC WRITTEN APPROVAL BY THE DIRECTOR GENERAL OF DEC.

9 FURTHER CONDITIONS (NUMBERED TO) ARE ATTACHED.

Bat Call Identifications

Specialised Zoological

Bat call identification

from Yandi, WA

Type:	Bat Call Analysis
Prepared for:	Biota Environmental Sciences
Date:	10 April 2009
Job No.:	SZ098
Prepared by:	Specialised Zoological Kyle Armstrong and Yuki Konishi ABN 92 265 437 422 0404 423 264 kyle.armstrong@graduate.uwa.edu.au kyle.n.armstrong@gmail.com

SZ098: *Bat call identification from Yandi, WA*

SUMMARY

Bat identifications from Anabat echolocation call recordings are provided from Yandi, Western Australia. Six species were identified as being present (Table 1).

The calls of the yellow-bellied sheath-tailed bat *Saccolaimus flaviventris* can sometimes be confused with those of the northern free-tailed bat *Chaerephon jobensis*. In all cases the calls appeared to be from *S. flaviventris*.

Details supporting the identifications are provided, as recommended by the Australasian Bat Society (ABS 2006). A summary of pulse parameters is provided in Table 2, and representative call sequences are illustrated in Figure 1. Further data is available should verification be required.

METHODS

Signals as recorded with Anabat SD1 and Anabat II – CF-ZCAIM units were supplied as downloaded sequences, which were examined in AnalookW 3.7a software. Three call variables were measured on good quality search phase pulses in representative call sequences: pulse duration (milliseconds), maximum frequency (kHz) and characteristic frequency (equivalent to minimum frequency; kHz). Species were identified based on information in McKenzie and Muir (2000). Nomenclature follows Armstrong and Reardon (2006).

Definition of confidence level codes:

H High. Unambiguous identification of the species at the site based on measured call characteristics and comparison with available reference material. Greater confidence in this ID would come only after capture and supported by morphological measurements or submission of a specimen/tissue to a museum.

NC Needs Confirmation. Either call quality was poor, or the species cannot be distinguished reliably from another that makes similar calls. Alternative identifications are indicated in the Summary section of this report. If this is a species of conservation significance, further survey work might be required to confirm the record.

ACKNOWLEDGEMENTS

The author would like to acknowledge and thank Suzi Wild and Arnika Tieman from Rio Tinto Iron Ore for their help and support throughout the timeframe of this project. Other help from Rio Tinto Iron Ore staff members include: Richard de Lange for accessing and collating Yandi bore data; Martin Brownlee for accessing and analysing discharge data; Corneli Van Der Merve for providing guidance in the selection of suitable bores adjacent to the dewatering bore field to represent groundwater drawdown over the time period of the study and Maree Swebbs for her GIS work in generating cross sections of the creek topography for monitoring site locations. The input provided by Richard, Martin, Corneli and Maree was very helpful and much appreciated. Thanks are also extended to Robert Lavis of the Department of Water for the timely and courteous provision of rainfall and streamflow data from their database. The provision of vegetation survey data collected by Mattiske Consulting and supplied in a database is also gratefully acknowledged. Frank Batini provided external peer review of this report, and his comments and suggestions were much appreciated by the author.

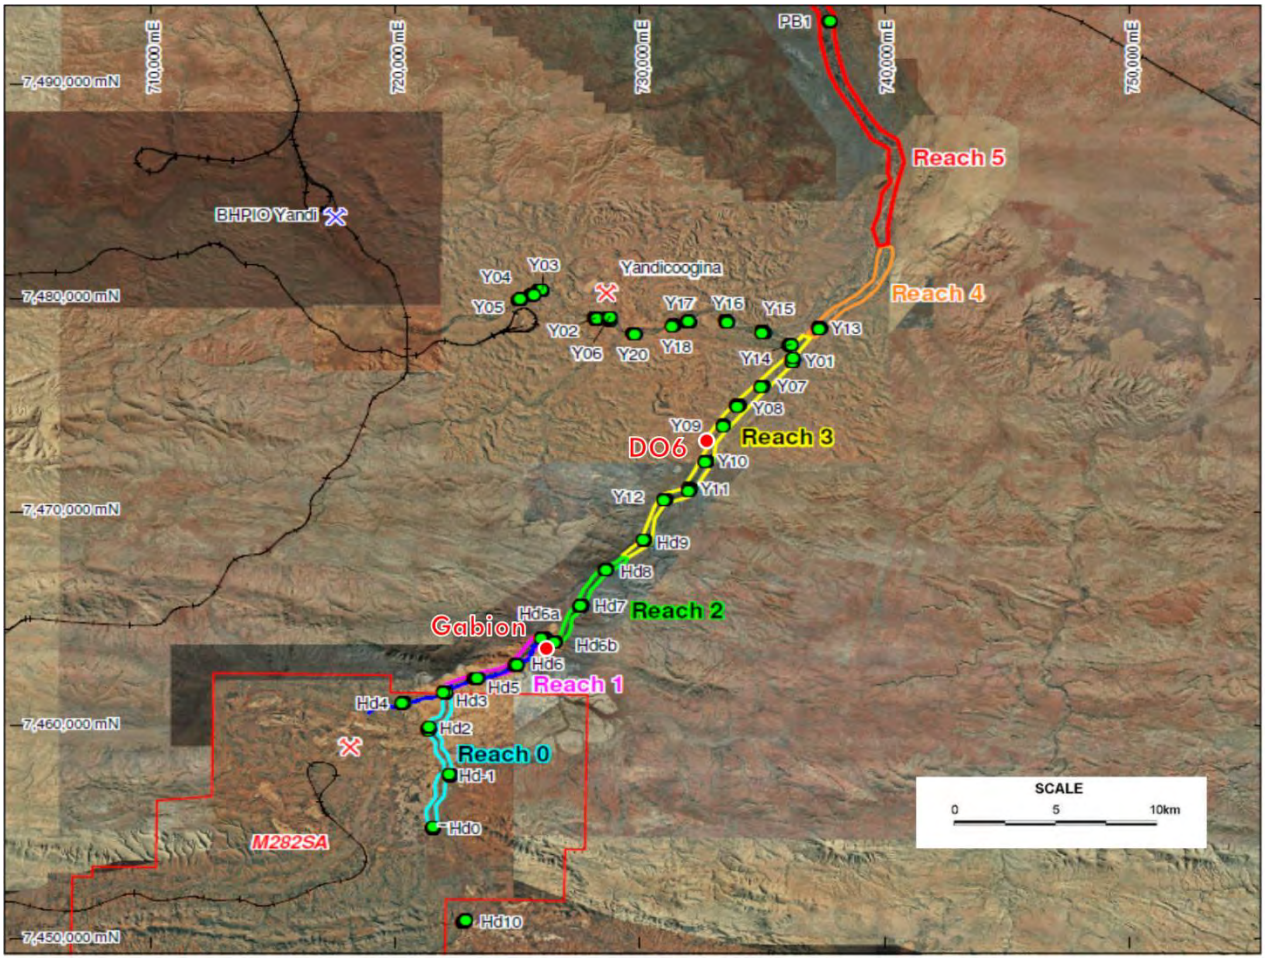
SUMMARY

This study collated and analysed relevant data and information on the response of riparian vegetation along Weeli Wolli Creek to drawdown and discharge associated with below water table mining activities at the Hope Downs 1 (HD1) and Yandicoogina (Yandi) mine sites (Figure 1). The aim was to undertake a comprehensive study to identify and better understand the mechanisms underlying the system's response to dewatering, and water discharges based on the integration of existing data. Understanding of these mechanisms and where they are operating in different parts of the system are important for predicting and managing the short and long-term impacts of dewatering and discharge.

Quarterly tree health monitoring data collected by digital canopy photography monitoring of crown and foliage cover was used to assess vegetation responses between October 2006 and December 2014. Data was collected at 26 sites distributed along Weeli Wolli Creek, including 3 reference sites assumed unaffected by drawdown or discharge (Figure 1). Some sites were located within the zone experiencing groundwater drawdown due to dewatering operations at HD1 and Yandi. Others were located downstream of two discharge outlets into Weeli Wolli Creek, the gabion and discharge outlet six (DO6, Figure 1). The species monitored were *Eucalyptus camaldulensis* and *victrix,* the most common tree species along the creek. More limited foliage and crown cover data was also available for *Melaleuca argentea* collected between June 2010 and December 2014.

Long-term rainfall and streamflow data sourced from the Department of Water (DoW) was collated and analysed to context post-impact rainfall and flows against historical norms. Discharge and reinjection data was sourced from Rio Tinto and analysed to quantify discharge rates and cumulative volumes for intervals between tree health monitoring. Transects of bores relevant to understanding the hydrological impacts of dewatering, discharge and reinjection on water levels beneath tree health monitoring sites were identified and all available data was accessed and collated. For sections of Weeli Wolli Creek where bore data was unavailable, water levels were estimated using river stage data from DoW. Since bores and river gauges were generally not located at tree health monitoring sites, estimated levels beneath these sites were derived by interpolation between adjacent monitoring points. These interpolations enabled estimation of depth to water at monthly intervals for the majority of tree health monitoring sites. Depth to water wasn't estimated for sites between the Tarina gauging station and bores at Yandi, because of the large distance between these monitoring points which increased uncertainty over the validity of interpolations. Relationships between foliage cover and rainfall, streamflow, discharge and depth to water were investigated using linear regression analyses.

Figure 1: Location of reaches and tree health monitoring plots on Weeli Wolli Creek. The figures also shows the location of discharge outlets at the gabion and DO6



Operations at both HD1 and Yandi mine sites impacted on hydrological parameters significant for riparian vegetation along Weeli Wolli Creek. Drawdown associated with dewatering at both sites reduced both groundwater levels and water levels in the alluvium. The disposal of water extracted by dewatering by reinjection into a borefield at Yandi and as discharge into Weeli Wolli Creek from the gabion and DO6 increased levels in the alluvium.

Substantial variation in foliage cover found between sites prior to the start of dewatering and discharge are indicative of the inherent variability of the riparian vegetation associated with Weeli Wolli Creek. Initial foliage covers in October 2006 ranged from 0.33 to 0.61 with a coefficient of variation of 14.7%. Foliage cover also exhibited temporal variation associated with seasonal conditions. For example, foliage cover at reference site HD0 ranged from 0.41 and 0.54 with a coefficient of variation of 8.5% for the period of monitoring.

Impacts of dewatering on groundwater levels at HD1 were observed to extend about 6.5 km downstream along Weeli Wolli Creek and about 6.4 km upstream. The significance and extent of influence of drawdown at Yandi on levels relevant for riparian vegetation along

Weeli Wolli Creek couldn't be readily assessed because impacts were confounded by discharge and reinjection.

Analyses of long-term rainfall and streamflow data downstream of the gabion at the Tarina station suggest that streamflow has increased disproportionately in years after the start of discharge. However streamflow at Waterloo Bore, downstream of both discharge outlets and the Marillana Creek confluence, remains unaffected by cumulative impacts of discharge from BHP Billiton and Rio Tinto Iron Ore operations at HD1 and Yandi. This supports the thesis that cumulative impacts of mining operations in Weeli Wolli catchments have not altered hydrological conditions at the Fortescue Marsh further downstream.

At sites closest to the dewatering bore field at HD1, groundwater was found to be at depths ranging from 3.7 to 11.5 m prior to dewatering, potentially accessible to tree roots. In response to dewatering at these sites, groundwater levels fell by more than 30 m. Foliage cover responses to drawdown were quite site-specific and confounded in places by changes in surface water hydrology. It was concluded that the *Eucalyptus* species studied were resilient to drawdown if surface water availability was maintained. Foliage cover of eucalypts in areas of drawdown was responsive to supplemental irrigation via a spur system. However, the data suggests that spur discharge may have over-compensated for any reduced water availability caused by drawdown. It is possible that *Eucalyptus* species have been over-irrigated such that enhanced foliage cover is in disequilibrium with water available under undisturbed conditions. This has implications for the cessation of spur discharge and the transition back to an unmanaged system.

A preliminary analysis of water levels in the alluvial aquifer suggests that both the frequency and duration of streamflow in unirrigated parts of Weeli Wolli Creek upstream of the gabion were reduced by drawdown. Thus falling water levels exert a dual influence through decreasing the accessibility of water from the saturated zone, and decreasing availability from unsaturated alluvium. Given this significance, an important consideration in understanding impacts of drawdown on vegetation health is adequate monitoring of depth to water as well as streamflow responses and water availability in the unsaturated zone.

Responses in eucalypt foliage cover to discharge indicate variable impacts of discharge on tree health. Foliage cover at sites downstream of the gabion showed statistically significant negative responses to gabion discharge rates or to cumulative discharges. Impacts extended as far as site HD9, approximately 6.2 km downstream of the gabion. However, sites beyond this point remained unaffected by impacts of HD1 discharge from the gabion. Closer to Yandi operations, foliage cover at all sites downstream of DO6 to Y13 were negatively impacted by discharge. Foliage cover showed statistically significant negative

responses to discharge rates and cumulative volumes. The greater impact on foliage cover of discharges at Yandi results from generally shallower water tables in the alluvium compared with sites impacted by HD1 discharge alone. Relationships between foliage cover and depth to water showed statistically significant reductions in foliage cover with rising levels at sites Y08 and Y01. However, the response of individual trees at a site wasn't uniform, and at most of the sites there were some trees that increased their foliage cover. This finding has significance since it suggests that a proportion of trees at each site occupy an ecological niche which has allowed them to maintain or increase their canopy. Trees maintaining or increasing foliage cover tended to be at higher elevations at some, but not all, sites.

The negative impacts of discharge on foliage cover of *Eucalyptus* species at some sites was supported by other responses observed in this study. In contrast with the generally positive responses in foliage cover to annual rainfall and streamflow observed for reference and drawdown sites, foliage cover at discharge sites was not enhanced in years with greater annual rainfall or streamflow. Foliage cover was either unresponsive or showed trends of declining foliage cover as annual rainfall and streamflow increased, suggesting conditions of water excess could be detrimental to cover. Lower foliage cover found at the start of this study for eucalypts at sites with perennial flow compared with annual sites was also indicative of negative responses to shallow water tables.

In contrast to the decline in foliage cover with cumulative discharge, a stress index calculated from qualitative assessments of tree condition for *Eucalyptus* species on vegetation survey transects at discharge sites showed no decrease with cumulative discharge. Where monitoring sites were in close proximity, there was no correlation between foliage cover and stress index parameters. These findings suggest that eucalypts selected for foliage cover monitoring may not be representative of trees across the riparian zone at each site location. Trees monitored for foliage cover may represent the more severely-affected trees, with vegetation monitoring transects better capturing responses of eucalypts across the riparian zone.

In this study, the trend in decreasing foliage cover with cumulative discharge observed for several discharge sites cannot be consistently attributed to rising water levels. Further investigation to establish with greater certainty the water levels at each site may confirm whether or not this is the key factor causing decline. Foliage cover responses to cumulative discharge may not be simply due to waterlogging, but could also relate to indirect effects of discharge e.g. through increasing disease, unknown impacts of precipitate or changing soil

chemistry and plant nutrition. If waterlogging isn't identified as the key determinant of foliage cover decline, further studies are warranted to understand the underlying mechanisms behind the decrease in foliage cover with cumulative discharge. Improved understanding of factors contributing to foliage cover decline will both inform management decisions and facilitate the prediction of discharge impacts from future below water table operations.

There is little evidence from this study to support differential responses of *E. victrix* or *E. camaldulensis* to drawdown, discharge or to rising water levels. However, the capacity to undertake a systematic comparison of their respective responses in this study was limited by the small number of trees of a species sampled at some sites (ie unequal replication).

Understanding responses of *Melaleuca argentea* to drawdown is limited in this study by the short timeframe of monitoring (June 2010 to December 2014) and the minimal drawdown (< 0.7 m) experienced over the monitoring period. Responses to irrigation by spur discharge may have also confounded melaleuca foliage cover response to drawdown. None of the components of melaleuca health monitored by digital canopy photography (foliage cover, crown cover and canopy cover) were found to be responsive to changing depth to water. The significance of discharge for the health of *Melaleuca argentea* is also unclear from this study, principally because of contrasting responses in foliage cover, crown cover and canopy cover to discharge. Further studies are warranted to understand the responses in foliage cover, crown cover and canopy cover of Melaleucas and to identify which parameter best represents their condition.

LIST OF TABLES

Table 1: River stage and water level at Tarina and Weeli Wolli Springs on 17/04/2015 14

1. INTRODUCTION

Dewatering and discharge to allow mining below the water table has been implemented at Rio Tinto Hope Downs 1 mine site since 2007. In subsequent years, substantial bodies of data relating to vegetation health, ground and surface water hydrology has been collected for compliance and other purposes. Further relevant datasets include long-term rainfall and streamflow records collected for catchments of Marillana and Weeli Wolli Creeks by the Department of Water (DoW).

This investigation integrates relevant existing data and information to identify and better understand the mechanisms underlying ecosystem response to dewatering, and water discharges. Understanding of these mechanisms and where they are operating in different parts of the ecosystem are important for predicting the short and long-term impacts of discharges in Weeli Wolli, Yandi and other river systems associated with below water table deposits. It is also important for managing water discharges as effectively as possible to meet the constraints of mining below the water table, whilst minimising impacts to the environment, including cumulative impacts.

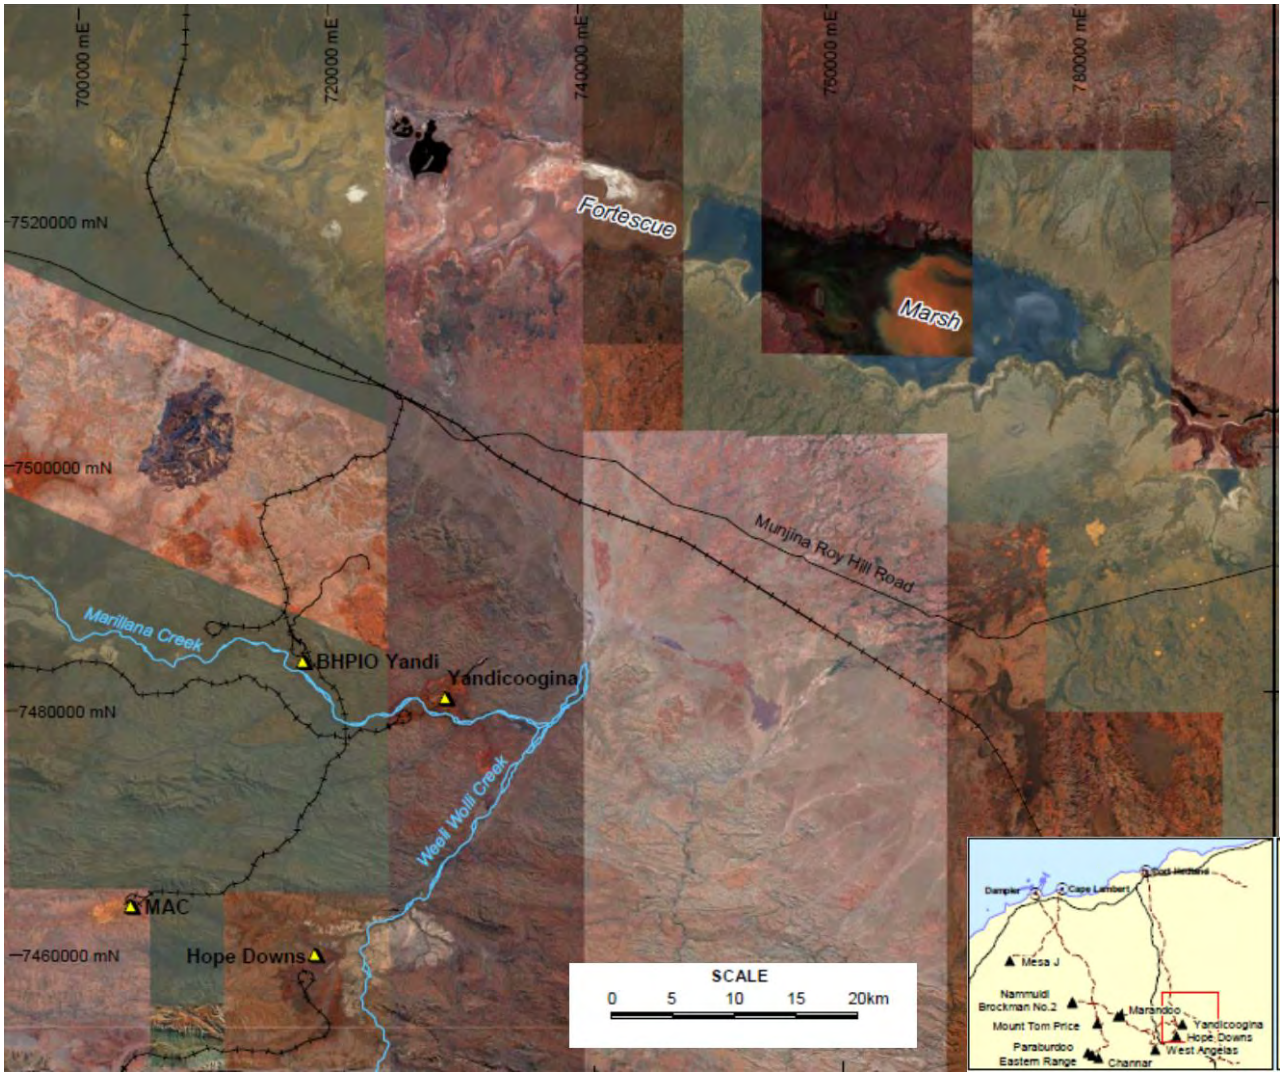
2. METHODOLOGY

2.1. Study location and background

Potential impacts of groundwater drawdown associated with mine site dewatering were investigated at the Hope Downs 1 (HD1) and Junction South East (JSE) deposit of the Yandicoogina (Yandi) mine site in the Eastern Pilbara (Figure 2). At these sites, water extracted and not used on site is discharged into the Weeli Wolli Creek system. At Yandi, a portion of this surplus water is disposed of through aquifer reinjection. Long-term discharge of water into tributaries of Weeli Wolli Creek has occurred since BHP Billiton commenced discharging into Marillana Creek as early as 1998. Dewatering associated with mining of various deposits associated with Rio Tinto's Yandi mine site has also resulted in discharges into Marillana Creek in subsequent years.

Weeli Wolli Creek has particular ecological significance in the arid Pilbara region because of the occurrence of Weeli Wolli Springs. These groundwater springs generate perennial streamflow which extends downstream of the creek for a distance of approximately 4 km. Flow in the creek is ephemeral upstream of the spring and beyond the zone of persistent groundwater discharge. Following intense, cyclonic rainfall events, flow from Weeli Wolli Creek extends north where it drains into the Fortescue River via Fortescue Marsh approximately 40 km downstream of the source of the spring.

Figure 2: Location of the study on Weeli Wolli Creek and Hope Downs 1 and Yandicoogina mine sites



Other than groundwater drawdown and discharge, open pit mining and the diversion of Pebble Mouse Creek, a tributary of Weeli Wolli Creek, away from the mine pit will impact on the hydrology of the creek.

2.2. Dewatering and Discharge at Hope Downs 1 and Yandi

This study investigated potential impacts of discharges from two separate locations associated with HD1 and Yandi dewatering. Surplus volumes of water generated by dewatering at HD1 are discharged from a discharge outlet at the gabion downstream of the mine site on Weeli Wolli Creek (Figure 1). Discharge from dewatering of Junction South East (JSE) flows from discharge outlet 6 (DO6) into Weeli Wolli Creek upstream of the confluence with Marillana Creek (Figure 1).

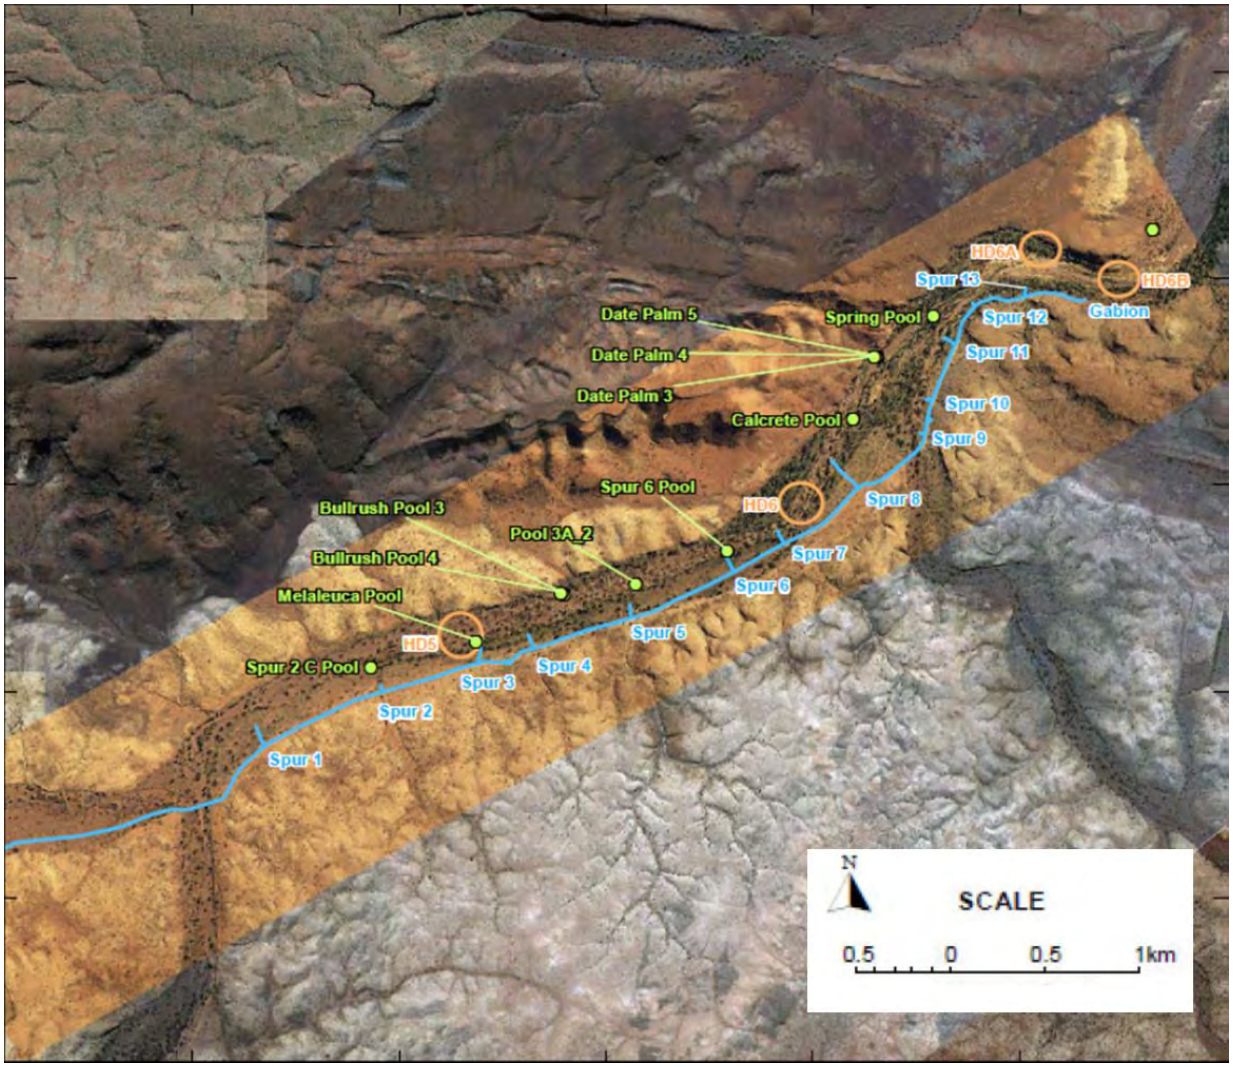
Rio Tinto Iron Ore have delineated sections of Weeli Wolli Creek into 6 separate reaches characterised by differences in their original flow regime and potential impacts of groundwater drawdown, discharge or supplemental irrigation (Figure 1). Reach 0 includes

the ephemeral section of the creek upstream of Weeli Wolli Springs, and potentially affected by groundwater drawdown from the adjacent HD1 mine. Reach 1 and 2 comprise sections of the creek encompassing the springs and pools which generally experienced perennial flows. Reach 1 is also potentially affected by groundwater drawdown, and contains the spur discharges to apply supplemental irrigation. Reach 2 is downstream of Weeli Wolli Springs and potentially affected by HD1 discharge from the gabion. Reach 3 formerly experienced ephemeral flows. For the purposes of this study, Reach 3 was subdivided into 2 sections to delineate sites subject to HD1 discharge only (Reach 3a), and sites downstream of DO6 which also received Yandi discharge (Reach 3b). Parts of Reaches 3a and 3b in proximity to the southern dewatering bore field of JSE were also potentially affected by dewatering. Reach 4 comprises a section of creek downstream of the confluence with Marillana creek. This reach would have historically experienced ephemeral flows, but has also been subject to potential impacts of long-term discharges into Marillana creek. This reach is also subject to potential impacts of combined discharges from HD1 and Yandi including those into both Weeli Wolli and Marillana Creeks. Reach 5 comprises a section of the creek extending beyond the surface expression of discharge and extending downstream towards the Fortescue Marsh.

A series of spurs were installed in the vicinity of Weeli Wolli Spring to provide supplemental irrigation to vegetation which included species assumed groundwater dependent. Water from the spurs also maintained the presence of pools and spring flow (Figure 3). The system discharges water from 13 spurs which can be controlled separately to vary flow rates or to stop discharging. The spurs became operational and water was discharged from February 2007.

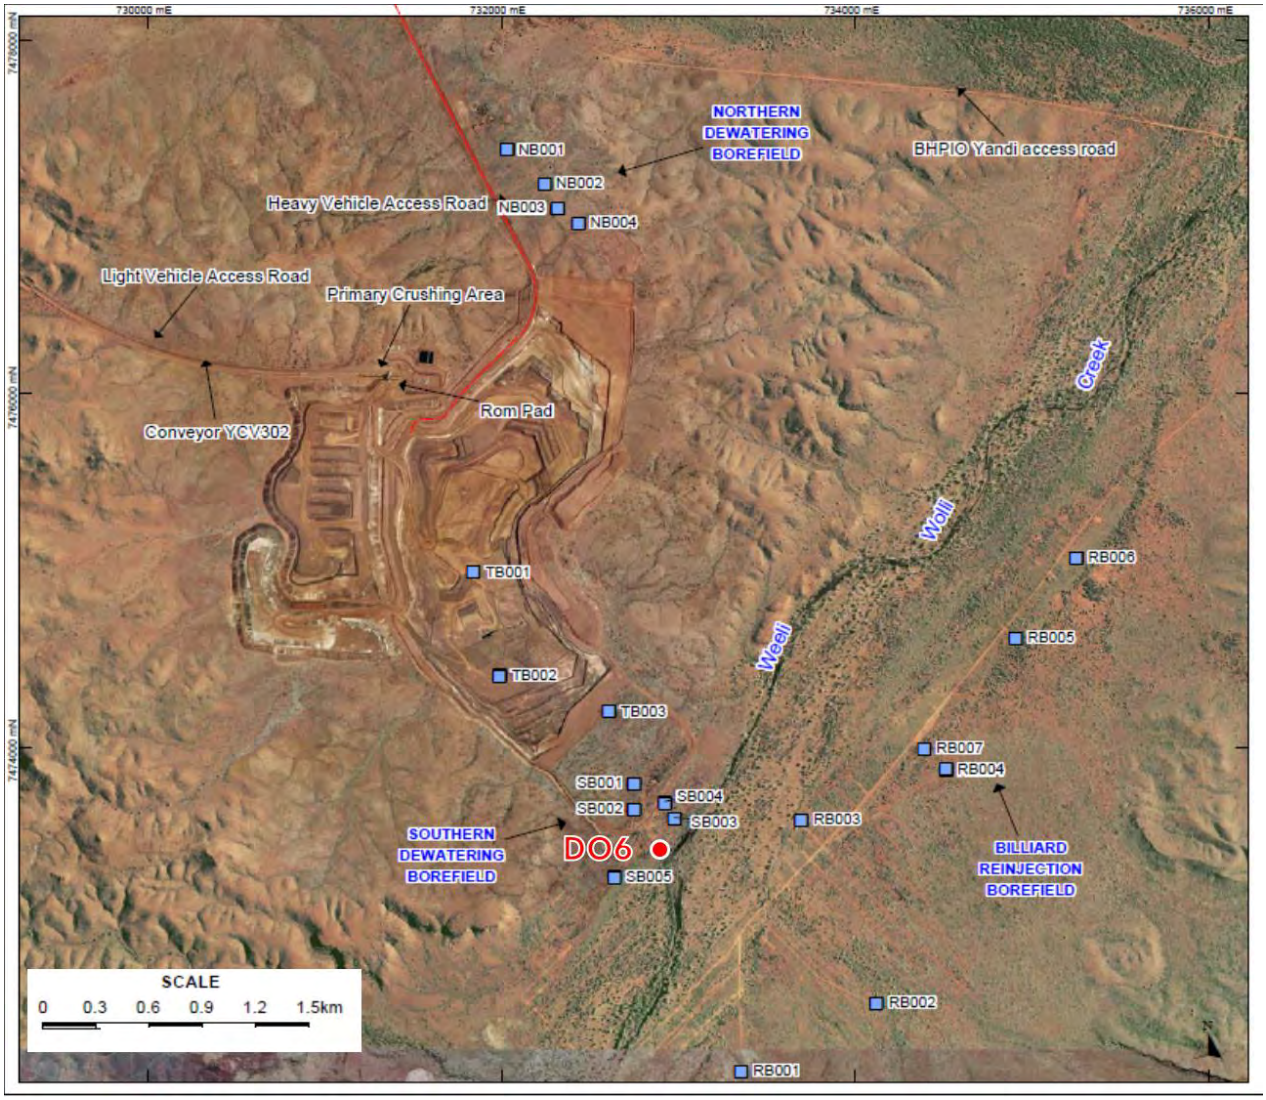
Monthly discharge from the gabion, DO6 and spurs were collated into total wet (October-April) and dry (May-September) season discharge volume for each year.

Figure 3: Location of the gabion discharge outlet and spurs in the springs area of Weeli Wolli Creek. The location of pools and tree health monitoring plots HD5, HD6, HD6a, HD6b, HDM1 and HDM2 are also shown



Bore fields installed at Yandi to dewater Junction South East (JSE) were located in the vicinity of Weeli Wolli Creek, with the Southern Borefield located immediately adjacent to the creek to the northwest (Figure 4). On the opposite side of the creek to the southeast, the Billiard Reinjection borefield was installed to reinject surplus water into the aquifer. DO6 was also located in the vicinity, adjacent to the Southern Borefield. Thus dewatering, reinjection and discharge operations at Yandi each occurred in close proximity to Weeli Wolli Creek.

Figure 4: Location of dewatering bore fields and Billiard Reinjection bore field in the vicinity of Weeli Wolli Creek at Yandi. The location of discharge outlet 6 into Weeli Wolli Creek (DO6) is also shown.

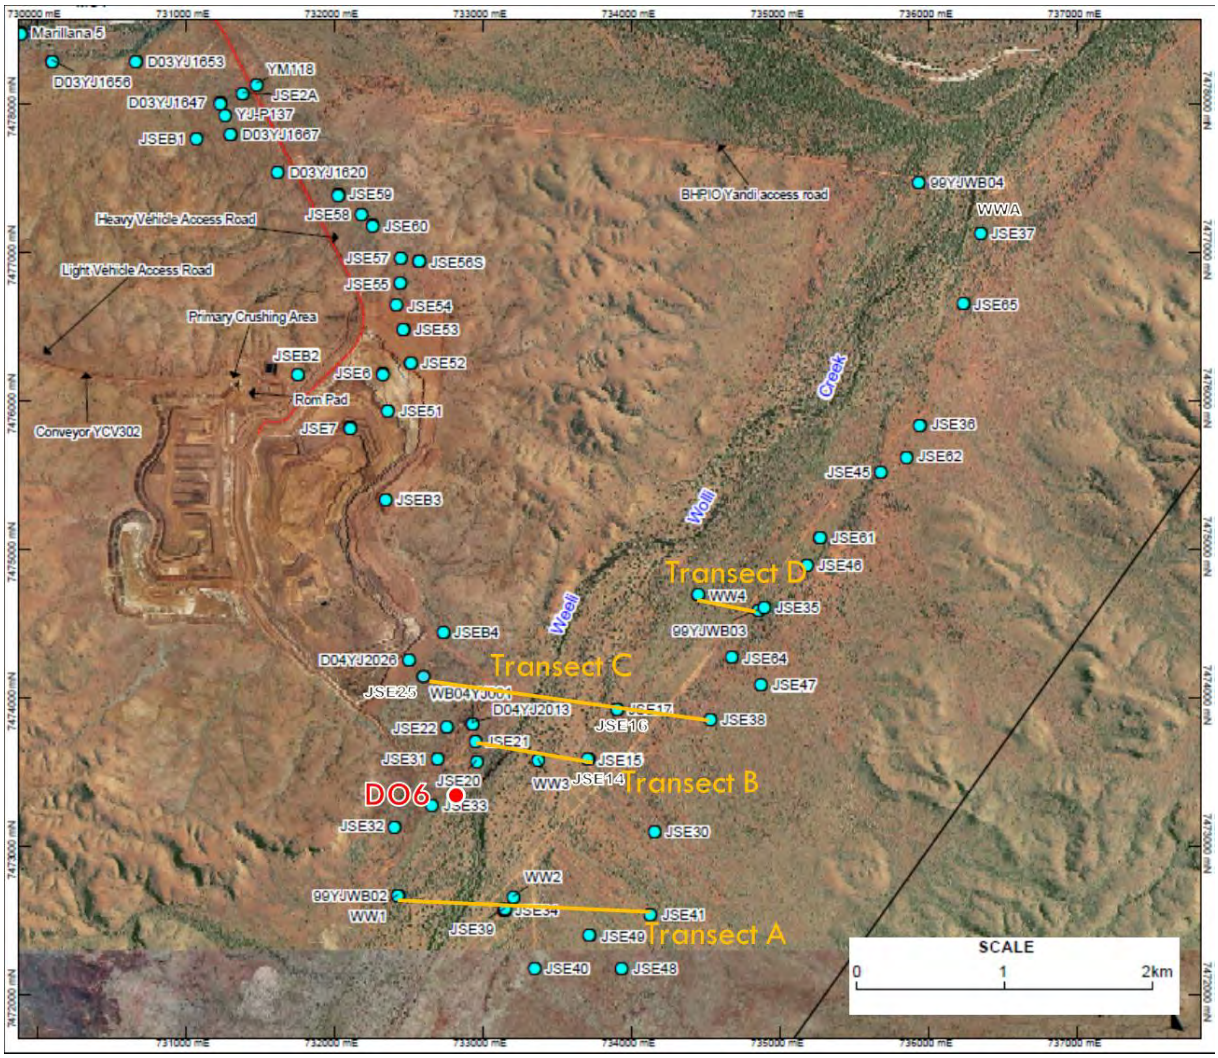


To investigate whether water levels in the alluvium experienced by riparian vegetation were primarily influenced by reinjection, dewatering or discharge, differences between relative levels in the alluvials and CID were examined for four transects across the creek (Transects A, B, C and D) at different locations (Figure 5). Where reinjection caused relative levels to be higher in the CID than in the alluvium, it was concluded that the hydraulic gradient was towards the creek, and that water from reinjection was influencing creek levels. Conversely where levels were higher in the alluvium than the CID as a result of dewatering of the CID or discharge into the creek (or both), it was concluded that hydraulic gradients were away from the creek and that discharge was influencing creek levels.

This analysis of the influence of reinjection, discharge and dewatering on levels in the alluvium is intended to be indicative only. Transects of bores investigated weren't formally installed for the purpose, and thus aren't perfectly aligned on a straight line, normal to the

creek. As a result of any misalignment some will be slightly further up- or downstream than others, possibly resulting in small differences in levels unrelated to any management impacts. So the analysis below generally disregards small differences in levels. Any inference that hydraulic gradients generate flows into or out of the alluvium assumes that the CID and alluvial aquifers are hydraulically connected. Assessing the magnitude and hence the significance of any flows towards or away from the creek would also require knowledge of the hydraulic conductivities of each aquifer, and a reliable estimation of the gradient. Such an analysis is beyond the scope of the present study.

Figure 5: Location of transects of bores in the CID and alluvial aquifers examined to assess the influence of dewatering, discharge and reinjection on water levels in the alluvium along Weeli Wolli Creek at Yandi.



2.3. Vegetation monitoring

Two key vegetation monitoring datasets were used to evaluate the impacts of groundwater drawdown and discharge on vegetation health. These included digital canopy photography (DCP) monitoring of crown and foliage cover by Rio Tinto staff, and vegetation survey data collected by Mattiske Consulting.

2.3.1. Digital Canopy Photography

Data from digital canopy photography (DCP) monitoring of crown and foliage cover by Rio Tinto staff was used to evaluate the impacts of groundwater drawdown and discharge on vegetation health. Foliage and crown cover data was available for *eucalyptus* species at 19 sites distributed along Weeli Wolli Creek (HD1 to HD9; Y07 to Y12, Y01 and PB1, Figure 1), and at 3 reference sites assumed unaffected by drawdown or discharge (HD0, HD10 and PB1). The species monitored were *E. camaldulensis* and *E. victrix,* selected at random when monitoring sites were established. For 14 of the eucalypts monitored, trees were identified as either *E. camaldulensis* or *E. victrix*, but the particular species remained unconfirmed. Foliage cover data was also available for *Melaleuca argentea* collected at 3 sites on Weeli Wolli Creek (HDM1 to HDM3) and at another reference site (HDM0).

When plots were established, 2 permanent photo locations were selected for each sample tree and marked by stakes. The monitoring technique and methods for image analysis are described more fully in McFarlane *et al*. (2007). Analyses of digital images allowed estimation of crown cover (Crc, defined as % of ground area covered by the vertical projection of crowns, assuming the crowns to be solid) and foliage cover (Fc, defined as the percentage of ground area covered by the vertical projection of foliage and branches). Canopy cover (Cc, defined as the percentage of ground area covered by the vertical projection of foliage and branches within the perimeter of crowns of individual plants) for canopies within each image each was subsequently calculated from Crc and Fc.

Monitoring commenced in October 2006 for all eucalypt monitoring sites and was subsequently carried out at approximately quarterly intervals in February/March; May/June; September/October and November/December each year until December 2014. Exceptions were the reference sites HD10 and PB1 which began in June 2009, and Y12 which began in February 2007. Monitoring at Melaleuca sites began in June 2010. Ten trees were typically monitored at sites associated primarily with Hope Downs 1 operations HD0 to HD9; HDM1 to HDM3 and at reference sites HDM0, HD10 and PB1. The exceptions were sites HD6a and HD6b where 5 trees were monitored until June 2010 when an additional 5 trees were included for monitoring. Twelve trees were typically monitored at sites associated with Yandi operations Y07 to Y12 and Y01. Exceptions were sites Y09 and Y01 where 6 and 15 trees, respectively, were monitored. No data for any sites were available for quarter 4 2008.

During the course of the monitoring period, stakes marking photo points were occasionally lost due to flood events or other disturbances, resulting in missing data points. In order to minimize the impact of missing data on the calculated mean, data was infilled where possible. When only one monitoring point was missing from a particular tree, missing data was infilled assuming the same percentage change measured for the other monitoring point for that tree over the time interval. Where both monitoring points were missing, data was infilled assuming a percentage change equivalent to the average change measured for the remaining live trees monitored at that site over the same time interval.

This study primarily sought to investigate changes with time in foliage cover in response to natural variation and management impacts, so data from the additional 5 trees at sites 6a and 6b monitored in June 2010 were excluded from all analyses to avoid any influence of a change in sampling regime on mean foliage cover for the sites. For the same reason, data for the entire monitoring period was excluded when sample trees were occasionally lost or badly damaged due to fire or clearing. Data for 3 sample trees from site HD2 and 4 from HD7 were excluded because of impacts of fire at these sites in March 2007 and February 2009 respectively. Data from three sample trees which were inadvertently felled in HD1 were also excluded. Data for one tree from Y10 and for 3 trees from Y13 were missing from the entire dataset without explanation.

When a tree died without any obvious cause other than potential impacts, the cover value for the image containing only branches and stems, measured at the next monitoring date, was entered for all subsequent monitoring dates.

2.3.2. Vegetation survey data collected by Mattiske consulting

Vegetation survey data from Mattiske consulting was used to investigate changes in foliage cover for different lifeforms, and changes in the degree of stress experienced by eucalypts at sites exposed to discharge. Site locations, sampling frequency and methods are described in Mattiske consulting reports (Mattiske, 2014). The different categories used for the qualitative assessment of tree stress were assigned numerical values. These were dead = 1; very stressed = 2; stressed = 3; slightly stressed = 4 and healthy = 5. A mean stress index for eucalypt species in each transect was subsequently calculated from the mean of these numerical values at each monitoring date. Stress indices for *E. camaldulensis* or *E. victrix* at sites subject to HD1 and Yandi discharge and for regional reference sites on Weeli Wolli Creek, Coondiner Creek and Mindy Mindy Creek were subsequently calculated from the mean of relevant vegetation transects.

2.3.3. Elevation of tree sites

The co-ordinates and elevation of stakes installed to map photo points for each of the trees monitored was downloaded from the Tree health monitoring Mapinfo layer. The data was used to calculate a mean elevation for each site.

2.3.4. Statistical analyses

The statistical significance of impacts on tree health under conditions of varying water availability due to drawdown or discharge was investigated by statistical analyses. 2-way Repeated Measures Analysis of Variance (RM ANOVA) was used to assess whether foliage cover responses differed significantly between sites or whether temporal changes observed were significant. Data was tested for sphericity and the Greenhouse and Geisser correction applied. Since RM ANOVA revealed statically significant responses, further 2-way and 1-way ANOVAs were used to investigate these differences in more detail. Where ANOVA revealed factors as significant, Tukey-testing was used to test the significance of differences between individual means.

To investigate the impacts of management, sites were grouped according to the water management regime applied (drawdown or discharge) and whether flow was historically typically ephemeral or perennial. The treatment groupings were sites HD1, HD2, HD3 & HD4 (drawdown ephemeral); HD5, HD6, HD6a (drawdown perennial); HD6b, HD7, HD8 (HD1 discharge perennial); HD9, Y12, Y11, Y10 (HD1 discharge ephemeral); Y09, Y08, Y07, Y01 (Yandi discharge ephemeral).

Analyses were also carried out to investigate whether differences in the distribution of *E. victrix* and *E. camaldulensis* between ephemeral and perennial sections of the creek were statistically significant. 2 sample T-tests were carried out using data on the number of each species sampled at THM sites located in each section.

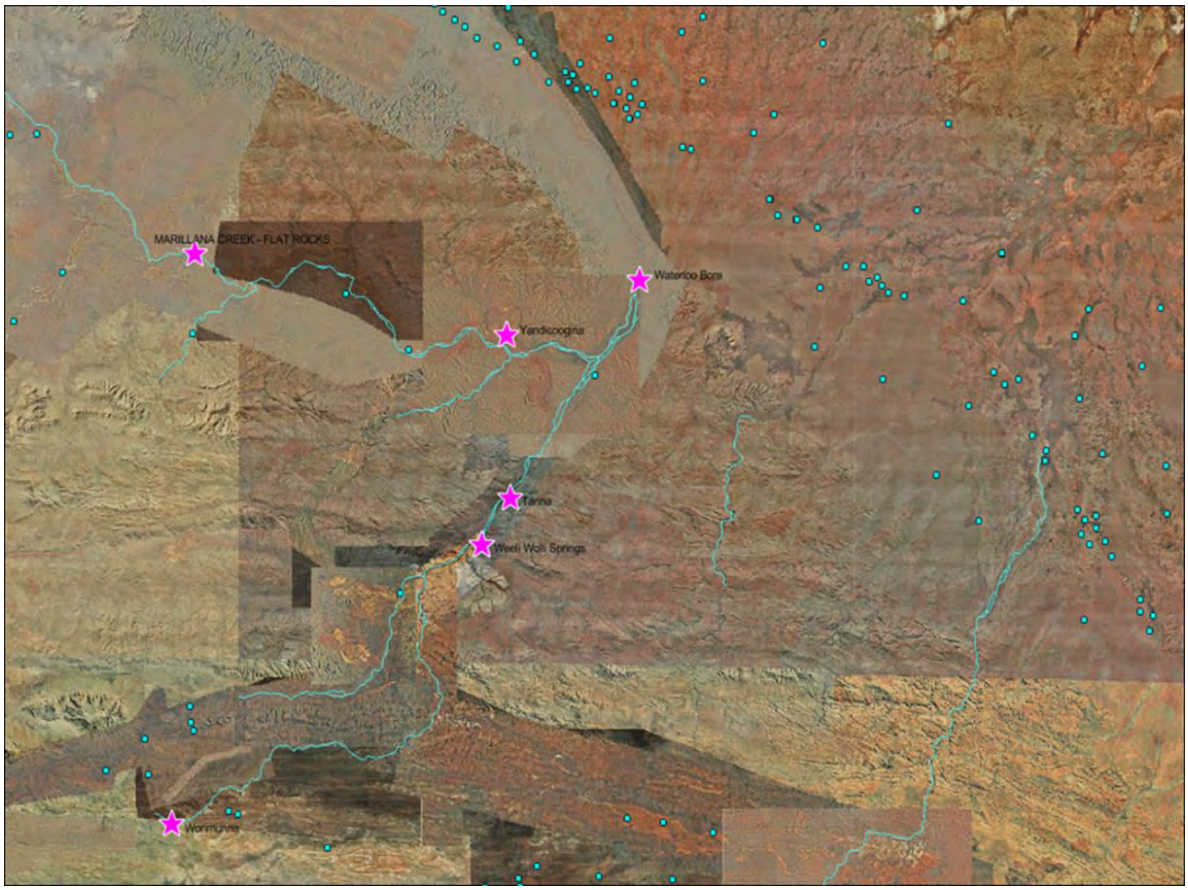
All differences reported following statistical analyses were significant at the 5% probability (or greater) level of significance.

2.4. Rainfall and streamflow

All daily rainfall, river stage and streamflow data available to December 2014 for the Weeli Wolli Springs, Tarina, Waterloo Bore and Flat Rocks stations (Figure 6) were accessed from the Department of Water (Hydstra database - time-series data accessed 31/01/2015. Department of Water (DoW), Water Information section, Perth, Western Australia). Streamflow is estimated from water level elevation (stage) at these stations. Some of the

recent data accessed had not been validated by DoW, but was assumed of adequate quality for the purposes of this study. Data was analysed to derive monthly and annual totals for rainfall and streamflow for each of the catchments. Wet and dry season rainfall and streamflow totals were also calculated, assumed to comprise the months of October to April (wet season) and May to September (dry season). These intervals were selected to be synchronous with quarterly vegetation monitoring. Annual rainfall and streamflow data for all years available without missing data were ranked for each year from 2006. Annual streamflow was plotted as a function of annual rainfall for the Tarina and Waterloo Bore catchments. Data from prior to and post 2006 were plotted separately to investigate any potential impacts of discharge or groundwater drawdown on rainfall-runoff relationships.

Figure 6: Location of Department of Water rainfall and streamflow monitoring stations on Weeli Wolli and Marillana Creeks.



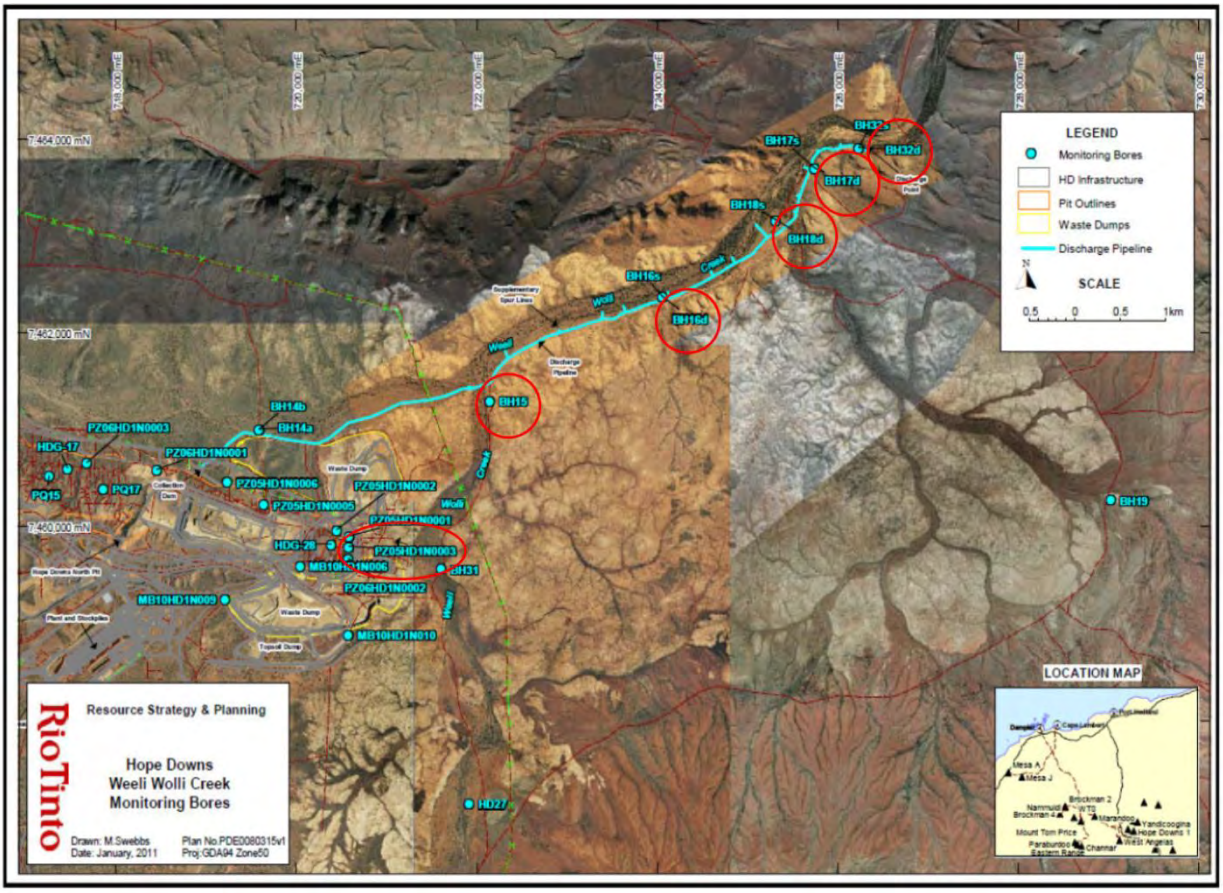
2.5. Surface and groundwater levels at vegetation monitoring sites

We used water levels from bore data and estimated from DoW river stage data to estimate the depth to water for each of the vegetation monitoring sites. Since water level generally wasn't measured at each site, this required interpolation between water levels measured on transects along the creek at varying distances from dewatering and discharge. The bore and river data used for these interpolations is described below.

2.5.1. Bore selection

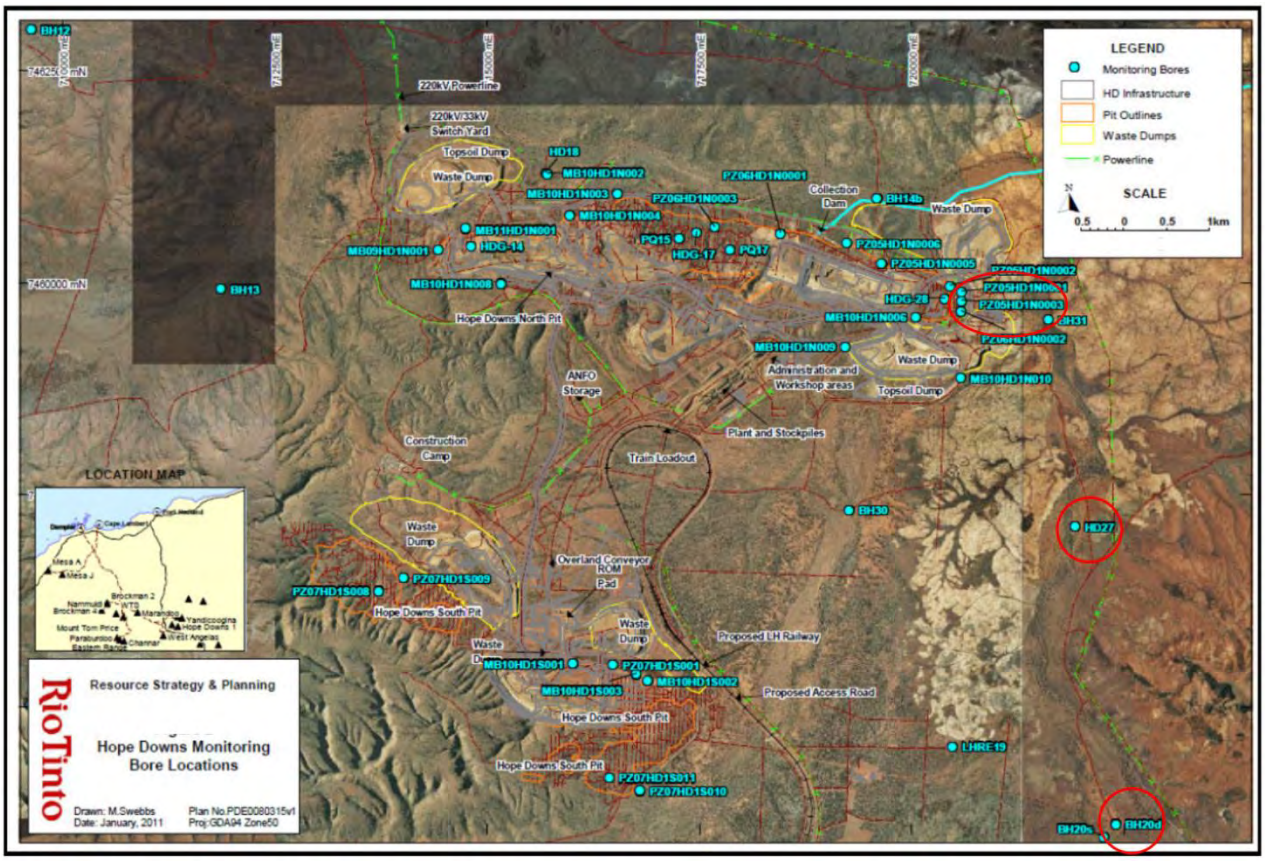
Rio Tinto's Mapinfo layer showing bore locations was scrutinised to identify bores in the proximity of Weeli Wolli Creek relevant to investigating the impacts of groundwater drawdown and discharges on vegetation health. Once potential bores were identified, data from all these bores were downloaded from EnviroSys, and examined to check for data availability extending over the study period from October 2006 to December 2014. A transect of bores (Transect 1, Figure 7) was identified that extended upstream along Weeli Wolli Creek from adjacent to dewatering at HD1 to close to the gabion. The transect included bores PZ05HD1N0003; BH15; BH16d; BH18d; BH17d and BH32d.

Figure 7: Location of bores on Transect 1 from adjacent to the dewatering borefield at PZ05HD1N0003 to just upstream of the gabion at BH32d. Transect bores are circled in red.



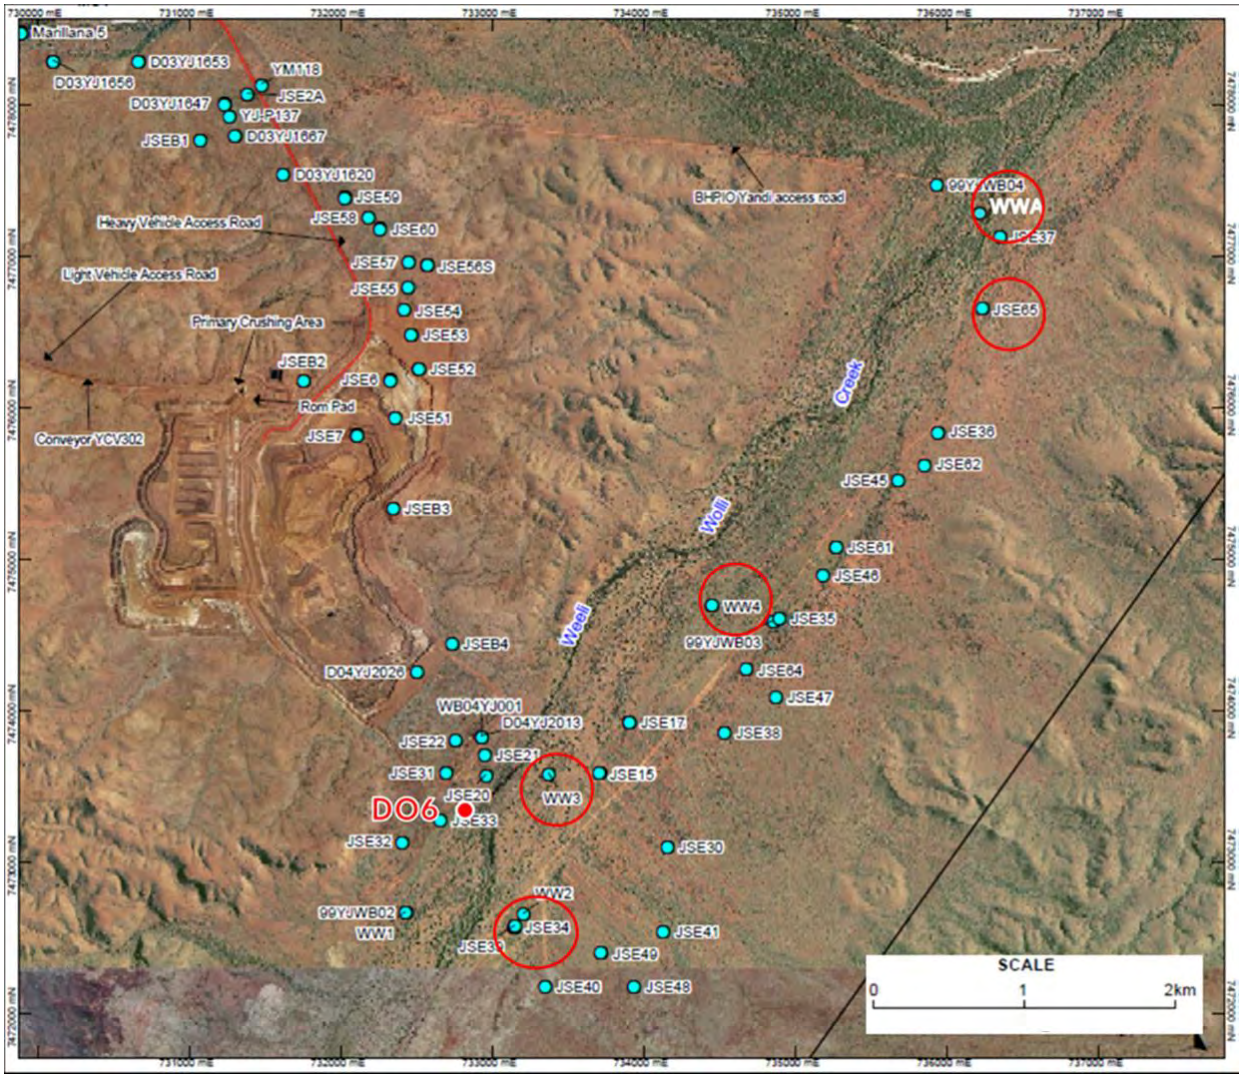
A second transect of bores extending south from dewatering along the creek (Transect 2) was identified including bores PZ05HD1N0003; HD27 and BH20d (Figure 8). There were no bores available between the gabion and just upstream of DO6 discharges at Yandi (Figure 1). However, there were a large number of bores associated with the dewatering of JSE to the northwest of the creek and the reinjection borefield to the southeast which were examined for data availability.

Figure 8: Location of bores on Transect 2 from PZ05HD1N0003 extending south upstream along Weeli Wolli Creek and including bores HD27 and BH20d. Transect bores are circled in red.



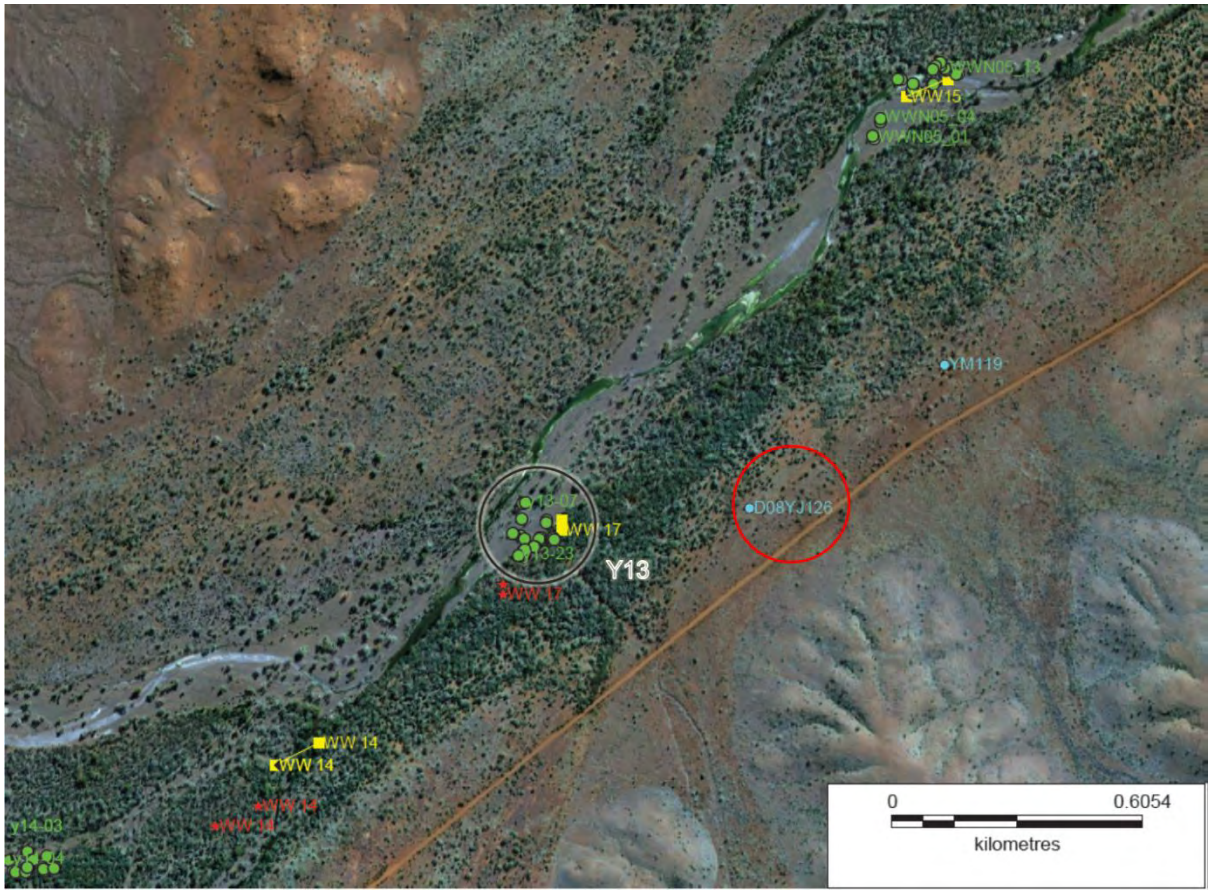
A series of alluvial bores extended along this section of the creek to the confluence with Marillana Creek. Bores (WW1; JSE14; JSE16; JSE34; WW2, WW3, WW4, JSE65; and WWA) were located at varying distances from and on both sides of the creek. Bores closest to the creek with adequate data availability over the study period were selected for further analyses to estimate water levels at monitoring sites (JSE34; WW3, WW4, JSE65 and WWA, Figure 9).

Figure 9: Location of alluvial bores at Yandi selected for inclusion on Transect 3. Transect bores are circled in red.



No alluvial bores were identified downstream of the confluence with Marillana Creek. Levels in CID bore D08YJ126 were used to represent levels relevant for tree health monitoring site Y13 downstream of the Marillana confluence (Figure 10). The CID and alluvial aquifers were assumed hydraulically connected at this location, since levels in D08YJ126 responded to discharge and to the passage of surface water expression of water in the creek.

Figure 10: Location of bore D08YJ126 (circled in red), adjacent to tree health monitoring site Y13.



2.5.2. Water levels at river gauging stations

In the absence of bores between the gabion and JSE34, stage levels from DoW gauging stations at Tarina and Weeli Wolli springs were used to estimate surface water levels for this section of the creek. Water levels at these gauges were surveyed on 17/04/2015 and are shown in Table 1. The stage reading for the Tarina gauge was simultaneously accessed from the DoW website which provides real time monitoring of water level and stage data for the Tarina station. (http://kumina.water.wa.gov.au/waterinformation/telem/stage.cfm). Stage data was not available online for the decommissioned Weeli Wolli Springs gauge, so this stage was estimated from a relationship between Weeli Wolli Springs and Tarina stage data derived for times when Tarina stage readings were close to 10.602 m in February 2008.

Table 1: River stage and water level at Tarina and Weeli Wolli Springs on 17/04/2015

	Surveyed Level (mAHD)	*Stage (m)*
Tarina	522.071	10.602
Weeli Wolli Springs	544.798	10.466

Establishing an elevation datum for Tarina and Weeli Wolli Springs river stages on 17/04/2015 allowed estimation of water levels from all stage data available for these stations. The relationship between water levels at Tarina and Weeli Wolli Springs was used to estimate water levels at Weeli Wolli Springs from Tarina levels for dates after the decommissioning of the station. A combination of bore and river level data was used to estimate water levels on Transect 3 which extended from a bore immediately upstream of the gabion (BH32s) to the confluence with Marillana Creek (WWA). Transect 3 incorporated bores BH32s; JSE34; WW3, WW4, JSE65 and WWA (Figure 9) as well as Weeli Wolli Springs and Tarina levels (Figure 6).

2.5.3. Estimating water levels at vegetation monitoring sites

For Transects 1 & 2, the distance from dewatering was estimated as the distance from the bore PZ05HD1N0003 immediately adjacent to dewatering bores. Distance from dewatering was estimated for all bores and vegetation monitoring sites on these transects. Distance from the gabion was estimated for all bores, river stations and vegetation monitoring sites on Transect 3.

Mean monthly water level (mAHD) was calculated from data from each of the bores or river stations along Transects 1 to 3. Where water level data was missing for a bore in any month, water levels were estimated from the level measured in a bore from a similar locality demonstrating a similar response. To do this, relationships between water levels measured in each of the bores over periods with concurrent data were derived by regression analyses. Only regressions with a correlation coefficient significant at the 5% probability level (or greater) were used to estimate missing data. Once datasets of monthly water levels were complete, monthly (2-dimensional) water level contours were originally derived by cubic spline interpolation of water level (mAHD) as a function of distance from dewatering (Transects 1 and 2) or distance from the gabion (Transect 3). However this method of interpolation did not appear to represent well water levels of some sites close to existing bores. Linear interpolation was subsequently used to estimate monthly water levels beneath each vegetation site. The mean elevation of each vegetation site was then used to estimate monthly values for depth to the water table beneath each site. Temporal means in depth to water table for months between each monitoring date were calculated for each site from monthly estimates. For example, the mean of monthly depth to water table for September, October and November was used to represent depth to water for the period between September and November monitoring.

2.5.4. Hydrological Modelling

A simple spreadsheet model was used to simulate streamflow in Weeli Wolli catchments using monthly climate and streamflow data (Kirby *et al.* 2010). A preliminary calibration of the model was undertaken and results presented below.

2.5.5. Relationships between vegetation health and water availability parameters

Relationships between foliage cover and different parameters relating to water availability were investigated using linear regression analyses. Parameters investigated were rainfall, streamflow, discharge and depth to water where these data were available and relevant to conditions at the site. Linear regression was used simply to identify whether or not the response in foliage cover to any of these variables was statistically significant at each site. Where correlation coefficients were statistically significant, the r^2 value shown with the regression equation on the appropriate figure below was annotated with an asterisk (*). Where the correlation coefficient wasn't found to be statistically significant, the r^2 value was annotated with NS (not significant).

3. RESULTS

3.1. Rainfall and streamflow

3.1.1. Rainfall

Annual rainfall for DoW Flat Rocks, Tarina and Waterloo Bore stations are shown below in Figure 11. Mean annual rainfall is also shown for each station for comparison with annual totals. Gaps in the data for any year imply missing data for part of that year making an annual total unavailable. Rainfall records were longest for the Flat Rocks station with the first complete year of data collected in 1974, and complete records available from 1986 for Waterloo Bore and Tarina stations.

As would be expected in Pilbara region, annual rainfall was highly variable for all 3 stations. Annual trends were generally similar for all stations with high or low rainfall conditions experienced in the same years at each station. Vegetation monitoring by DCP commenced in October 2006. That year represented a very high rainfall year at all stations, being the highest on record at Tarina. This was followed by a 4-year period of below-average rainfall from 2007 to 2010, with Tarina rainfall in 2010 being the lowest on record.

Figure 11: Annual rainfall for DoW stations Flat Rocks, Tarina and Weeli Wolli Bore

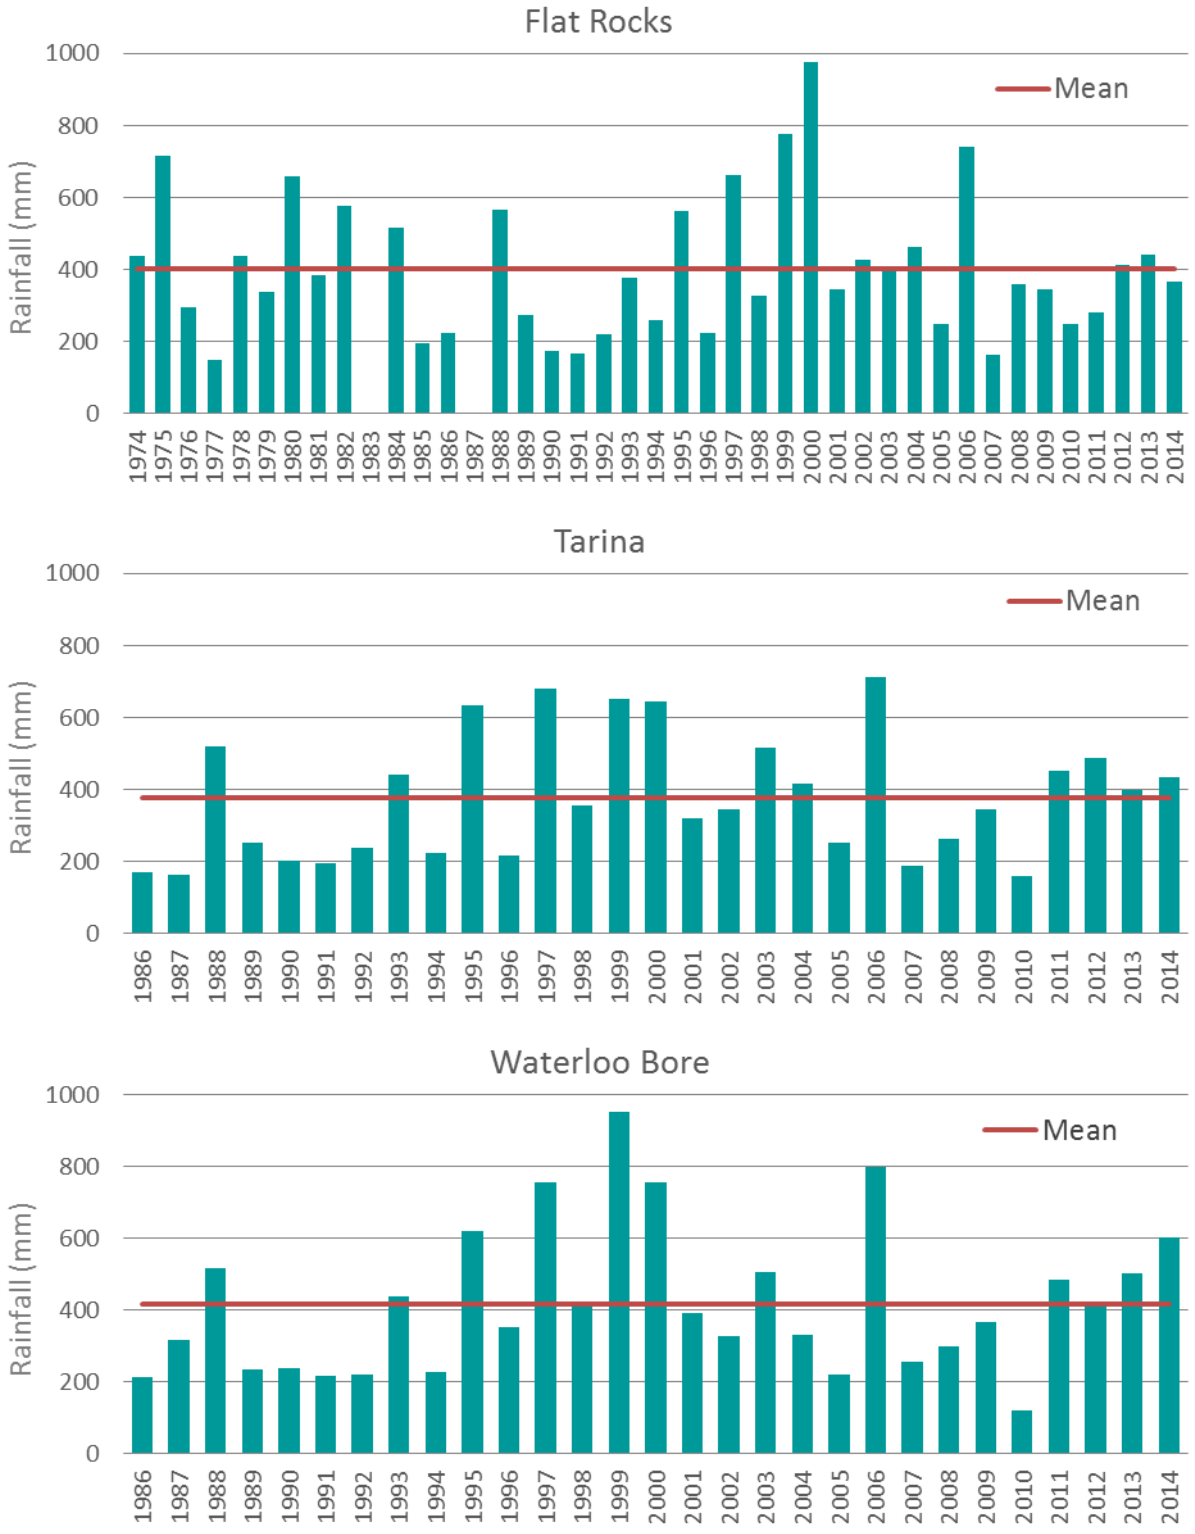


Figure 12 shows the wet and dry season rainfall at Tarina for the years of vegetation monitoring from 2006 to 2014. Wet season rainfall in any year includes rainfall measured from October of the previous year to April of that year. Mean wet and dry season rainfall for all rainfall years on record at Tarina are also shown for comparison in Figure 12. Similar to the trend in annual rainfall, wet season rainfall was high in 2006 compared with the long-term average at Tarina. Both wet and dry season rainfall was below average for the years 2007 to

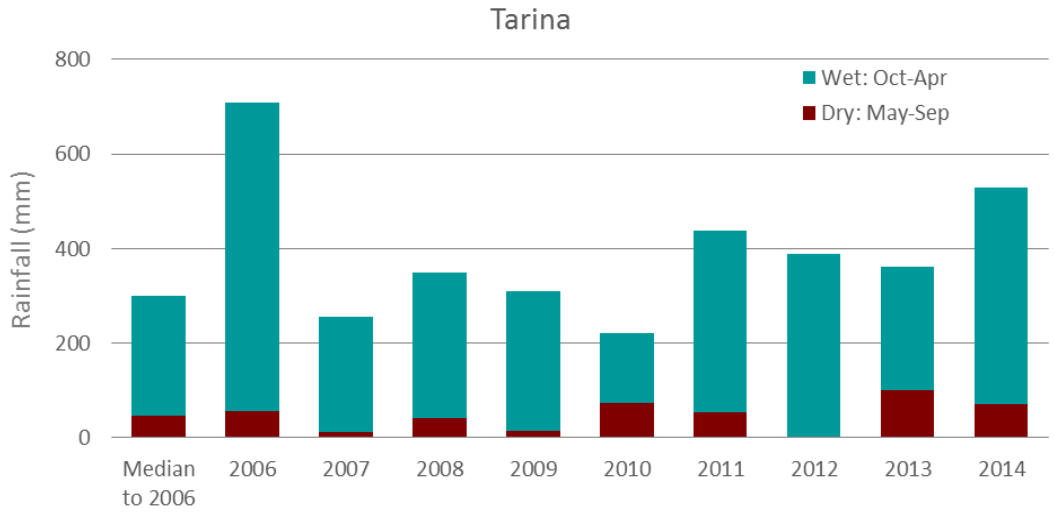
2009, and wet season rainfall was also below average in 2010. Dry season rainfall in 2012 was the lowest on record, with a 5 month drought period between April and September with only 2.3 mm of rainfall received. This followed a wet season of above average rainfall in 2012.

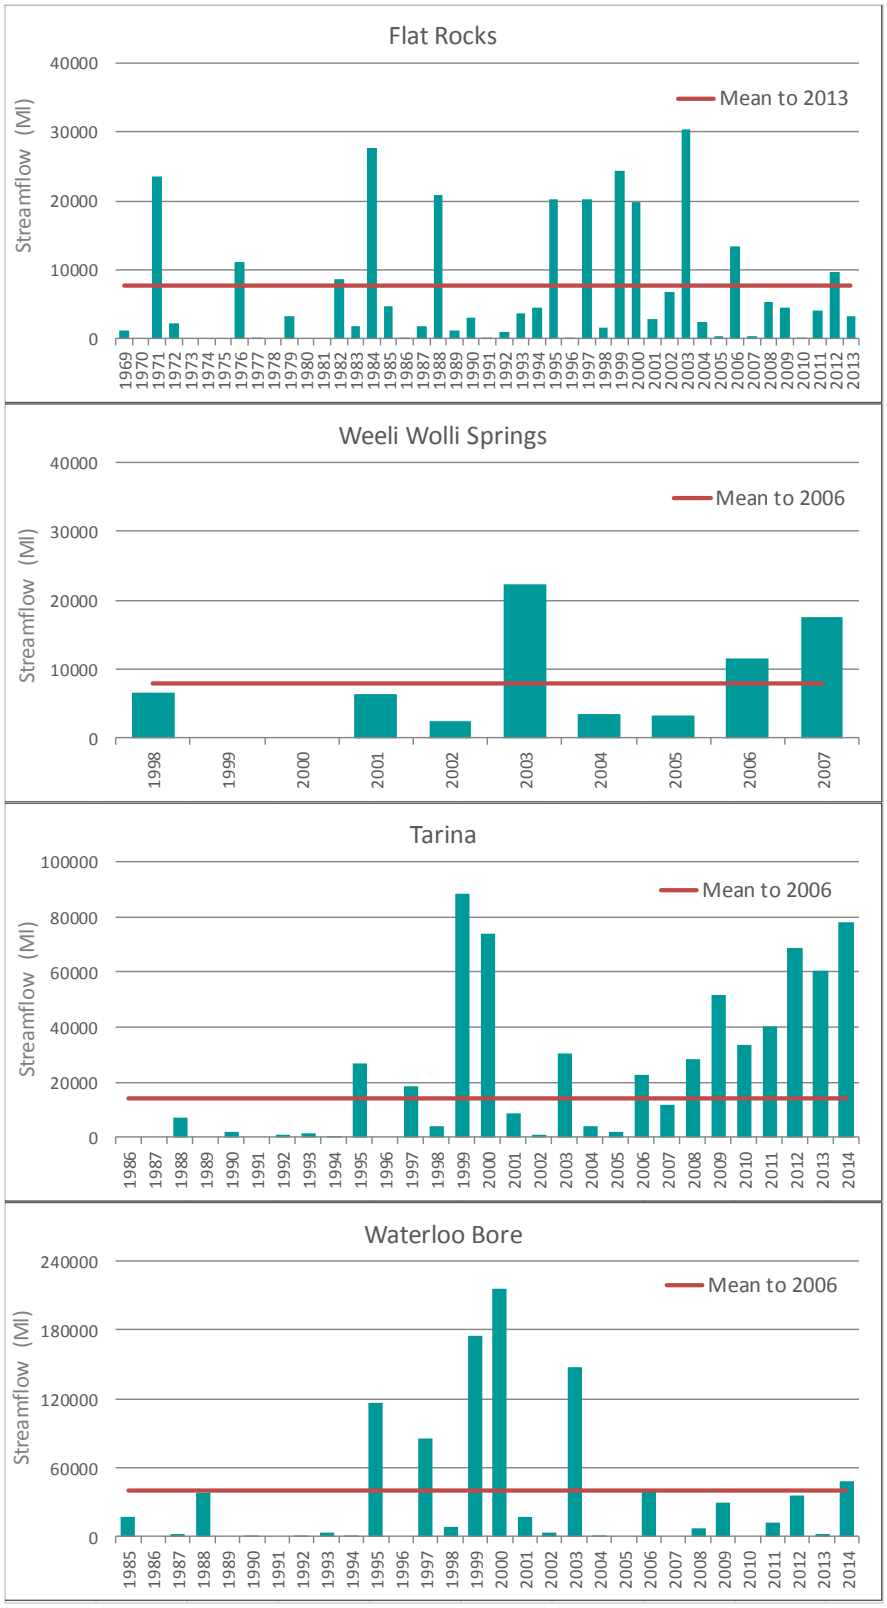
Figure 12: Wet and dry season rainfall during years of vegetation monitoring at Tarina



3.1.2. Streamflow

Consistent with annual rainfall, annual streamflow showed large year to year variation at the Flat Rocks, Weeli Wolli Springs, Tarina and Waterloo Bore stations (Figure 13).

Figure 13: Annual streamflow measured at Flat Rocks, Weeli Wolli Springs, Tarina and Waterloo Bore stations



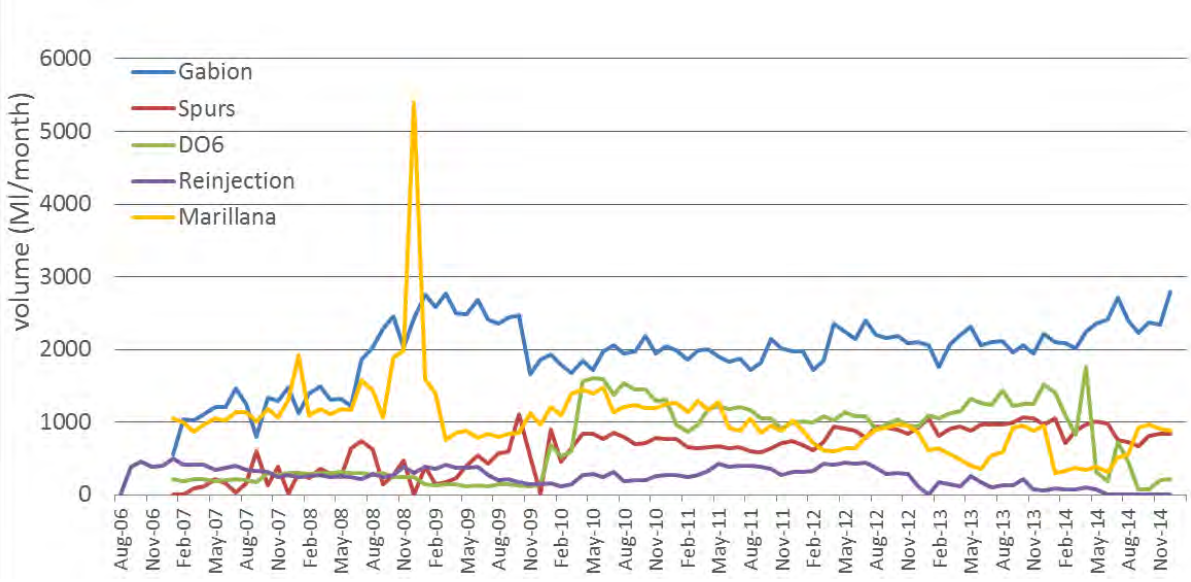
3.2. HD1 and Yandi discharge and reinjection

Dewatering at HD1 and discharge from the gabion commenced in February 2007 (Figure 14). Spur discharges applied to maintain pool levels and as supplementary irrigation for riparian vegetation also began in February 2007. Dewatering of JSE at Yandi and reinjection began in August 2006. Discharge from DO6 into Weeli Wolli Creek began in January 2007.

3.2.1. Reinjection and discharge volumes

Volumes of reinjection and discharge for HD1 and Yandi are shown in Figure 14. Discharge from the gabion was generally greater than all other discharges into the system, except for throughout 2007 and 2008 when gabion discharge was periodically similar to or smaller than discharges into Marillana Creek (Figure 14). Spur discharges at HD1 were initially relatively small in proportion to discharge from the gabion. From 2010 spur discharges increased and volumes subsequently formed a greater proportion of discharges from HD1. Spur discharge from 2010 to 2014 was 39.5 % of the gabion discharge over the same period.

Figure 14: Volumes discharged into Weeli Wolli Creek from the spurs and gabion at HD1 and DO6 at Yandi. Volumes reinjected adjacent to the creek at Yandi, and the total discharge into Marillana Creek are also shown.

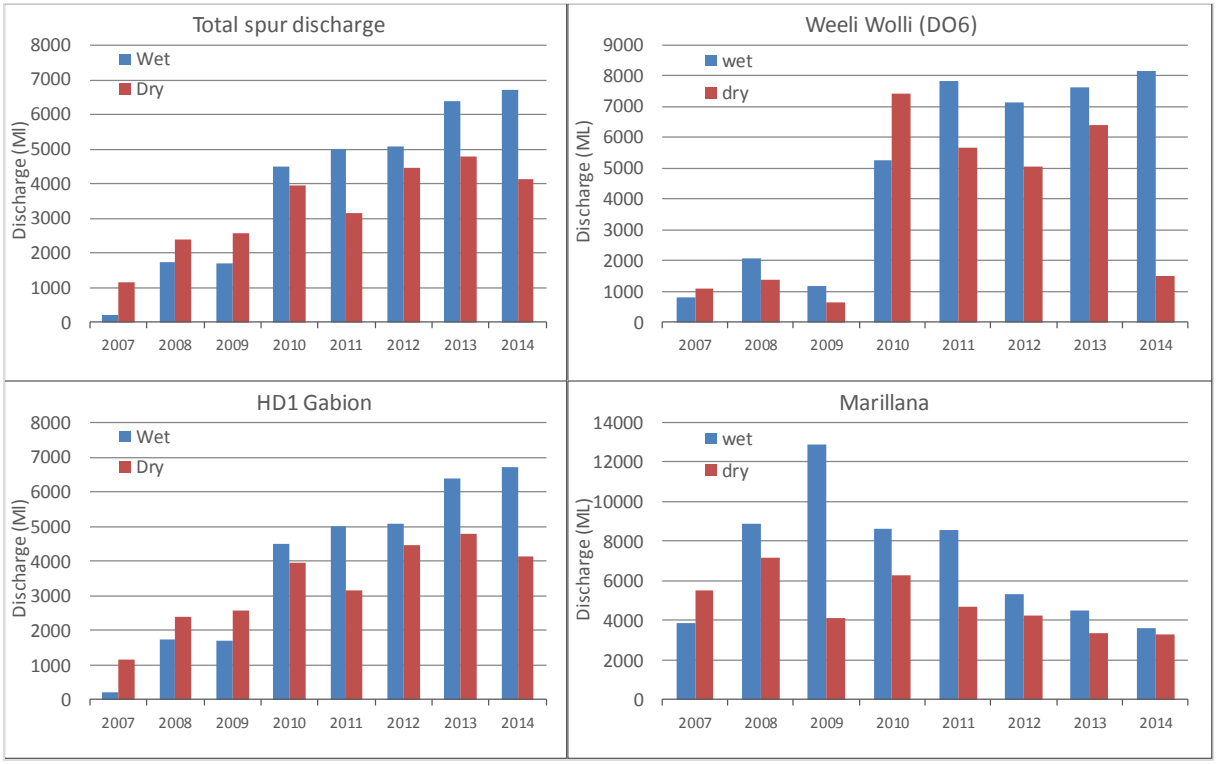


Reinjection volumes (Figure 14) at Yandi were either greater than or similar to discharges from DO6 until the end of 2009. From 2010, discharges from DO6 increased substantially and remained close to or greater than 1000 Ml/month throughout 2010 to 2013. Both reinjection and DO6 discharge volumes tended to decrease in 2014, with reinjection ceasing from July 2014. Discharges into Marillana Creek were consistently greater than both reinjection volumes and DO6 discharges until April 2010 when volumes from DO6 increased. Discharges into Marillana and from DO6 remained high throughout 2010 to 2012, and

subsequently increased from DO6 in 2013. There is little data available to interpret the combined impact of these discharges on levels and flows in Weeli Wolli Creek beyond the confluence with Marillana Creek.

Collation of discharge data into totals for the wet (October-April) and dry (May-September) season each year (Figure 15) revealed a trend for wet season discharge from the spurs, gabion and DO6 to increase with time, but wet season discharges into Marillana Creek decreased from 2009. Although dry season discharges at all locations except Marillana were generally greater from 2010 onwards than in earlier years, they didn't show the consistently increasing trend with time found for wet season discharges. There appeared to be no direct relationship between rainfall and discharge volumes each year (Figure 12)

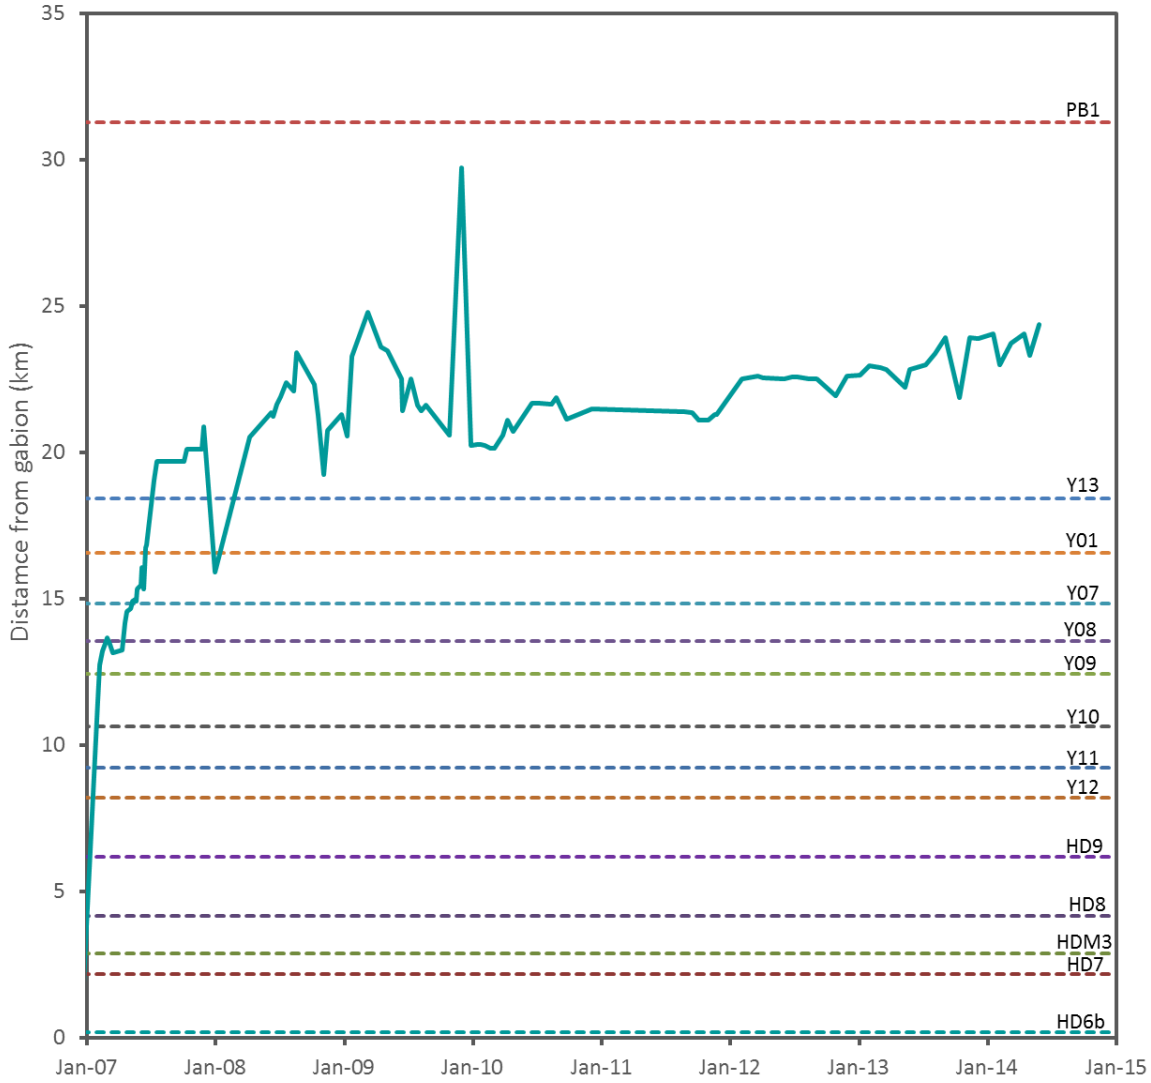
Figure 15: Wet and dry season discharges from the gabion, spurs, DO6 and total Rio Tinto discharge into Marilla Creek from 2007 to 2014.



3.2.2. Surface expression of discharge

The surface expression of discharge progressed rapidly down Weeli Wolli Creek after discharge from the gabion began (Figure 16). The first available data is for 17/02/2007 when the extent of the surface expression had already extended a distance of 11.5 km downstream of the gabion. Thus THM sites HD6b, HD7, HDM3, HD8, HD9, Y12, Y11 and Y10 were experiencing surface expression of discharge within 3 months of discharge commencing. By 23/02/2007, the wetting front had progressed past DO6 and YO9. Since discharge from DO6 had already started by this date, it isn't possible to determine the respective influences of discharge from DO6 and the gabion on the advancing wetting front.

Figure 16: Progression of surface expression of discharge past Tree Health Monitoring sites downstream of the gabion.



The front reached Y08, Y07, Y01 and Y13 by approximately 15 March, 26 May, 4 July and 26 July, respectively. By December 2014, the surface expression of discharge hadn't reached the THM site PB1 which lay > 31 km downstream. Although progression of the wetting front was slower from the start of 2009, it continued to extend to greater distances throughout subsequent years. This trend continued to the end of the study period in December 2014.

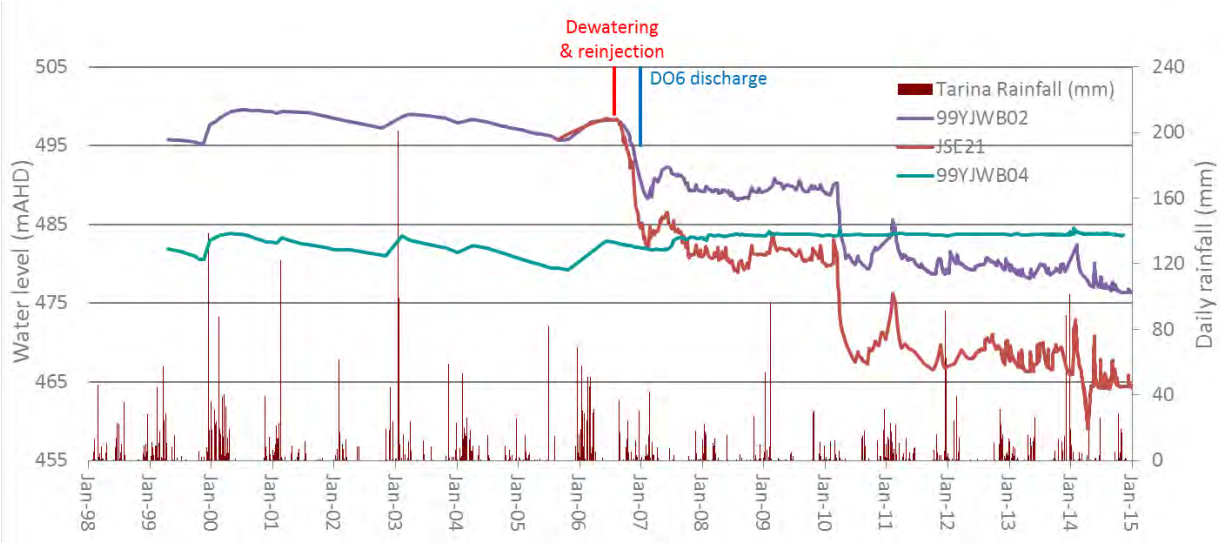
3.3. Water levels

3.3.1. Water level response to dewatering, reinjection and discharge at Yandi

Bores 99YJWBO2, JSE21 and 99YJWBO4 (Figure 17) reveal variable responses to dewatering and discharge in the CID aquifer to the northwest of Weeli Wolli Creek at Yandi

(Figure 17). Bore 99YJWBO2 is upstream of the DO6 discharge outlet, and both JSE21 and 99YJWBO4 lie downstream of it (Figure 9). Longer-term records for 99YJWBO2 and 99YJWBO4 show the natural variation in levels since 1999 in response to seasonal rainfall and streamflow. Prior to the start of dewatering in 2006, variation was generally less than 5m. However water levels in the bores closest to the dewatering bore field 99YJWBO2 and JSE21, showed rapid responses to dewatering that weren't mitigated by reinjection on the other side of the creek. By early February 2007, levels had fallen by approximately 10 m and 16 m respectively in 99YJWBO2 and JSE21, but there was no response to dewatering further downstream in bore 99YJWBO4.

Figure 17: Water levels in the CID to the northwest of Weeli Wolli Creek at Yandi and daily rainfall at Tarina



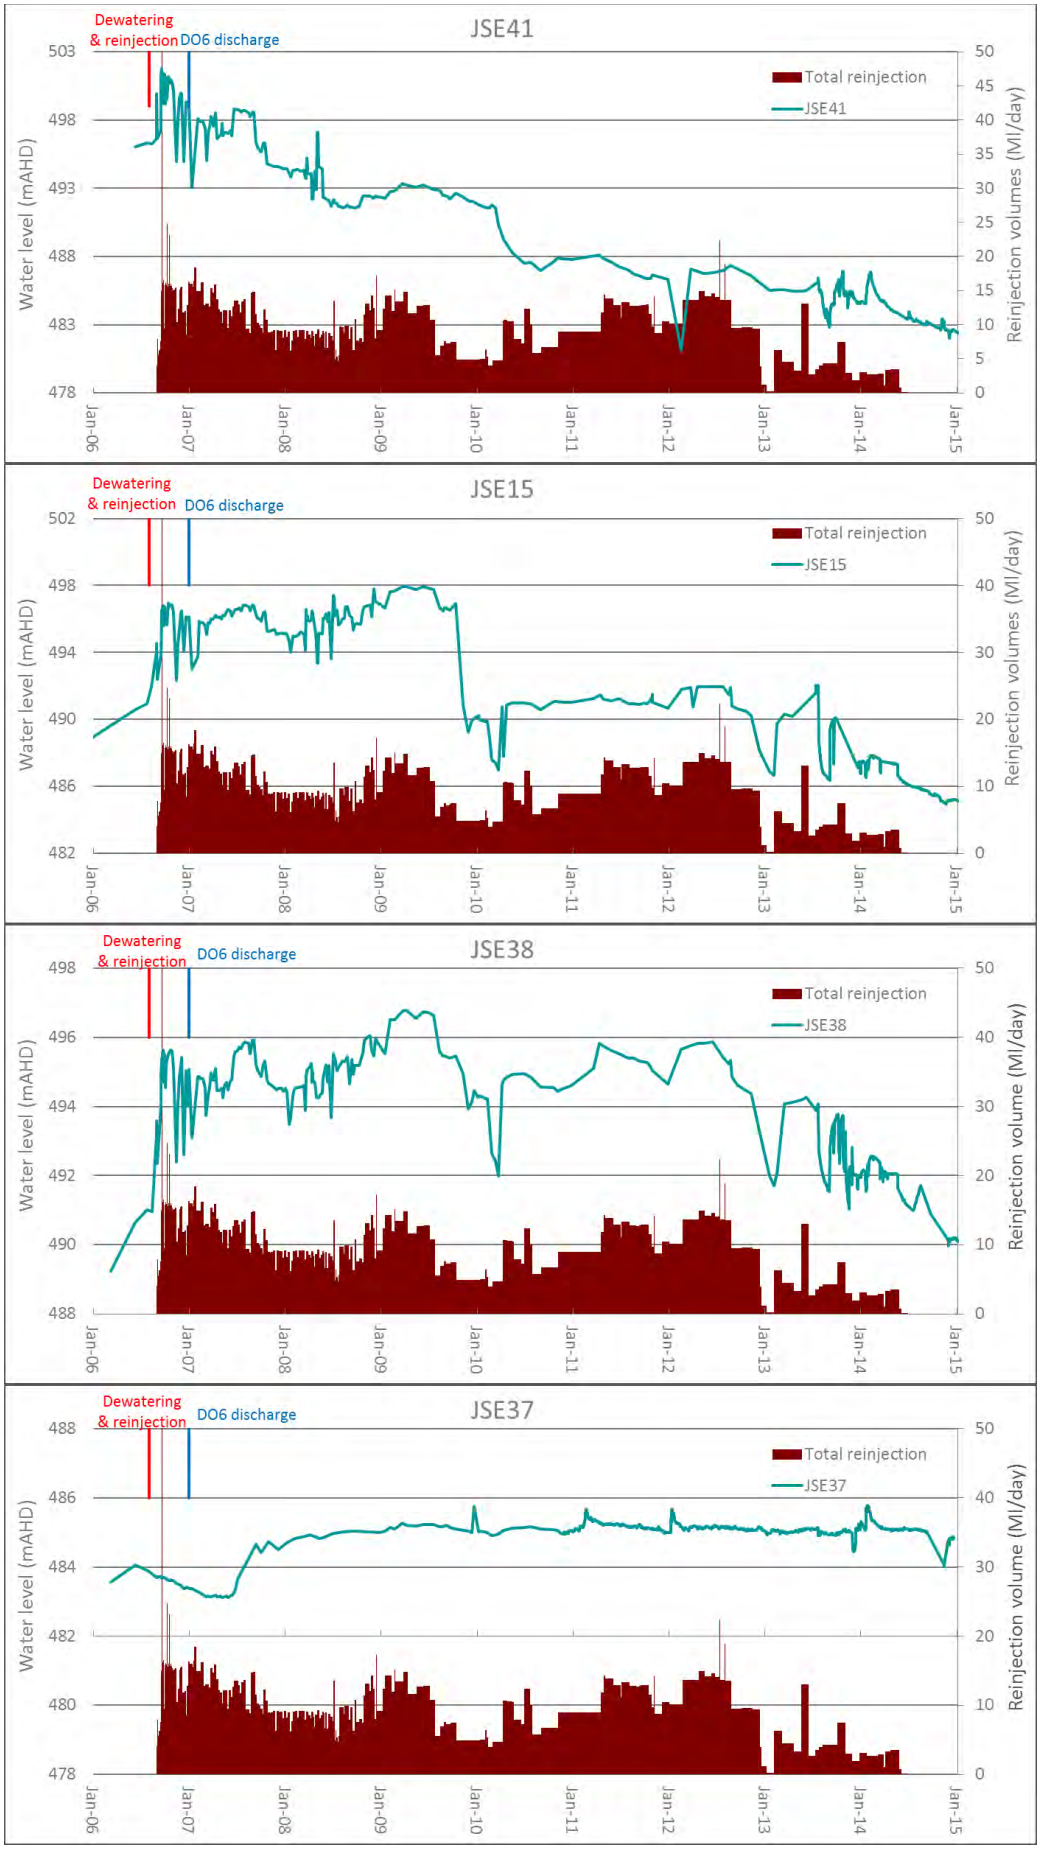
All three bores showed apparent responses to the start of discharge into Weeli Wolli Creek, with levels increasing in both 99YJWBO2 and JSE21 by approximately 4 m. The rise may also be partly in response to wet season rainfall, but since both rainfall and streamflow were below median in 2007, it seems unlikely that it could be fully attributed to wet season flows. A more muted response to discharge is discernible in bore 99YJWBO4 further downstream, which began to rise in June 2007, with levels increasing by about 2 m in subsequent months. The response of water levels in CID bores corresponded with the passage of surface expression of discharge in the adjacent creek. This occurred in February 2007 at both 99YJWBO2 and JSE21, and in early July at 99YJWBO4. Since 99YJWBO2 lies upstream of the DO6 outlet, the surface expression of water and bore response may be related to discharges from the gabion at HD1.

Throughout 2008 and 2009, levels in all three bores were largely stable, showing responses to seasonal rainfall. However, from March 2010 levels in 99YJWBO2 and JSE21 declined rapidly, falling by about 13 m and 11 m respectively by September 2007. Levels continued to

respond to seasonal rainfall, but showed evidence of a more gradual decline until the end of 2014. There was no impact of dewatering on water levels further downstream at bore 99YJWBO4 which remained very stable throughout 2008 to 2014.

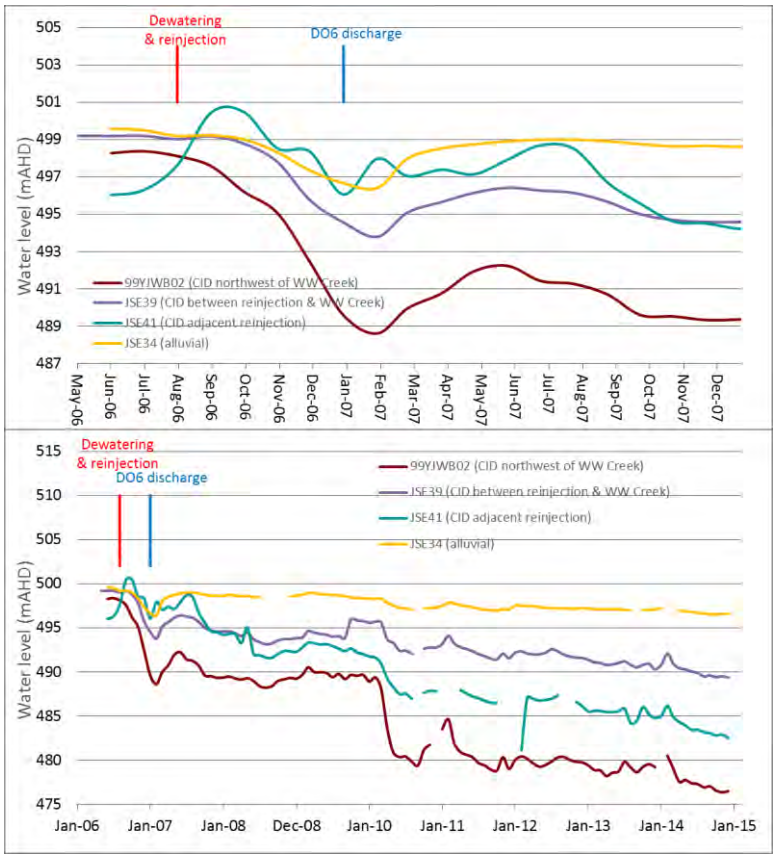
Water levels in the CID to the southwest of Weeli Wolli Creek responded to reinjection of water, but levels in some of these bores also declined in response to dewatering (Figure 18). Levels in each of the bores JSE41, JSE15 and JSE38 rose by 4 to 6 m after the start of reinjection in August 2006. All of these bores responded to reinjection, showing peaks and troughs in synchrony with increasing and decreasing reinjection volumes and a reduction in levels throughout 2013 and 2014 as volumes decreased. Dewatering of the CID on the other side of Weeli Wolli Creek had the greatest impact on water levels in the CID bores further upstream, with decreases of 19 m and 13 m from maximum levels observed in JSE41 and JSE15 respectively by December 2014. This represented a 5 m reduction in water levels from those measured in January 2006. In contrast, levels in JSE38 reflected a closer correlation with reinjection volumes, and water levels in December 2014 were approximately 1m higher than levels measured in March 2006. None of these bores showed a discernible response to the start of discharge in January 2007 (Figure 18). Further downstream at bore JSE 37, levels were less responsive to reinjection volumes. Levels here were more responsive to discharge, showing an immediate rise after April 2007 when the discharge wetting front passed this section of the creek.

Figure 18: Water levels in the CID to the southeast of Weeli Wolli Creek in response to re-injection and dewatering.



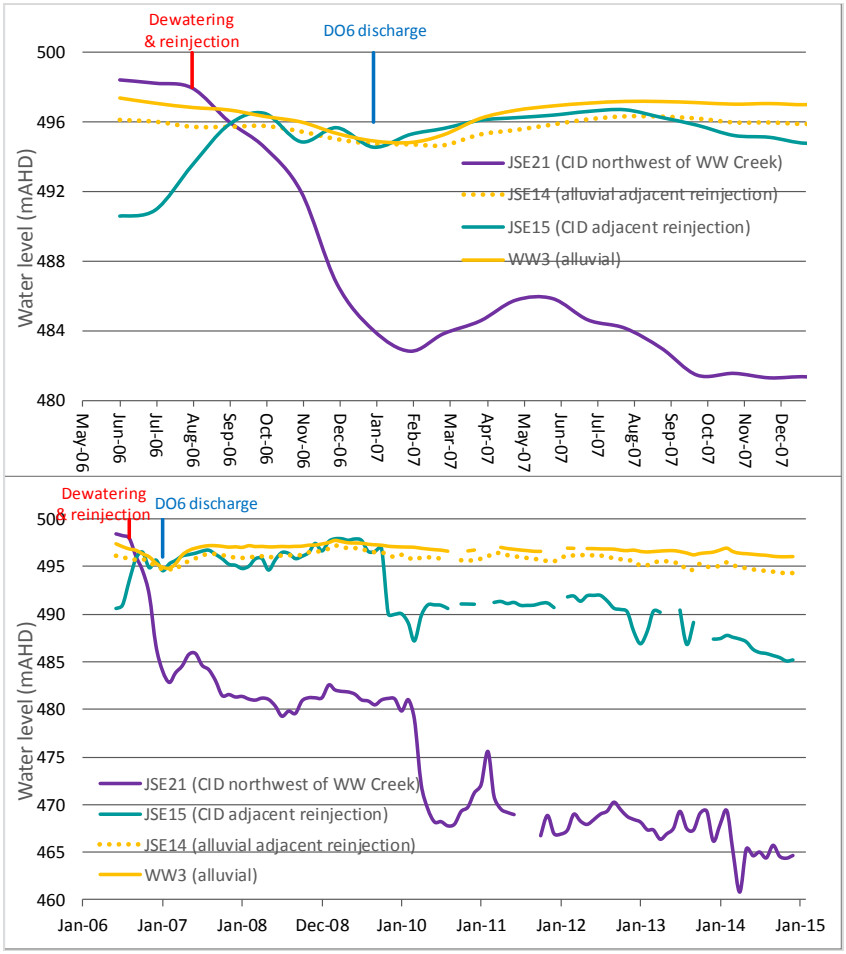
Factors influencing water levels in the alluvium at tree health monitoring plot Y10 may be inferred from the response in bores in the nearby Transect A (Figure 5). In June 2006, prior to the start of the dewatering, levels at Transect A upstream of DO6 were highest in the alluvial aquifer JSE34 (Figure 19). Hydraulic gradients were away from the creek with lower relative levels in the CID adjacent to the creek to the northwest (99YJWBO2) and the southeast (JSE39). Levels were lower again in the CID further from the creek in bore JSE41 close to a reinjection bore. Following the start of dewatering in August 2006, water levels decreased in the CID bores 99YJWBO2 and JSE39 adjacent to the creek, whilst reinjection caused levels in JSE41 to increase. By October 2006, levels were higher in JSE41 than in other CID and alluvial bores in the transect, and hydraulic gradients were towards the creek from the reinjection borefield to the southeast, and away from the creek towards dewatering to the northwest. Water levels increased in the alluvial aquifer after the surface expression of discharge from HD1 passed this point in February 2007. From March 2007 to December 2014, water levels were consistently greater in the alluvial bore JSE34 than in CID bores on both sides of the creek where dewatering caused a continuing decline in levels. The increasing difference in water levels in JSE34 and the adjacent CID bore JSE39 suggest the hydraulic connection between alluvial and CID aquifers is poor in this vicinity.

Figure 19: Mean monthly levels measured in a transect of bores (Transect A) across Weeli Wolli Creek, upstream of DO6 at Yandi. The upper figure shows short-term responses from May 2006 to December 2007, and the lower figure the longer-term responses through to December 2014.



Further downstream and past DO6 at Transect B (Figure 5), June 2006 levels prior to dewatering in the CID aquifer were 8 m higher at bore JSE21 to the northwest of the creek than at JSE15 adjacent to reinjection (Figure 20). Levels in the alluvial bores WW3 and JSE14 were consistent with a declining gradient along the transect from the northwest.

Figure 20: Mean monthly levels measured in a transect of bores (Transect B) across Weeli Wolli Creek, downstream of DO6 at Yandi. The upper figure shows short-term responses from May 2006 to December 2007, and the lower figure the longer-term responses through to December 2014.

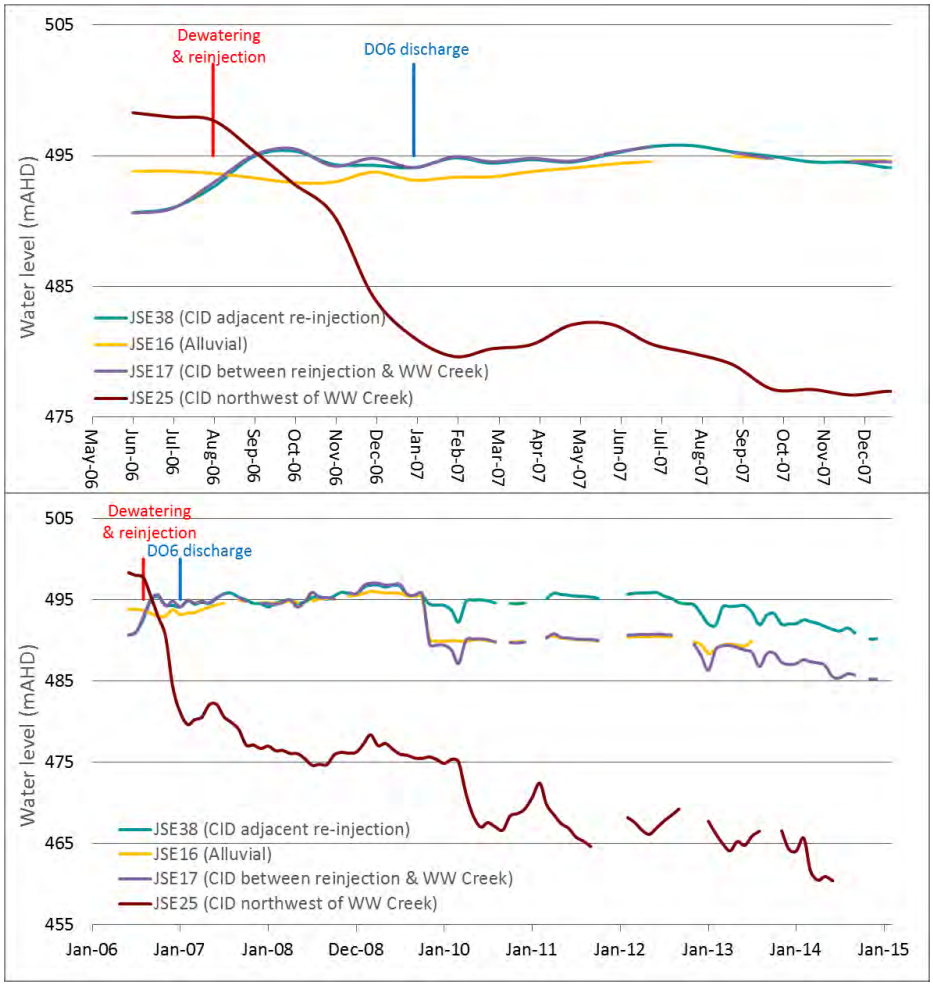


Following the start of dewatering in August 2006, water levels declined in the CID at JSE21, but rose in JSE15 adjacent to reinjection, and by November 2006, the hydraulic gradient in the CID had reversed. Levels in the alluvial bores JSE14 and WW3 were influenced more by dewatering than reinjection, decreasing from August 2006 to February 2007. The decline in levels was less at JSE14 adjacent to reinjection than at WW3 which was closer to the creek and to dewatering. Over the 6 month period between the start of dewatering and the first discharge from DO6, levels at WW3 declined by 2 m. Levels in the alluvium recovered in subsequent months after discharge commenced, and there are indications that reinjection may have also contributed to this recovery as levels in the CID at JSE15 were intermittently higher for intervals than in alluvial bores when reinjection volumes were high. However, reinjection volumes were insufficient to maintain these levels as the spatial extent of dewatering impacts increased and levels in JSE15 fell in November 2009. Levels in the

alluvial aquifer were maintained by discharge with hydraulic gradients away from the creek until the end of the study in December 2014.

Further downstream at Transect C (Figure 5) water levels in the CID in June 2006 were higher to the northwest of the creek in JSE25 than in CID bores JSE17 and JSE38 to the southeast (Figure 21). Levels in the alluvial aquifer at JSE16 were 3.2 m higher than in the CID at the adjacent bore JSE16 in June 2006.

Figure 21: Mean monthly levels measured in a transect of bores (Transect C) across Weeli Wolli Creek, downstream of DO6 at Yandi. The upper figure shows short-term responses from May 2006 to December 2007, and the lower figure the longer-term responses through to December 2014.

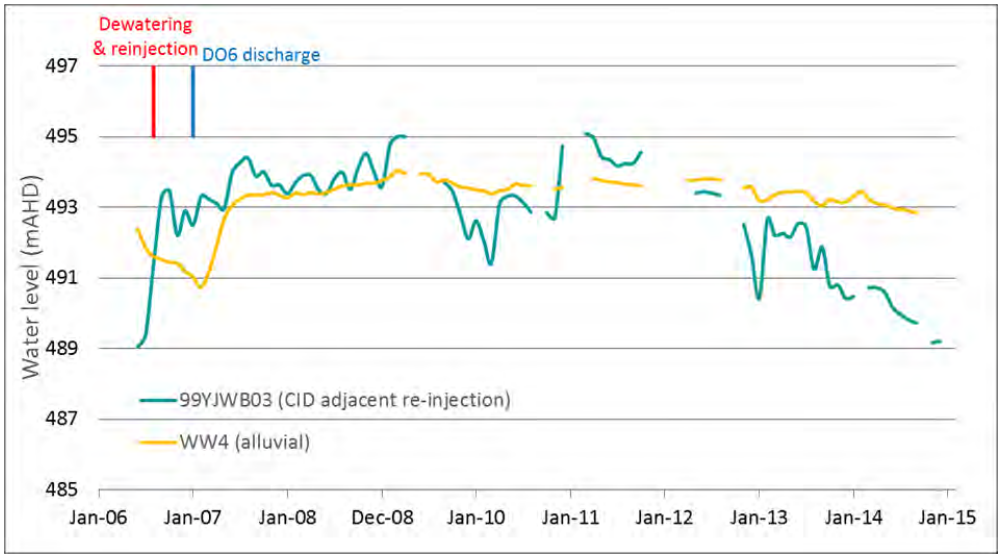


At the start of dewatering, levels in JSE25 began to fall, but levels in JSE17 and JSE38 rose in response to reinjection. By November 2006 the direction of the hydraulic gradient reversed, and levels in the CID to the southeast became higher than in the alluvium. These higher levels in the CID at JSE17 and JSE38 were sustained by reinjection through to October 2009, and the hydraulic gradient remained predominantly towards the creek. Over this period, levels in the alluvium reflected small variations in the CID bores JSE17 and

JSE38, suggesting hydraulic connectivity between the two aquifers in this vicinity and a contribution from reinjection to levels in the alluvium. From November 2009, the impact of the increasing spatial extent of dewatering caused a rapid decrease in levels in JSE17 and in the alluvium at JSE16, but little response in JSE38. Levels in all these bores were subsequently largely maintained until June 2012, after which they began to decline, with the alluvial bore JSE16 becoming dry in August 2013. This decline could relate to impacts of dewatering and/or a reduction in reinjection volumes from 2013.

Further downstream there are few bores to consider in evaluating the potential contribution of re-injection and discharge. However, differences between levels in bores 99YJWBO3 and WW4 (Transect D, Figure 5) provide indications of the responses there (Figure 22). Levels in 99YJWBO3 show fluctuations in response to reinjection volumes, consistent with other CID bores. Levels in the alluvial bore WW4 respond to the start of dewatering in 2006, and to discharge from DO6 in early 2007. The differences between levels in the CID and alluvium suggest the direction of hydraulic gradient changes with time as levels in the CID fluctuate in response to changing reinjection volumes. The gradient was predominantly towards Weeli Wolli Creek from August 2006 to April 2009, and away from the creek from May 2012 until December 2014.

Figure 22: Mean monthly levels measured in CID bore 99YJWBO3 and WW4 in the alluvium at Weeli Wolli Creek.

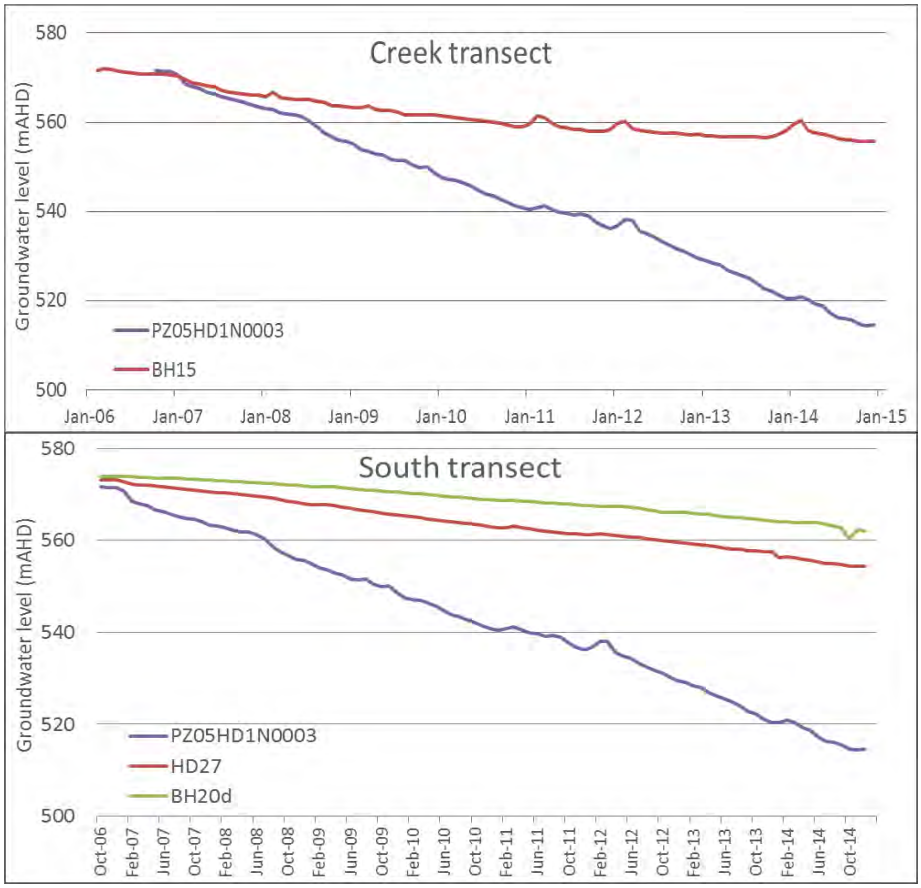


Thus the influence of dewatering, reinjection and discharge on water levels in the alluvium at Yandi varied at different positions along Weeli Wolli Creek, and conditions at tree health monitoring plots varied accordingly.

3.3.2. Water level response to dewatering at HD1

Responses in water levels of bores on Transect 1 (Figure 7) and Transect 2 (Figure 8) in ephemeral sections of Weeli Wolli Creek in response to dewatering at HD1 are shown in Figure 23. Levels in bore PZ05HD1N0003 adjacent to dewatering showed an immediate response to groundwater pumping, and declined progressively throughout the study period from 2007 to December 2014. Levels fell from 570.7 m to 514.6 m (56.1 m) over this period, a mean rate of 7.01 m/year. The rate of fall was relatively uniform with time, although levels increased slightly in response to wet season rainfall and streamflow events. Further from dewatering at bores BH15, HD7 and BH20d, levels also responded to dewatering. As may be expected, the rate of fall and change in water levels between 2007 and 2014 was smaller at locations further from dewatering.

Figure 23: Mean monthly water levels in bores on Transect 1 (Creek transect) and Transect 2 (South transect) in response to dewatering at HD1. Bores are located in ephemeral reaches of Weeli Wolli Creek.

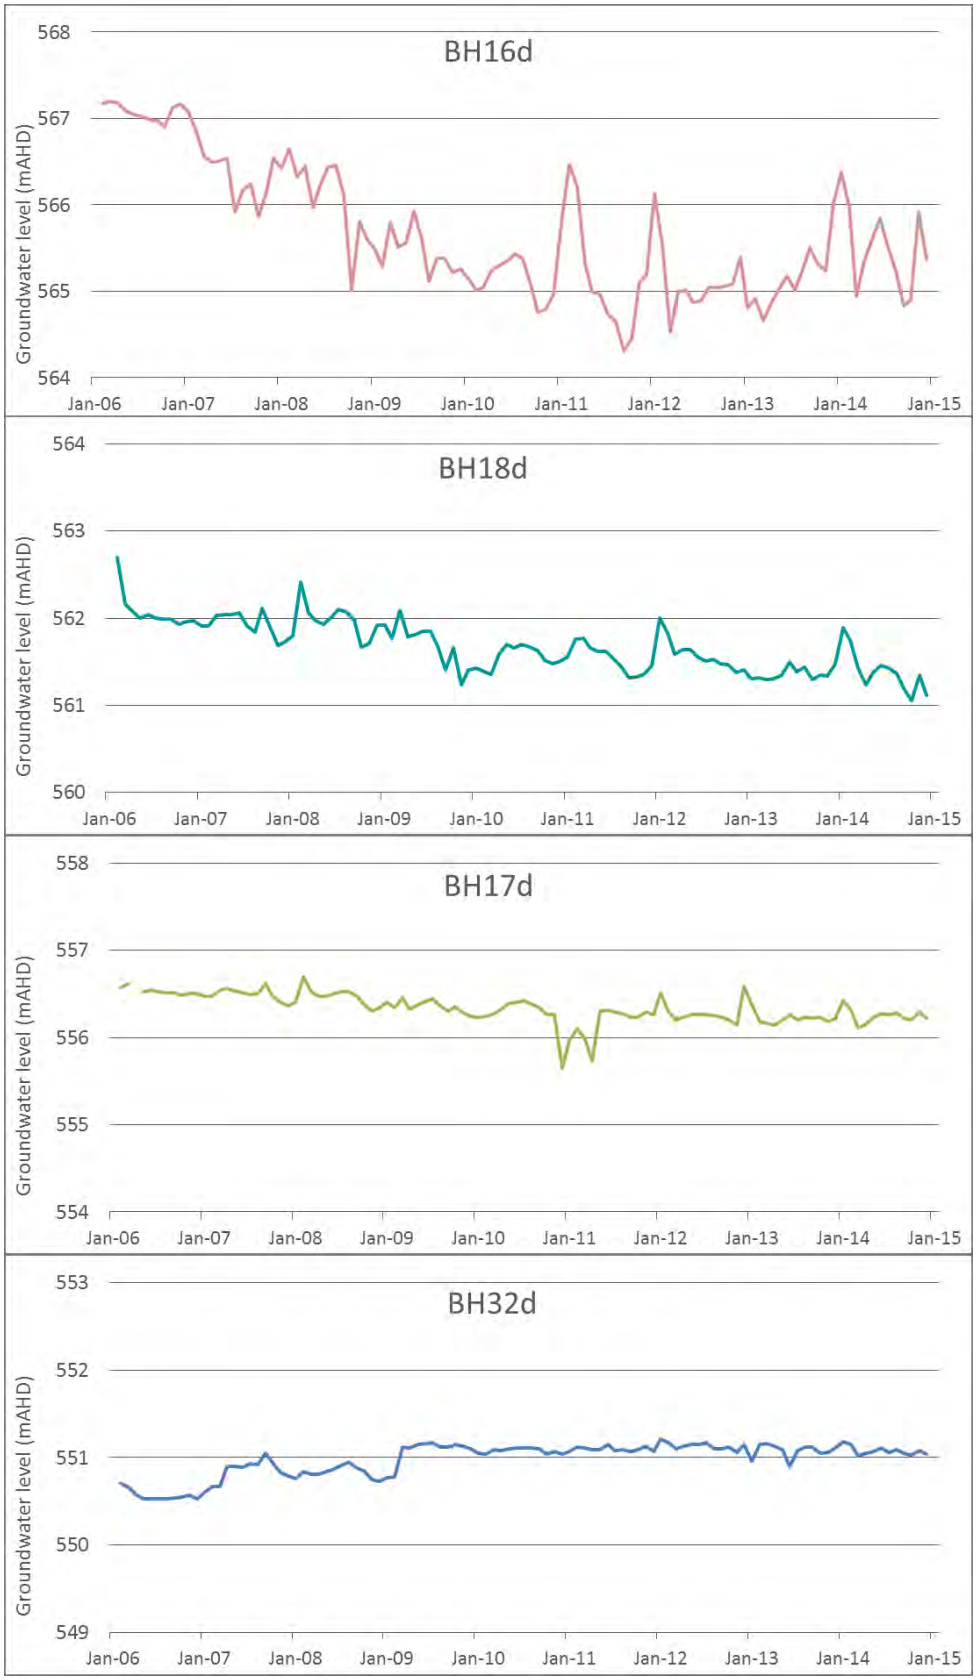


Water levels in the majority of the bores on the previously perennial section of Weeli Wolli Creek along Transect 1 also declined in response to dewatering (Figure 24).

The magnitude of the decline was greatest at BH16d (2.9m), becoming progressively smaller at BH18d (1.7 m), and BH17d (0.9m) further downstream. At the bore on the transect furthest from dewatering (BH32d), water levels tended to increase from February 2007 to

March 2009, and subsequently remained relatively constant until December 2014. The water level here increased by about 0.4 m from its value at the start of dewatering.

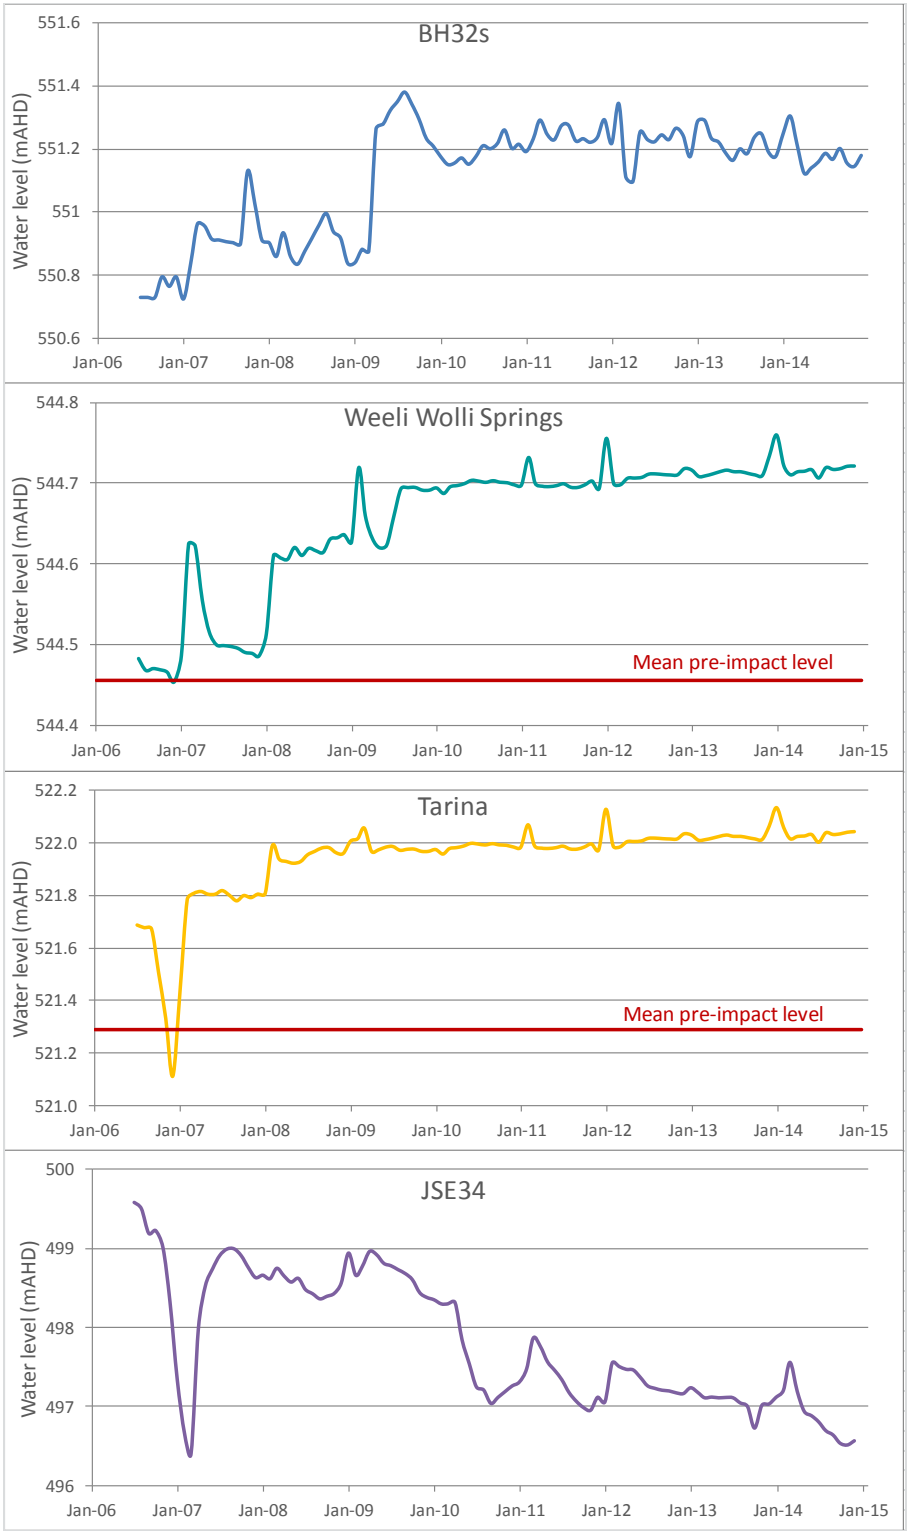
Figure 24: Mean monthly water levels in bores BH16d; BH18d; BH17d and BH32d on Transect 1 (Creek transect) at HD1. Bores are located in the sections of Weeli Wolli Creek receiving supplemental irrigation from spurs and with largely perennial flows prior to dewatering.



3.3.3. Water level responses downstream of the gabion to Yandi

Water levels responses on Transect 3 from bore BH32s and downstream of the gabion to Yandi are shown in Figure 25.

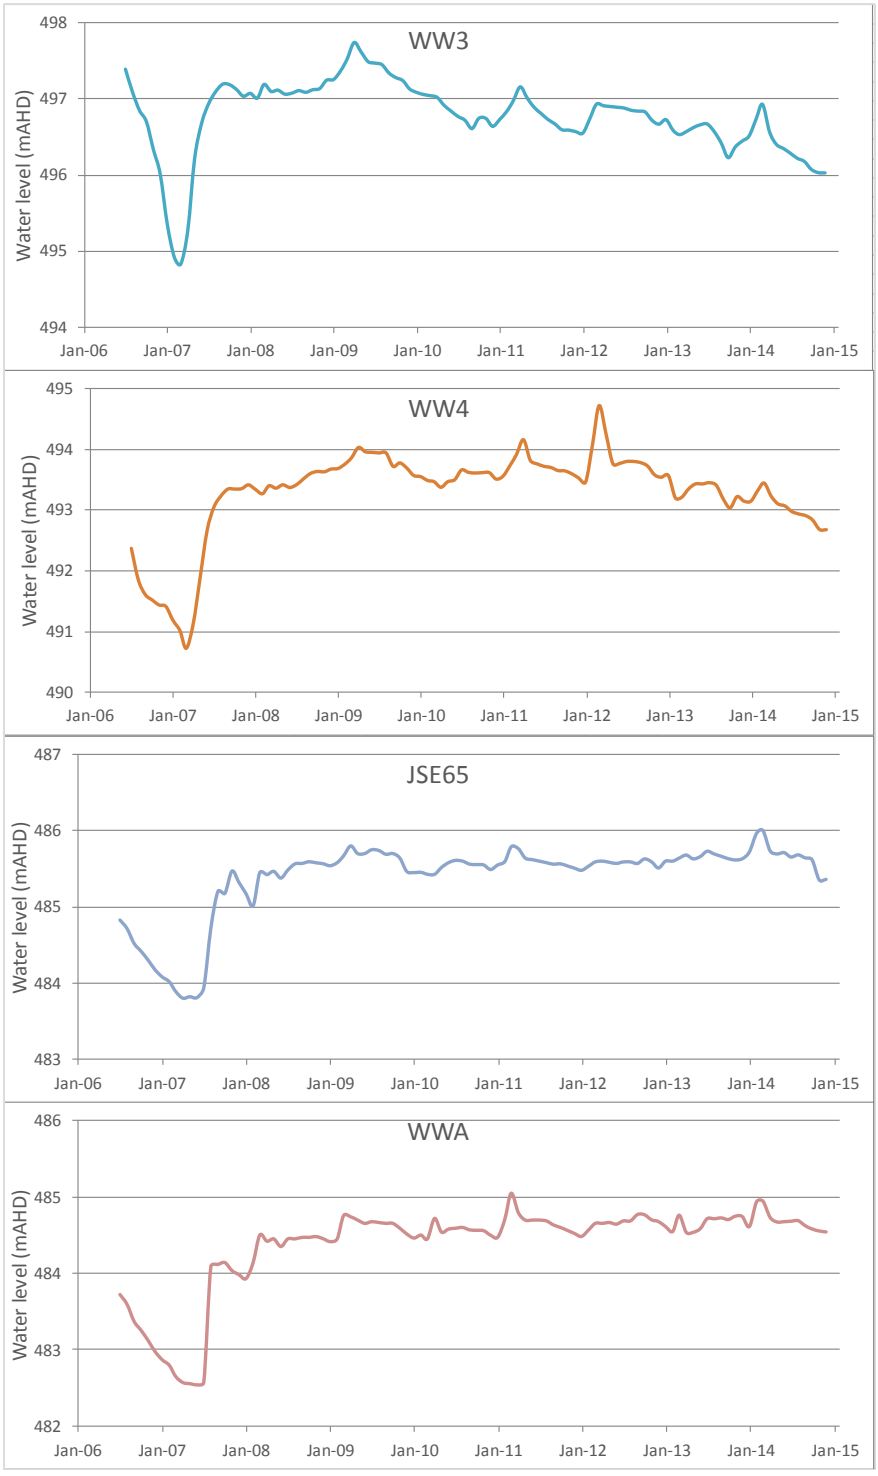
Figure 25: Mean monthly water levels on Transect 3 from bore BH32s and downstream of the gabion to JSE34 at Yandi.



Trends in the response of water levels are different depending on the location on Weeli Wolli Creek as sites are differentially impacted by discharge, drawdown and re-injection. Water

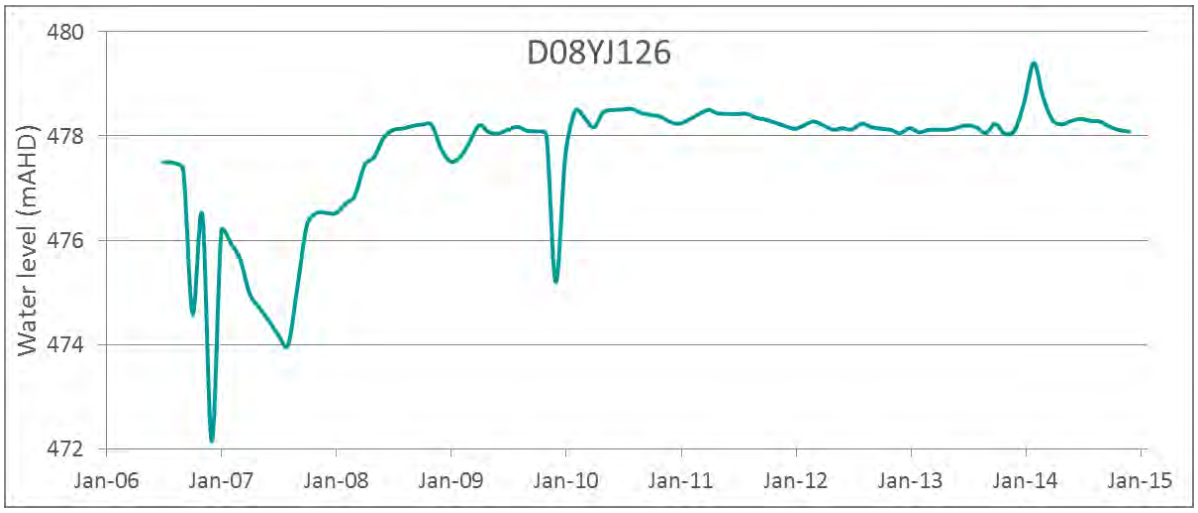
levels at BH32s, Weeli Wolli Springs and Tarina increased in response to discharge from HD1. Increases in levels were initially relatively rapid, but became more gradual from 2009, with indications in December 2014 that the upward trajectory was increasing. Levels at Weeli Wolli Springs and Tarina had increased by 0.26 m and 0.75 m respectively by December 2014 compared with mean levels prior to the start of discharge. In contrast, further downstream at JSE34 (Figure 25) and WW3 (Figure 26) water levels in the alluvium decreased with time in response to dewatering of JSE.

Figure 26: Mean monthly water levels on Transect 3 from bore WW3 to WWA at Yandi.



Further downstream, the influence of dewatering was progressively diminished, and levels increased at WW4, JSE5 and WWA due to differential impacts of discharge and reinjection (Figure 26). Past the confluence with Marillana at bore DO8YJ126 water levels also increased due to impacts of combined discharges into Marillana and Weeli Wolli Creeks (Figure 27).

Figure 27: Mean monthly water levels past the confluence of Marillana Creek at DO8YJ126



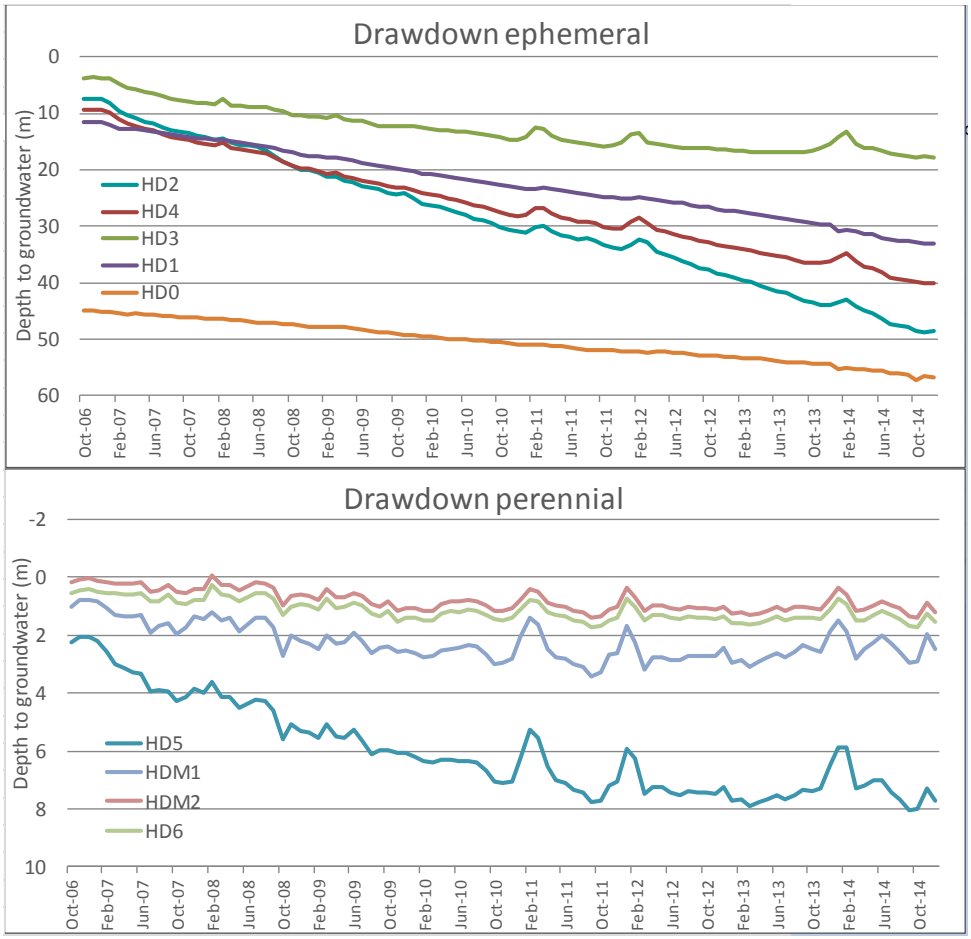
3.3.4. Depth to water table responses in tree health monitoring plots

HD1 drawdown sites

Groundwater levels at each of the THM sites upstream of the gabion were impacted by dewatering (Figure 28). Impacts were greater at ephemeral sites closer to the dewatering than further downstream at the previously perennial sites, which also received supplementary water from the spurs. Prior to the start of dewatering, depth to groundwater at ephemeral sites HD1, HD2, HD3 and HD4 ranged from 3.7 to 11.5 m in October 2006, levels potentially accessible to tree roots. Further upstream at HD0, the water table was less accessible at a depth of 45.0 m making it unlikely that groundwater formed a significant component of tree water uptake at the site. Given this, tree responses at HD0 are useful as a reference for comparison with the response of trees more likely to be accessing groundwater.

Downstream in the springs area at sites HD6, HDM1 and HDM2, groundwater was readily accessible within 1 m of the surface and at 2.2 m depth at HD5 in October 2006 (Figure 28). The rate of groundwater drawdown observed at different sites was a function of the distance from dewatering. Close to dewatering at HD2, levels fell at an average rate of 13.8 mm/day between October 2006 and December 2014, compared with only 0.34 mm/day at HD6, the site just upstream of discharge from the gabion.

Figure 28: Depth to groundwater at tree health monitoring sites at previously ephemeral and perennial sites upstream of the gabion at HD1.



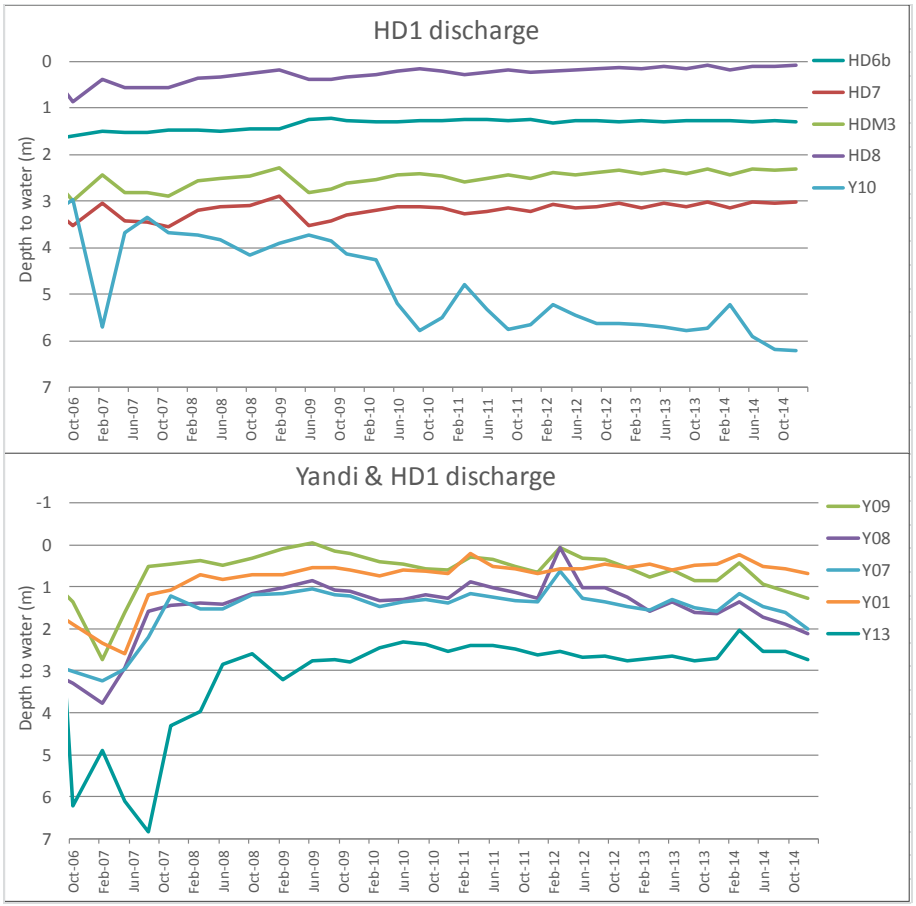
HD1 discharge sites

Figure 29 shows depth to water for sites between the gabion and Yandi, as well as for sites downstream of DO6 at Yandi. The accuracy of estimated depth to water for sites between the gabion at HD1 and Yandi are constrained by the absence of bores along this part of Weeli Wolli creek and the reliance on levels measured at only 2 locations (the Weeli Wolli Springs and Tarina stations). The accuracy of absolute values of water levels estimated for sites may be low because of the distance between monitoring locations. However trends in levels at sites between the gabion and Tarina station (HD6b, HD7, HDM3 and HD8) are likely to be relatively reliable because of good quality data available for the gauging stations. No water level data is available for a distance of 6 km downstream of Tarina. Trends in water levels are likely complex along this part of the creek, since levels are increased by discharge from the gabion at one end, and decreased by dewatering at the other. There are no data to inform how water levels are responding in between. Given that HD1 drawdown impacted on water levels of bores almost 6.5 km from dewatering (e.g. BH17d), it appears possible that JSE dewatering may influence levels at sites HD9, Y12, Y11. Hence both trends and absolute values for water levels estimated for these sites are considered too unreliable to be

useful. Levels estimated for site Y10 are included because of the site's proximity (< 400 m) to bore JSE34.

In October 2006, estimated depth to water was relatively shallow (<3.6 m) at sites HD6b, HD7, HD8, HDM3 and Y10. Following the start of discharge from the gabion, levels tended to increase at each of the sites except Y10 where levels decreased because of the site's proximity to dewatering at JSE (Figure 19). Mean rates of water levels rise were slow, with the lowest rates observed at HD6b (0.10 mm/day). The rate of rise increased progressively for sites further downstream to 0.26 mm/day at HD8. At Y10, depth to water increased from 3.0 m in October 2006 to 6.2 m in December 2014, falling at a mean rate of 1.1 mm/day.

Figure 29: Depth to water at tree health monitoring sites downstream of the gabion receiving discharge from HD1, and at sites downstream of both HD1 and Yandi discharges.



Sites downstream of discharge from both HD1 and Yandi

Interpretation of water level responses at tree health monitoring sites downstream of DO6 is complex because of potential impacts from dewatering, discharge and reinjection along this section of Weeli Wolli Creek. It is also constrained both by the limited number and distribution of bores downstream of the gabion, but also by the short timeframe of monitoring that has occurred in alluvial bores. Long-term river stage data from the Weeli Wolli springs and Tarina gauges allows us to conclude with some confidence how much water levels have

changed from the natural condition prior to discharge. However, the earliest data available for alluvial bores at Yandi is from October 2004, allowing less than 2 years of information on the natural variation in levels prior to dewatering, discharge and reinjection. Where bores were installed in 2004, subsequent data collection is erratic, with only 1 to 3 readings in 2005 and limited readings in 2006 before the time of potential impact. Data is inadequate to establish pre-impact water levels and their annual and seasonal variation. Given these constraints, we can only infer with limited confidence the nature and size of the impact of operations on water levels.

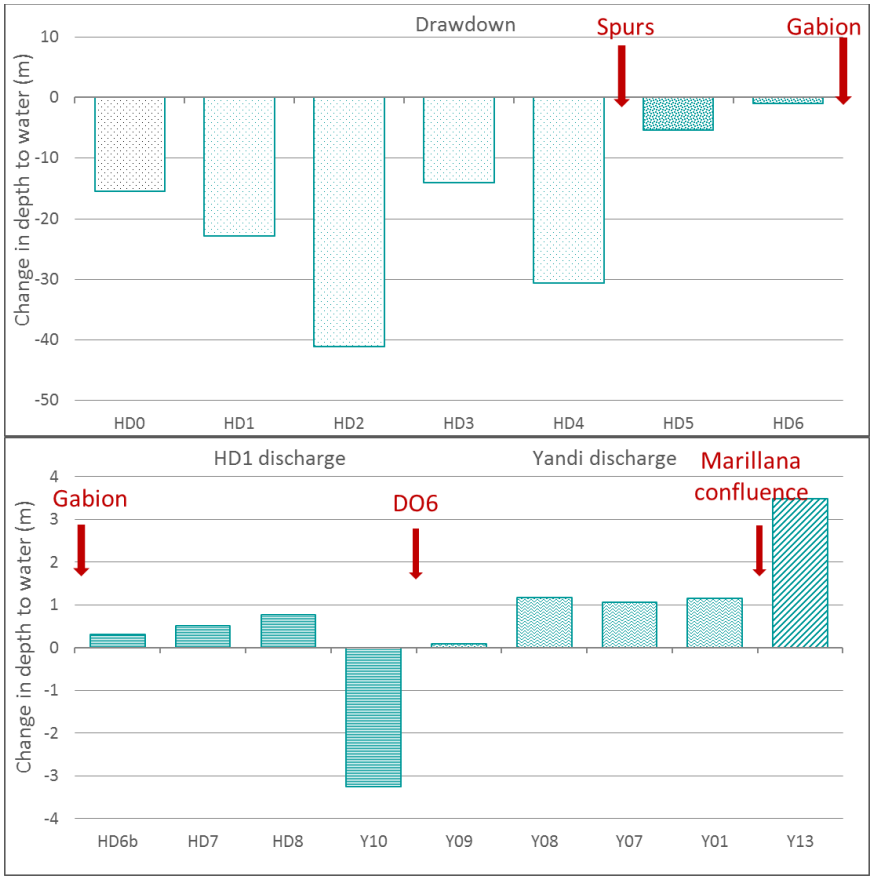
Water levels rose at all sites downstream of DO6 compared with levels measured in October 2006 (Figure 29). The most rapid increases were experienced in 2007 at all these sites, and levels at sites Y09, Y08, Y07 and Y01 had stabilised somewhat by the end of that year. Levels rose further in early 2008 at Y13, becoming more stable mid-way through that year. All sites downstream of DO6 showed a trend of decreasing levels from February 2014 as reinjection and discharge volumes were reduced. The water table was shallowest at Y09 and Y01, and remained within 1 m of the surface from early 2008 through to December 2014 in Y01 and mid-December 2014 in Y09. The water table was deeper at Y07 and YO8, generally within 1.5 m of the surface from 2008 to mid-2012. Estimated levels were deeper again downstream of the confluence with Marillana at Y13, remaining between about 2 to 3m depth from 2009 to the end of 2014.

Change in depth to water over the study period

The net change in depth to water at tree health monitoring sites between October 2006 and December 2014 was quite variable (Figure 30). Drawdown was greatest at sites closest to dewatering where levels fell by more than 30 m and 40 m at HD4 and HD2, respectively. The impact of drawdown was less pronounced further from the bore field, but was still greater than 10 m at all other sites without supplemental irrigation.

Drawdown at sites HD5 and HD6 in the springs area of Weeli Wolli Creek was 5.5 and 1.0 m respectively, and drawdown at Y10 adjacent to JSE dewatering was -3.3 m. Downstream of the gabion, water levels at all sites except Y10 rose in response to discharge from HD1 and Yandi (Figure 30). Water level rises were generally smaller for perennial sites immediately downstream of HD1 discharge than for sites receiving discharge from Yandi. The largest response to discharge from the gabion was observed at HD8 where levels rose by 0.76 m.

Figure 30: Change in estimated depth to water between October 2006 and December 2014 for drawdown and discharge sites.



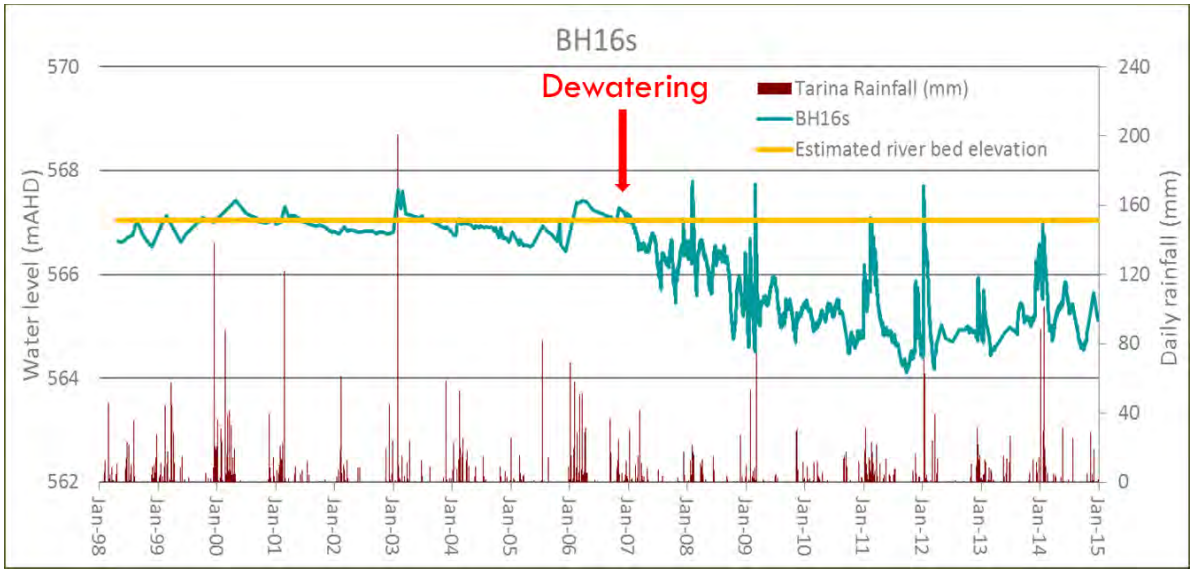
Downstream of DO6, levels rose by > 1 m at all sites except Y09 where levels increased by only 0.1 m, suggesting that dewatering could be mitigating water level rises due to discharge at this site. The greatest increase was observed at Y13 where levels rose by 3.5 m over the study period, with discharges into both Marillana and Weeli Wolli Creeks potentially contributing to this rise.

3.4. Responses in runoff and streamflow

3.4.1. Impacts of drawdown on streamflow in Weeli Wolli Creek

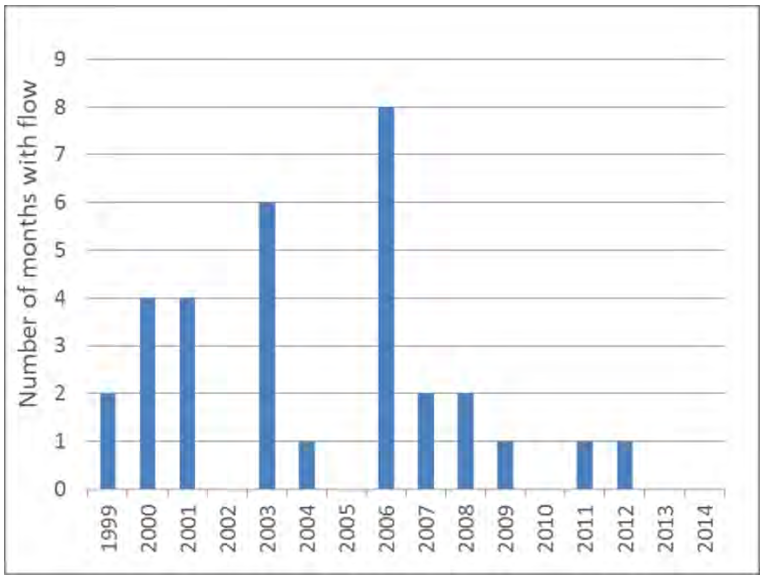
No streamflow data was available to evaluate potential impacts of drawdown at HD1 on runoff and streamflow in Weeli Wolli creek upstream of the gabion. As a surrogate analysis, the response in water levels at BH16s within the drawdown zone along Weeli Wolli creek (Figure 7) were used as an indicator of the frequency and duration of flows in the creek (Figure 31).

Figure 31:Temporal changes in water level at bore BH16s, adjacent to Weeli Wolli Creek. The estimated elevation of the river bed and daily rainfall at the Tarina station are also shown.



Flow was assumed to occur when the water level at BH16s was greater than the estimated elevation of the river bed. Prior to the start of dewatering, levels in BH16s remained within 0.6 m below the river bed. Dewatering caused water levels to fall, reaching depths close to 3 m lower than the level of the bed. As a result, the frequency and duration of intervals when the water level at BH16s was above the level of the river bed was reduced compared with conditions prior to dewatering (Figure 31). This suggests that both the frequency and duration of streamflow in Weeli Wolli Creek upstream of the gabion was reduced by dewatering. The number of months each year when water levels in BH16s were above the river bed elevation was calculated for years before and after the start of dewatering (Figure 32).

Figure 32: Number of months in each year that water levels at BH16s exceeded river bed elevation, indicative of months with flow in Weeli Wolli Creek

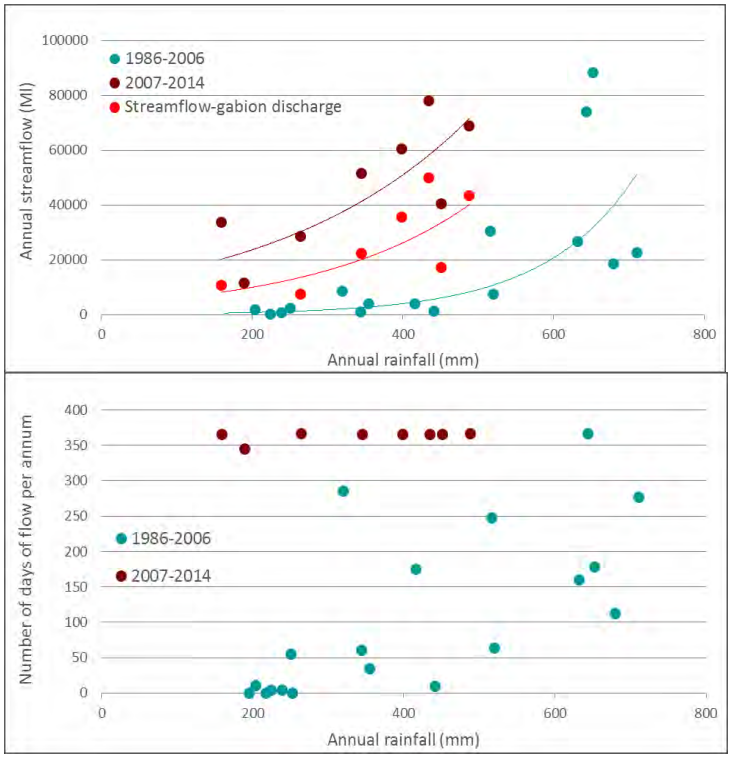


For years prior to the start of dewatering the number of months with flow is likely underestimated since bores were monitored only once or twice per month, and there were several months when no monitoring occurred (e.g. February and December 2002). From December 2006, levels in BH16s were monitored twice per day, so the number of months with flow could be reliably determined after dewatering started. Dewatering reduced the number of months per year with flow at BH16s, with up to 8 months per year prior to dewatering and a maximum of only 2 months per year afterwards. The mean number of months with flow for years 1999-2006 and 2007-2014 was 3.2 and 0.9 respectively.

3.4.2. Impacts of discharge on streamflow downstream of the gabion

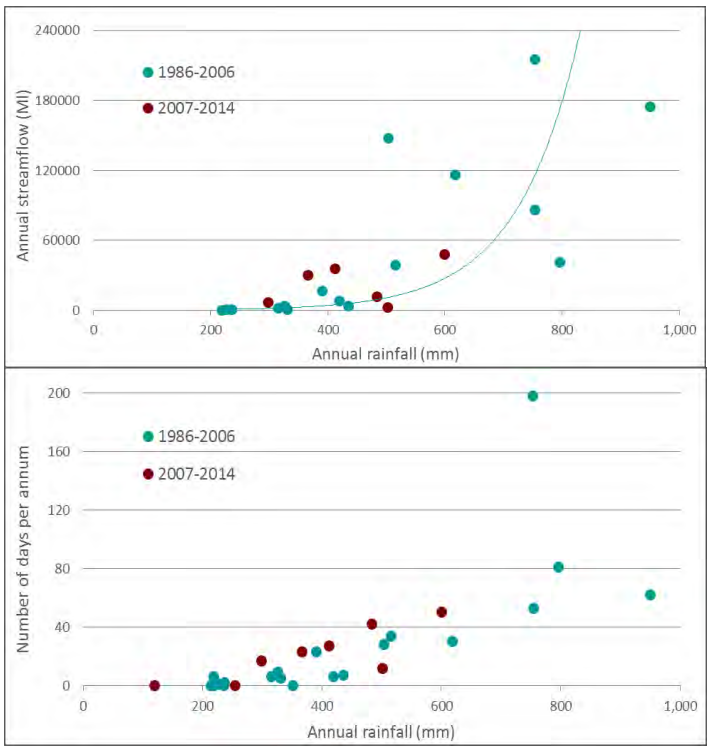
Annual rainfall and streamflow data from the Tarina station was used to assess changes to streamflow downstream of the gabion after the start of dewatering and discharge operations. As expected, streamflow at Tarina was increased by discharge into Weeli Wolli Creek (Figure 33). Both the volume of streamflow and the number of days per year of flow at Tarina were increased by discharge. Prior to 2007, the number of days of flow per year ranged from 0 to 366 in a leap year (2000), but after 2007 flow was continuous throughout the year. Increases in the volume of streamflow were greater than would be expected if the increase were simply due to the volumes discharged each year.

Figure 33: Relationship between annual rainfall and streamflow measured at the Tarina station. Separate figures are shown for response in streamflow volumes and the number of days per annum of flow as a function of rainfall. Separate relationships are shown for years 1986-2006 and 2007-2014, years before and after potential impacts. Data for annual streamflow minus gabion discharge for the period 2007-2014 are also shown.



Further downstream at Waterloo Bore (Figure 34) streamflow did not appear to be impacted by discharges from HD1 or Yandi. Neither the volume of streamflow, nor the number of days of flow each year appeared to be increased by the combined impacts of these discharges.

Figure 34: Relationships between annual rainfall and streamflow measured at the Waterloo Bore station. Data are shown separately for years 1986-2006 and 2007-2014, years before and after potential impacts. Separate figures are shown for response in streamflow volumes and the number of days per annum of flow as a function of rainfall.



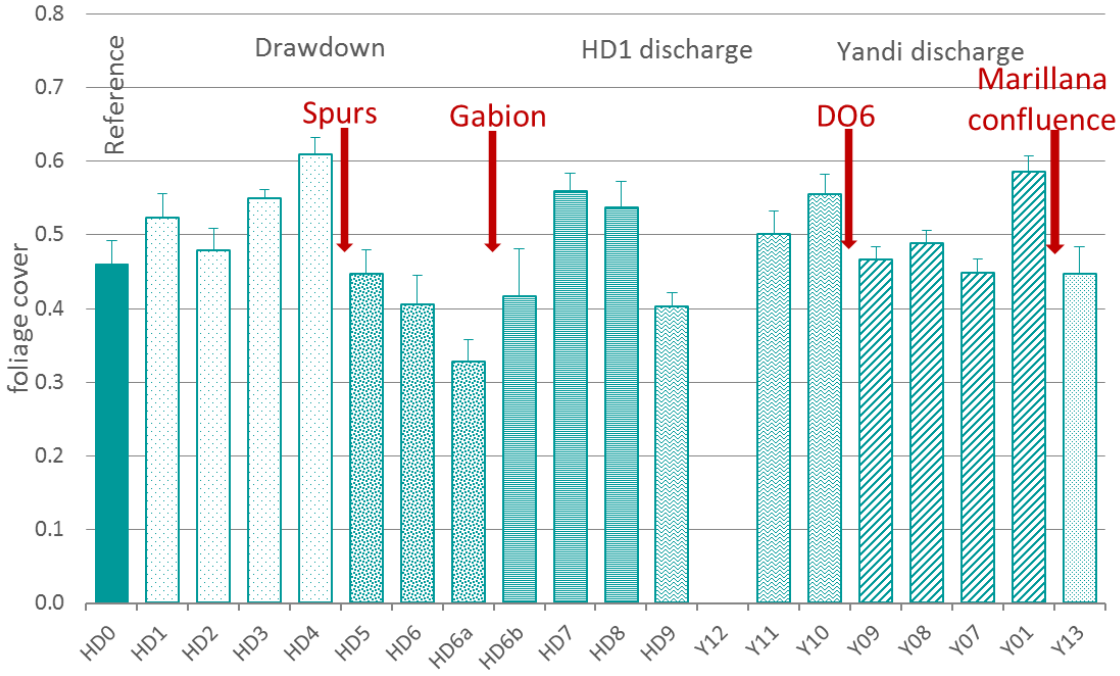
3.5. Vegetation responses

3.5.1. Temporal changes in foliage cover

2- way repeated measures ANOVA of site and temporal responses in foliage cover gave statistically significant responses for both site and time (Appendix 1), and for the interaction of these factors. Given this, further statistical analyses were applied to investigate in more detail the significance of different responses observed in the figures presented below.

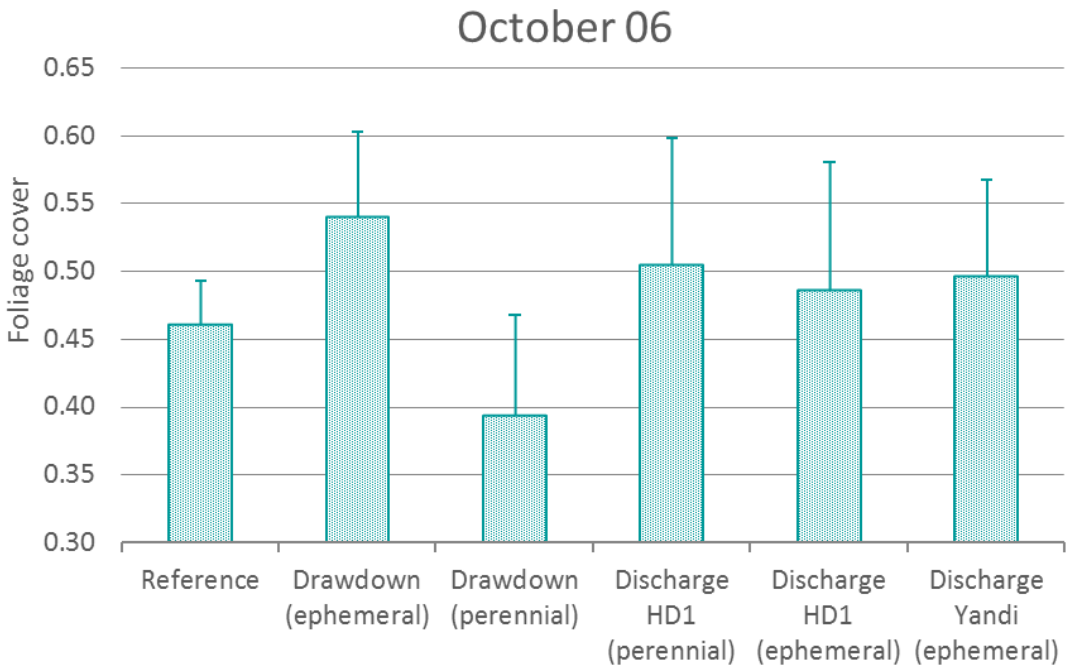
Prior to the start of dewatering at HD1 and discharge from the gabion and DO6 there was already considerable variation in eucalypt foliage cover at different sites (Figure 35). Foliage cover ranged from 0.33 at HD6a to 0.61 at HD4. Foliage cover was low in the springs/pools area of Weeli Wolli Creek (drawdown ephemeral treatment) and high in upstream areas (drawdown perennial treatment, Figure 36).

Figure 35: Foliage cover in October 2006 prior to the start of dewatering and prior to discharge from HD1 and Yandi DO6. Foliage cover at Y12, and reference sites PB1 & HD10 were unavailable for October 2006.



Foliage cover in the springs/pools area was significantly lower than all other treatments, including those further downstream that also historically received perennial flow (HD1 discharge perennial). There were no significant differences in foliage cover between any of the other treatments in October 2006.

Figure 36: Mean foliage cover of treatment groups at the start of monitoring in October 2006.

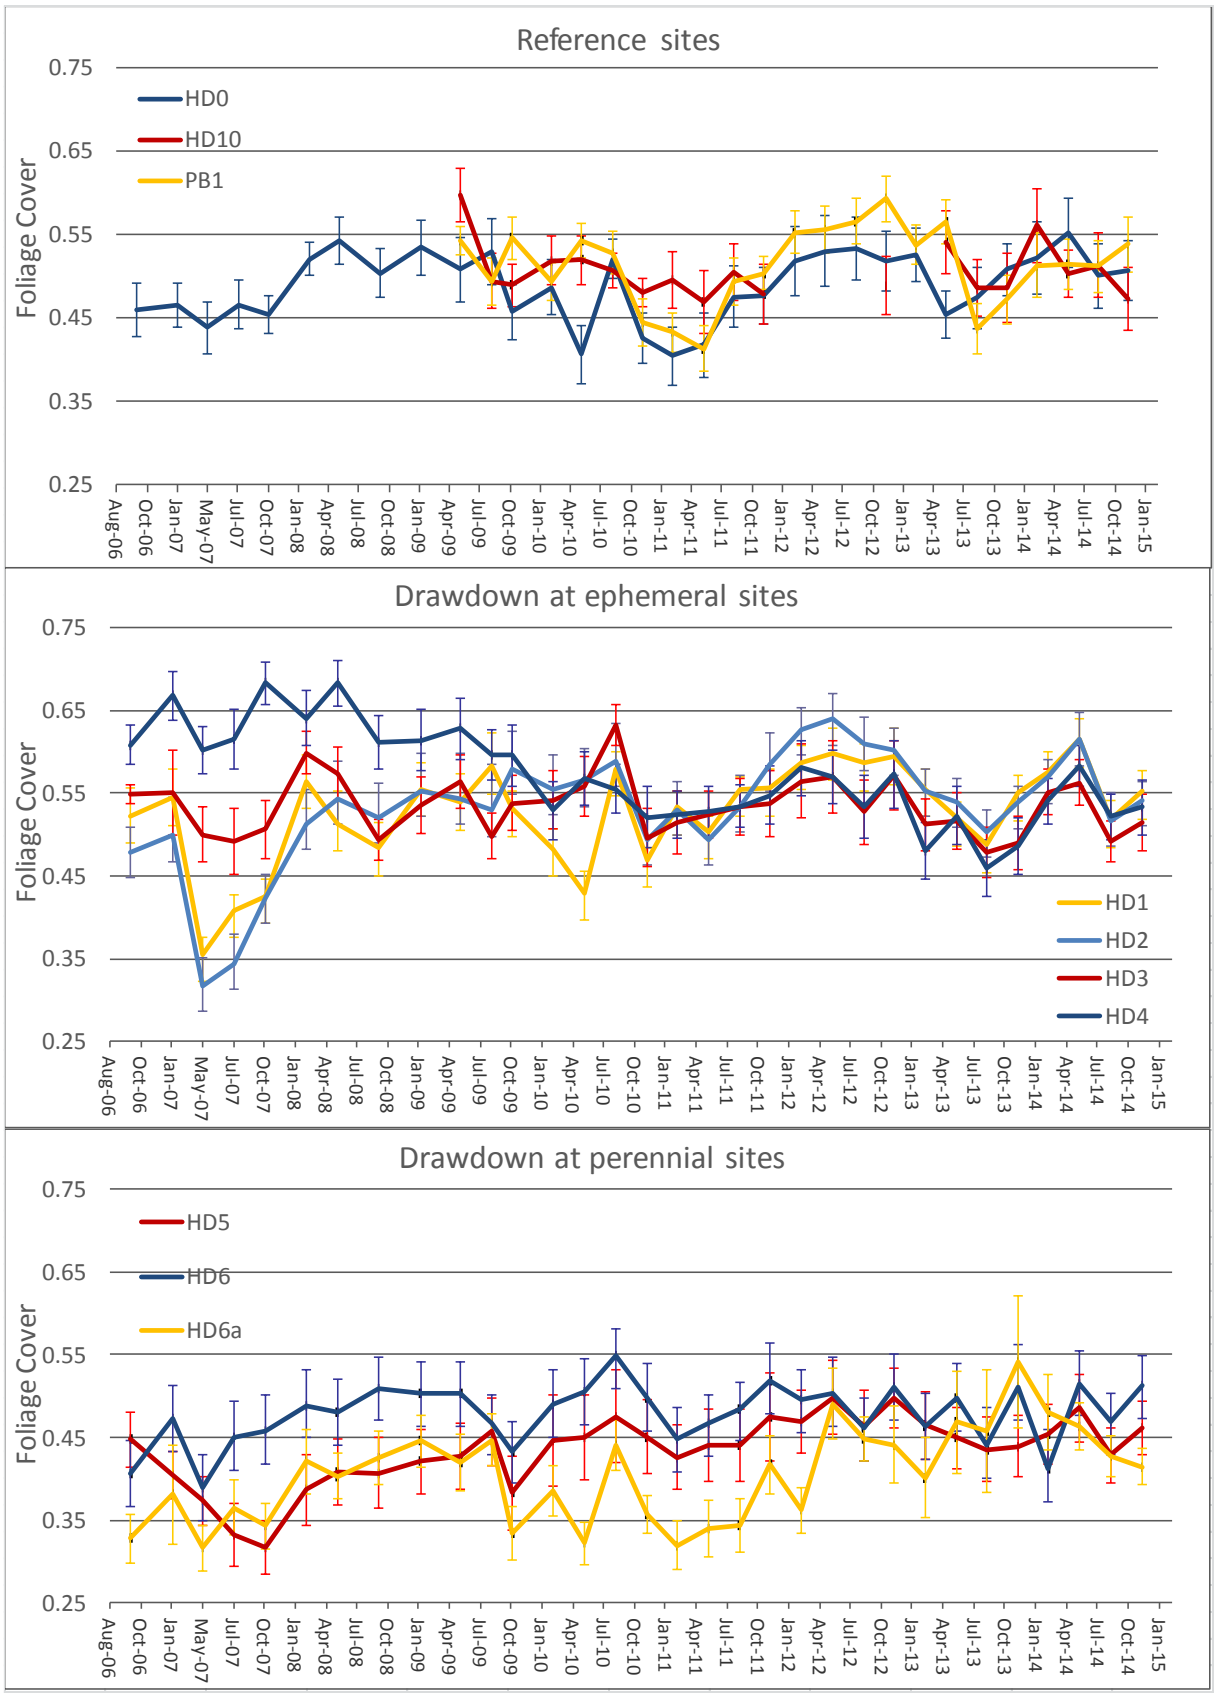


As would be expected at sites experiencing high seasonal and annual variation in rainfall, and subject to disparate water management regimes, temporal responses in foliage cover were very dynamic at all sites (Figure 37 and Figure 38). Over the time period with concurrent monitoring at the reference sites HD0, HD10 and PB1, seasonal trends were generally consistent between sites lending confidence to the selection of HD0 as a reference site (Figure 37).

When monitoring commenced, foliage cover at sites in the drawdown ephemeral treatment was initially quite variable (Figure 37). Cover decreased at all of these sites between February and May 2007, soon after the start of dewatering. Sites HD1 and HD2 showed greater foliage cover reductions than HD3 and HD4 (Figure 37). The impact of any stress was short-lived, and foliage cover recovered progressively over subsequent monitoring intervals. By March 2008 cover was similar to levels measured prior to potential impact in October 2006. From September 2010 to December 2014, trends in foliage cover were similar at all these sites.

Trees in the drawdown perennial treatment showed much smaller declines in foliage cover after dewatering commenced than those upstream subject to ephemeral flows (Figure 37). The largest decline occurred in HD5, the perennial site closest to dewatering. The response at HD5 appeared delayed compared with ephemeral sites, as foliage cover continued to decline progressively from May reaching a minimum in October 2007. The delay in response may simply reflect the greater distance from dewatering at HD5 compared with ephemeral sites upstream, and longer timeframes for groundwater to respond. Similar to the upstream trend, foliage cover at HD5 subsequently recovered. Foliage cover was quite variable between sites in the drawdown perennial treatment, possibly a response to differential applications of water from spurs due to variations in the distance from a spur and the volumes applied at each site. Foliage cover at HD6 was consistently greatest for several years from 2007 to mid-2012, and cover was lowest at HD6a from June 2009 to April 2013.

Figure 37: Temporal responses in foliage cover for reference sites and for both ephemeral and perennial sites in areas potentially impacted by groundwater drawdown.

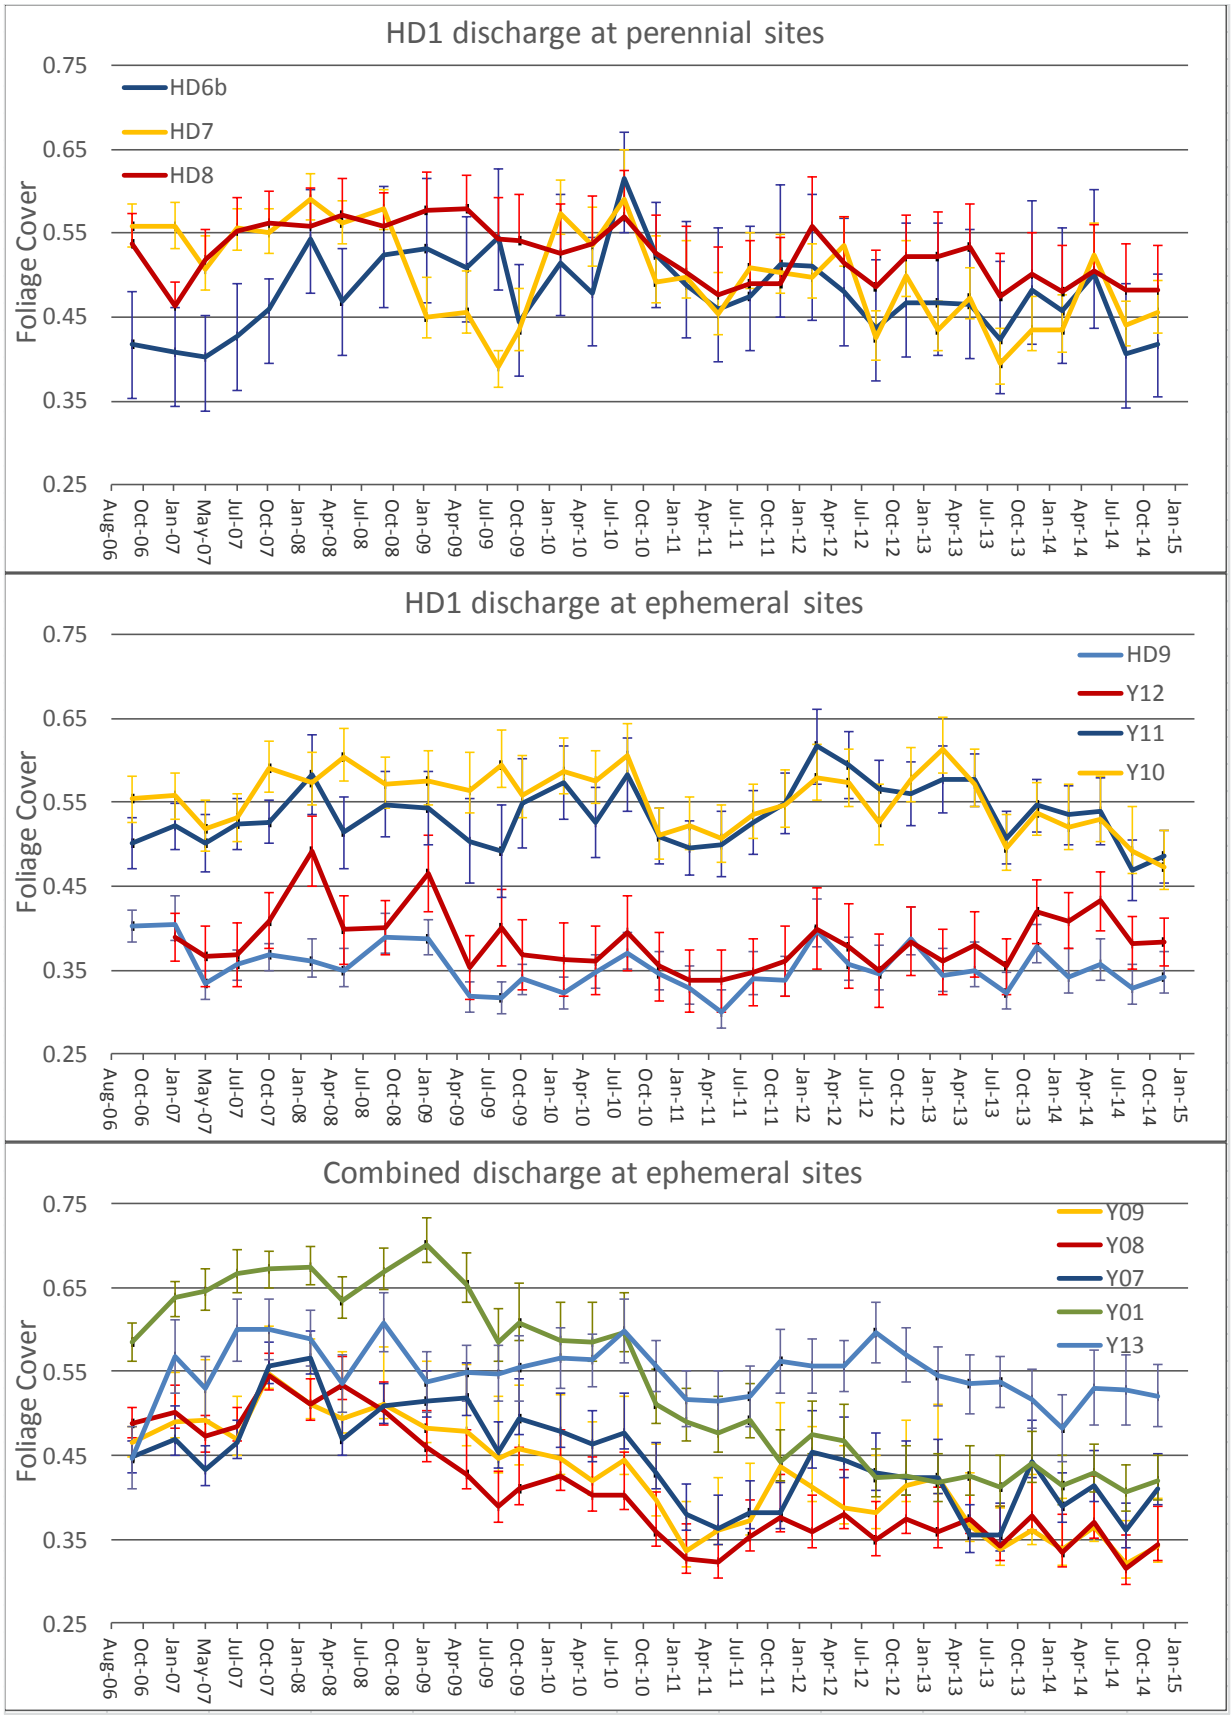


At perennial sites downstream of the gabion, sites subject to discharge from HD1 showed no evidence of early decline due to impact (Figure 38). Foliage cover was initially low in HD6b compared with other sites in this treatment, but tended to increase throughout 2007 and 2008. Foliage cover in HD7 showed a sharp decline in February 2007, the result of impacts of a bushfire at this site. These impacts persisted for some time, with foliage cover in HD7 declining further by September 2009, but subsequently recovering to levels similar to other sites by March 2010. Despite showing some seasonal responses, foliage cover in all sites in the perennial discharge treatment showed evidence of a gradual decline in foliage cover from September 2010 to 2014, a possible response to long-term or cumulative impacts of discharge.

The foliage cover of ephemeral sites subject to discharge from HD1 was initially quite variable (Figure 38) with lower foliage cover found in upstream sites closest to the springs (HD9 and Y12) compared downstream sites (Y11 and Y10). These differences persisted throughout the study period from 2007 to 2014. There was evidence for a gradual decline in foliage cover throughout the study period in the upstream ephemeral site closest to the gabion (HD9), and cover in Y11 and Y12 showed evidence of a gradual decline from 2013.

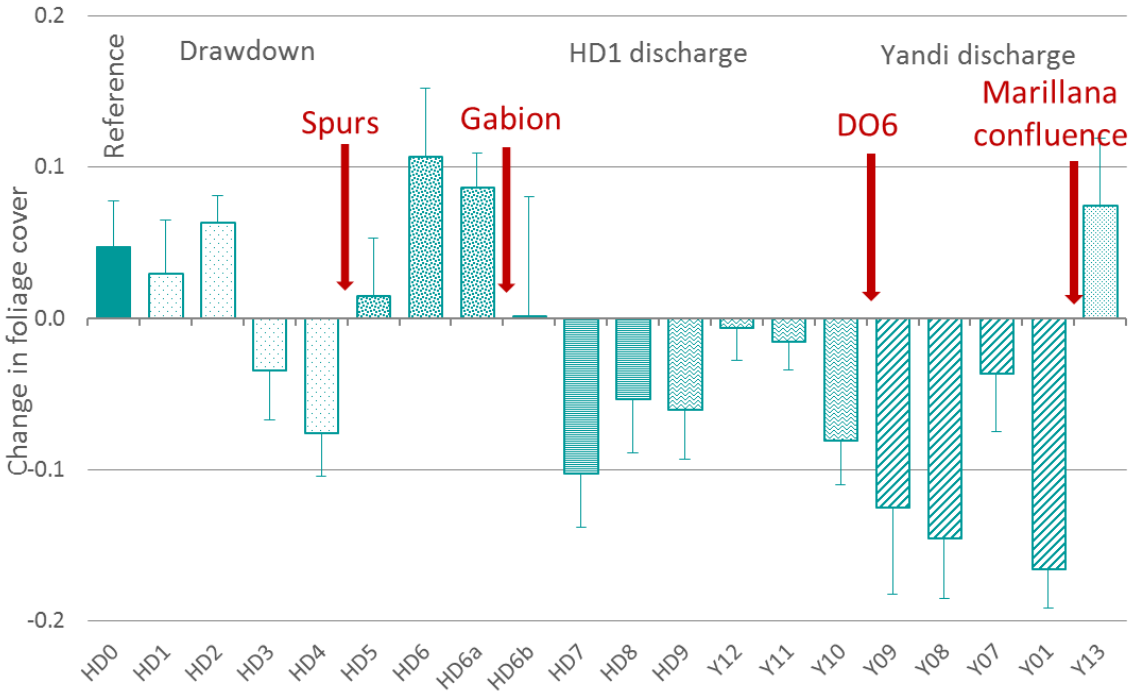
Ephemeral sites further downstream showed differing responses in foliage cover to combined discharges from HD1 and Yandi (Figure 38). Foliage cover at the site downstream of the confluence with Marillana (Y13) was initially low, but increased following the start of discharge from DO6. Trees at Y13 largely maintained this level of cover throughout subsequent years, but showed evidence of decline from September 2012. Trees at this site had potentially been subject to impacts of discharges into Marilla Creek for some years prior to the start of this study. Foliage cover at Y01, close to the confluence with Marillana, was greater at the start of monitoring than all other sites downstream of DO6 discharge. After an initial increase to February 2009 foliage cover progressively declined at this site, reaching a minimum in September 2014. It may be possible that this response reflect the impacts of Yandi discharges into both Marillana and Weeli Wolli Creeks, due to the site's proximity to the confluence. Foliage cover of trees at sites (Y07, Y08 and Y09) increased slightly from August to November 2007, each reaching maxima for the study period in either late 2007 or early 2008. Cover at all these sites subsequently showed a gradual decline for the remainder of the study, reaching minima in September 2014.

Figure 38: Temporal responses in foliage cover for sites potentially affected by discharge. Foliage cover is shown for both ephemeral and perennial sites downstream of HD1 discharge and for ephemeral sites downstream of combined discharges from HD1 and Yandi.



The impacts of the different water management regimes on eucalypt foliage cover over the entire study period are represented below in Figure 39. In this figure, positive values represent an increase in foliage cover between October 2006 and December 2014, and negative values a decrease. With the exception of ephemeral sites subject to drawdown, site responses in foliage cover were generally consistent within treatments.

Figure 39: Change in foliage cover of study sites from the start of monitoring in October 2006 to December 2014. Sites in similar treatments (drawdown ephemeral; drawdown perennial; HD1 discharge perennial, HD1 discharge ephemeral and Yandi discharge ephemeral) are represented by bars with similar fill patterns.

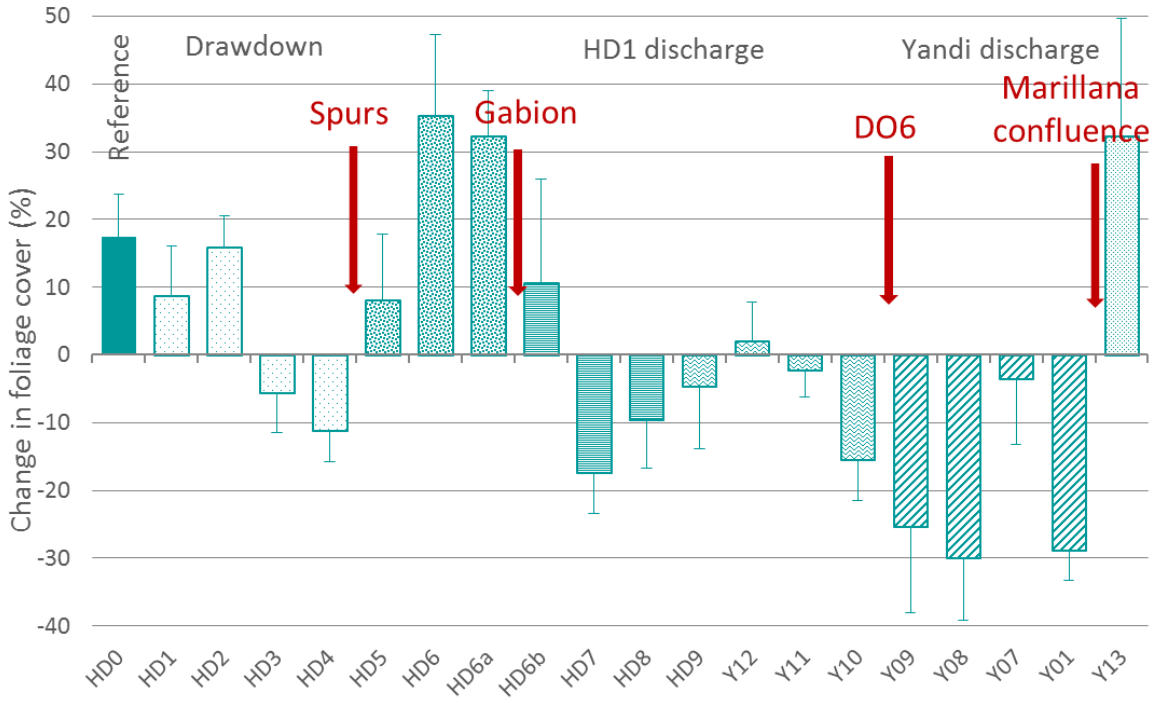


Foliage cover increased over the study period at the reference site HD0. Cover also increased in the perennial drawdown sites, most likely a response to spur discharges along this section of Weeli Wolli Creek. Site responses were variable at the ephemeral drawdown sites upstream of the spurs, as foliage cover increased at sites HD1 and HD2, but decreased at HD3 &HD4. It is possible that these contrasting responses resulted from changes in surface water management associated with the HD1 mine site, and the diversion of Pebble Mouse Creek. This may have reduced surface water availability to HD4, and increased availability to HD2. Thus any impacts of drawdown at these sites may be either masked or magnified by surface water management interventions.

Tree responses to discharge over the study period were largely consistent, with foliage cover decreasing at sites in both ephemeral and perennial areas of Weeli Wolli Creek (Figure 39). Exceptions were sites HD6b where foliage cover was similar at the start and finish of the study, and Y13 where foliage cover increased.

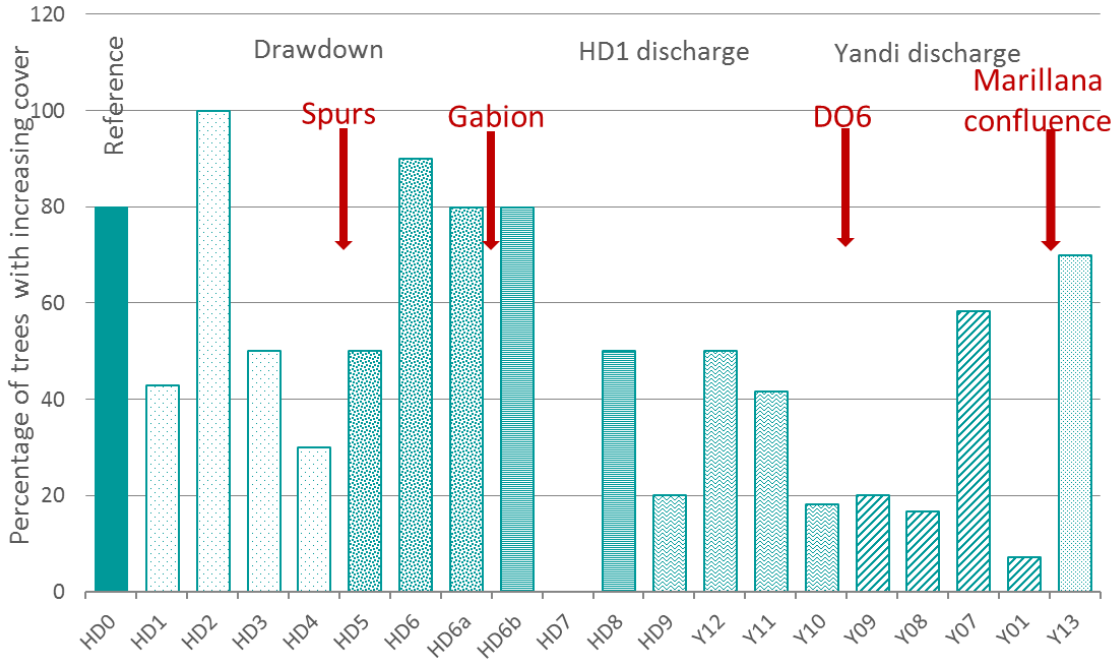
Trends in the percentage change in foliage cover over the study period (Figure 40) are generally consistent with the absolute changes in foliage cover shown above (Figure 39). Increases in foliage cover at sites in the perennial drawdown treatment ranged from 8.1% to 35.2%, and foliage cover of trees at Y13 increased by 32%. Decreases in foliage ranged from -2.3% in Y11 to -29.9% at the worst affected site, Y08. A small net decrease in foliage cover at Y12 represented a mean relative increase of 2% in cover at this site. This occurs because increases in foliage cover found for some trees at the site were larger relative to their original cover than the relative size of the decrease occurring in others. This suggests that the responses of all trees at a particular site to management impacts aren't necessarily consistent.

Figure 40: Percentage change in foliage cover of study sites from the start of monitoring in October 2006 to December 2014. Sites in similar treatments (drawdown ephemeral; drawdown perennial; HD1 discharge perennial, HD1 discharge ephemeral and Yandi discharge ephemeral) are represented by bars with similar fill patterns.



The variability in response between trees at a site is further illustrated by Figure 41, which shows the proportion of trees at each site which increased their foliage cover over the study period. HD2 was the only site where foliage cover of all trees increased, and HD7 the only site where cover declined in all trees. At sites showing the greatest decreases in foliage cover (Y01 and Y08), foliage cover increased in 7.1% (1 in 14) and 16.7% (2 in 12) of trees at the site, respectively.

Figure 41: Percentage of trees at each site showing an increase in foliage cover over the study period from October 2006 to December 2014.



3.6. Factors influencing foliage cover responses

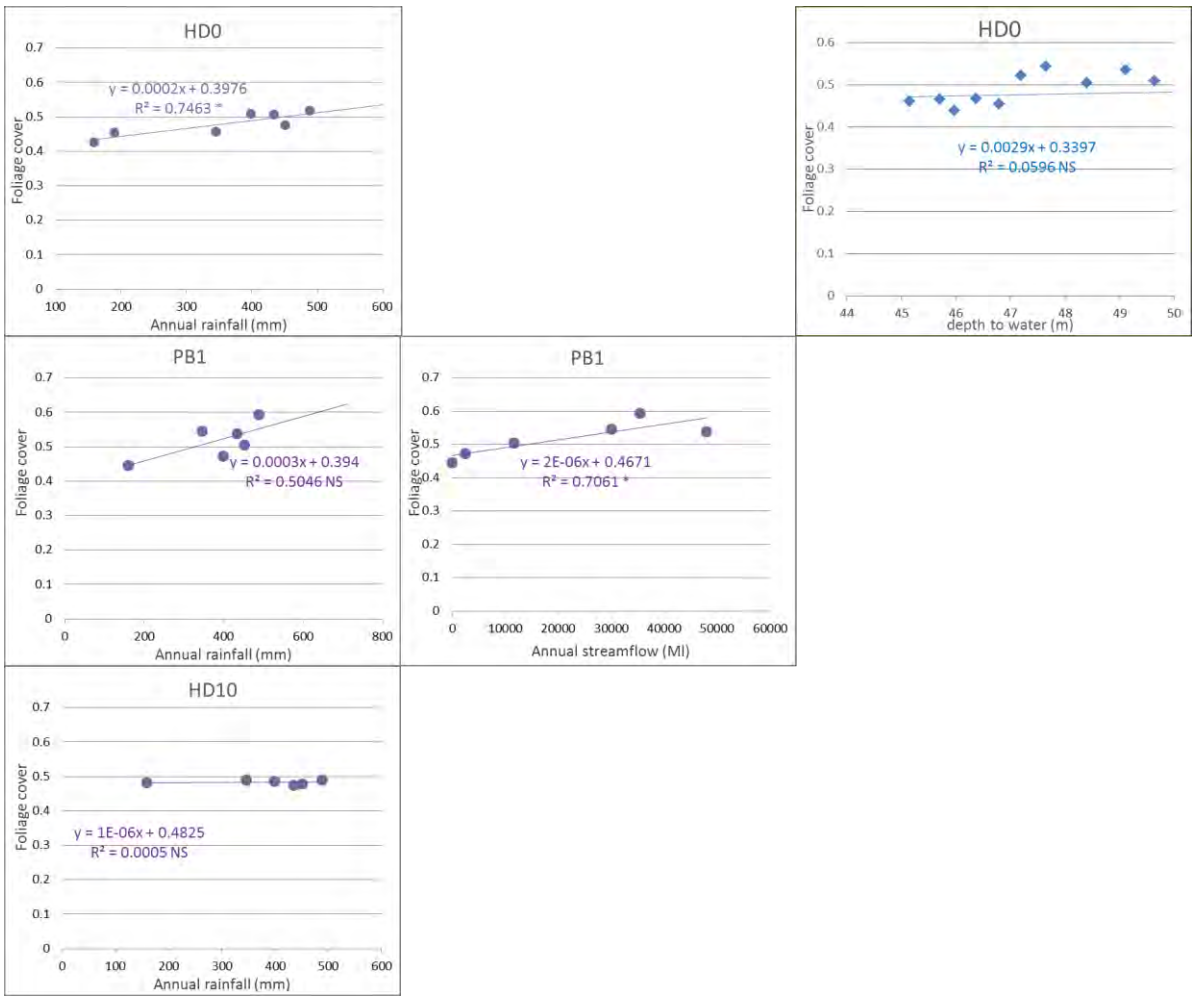
Correlations between foliage cover and hydrological variables including rainfall, streamflow, estimated depth to water and discharge reveal the key influences on vegetation responses at the different sites. To identify the most useful relationships, different rainfall statistics such as annual rainfall, wet and dry season rainfall and quarterly rainfall were used to correlate separately with foliage cover measured in Q1, Q2, Q3 and Q4 (data not shown). The rainfall statistic and quarterly foliage cover that gave the most frequent significant correlations across all sites was Q4 foliage cover regressed against annual rainfall. This result may appear counter-intuitive given that a proportion of annual rainfall may not have been received when Q4 monitoring was undertaken. Part of the explanation for this result may lie with the fact that monitoring was carried out in December for 5 out of the 7 years of monitoring. A further explanation is that vegetation growth may be particularly responsive to water availability under the warm temperature conditions of spring, and this response is best captured in the Q4 data. Correlations between annual rainfall and Q4 foliage cover was thus selected as the most reliable indicator of site response to rainfall.

3.6.1. Factors influencing foliage cover responses at reference sites

Estimates of groundwater depth were unavailable for sites HD10 and PB1, and streamflow data were unavailable for HD0 and HD10. Foliage cover at reference site HD0 did not respond significantly to changing groundwater depth due to drawdown (Figure 42), most likely because it was too deep (>45 m) to be readily accessible for uptake by tree roots.

This lack of a significant relationship with groundwater supports the use of HD0 as a reference site, given that foliage cover data is only available from June 2009 for sites HD10 and PB1.

Figure 42: Relationships between foliage cover and annual rainfall, annual streamflow and estimated depth to water for reference sites HD0, PB1 and HD10. Q4 foliage cover is used to correlate with annual rainfall and streamflow at Waterloo Bore. Foliage cover for all monitoring dates is correlated with estimated depth to water for that month.



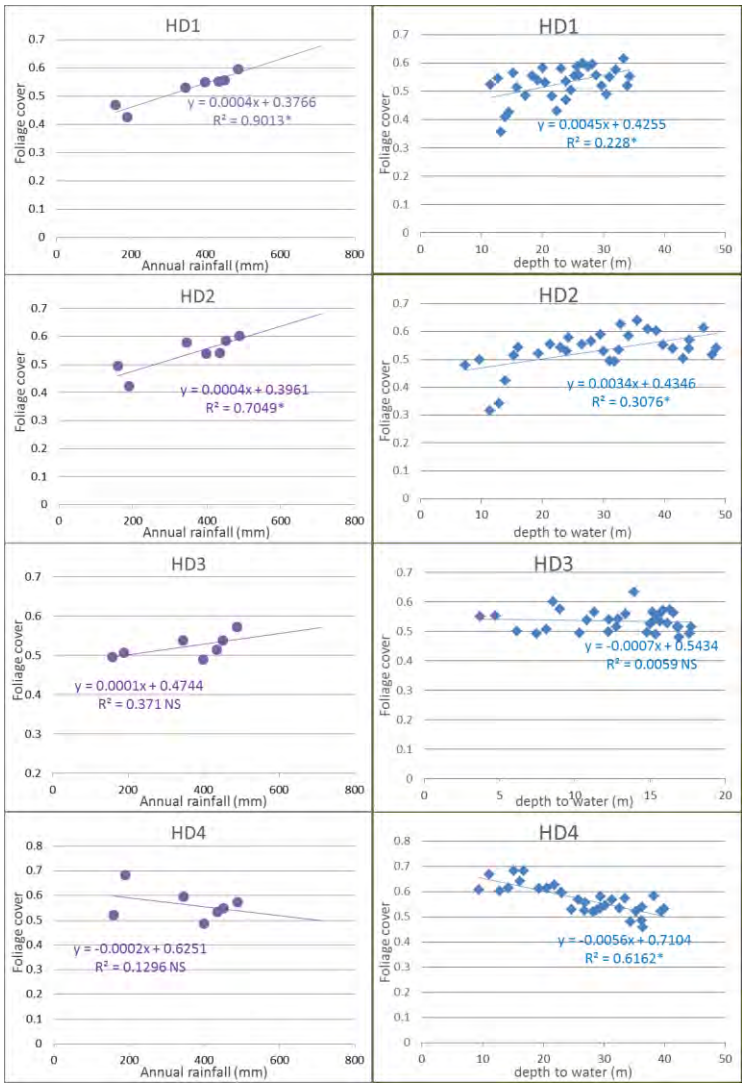
Foliage cover at HD0 was positively correlated with annual rainfall, but relationships for PB1 and HD10 were not significant. However, PB1 foliage cover was positively correlated with streamflow at Waterloo Bore. The lack of a significant relationship with rainfall at PB1 may partly result from the few data points and lower degrees of freedom to test the statistical significance of the correlation. Q4 foliage cover at HD10 showed little change with time, making it unlikely that a statistically significant relationship could result from regression analyses.

3.6.2. Factors influencing foliage cover responses at ephemeral drawdown sites

Foliage cover at HD1 and HD2 were positively correlated with annual rainfall, but relationships for HD3 and HD4 were not significant (Figure 43). The sites showed

contrasting responses to impacts of drawdown, with foliage cover at HD4 decreasing as groundwater levels fell, whilst cover at HD1 and HD2 increased with increasing depth. It is likely these contrasting responses result from changes to surface water management due to the diversion of Pebblemouse creek. This would have reduced the volume of streamflow to HD4 located downstream of the diversion on Pebblemouse Creek, and increased flow to sites along Weeli Wolli Creek.

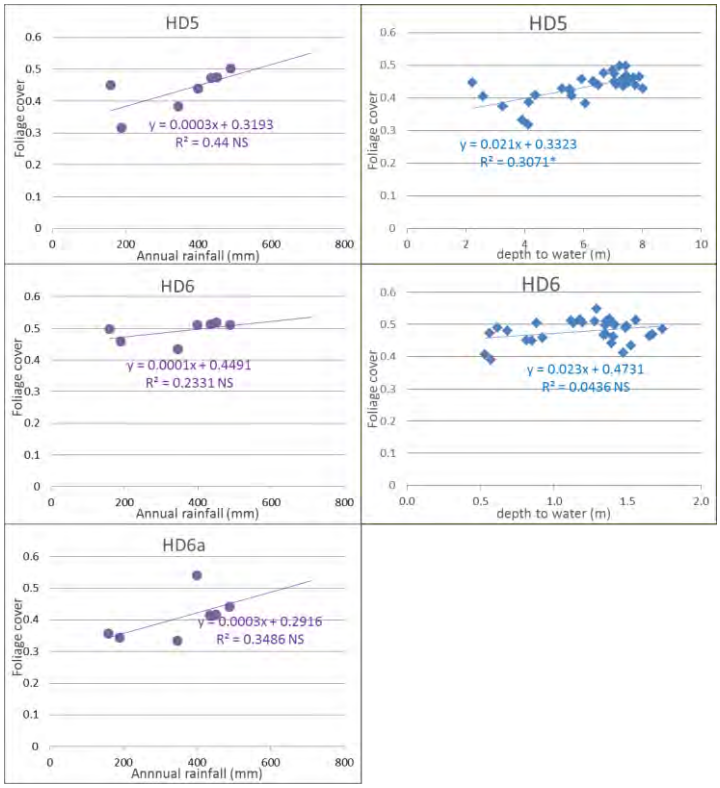
Figure 43: Relationships between foliage cover and annual rainfall and estimated depth to water for ephemeral drawdown sites HD1, HD2, HD3 and HD4. Q4 foliage cover is used to correlate with annual rainfall and foliage cover for all monitoring dates is correlated with estimated depth to water for that month.



3.6.3. Factors influencing foliage cover responses at perennial drawdown sites

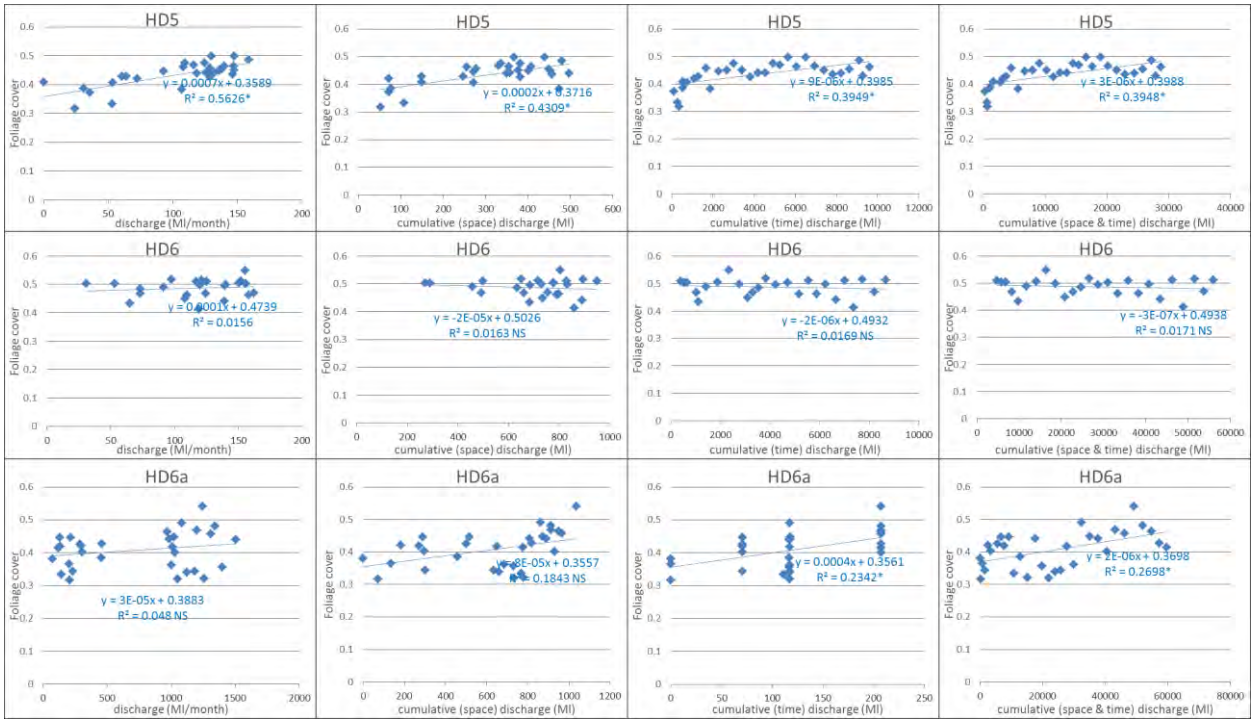
Although each of the eucalypt sites in the perennial drawdown zone HD5, HD6 and HD6a showed increasing trends with rainfall, correlation coefficients for the relationships weren't statistically significant (Figure 44).

Figure 44: Relationships between foliage cover and annual rainfall and estimated depth to water for perennial drawdown sites HD5, HD6, and HD6a. Q4 foliage cover is used to correlate with annual rainfall and foliage cover for all monitoring dates is correlated with estimated depth to water for that month.



Foliage cover at HD5 showed a positive correlation with increasing depth to water. This most likely occurs through the co-incidence of increasing volumes of spur discharge with time as groundwater levels decreased (Figure 15). Foliage cover at HD5 was closely correlated with the rate of discharge from the nearby spur, and also correlated with discharges accumulated from upstream spurs and with time (Figure 45). At perennial sites further downstream (HD6 and HD6a) where impacts of drawdown were less pronounced, foliage cover was generally unresponsive to local spur discharge. However, the increase through time in foliage cover observed at HD6a (Figure 37) could be explained through the significant response to cumulative spur discharges (Figure 45).

Figure 45: Relationships between foliage cover and discharge from the nearest spur for perennial drawdown sites HD5, HD6, and HD6a. Separate relationships are shown for discharge rates; cumulative (space) discharge which includes discharge accumulated from all upstream spurs; cumulative (time) discharge which includes all discharge from the nearest spur accumulated with time; and cumulative (space and time) discharge which includes all discharge from upstream spurs accumulated with time.



3.6.4. Factors influencing foliage cover responses at perennial discharge sites

Downstream of the gabion, foliage cover at perennial sites HD6a, HD7 and HD8 all tended to decrease with increases in both rainfall and streamflow (Figure 46), but these relationships weren't statistically significant. None of these sites showed a statistically significant response to the rising water levels that resulted from discharge (Figure 46). However, foliage cover at both HD7 & HD8 showed evidence of a negative response to volumes of discharge from the gabion (Figure 47). Foliage cover at HD7 decreased with increasing rates of gabion discharge and with volumes of discharge accumulated both through space and time. HD8 foliage cover was negatively impacted by cumulative discharge. It is possible that some decline in foliage cover at HD7 resulted from impacts of bushfire. However, evidence of the subsequent recovery after the fire (Figure 38) and the negative response to cumulative discharge observed at HD8 further downstream together suggest that discharge is impacting negatively on tree health at these sites. The consistency in trends of decreasing foliage cover with increasing rainfall and streamflow at all 3 sites also supports a hypothesis that an excess of water is impacting on tree health.

Figure 46: Relationships between foliage cover and annual rainfall; annual streamflow and estimated depth to water for perennial discharge sites downstream of the gabion (HD6b, HD7 and HD8). Q4 foliage cover is used to correlate with annual rainfall and streamflow and foliage cover for all monitoring dates is correlated with estimated depth to water for that month.

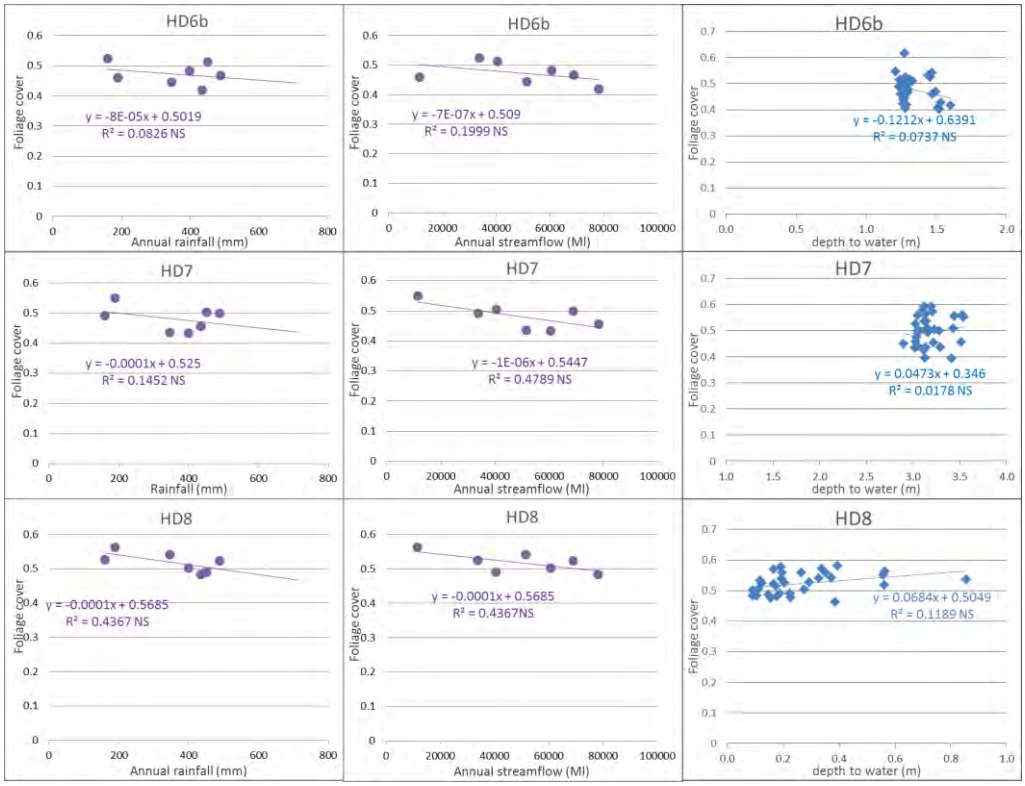


Figure 47: Relationships between foliage cover and discharge for perennial discharge sites downstream of the gabion HD6b, HD7 and HD8. Separate relationships are shown for gabion discharge rates; cumulative (space) discharge which includes discharge accumulated from the gabion and spurs; cumulative (time) discharge which includes discharge from the gabion accumulated with time; and cumulative (space and time) discharge which includes all discharge from the gabion and spurs accumulated with time.

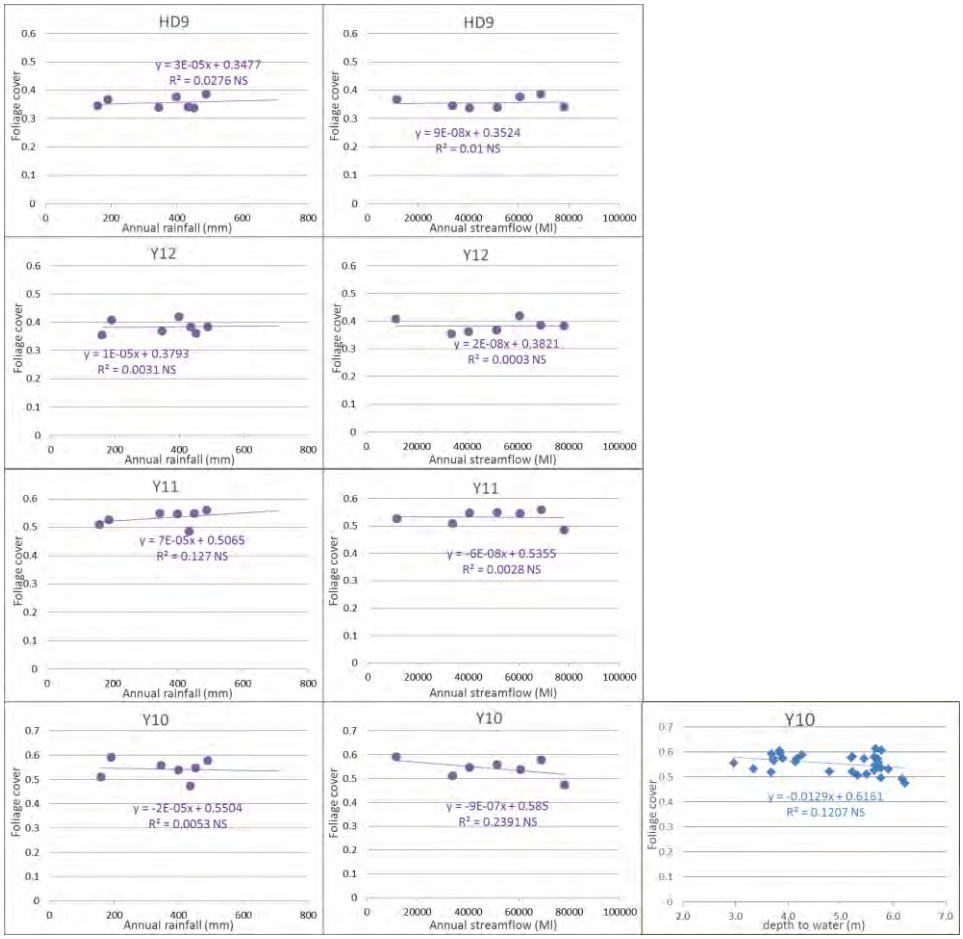
3.6.5. Factors influencing foliage cover responses at annual discharge sites between the gabion and Yandi

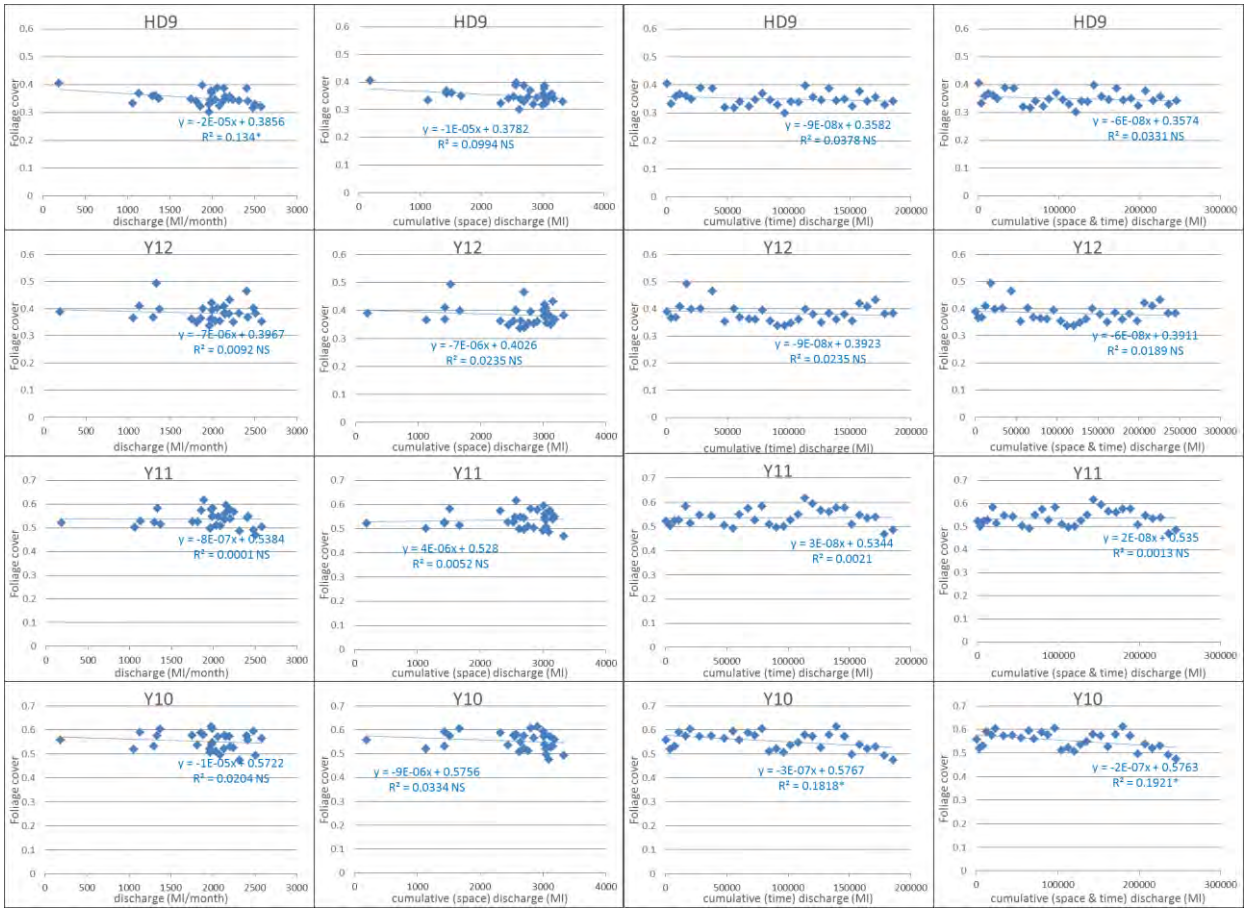
Further downstream, Q4 foliage cover at previously ephemeral sites HD9, Y12, Y11 and Y10 exposed to discharge from the gabion, didn't respond to increasing annual rainfall or streamflow (Figure 48). Declining foliage cover at Y10 also didn't appear to be related to falling water levels caused by dewatering at JSE (Figure 48). However, the decline in foliage cover observed at the ephemeral site closest to the gabion (HD9) was significantly related to the rate of discharge from the gabion (Figure 49).

Figure 48: Relationships between foliage cover and annual rainfall; annual streamflow and estimated depth to water for annual discharge sites downstream of the gabion (HD9, Y12, Y11 and Y10). Q4 foliage cover is used to correlate with annual rainfall and streamflow and foliage cover for all monitoring dates is correlated with estimated depth to water for that month.



Further downstream, foliage cover at Y10 showed a negative response to cumulative discharge (Figure 49). However, eucalypts at sites between HD9 and Y10 (Y12 and Y11) weren't adversely affected by discharge volumes. Thus responses to discharge were somewhat variable along the ephemeral section of Weeli Wolli Creek between the gabion and Yandi.

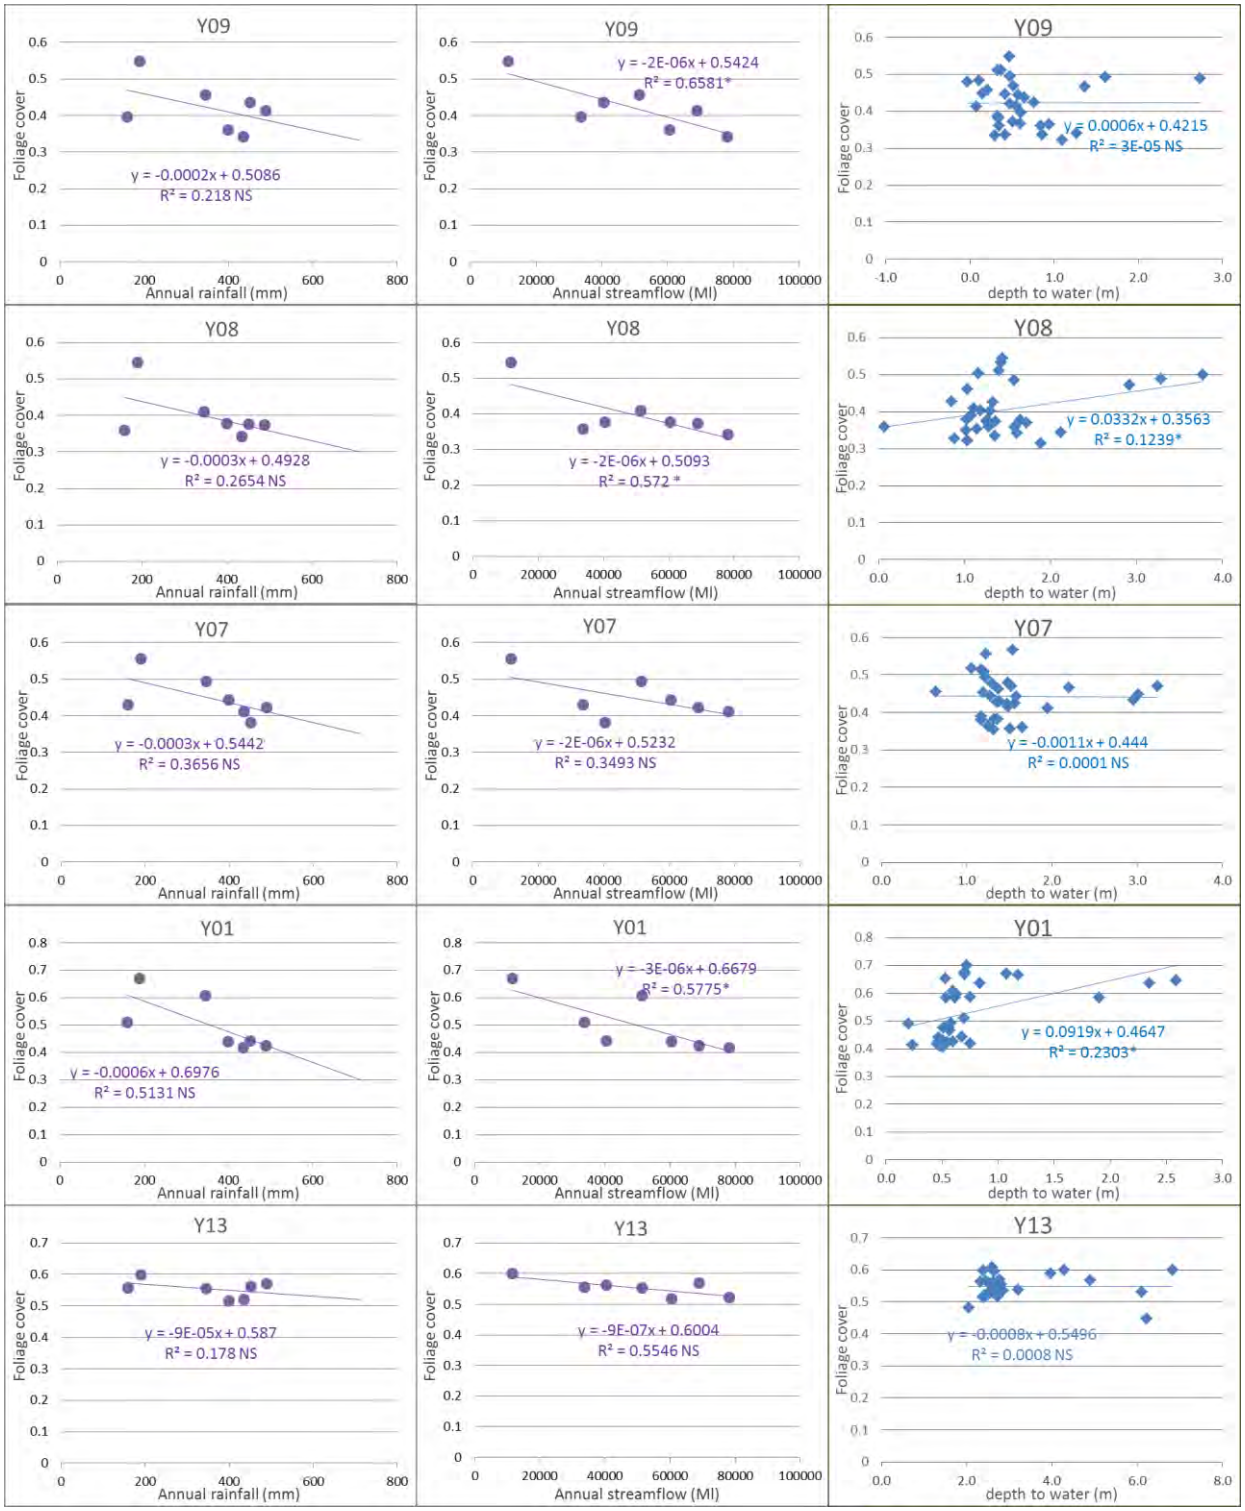
Figure 49: Relationships between foliage cover and discharge for annual discharge sites downstream of the gabion (HD9, Y12, Y11 and Y10). Separate relationships are shown for gabion discharge rates; cumulative (space) discharge which includes discharge accumulated from the gabion and spurs; cumulative (time) discharge which includes discharge from the gabion accumulated with time; and cumulative (space and time) discharge which includes all discharge from the gabion and spurs accumulated with time.



3.6.6. Factors influencing foliage cover responses at discharge sites downstream of Yandi D06

The foliage cover at sites downstream of DO6, Y09, Y08, Y07, Y01 and Y13 all responded similarly to annual rainfall and streamflow, showing a decreasing trend as these factors increased (Figure 50). Relationships between foliage cover and rainfall were not statistically significant for any of the sites, but relationships with annual streamflow were significant for sites Y09, Y08 and Y01. Foliage cover at Y08 and Y01 also showed significant responses to changing depth to water, with rising water levels associated with decreasing foliage cover (Figure 50).

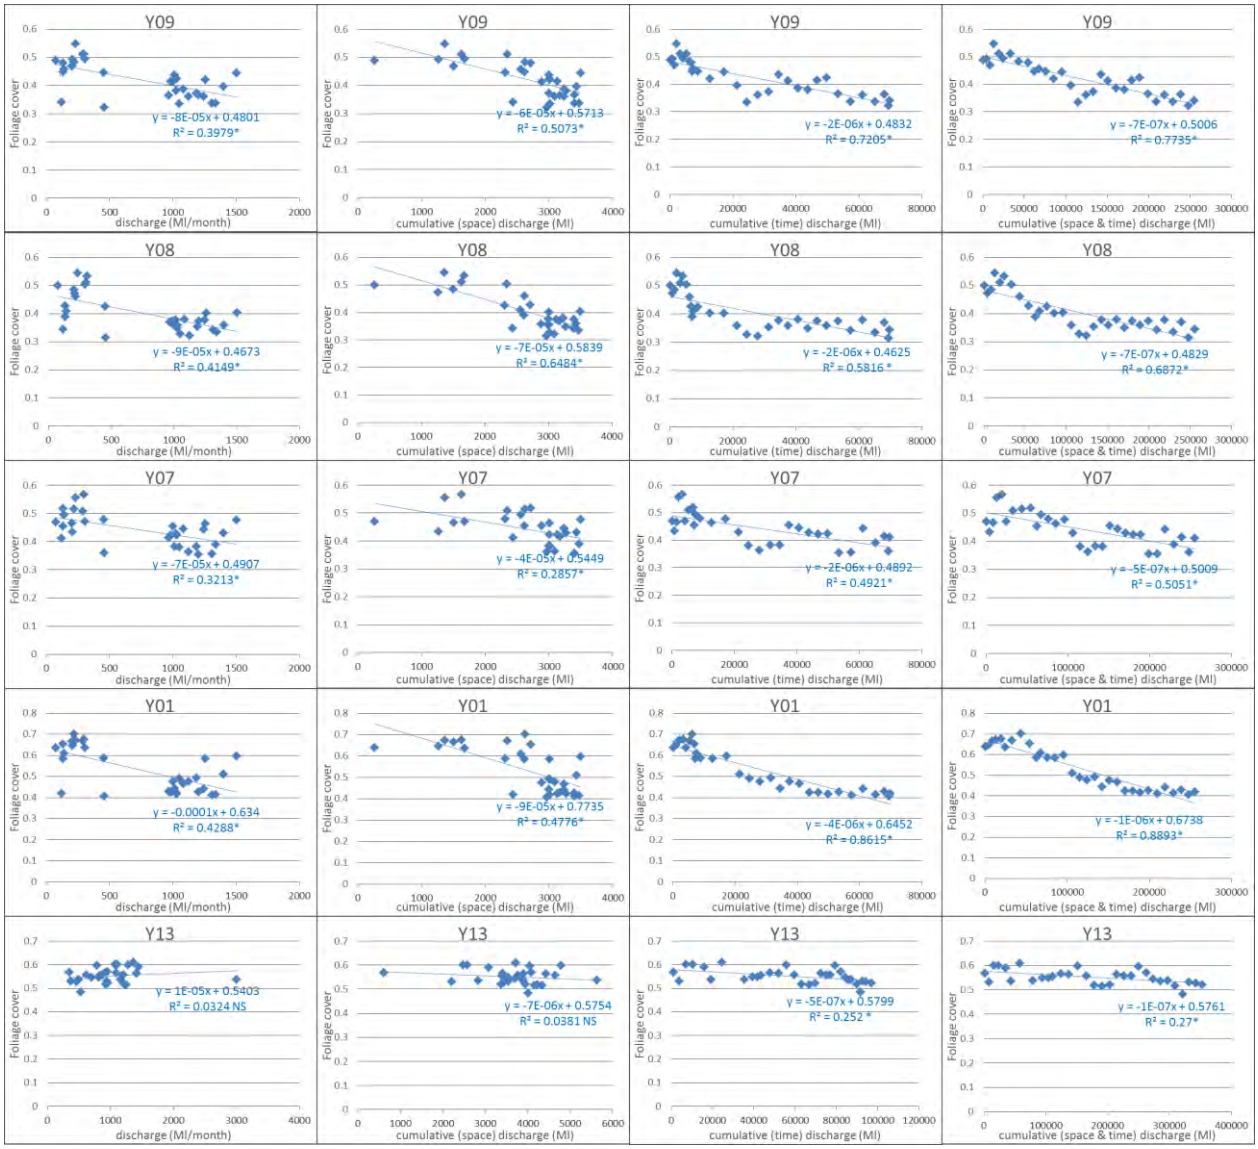
Figure 50: Relationships between foliage cover and annual rainfall; annual streamflow and estimated depth to water for annual discharge sites downstream of Yandi discharge outlet DO6 (Y09, Y08, Y07, Y01 and Y13). Q4 foliage cover is used to correlate with annual rainfall and streamflow and foliage cover for all monitoring dates is correlated with estimated depth to water for that month.



Increasing rates of discharge from D06 reduced foliage cover for each of the sites Y09, Y08, Y07 and Y01 (Figure 51), and relationships between foliage cover and discharge rate were found to be significant for each of these sites. In addition to negative impacts of local

discharge rates, there was also evidence of cumulative impacts on vegetation health, with a trend of increasingly significant responses in foliage cover to discharge accumulated in space and in time. At sites Y09, Y08, Y07 and Y01 correlations with discharge were most significant for relationships with volumes accumulated through both space (i.e. including discharge from DO6, the gabion and spurs) and time (Figure 51). In contrast to these sites, foliage cover further downstream at Y13 wasn't responsive to combined rates of local discharge from DO6 and into Marillana Creek (Figure 51).

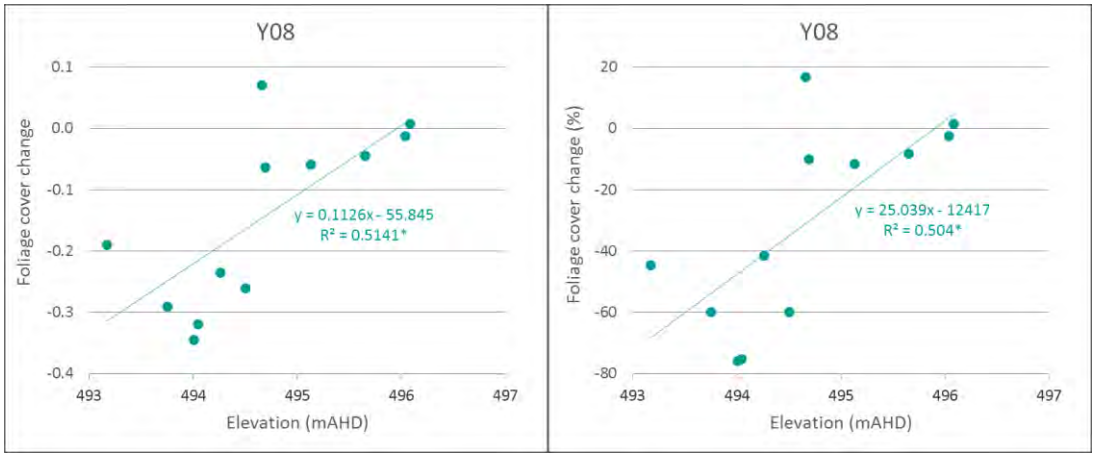
Figure 51: Relationships between foliage cover and discharge for discharge sites downstream of downstream of Yandi discharge outlet DO6 (Y09, Y08, Y07, Y01 and Y13). Separate relationships are shown for DO6 discharge rates; cumulative (space) discharge which includes all discharge accumulated from upstream; cumulative (time) discharge which includes discharge from DO6 accumulated with time; and cumulative (space and time) discharge which includes all discharge from DO6, the gabion and spurs accumulated with time.



This contrast most likely arises because of the difference in the depth to water table experienced by trees at Y13 compared with those at the other sites (Figure 29). The water table remained at a depth of greater than 2 m at Y13, but was consistently shallower throughout the study period at sites Y09, Y08, Y07 and Y01. From 2008 to early 2014, levels were less than 1 m depth at Y09 and Y01. Although foliage cover of trees at Y13 weren't influenced by local discharge rates, there was evidence that they experienced a decline due to cumulative impacts of discharge (Figure 51). The effect appeared to be principally related to volumes of local discharge from DO6 and into Marillana Creek accumulated through time, since the response in foliage cover to discharge volumes accumulated from upstream (Marillana, DO6, gabion and spurs) was not significant.

Although site mean foliage cover data indicated declining foliage cover at discharge sites, responses of individual trees at some sites were related to their elevation. Trees at low elevations tended to show larger declines in foliage cover and those at higher elevations increased their cover. For example, at site Y08 there was significant positive relationship between the change in foliage cover from October 2006 to December 2014 and elevation (Figure 52). This response most likely results from greater impacts of waterlogging on tree health for those trees in lower landscape positions. In contrast, trees at higher elevations may benefit from greater access to water from the capillary fringe.

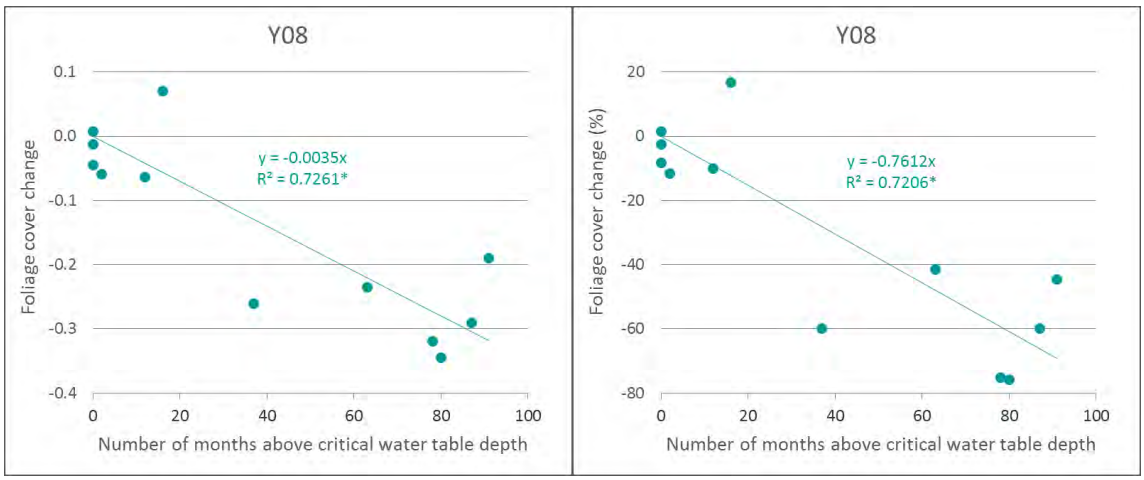
Figure 52: Relationship between elevation and change in foliage cover from October 2006 to December 2014 for individual trees at site Y08. The relationship between elevation and percentage change in foliage cover is also shown.



Given the dependence of tree foliage cover on elevation, and the significant relationship between mean foliage cover and depth to water for Y08 (Figure 50) over the study period, analyses were undertaken to identify a critical depth to water influencing foliage cover decline at Y08. The number of months over the study period that depth to water was less than this critical depth was calculated from estimated water levels (Figure 29) and elevation for each tree at Y08. Change in foliage cover over the study period was plotted as a function of the number of months levels were above the critical level, and regression analysis used to

identify the critical depth that gave the best correlation for this relationship for trees at Y08 (Figure 53). A depth to water of about 1 m (0.98 m) was found to be the critical depth that best explained the change in foliage cover over the study period for individual trees at Y08.

Figure 53: Relationship between change in foliage cover from October 2006 to December 2014 and the number of months that depth to water was less than 1.0 m for individual trees at site Y08. The relationship between the number of months and percentage change in foliage cover is also shown.

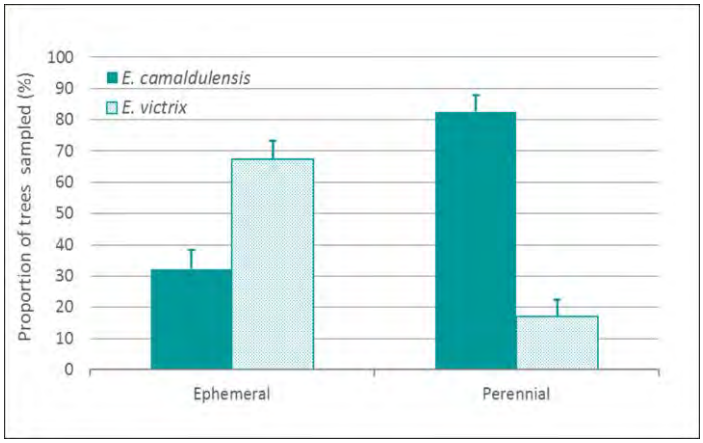


3.6.7. Responses of *Eucalyptus victrix* and *Eucalyptus camaldulensis* to drawdown and discharge

Distribution of Eucalyptus victrix and Eucalyptus camaldulensis

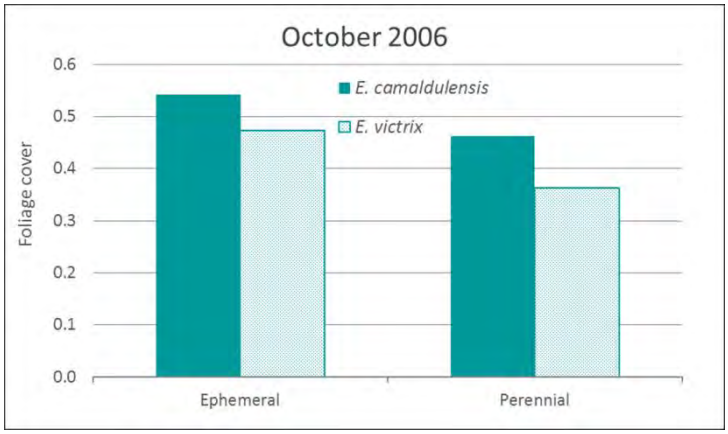
Analysis of the proportion of trees monitored at each site that were *E. camaldulensis* (Ec) or *E. victrix* (Ev) revealed statistically significant differences in their distribution between sites with previously ephemeral or perennial flow (Figure 54). Ec occurred more frequently than Ev at sites with perennial flow (Figure 54) but Ev was found to be more common at ephemeral sites. An analysis of the distribution of these species between beds and banks at perennial and ephemeral sites found no significant difference in their distribution (i.e. Ev was equally likely to be found on beds or banks at ephemeral and perennial sites as Ec).

Figure 54: The proportion of trees monitored at ephemeral and perennial sites that were *E. camaldulensis* or *E. victrix*



Two-way ANOVA was used to compare the foliage cover of Ev and Ec at ephemeral and perennial sites in October 2006 (i.e. prior to drawdown or discharge). Foliage cover of both Ev and Ec was found to be significantly greater at ephemeral compared with perennial sites (Figure 55). However, there was no significant different in the foliage cover of each species at ephemeral compared with perennial sites.

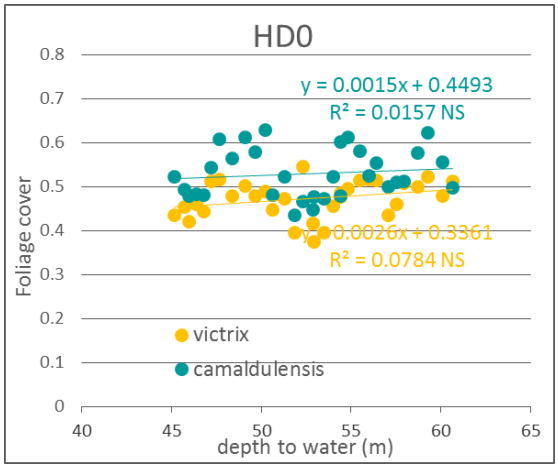
Figure 55: Mean foliage cover of *E. camaldulensis* and *E. victrix* at ephemeral and perennial sites in October 2006.



Responses to drawdown and discharge

At the reference site HD0 where the groundwater was originally greater than 45 m, the responses of *E. camaldulensis* and *E. victrix* were similar, with neither species showing a change in foliage cover with falling water levels (Figure 56).

Figure 56: Relationships between foliage cover and estimated depth to water for *Eucalyptus victrix* and *Eucalyptus camaldulensis* at reference site HD0



The responses of Ev and Ec to drawdown and changing streamflow due to the diversion of Pebblemouse Creek were not consistent between sites (Figure 57). The statistically significant relationships between mean foliage cover and groundwater depth observed at sites HD1 and HD2 (Figure 43) reflected significant relationships for Ev at HD1 and Ec at HD2 (Figure 57).

Further downstream at HD3, the foliage cover of neither species responded to changing groundwater depth. The decrease in foliage cover with increasing depth to groundwater observed at HD4 (Figure 43) was due solely to responses of Ev, since there were no Ec monitored at this site.

Figure 57: Relationships between foliage cover and estimated depth to water for *Eucalyptus victrix* and *Eucalyptus camaldulensis* at ephemeral drawdown sites HD1, HD2, HD3 and HD4.

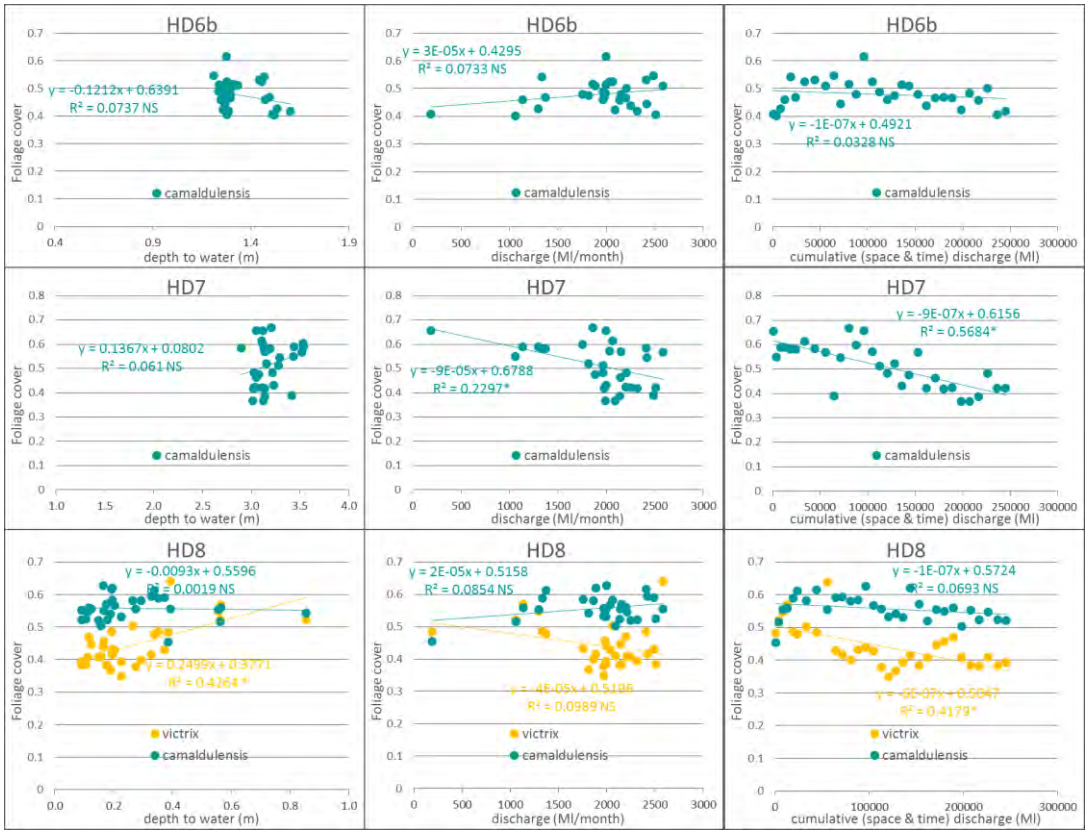
The responses of Ev and Ec to drawdown and discharge were also inconsistent between sites in the previously perennial springs area of Weeli Wolli Creek (Figure 58).

Figure 58: Relationships between foliage cover of *Eucalyptus victrix* and *Eucalyptus camaldulensis* and estimated depth to water and discharge from the nearest spur for perennial drawdown sites HD5, HD6, and HD6a. Separate relationships are also shown for cumulative (space and time) discharge which includes all discharge from upstream spurs accumulated with time.

The increases in mean foliage cover with increasing depth to groundwater observed at HD5 (Figure 44) resulted from changes in Ec foliage cover, and Ev appeared unresponsive to either parameter. In contrast, foliage cover of Ev increased as depth to water increased at HD6 (Figure 58), with Ec showing no response at this site. Ev and Ec also showed inconsistent responses to spur discharge, with foliage cover of Ec increasing as discharge increased at HD5, and Ev showing a significant response to discharge at HD6a. Neither species responded to discharge volumes at HD6.

At perennial discharge sites beyond the gabion, relationships between foliage cover of Ec and depth to water were not significant at any of the sites HD6b, HD7 and HD8 (Figure 59). Responses of Ec to discharge were inconsistent between these sites, with foliage cover declining in response to increasing discharge rates and volumes at HD7, but no significant response observed at HD6b and HD8. Ev was not present at sites HD6b and HD7 but further downstream at HD8, foliage cover of Ev appeared more sensitive to impacts of discharge than Ec. Ev foliage cover decreased with decreasing depth to water at this site, and was also significantly reduced at increasing discharge rates and cumulative volumes.

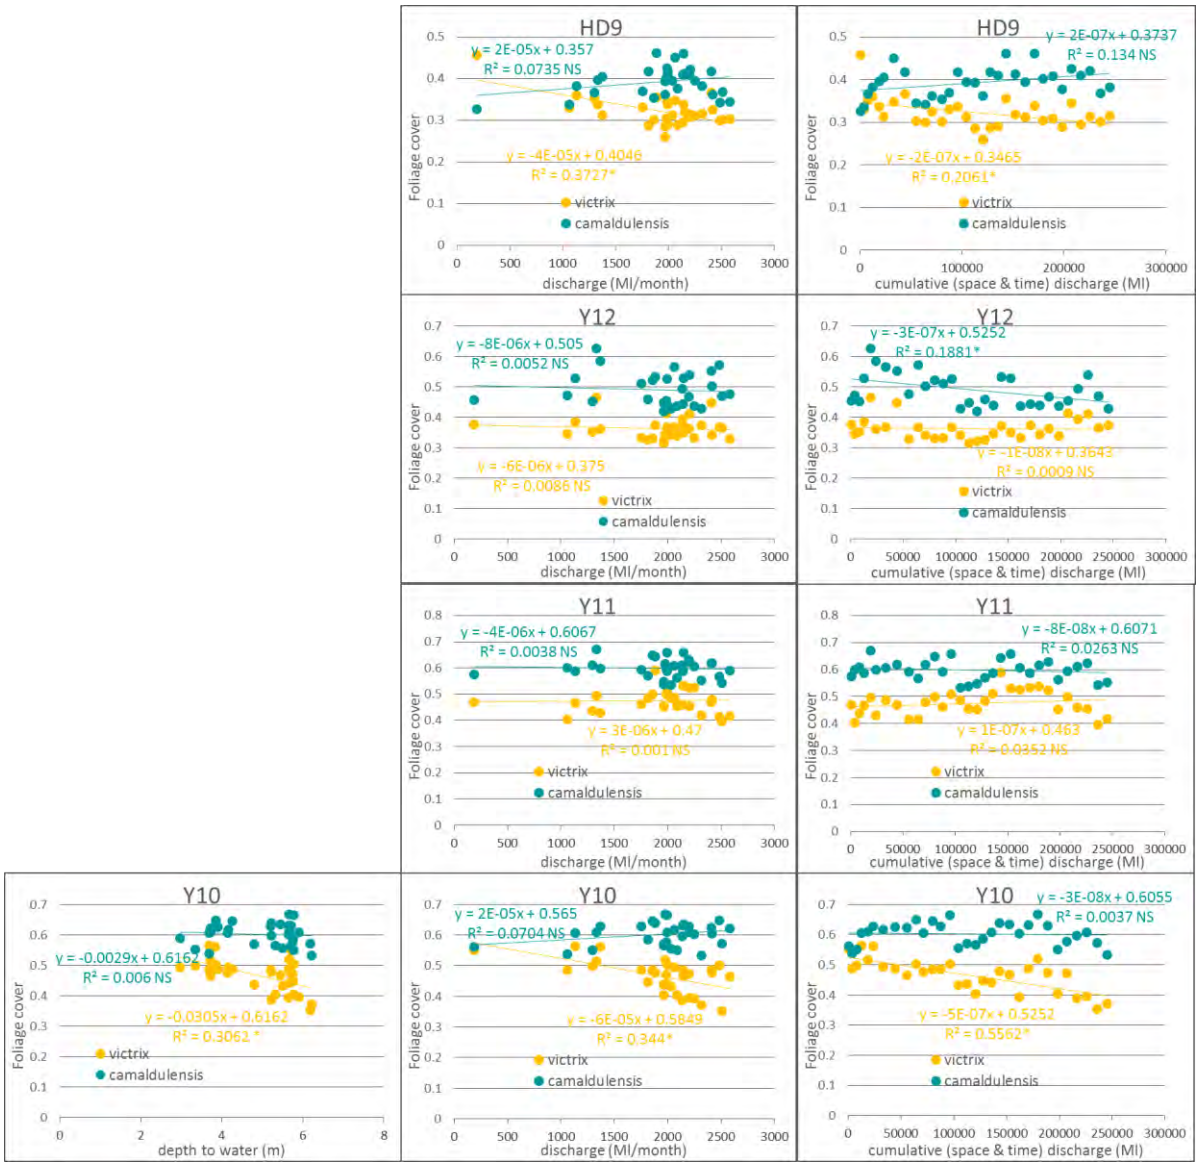
Figure 59: Relationships between foliage cover of *Eucalyptus victrix* and *Eucalyptus camaldulensis* and estimated depth to water and discharge for perennial discharge sites downstream of the gabion HD6b, HD7 and HD8.



At ephemeral sites downstream of the gabion there was also some evidence of greater sensitivity of foliage cover of Ev to discharge compared with Ec. Foliage cover of Ev declined

with increasing discharge rate and volumes at sites HD9 and Y10, but Ec showed no response to either parameter at these sites (Figure 60). At Y12 however, Ec foliage cover declined in response to cumulative discharge, but foliage cover of Ev wasn't adversely impacted, and neither species was impacted by discharge at Y11.

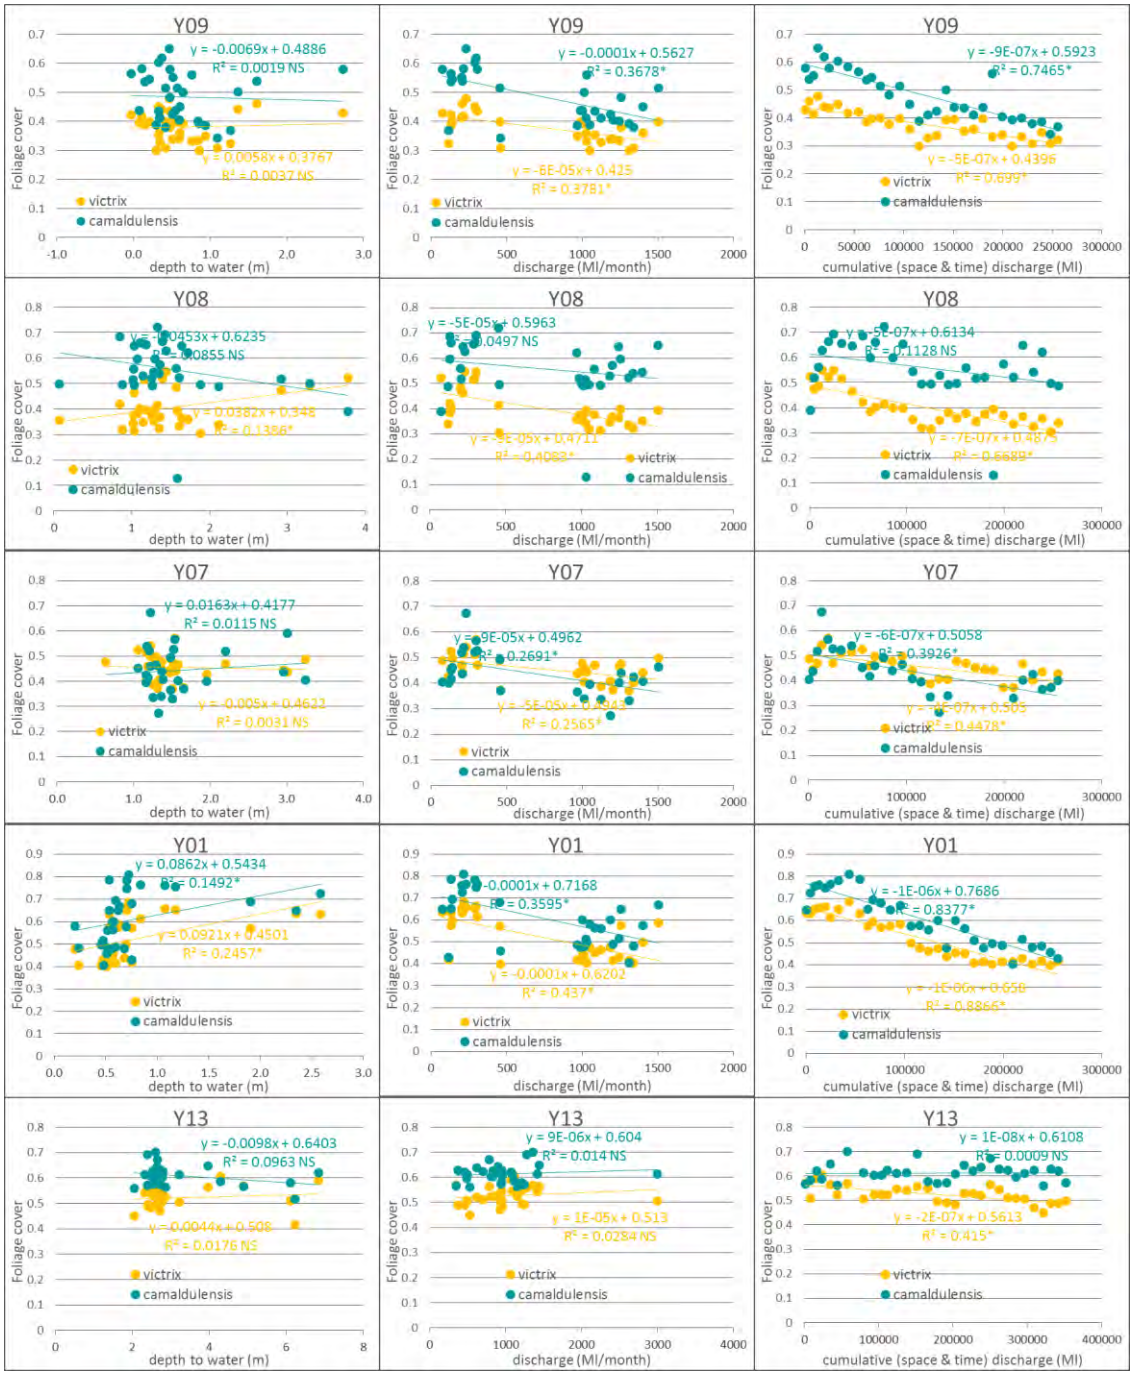
Figure 60: Relationships between foliage cover of *Eucalyptus victrix* and *Eucalyptus camaldulensis* and estimated depth to water and discharge for annual discharge sites downstream of the gabion HD9, Y12, Y11 and Y10.



Responses in foliage cover of Ev and Ec were largely similar at monitoring sites downstream of DO6, showing a decreasing trend with increasing discharge rates and cumulative volumes at Y09, Y08, Y07 and Y01 (Figure 61). These relationships were statistically significant for Ev at each of these sites, and for Ec at Y09, Y07 and Y01. The decline in foliage cover with increasing discharge was associated with significant negative responses of Ev and Ec foliage cover to decreasing water depth at Y01, and negative responses of Ev to rising levels at Y08. Further downstream past the confluence with Marillana Creek at Y13, levels were somewhat

deeper and the foliage cover of neither species responded to rising levels. However, the significant decline in mean foliage cover with cumulative discharge observed at this site (Figure 51) was related to the declining cover of Ev with no significant impact on Ec.

Figure 61: Relationships between foliage cover of *Eucalyptus victrix* and *Eucalyptus camaldulensis* and estimated depth to water and discharge for discharge sites Y09, Y08, Y07, Y01 and Y13 downstream of DO6.

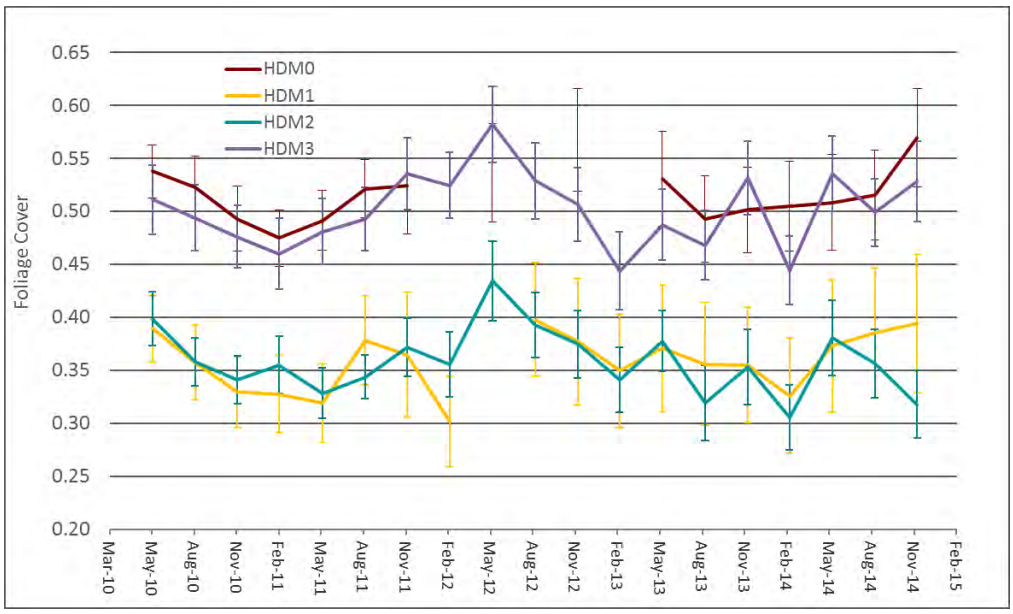


3.6.8. Responses of *Melaleuca argentea* to drawdown and discharge

Monitoring of foliage cover of *Melaleuca argentea* by digital canopy photography started in June 2010, more than 3 years after the start of drawdown and discharge operations at HD1.

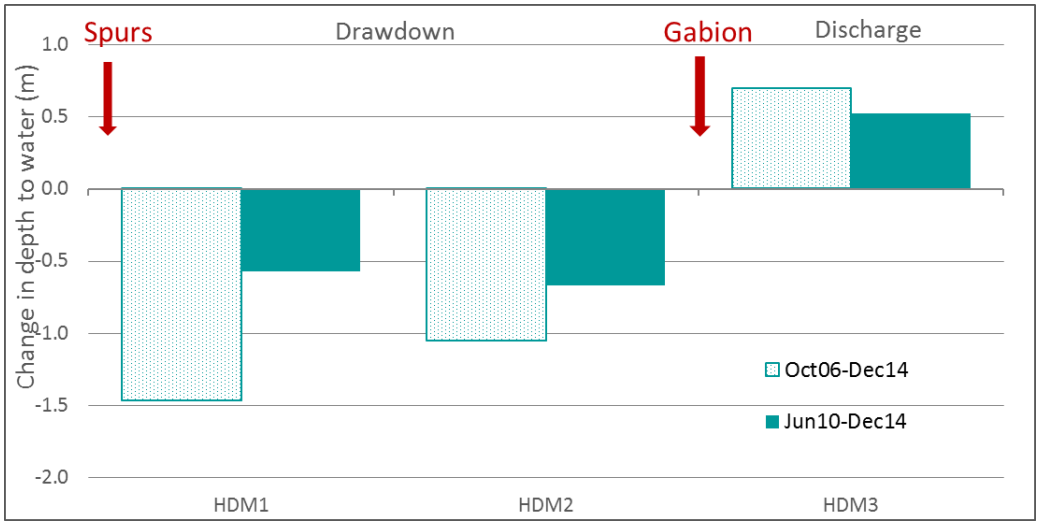
At intervals through the period of monitoring, data was missing for particular trees, sometimes for relatively extended periods. The dataset is thus incomplete making it difficult to reliably define trends and responses to drawdown or discharge. In June 2010, foliage cover of *M. argentea* at site HDM3 downstream of the gabion was similar to cover at the reference site HDM0, and their foliage cover remained largely similar throughout the study (Figure 62). In contrast, foliage cover in June 2010 was lower at HDM1 and HDM2 in the springs area of Weeli Wolli Creek than at HDM0 (Figure 62), and these differences were maintained throughout the study. Lower foliage cover of melaleucas in the springs area is consistent with response in foliage cover of eucalypts which also had lower foliage cover in this part of the creek than at other sites (Figure 35). Seasonal trends in foliage cover were generally similar at the reference and potential impact sites. However, there was some divergence in response in December 2014 when foliage cover decreased at HDM2 whilst foliage cover increased at other melaleuca sites.

Figure 62: Temporal responses in foliage cover for melaleuca monitoring sites HDM0, HDM1, HDM2 and HDM3



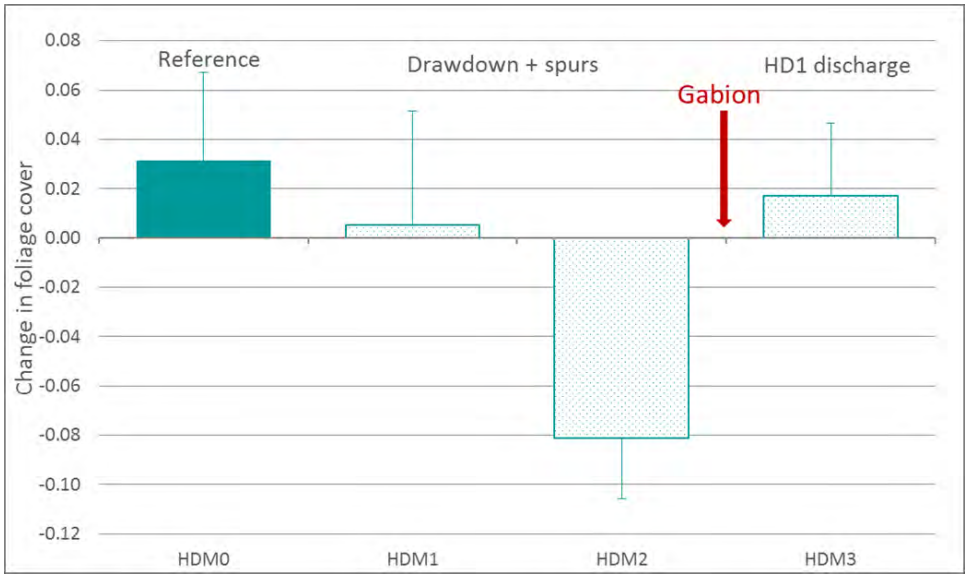
When monitoring began in June 2010, water levels for melaleuca sites HDM1 and HDM2 had already declined in response to dewatering (Figure 28). Water levels continued to decline throughout the period of monitoring. By December 2014 levels had fallen by almost 1.5 m at HDM1 and by > 1m at HDM2 from levels at the start of dewatering (Figure 63). In contrast, discharge from the gabion increased levels at HDM3 by 0.7 m over the same period.

Figure 63: Change in estimated depth to water at melaleuca monitoring sites HDM1, HDM2 and HDM3. Changes are shown from October 2006 to December 2014 and from the start of monitoring in June 2010 to December 2014.



Changes in foliage cover at melaleuca sites over the period of monitoring between were relatively small (Figure 64), but may not fully represent changes since the start of drawdown and discharge operations. Foliage cover increased at the reference site HDM0, possibly a result of contrasting rainfall conditions between the year monitoring commenced (2010) and in 2014. 2010 was a very dry year and 2014 a relatively wet one (Figure 11 and Figure 12). Despite a fall in water levels, foliage cover also increased in HDM1 and at HDM3 where levels increased. In contrast to the increase in cover at HDM1, foliage cover at HDM2 decreased over the period of monitoring, although both sites experienced a similar drawdown in levels between June 2010 and December 2014 and drawdown over the study period was greater at HDM1.

Figure 64: Change in foliage cover at melaleuca monitoring sites from the start of monitoring in June 2010 to December 2014.

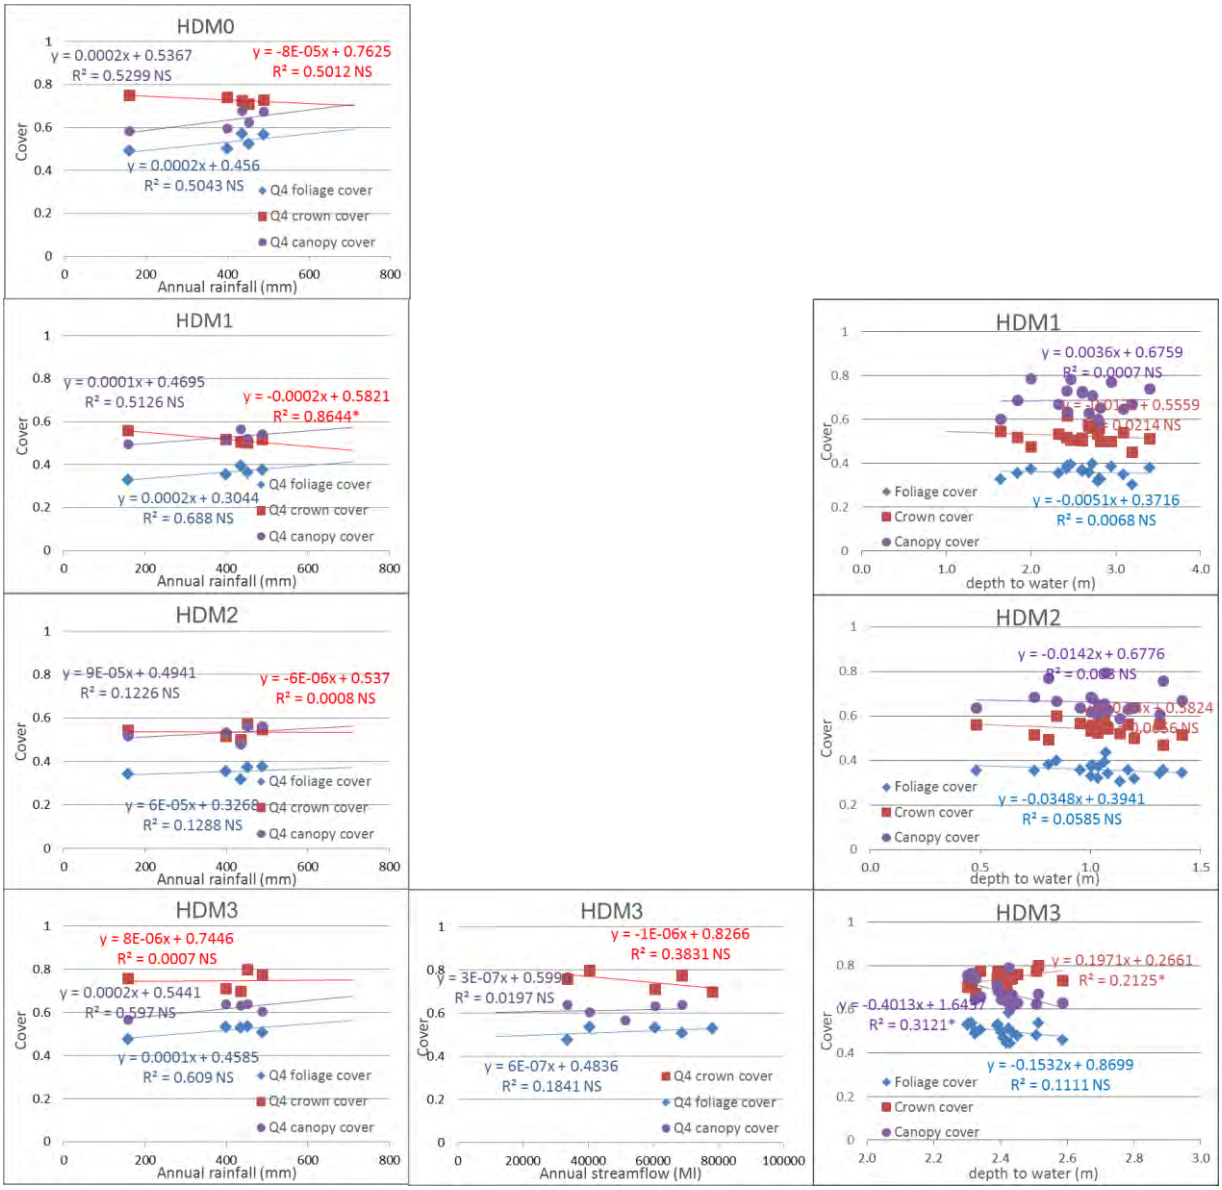


For the eucalypts under investigation in this study, the responses in Fc and crown cover (Crc) captured by digital canopy photography were generally similar at each site (data not

shown). However responses in Fc and Crc weren't always consistent for *Melaleuca argentea* sites. Because of this inconsistency, responses in all 3 tree health monitoring parameters (Fc, Crc and canopy cover, Cc) to key hydrological parameters are presented in Figure 65 and Figure 66 below.

Relationships between Q4 vegetation cover parameters and annual rainfall and streamflow were generally not statistically significant, partly because of the limited number of data points afforded by the shorter period of monitoring for melaleuca sites (Figure 65). The exception was for site HMD1 where crown cover of melaleucas decreased in response to increasing annual rainfall (Figure 65).

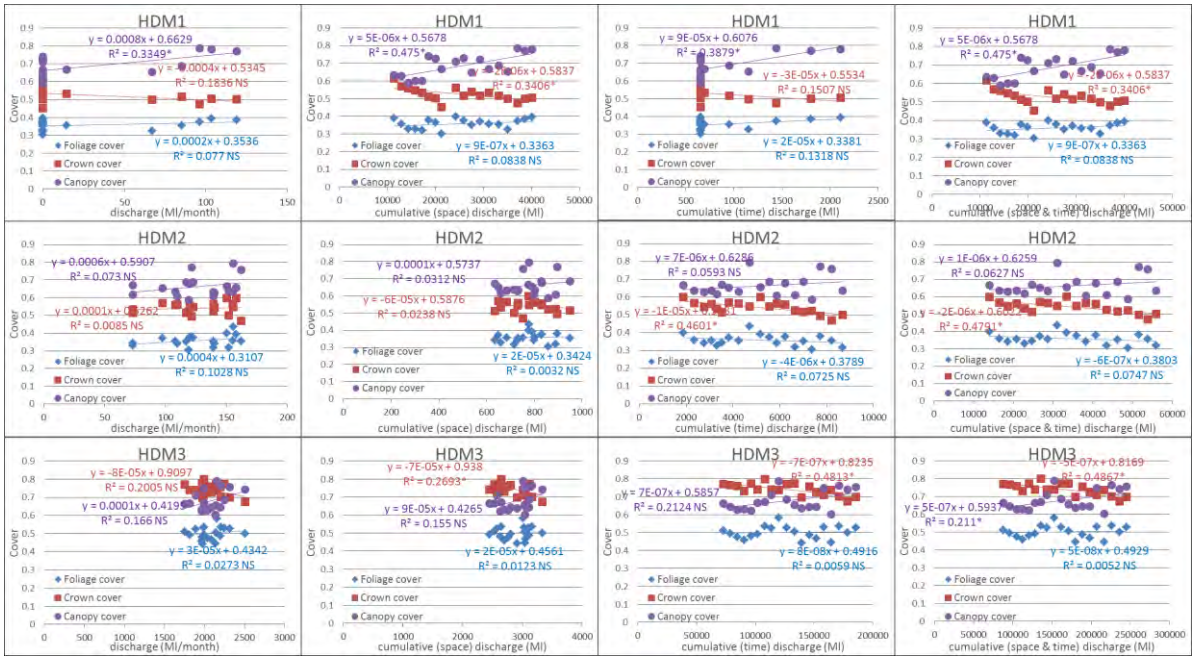
Figure 65: Relationships between foliage, crown and canopy cover and annual rainfall, annual streamflow and estimated depth to water for melaleuca sites HDM0, HDM1, HDM2 and HDM3. Q4 foliage cover is used to correlate with annual rainfall and streamflow at Tarina for HDM3. Foliage cover for all monitoring dates is correlated with estimated depth to water for that month.



None of the melaleuca sites showed a significant relationship between foliage cover and depth to water, but at HDM3 the crown cover of melaleucas increased and canopy cover decreased with increasing depth to water (Figure 65). Similarly, melaleuca foliage cover at each of the sites showed no response to discharge rates or cumulative volumes of discharge (Figure 66).

In contrast, crown cover at each of the melaleuca sites decreased as discharge accumulated from upstream sources and with time increased (Figure 66). At site HDM1, melaleuca canopy cover increased as rates and cumulative volumes of discharge increased. Canopy cover of HDM3 also increased in response to discharge accumulated with both space and time.

Figure 66: Relationships between foliage, crown and canopy cover and discharge for melaleuca sites HDM1, HDM2 and HDM3. Separate relationships are shown for local discharge rates; cumulative (space) discharge which includes discharge accumulated from all upstream sources; cumulative (time) discharge which includes all discharge from the nearest source accumulated with time; and cumulative (space and time) discharge which includes all discharge from upstream sources accumulated with time.



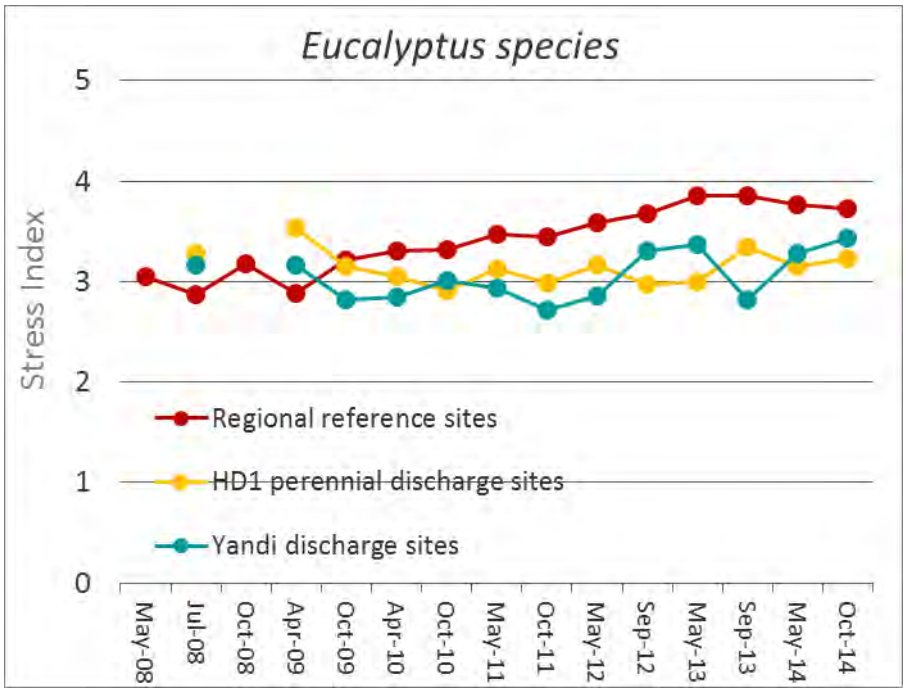
3.7. Vegetation responses from the Mattiske vegetation survey

The percentage cover of different lifeforms in each quadrat of all sample transects in the Weeli Wolli Springs area (Reach 1) are shown in Appendix 2. Percentage cover for each transect is shown on a separate graph for each sampling date from October 2008 to May 2014. Figures in Appendix 2 reveal the great spatial variation in cover of lifeforms across each transect, and variation between transects. For some quadrats and sites, foliage cover was greater than 100%. This result may seem counter-intuitive, but results from the ovelapping of canopies of overstorey and understorey vegetation. Comparison of cover on

transects monitored at different dates between 2008 and 2014 reveal that cover of different lifeforms also varied through time. The dominant trend through time for vegetation in the majority of transects in Reach 1 was for cover to increase with time. This trend is consistent with the enhancement of foliage cover measured by DCP, resulting from positive response to spur discharge in the Weeli Wolli Springs area. Thus the Mattiske data suggest that both understorey and overstorey cover were generally enhanced by spur discharge. The variation in tree foliage cover along each transect is consistent with the different response in foliage cover of trees measured by DCP at different topgraphical positions and elevation at a site. Thus data from Mattiske transects that extend across the full width of the riparian zone may better capture the overall response in tree health to discharge or drawdown than DCP data largely monitored for trees located close to or within the creek.

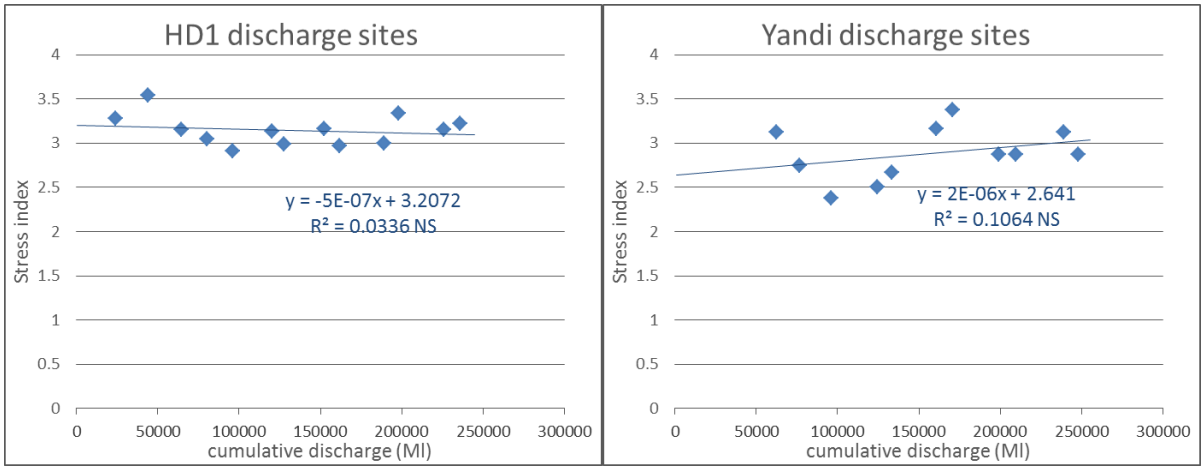
Mean stress indices for eucalypts on vegetation survey transects at sites exposed to HD1 and Yandi discharge and for regional reference sites are shown in Figure 67. The mean level of stress at regional references sites was initially close to 3 (ie. "stressed"), but stress levels tended to decrease with time towards "slightly stressed" levels. In contrast, stress levels at discharge sites varied around a value of 3 or "stressed". Stress levels at discharge sites in October 2014 were largely similar to levels when Mattiske vegetation monitoring was commenced (ie close to 3 or "stressed").

Figure 67: Mean stress index of eucalyptus species on transects exposed to HD1 and Yandi discharge. The mean stress index for eucalypts at regional reference sites on Weeli Wolli Creek, Coondiner Creek and Mindy Mindy Creek is also shown. Increasing values for the index is indicative of decreasing levels of stress, with 1 = dead; 2 = very stressed; 3 = stressed; 4 = slightly stressed and 5 = healthy trees.



Levels of the stress index for eucalypts at HD1 perennial and Yandi discharge sites showed no correlation with cumulative discharge (Figure 68). These responses contrast with the significant decline in foliage cover measured by DCP with cumulative discharge observed for these sites. An explanation for the contrasting response in DCP compared with stress index data may be that eucalypts selected for DCP monitoring aren't representative of trees across the riparian zone at each site location. Trees selected for DCP monitoring may represent the more severely-affected trees, with the Mattiske monitoring better capturing responses of eucalypts across the riparian zone.

Figure 68: Relationship between cumulative discharge and mean stress index for eucalypts on transects at HD1 perennial discharge sites and for Yandi discharge sites.



For sites where Mattiske vegetation monitoring was in close proximity to DCP monitoring sites (WW28 and HD9; WW9 and HD3; WW01 and HD5; WW02 and HD5; WW13 and Y01; WW17 and Y13) foliage cover was regressed against the mean water stress index from Mattiske vegetation data. However, no statistically significant relationships were found between foliage cover and water stress index for any site. Poor correlations between DCP and Mattiske data could arise because the trees selected for DCP sampling aren't representative of trees across the riparian zone monitored by the Mattiske survey. It could also be partly attributable to DCP and the Mattiske monitoring being carried out in different months of the year.

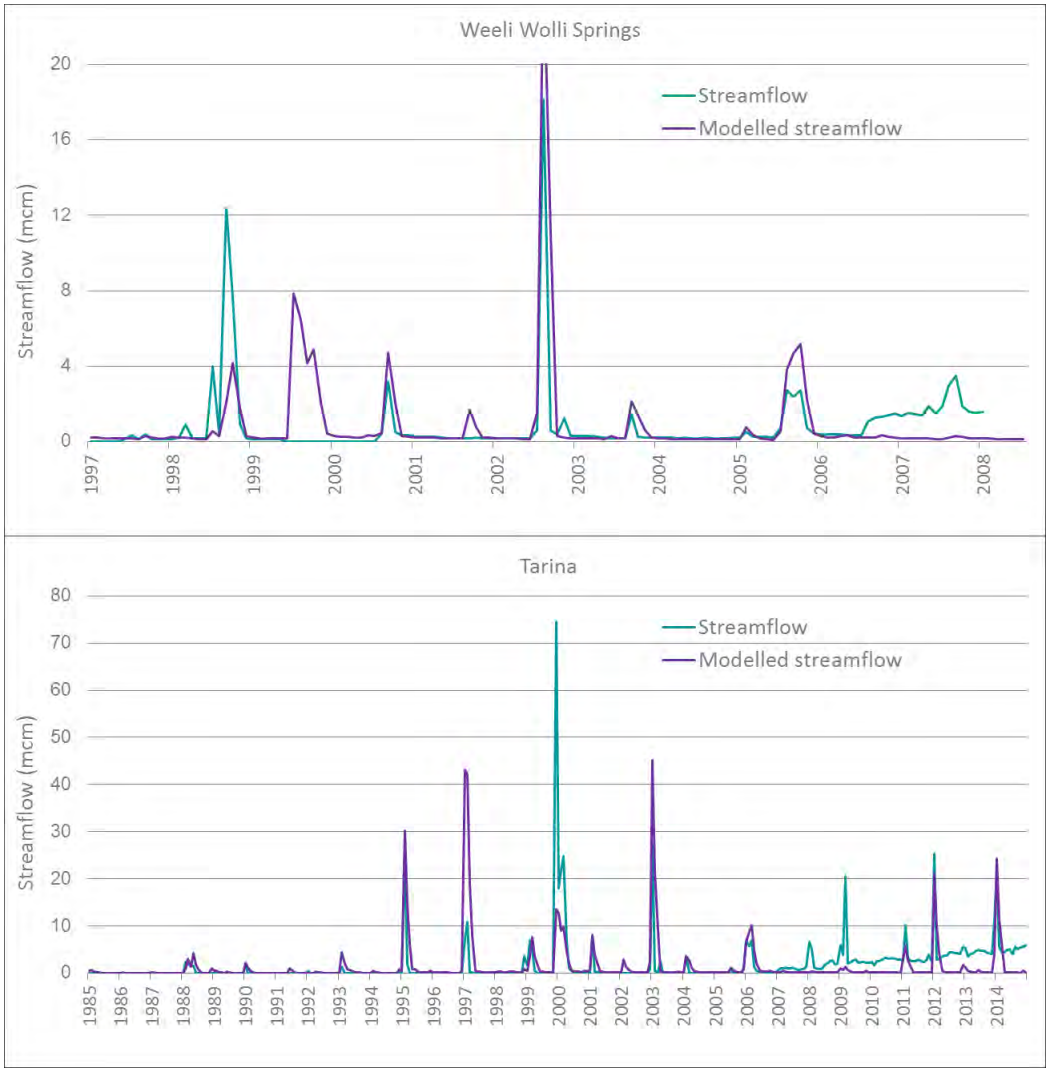
3.8. Hydrological modelling

Measured and modelled streamflow for the Weeli Wolli Springs and Tarina stations show reasonably good agreement for the period prior to discharge (Figure 69). The baseflow component is generally well represented, but the higher flows experienced during flood events are captured less reliably. Factors contributing to discrepancies between modelled and measured peak flows may include high localised spatial variability in rainfall and limitations to accurately measuring streamflow in high energy and flow environments. Thus rainfall measured at a rain gauge in a catchment may not represent average rainfall

conditions experienced across the catchment which contribute to runoff and streamflow, and streamflow at a gauging station may not be accurately measured at high flows.

The response in streamflow to discharge from the gabion can be observed from the divergence between measured and modelled flow for both gauges from 2007 (Figure 69). The impact of the transition from ephemeral to perennial flow at Tarina may be quantified by comparing the duration of modelled and measured flows from 2007. After the start of discharge, measured streamflow at Tarina persisted for 12 months of the year, but modelled flows indicate zero flow throughout 2007 and 2010. The duration of modelled flow in other years was 3 months in 2014 and 4 months in 2009, 2011, 2012 and 2013.

Figure 69:Streamflow and modelled streamflow for the Weeli Wolli Springs and Tarina stations on Weeli Wolli Creek.



4. DISCUSSION AND CONCLUSIONS

4.1. Study limitations

The responses in water levels to dewatering, reinjection and discharge at vegetation monitoring sites at HD1 and Yandi haven't been monitored because bores were not installed at these sites. This study has attempted to estimate levels for each site through interpolation between levels at bores upstream and downstream of the site. However, such estimates are likely to incur errors, particularly when bores used in interpolations are some distance apart. Alluvial bores are generally installed at some distance from the creek, so errors may also be incurred in estimating levels for vegetation adjacent to the creek if water levels vary across it, for example if mounding occurs under discharges. The significance of any error is generally likely to be greater when assessing impacts of discharge compared with drawdown. This is because changes in water levels under impacts of discharge are generally small compared with the magnitude of changes due to drawdown. Furthermore, discharge impacts are largely incurred at levels closer to the ground surface than drawdown, rendering them more likely to be significant for tree health. Interpretation of the significance of changing water levels on tree health at Yandi is also compromised by very limited baseline data for levels prior to the start of dewatering and discharge. Data to assess long-term levels and their seasonal response for comparison with post-impact levels is unavailable. The uncertainty is exacerbated by wet conditions for baseline monitoring, with rainfall being the highest on record at Tarina in 2006.

Pre-impact vegetation monitoring data is also very limited, with digital canopy photography starting in October 2006 at all eucalypt sites except Y12. Monitoring at Y12 was started in February 2007 and monitoring at melaleuca sites in June 2010. The coincidence of the timing of the start of operations with the unusually wet year in 2006 is unfortunate, and lends uncertainty over the suitability of early foliage cover measurements as an appropriate baseline. Since dewatering and reinjection at Yandi began in August 2006, it is also possible that foliage cover at nearby sites may have been impacted prior to the start of monitoring.

The original intent of this project was to interrogate in depth the Mattiske vegetation dataset. However, closer inspection of the database revealed analyses were less straightforward than anticipated because of inconsistencies and constraints in data entry. Thus there was insufficient time and resources to complete the analyses within this study. Some preliminary work on the data was carried out. Further analyses and collation of these results will be

required to identify vegetation responses to changing hydrological conditions similar to the relationships with depth to water table and discharge identified for DCP data for different sites.

4.2. Hydrological impacts of dewatering, discharge and reinjection

Operations at both HD1 and Yandi mine sites impacted on hydrological parameters significant for riparian vegetation along Weeli Wolli Creek. Drawdown associated with dewatering at both HD1 and JSE at Yandi reduced both groundwater levels and water levels in the alluvium. The disposal of water extracted by dewatering by reinjection into a borefield at Yandi and as discharges into Weeli Wolli and Marillana Creeks increased levels in the alluvium.

The potential influence of reinjection on water levels relevant for riparian vegetation has not been quantified in this study. However, gradients in levels measured in transects of bores at intervals along Weeli Wolli creek at Yandi suggest that its influence varies both spatially and temporally. Levels at sites Y10, Y09 and Y08 are the most likely to have been influenced by reinjection, with hydraulic gradients towards the creek occurring periodically between September 2006 and February 2007, October 2009 and December 2011 respectively at these sites. The potential influence of reinjection on water levels relevant to vegetation at sites further north on Weeli Wolli Creek (Y07, Y01 and Y13) are unknown, but likely to become increasingly insignificant with distance from the re-injection bore field.

It appears likely that discharge had a more significant influence than re-injection on water levels relevant to riparian vegetation over the study period. Although reinjection volumes were initially similar to or greater than discharges from DO6, discharge volumes increased from January 2010 and consistently exceeded reinjection volumes for the remainder of the study. Furthermore, volumes from D06 were supplemented by HD1 discharges, as indicated by the rapid progression of surface expression of discharge along the creek downstream of the gabion. Gabion discharge contributed to flows from DO6 from February 2007 and impacts of discharge (as indicated by the surface expression of discharge) extended beyond the most northern tree health monitoring site at Yandi (Y13) from July 2007 onwards. Thus the spatial extent of influence of discharge on water levels relevant for riparian vegetation likely exceeded those of re-injection.

Hydraulic gradients influencing the rate of water movement to riparian vegetation may also be greater for discharge compared with reinjection. Water is discharged from an outlet above the ground surface and the level of the alluvial aquifer, creating a positive head. In contrast, water is discharged from re-injection bores installed below ground and slotted at depths of 18.0 to 89.7 m. Gradients are also influenced by distance from the source of

water, and the location of reinjection bores at some distance from the creek contribute to the probability of higher gradients from discharge because of its closer proximity to trees along the creek. These factors point to discharge as a more significant influence than re-injection on water levels relevant for riparian vegetation over the study period. Given this, the discussion below on foliage cover responses at Yandi refers principally to impacts of discharge. However, it is recognised and acknowledged that both reinjection and discharge are likely to influence tree health if they contribute significantly to rising water levels in the root zone.

Impacts of dewatering on groundwater levels at HD1 extended for several kilometres from the dewatering borefield. Impacts on water levels were observed to extend about 6.5 km to the northeast of the borefield along Weeli Wolli Creek at BH17d. Impacts also extended about 6.4 km along Weeli Wolli Creek towards bore BH20d in the south. The significance and extent of influence of drawdown at Yandi on levels relevant for riparian vegetation along Weeli Wolli Creek cannot be readily assessed because impacts are confounded by discharge and reinjection. Levels at Y10 and Y09 are likely to be influenced by drawdown, as nearby alluvial bores WW1 and JSE16 became dry during the course of this study. There is little evidence for drawdown influencing levels significantly further downstream at Y08 and no bore data south of Y10 to inform whether impacts extend upstream to Y11. However, any influence at Y11 appears unlikely given the distance from dewatering and assuming that dewatering impacts propagate similar distances upstream as downstream.

Long-term gauging of streamflow at the Tarina and Waterloo Bore stations has facilitated an analysis of the impacts of below water table mining operations on streamflow in Weeli Wolli Creek downstream of the gabion. Early indications are that streamflow at Tarina has increased disproportionately in years after the start of discharge. The reasons behind this apparent increase are unknown, but could relate to the lack of opportunity for riparian storages to absorb a volume of runoff, since these have already been filled to capacity by discharge. Other factors potentially influencing the surface water hydrology (e.g. area open for mining) could also be significant. There are indications that streamflow downstream at Waterloo Bore remains unaffected by cumulative impacts of discharge from BHP Billiton and Rio Tinto Iron Ore operations at HD1 and Yandi, since neither the volume nor duration of flow have changed. This supports the thesis that mining operations in Weeli Wolli catchments haven't altered the hydrology of the Fortescue Marsh further downstream.

4.3. Foliage cover responses to drawdown

The only tree health monitoring site where water levels appeared to decline in response to dewatering at JSE at Yandi was Y10, where depth to water increased from 3.0 to 6.2 m.

Foliage cover of trees at this site didn't appear to respond to drawdown, and the relationship between foliage cover and depth to water wasn't significant for this site. Any response to drawdown was likely confounded by responses to discharge from HD1, which reached Y10 by February 2007.

Foliage cover responses to groundwater drawdown at HD1 were quite site-specific and confounded in places by changes in surface water hydrology as a result of the diversion of Pebblemouse Creek. Discharge from spurs also masked any response of eucalypts to drawdown in the springs area of Weeli Wolli Creek. The lack of response in foliage cover to groundwater drawdown at HD0 confirms that *E. victrix* and *E. camaldulensis* aren't accessing significant water from very deep (> 40 m) groundwater. The rapid decline in foliage cover close to dewatering at sites HD1 and HD2 between February and May 2007 suggest that these eucalypts may be vulnerable to dewatering if drawdown is rapid and water levels are initially shallow enough to be accessible for uptake by tree roots. However, the subsequent recovery in foliage cover at these sites suggests adaptation to the changed hydrological conditions is possible if the availability of surface water resources is maintained. In contrast, foliage cover at HD4 declined with increasing drawdown because surface water availability was also reduced by the diversion of Pebblemouse Creek. Foliage cover further downstream at HD3, a site where diversion of Pebblemouse Creek would likely have minimal impact, showed no response to significant but relatively gradual drawdown of groundwater from depths readily accessible to tree roots. The response suggests that these *Eucalyptus* species are resilient to drawdown if surface water availability remains unaffected.

The importance of surface water availability in maintaining foliage cover of eucalypts is supported by other responses observed in this study. With the exception of HD4, foliage cover at all HD1 drawdown sites (i.e. HD1, HD2, HD3, HD5, HD6 and HD6a) showed a positive response to annual rainfall which was statistically significant for HD1 and HD2. Positive responses to rainfall are also observed at reference sites HD0 and PB1. Though the response at PB1 wasn't statistically significant, foliage cover at this site showed a significant positive response to streamflow. Foliage cover of *Eucalyptus* species in the springs was also responsive to spur discharge, an alternate source of surface water. Trees at HD5 and HD6a all showed a significant positive response to volumes of spur discharge, despite a very significant fall in groundwater levels from approximately 2 to 8m at HD5. Indeed, there is a suggestion that spur discharge has over-compensated for any reduced water availability caused by drawdown. Foliage cover increased between October 2006 and December 2014 at all eucalypt sites in the springs area receiving supplemental irrigation from spurs. Increases at HD6 and HD6a were greater than at any other sites, including at the reference site HD0. These increases were positively correlated with discharge volumes at both HD5 and HD6a. It is possible that eucalypts here have been over-irrigated and the enhanced foliage cover is in disequilibrium with water available under undisturbed conditions. This has

implications for the cessation of spur discharge and the transition back to an unmanaged system. Adopting and trialling a system for scheduling supplementary water applications through the spurs to better match vegetation demand for water would facilitate this transition through improved understanding of the system and vegetation responses.

Given the significance of surface water availability for tree health, impacts of groundwater drawdown are likely to be more significant in situations where drawdown also influences the frequency and duration of streamflow. A preliminary analysis of changing levels at bore BH16s in this study suggest that both the frequency and duration of streamflow in Weeli Wolli Creek upstream of the gabion was reduced by drawdown. This response decreases the frequency with which water stored in unsaturated sediments and used by riparian vegetation is replenished. It also prolongs the length of time between flood events, and increases the risk of water deficits developing. Thus falling water levels exert a dual influence through decreasing the accessibility of water from the saturated zone, and decreasing availability from unsaturated alluvium. Given this significance, an important consideration in understanding impacts of drawdown on vegetation health is adequate monitoring of depth to water as well as streamflow responses and water availability in the unsaturated zone. Reinstating the gauging of streamflow at the Weeli Wolli Springs station would allow a quantitative analysis of streamflow responses to drawdown at HD1. Monitoring of streamflow at other locations upstream of the gabion would also be relevant, but would not have the advantage of a longer term dataset to compare pre- and post-impact responses.

4.4. Foliage cover responses to discharge

Responses in *Eucalyptus* foliage cover at sites downstream of discharges from the gabion at HD1 and D06 at Yandi indicate variable impacts of discharge on tree health. Sites HD6b, Y12 and Y11 downstream of the gabion didn't respond negatively to discharge rates or cumulative volumes. However, foliage cover at sites HD7 and HD9 showed statistically significant negative responses to gabion discharge rates, and sites HD7, HD8 and Y10 significant negative responses to cumulative discharges.

Foliage cover responses at sites downstream of DO6 at Yandi were more consistent and significant than responses to discharge from HD1. Foliage cover showed statistically significant negative responses to DO6 discharge rates and cumulative volumes at sites Y09, Y08, Y07 and Y01. Site Y13 also showed a negative response to cumulative discharge. The greater impact on foliage cover of discharges at Yandi results from generally shallower water tables in the alluvium compared with sites impacted by HD1 discharge. Relationships between foliage cover and depth to water showed statistically significant reductions in foliage cover with rising levels at sites Y08 and Y01. However, the response of individual trees at a

site wasn't uniform, and at most of the sites there were some trees that increased their foliage cover. This finding has significance since it suggests that a proportion of trees at each site occupy an ecological niche which has allowed them to maintain or increase their leaf area. It also has significance for the regeneration of the ecosystem in the longer term.

The negative impacts of discharge on foliage cover of *Eucalyptus* species at some sites is supported by other responses observed in this study. In contrast with the generally positive responses in foliage cover to annual rainfall and streamflow observed for reference and drawdown sites, foliage cover at discharge sites was not enhanced in years with greater annual rainfall or streamflow. At discharge sites HD9, Y12, Y11 and Y10, foliage cover was unresponsive to annual rainfall and streamflow. However, trends of declining foliage cover with increasing annual rainfall and streamflow were found for all perennial discharge sites downstream of the gabion and for all sites at Yandi downstream of DO6. Trends of decreasing foliage cover with increasing annual streamflow were statistically significant at sites Y09, Y08 and Y01. Lower foliage cover found in *Eucalyptus* species at perennial compared with annual sites at the start of this study is also indicative of negative responses to shallow water tables. However, it is possible that differences in foliage cover between perennial and annual sites, and responses to cumulative discharge, may result from anomalies associated with the DCP technique. Consistent differences between response to different factors (e.g. tree height, maturity, canopy form and distribution, or size of branches and stem etc.) at a site may contribute to apparent differences in their foliage cover measured by the technique. To my knowledge, the application of the DCP technique to capture long- term changes in foliage cover of individual trees hasn't been investigated to ascertain whether anomalies/inaccuracies may occur. Given the widespread application of the technique for compliance monitoring within Rio Tinto Iron Ore, it would be appropriate to investigate this for a long-term dataset.

The decrease in foliage cover with rising water levels observed for some of the sites in this study is not unexpected, and consistent with reports of negative impacts of waterlogging on health of some eucalypts. That foliage cover changes relate to the elevation of individual trees at site Y08 also suggests that depth to water is a key factor. The preliminary analysis of foliage cover decline for individual trees at Y08 suggests a critical depth to water for foliage cover decline of about 1 m. The relationship between percentage change in foliage cover and the duration of water levels above the critical level derived for Y08 suggests a 9.1% decline in foliage cover for each year that levels are within 1m of the surface (Figure 53).

The depth of 1 m identified as the critical depth to water explaining foliage cover decline for trees at Y08 should be taken as indicative only, since it was determined only for a single site and using estimated rather than measured water levels. The identification of a critical depth

to water for explaining foliage cover decline is useful for predicting impacts of discharge on riparian vegetation where depth to water can be estimated or measured. It also informs better management of discharge to maintain levels below this critical depth. Confirmation of actual water levels at tree health monitoring sites will enable critical levels for foliage cover decline to be determined with greater confidence.

In this study, the trend in decreasing foliage cover with cumulative discharge observed for several discharge sites cannot be consistently attributed to rising water levels. Further investigation to establish with greater certainty the water levels at each site may confirm whether or not this is the key factor causing decline. Foliage cover responses to cumulative discharge may not be simply due to waterlogging, but could also relate to indirect effects of discharge e.g. through increasing disease, unknown impacts of precipitate or changing soil chemistry and plant nutrition. Further studies are warranted to understand the underlying mechanisms behind the decrease in foliage cover with cumulative discharge.

A comparison of the two different tree health parameters monitored on Weeli Wolli Creek (foliage cover and stress index calculated from the Mattiske qualitative assessments of tree condition) reveals contrasting responses to discharge. Where monitoring sites were in close proximity, there was no correlation between these parameters. These findings suggest that eucalypts selected for foliage cover monitoring aren't representative of trees across the riparian zone at each site location. Trees monitored for foliage cover may represent the more severely-affected trees, with the Mattiske monitoring transects better capturing responses of eucalypts across the riparian zone. Alternatively, the qualitative assessment method may not adequately capture a decline in tree health at discharge sites. This alternative explanation appears unlikely, since the stress index is effective in revealing differences in response between reference and discharge sites.

4.5. Responses of *E. victrix*, *E. camaldulensis* and *M. argentea* to drawdown and discharge

The capacity to undertake a systematic comparison of the responses of *E. victrix* or *E. camaldulensis* in this study was limited by the small number of trees of a species sampled at some sites (ie unequal replication). However, there is little evidence to support differential responses of these species to drawdown, as their responses are somewhat inconsistent at the different sites. There is also little evidence that *E. victrix* or *E. camaldulensis* are responding differently to discharge or to rising water levels. Both species show either no response or negative relationships between foliage cover and discharge rates or cumulative volumes, and their responses are often very similar at discharge sites. More detailed and fine-scaled investigations of individual tree response at a site, or using more sophisticated

physiological monitoring techniques may reveal differences between them. Alternatively, the lack of differentiation between their responses may also reflect incorrect species identification, given observations that their form may vary somewhat depending on site conditions.

Understanding responses of *Melaleuca argentea* to drawdown is limited in this study by the short timeframe of monitoring and the confounding responses to spur discharge. However, none of the components of tree health monitored by digital canopy photography (foliage cover, crown cover and canopy cover) were responsive to changing depth to water. This is perhaps unsurprising given the relatively small changes in depth to water experienced at melaleuca drawdown sites. Depth at HDM1 varied between 1.6 and 3.4 m, and between 0.5 and 1.4 m at HDM2. These depths are well within the range in depth to water reported by Loomes (2010) for *Melaleuca argentea* at sites in the Pilbara.

The significance of discharge for the health of *Melaleuca argentea* is unclear from this study, principally because the significance of contrasting responses in foliage cover, crown cover or canopy cover cannot be determined without a separate, independent measure of tree health. Foliage cover at sites HDM1, HDM2 and HDM3 were not responsive to rates or cumulative volumes of discharge from spurs or the gabion. However crown cover of melaleucas at all these sites gave a significant decline in response to increasing cumulative discharge volumes, whilst canopy cover increased significantly with increasing cumulative discharges at sites HDM1 and HDM3. Except for a statistically significant decrease in crown cover with increasing annual rainfall at HDM1, none of the parameters of tree health responded to annual rainfall at melaleuca sites including the reference site HDM0. Tree health parameters were also unresponsive to annual streamflow at HDM3. The lack of response to rainfall and streamflow may simply reflect the low degrees of freedom (df) for determining the statistical significance, given the short timeframe for monitoring. However, it may also indicate that the health of melaleucas at all sites isn't limited by water deficits.

Further studies are warranted to understand the responses in foliage cover, crown cover and canopy cover of Melaleucas and to identify which parameter best represents their condition. This will allow determination of whether or not cumulative discharge is impacting negatively on tree health. If negative impacts are identified, further studies are warranted to understand the underlying mechanism for this response.

4.6. Conceptual models developed in this study and steps required to facilitate prediction of impacts at other sites

Conceptual models developed in this study relevant to predicting potential impacts of drawdown and discharge on vegetation health at other sites include:

i) Identification of a critical depth above which the duration of waterlogging impacts negatively on foliage cover of eucalypt species. Verification of estimated water levels is required, followed by deriving a critical depth that explains foliage decline across more than one of the sites studied. These steps will allow Rio Tinto Iron Ore to more confidently apply the criteria to predict impacts at other sites in conjunction with streamflow modelling to predict water levels in the alluvium.

ii) The response in foliage cover of eucalypts exposed to discharge is related to cumulative discharge volume. Further investigation to investigate mechanisms causing this decline is warranted to facilitate the application of the model to other sites.

iii) Riparian eucalypts growing at ephemeral sites are resilient to drawdown provided surface water availability and flows remain unaffected. Given the limited replication of sites available at HD1 to test this conclusion, similar analyses for vegetation at other sites with drawdown should be carried out to confirm the wider application of this result.

4.7. Significance of study findings for Pockets and Billiards South

The finding from this study that foliage cover of *E. victrix* and *E. camaldulensis* are resilient to impacts of drawdown if streamflow and hence surface water availability remain undisturbed is of significance for dewatering of Pockets and Billiards South. Since Weeli Wolli Creek was ephemeral at Yandi prior to discharge from HD1 and DO6, the cessation of perennial flow in the creek may simply represent a return to the original, undisturbed condition. However, if drawdown or other operations reduce the frequency, duration or extent of flood events, the health of riparian vegetation may be compromised.

Irrespective of the longer term impacts of drawdown on vegetation, the transition from existing to a new equilibrium condition should be managed to minimise adverse impacts. Given evidence from this study that foliage cover of *Eucalyptus* species at Yandi has largely declined under impacts of discharge, it is possible that an adjustment to new equilibrium conditions without perennial discharge will involve an increase in foliage cover from existing levels. This suggests an easier transition to a new equilibrium than would be expected if foliage cover had been enhanced by discharge. However, it is also likely that prolonged waterlogging as a result of shallow water tables in the alluvium has caused the senescence of deeper roots and promoted the development of shallow roots. A rapid reduction in water

levels in the alluvium could be detrimental to tree health if water availability in the shallow root zone becomes limiting. If drawdown occurs during months of high evaporative demand, water stress could develop relatively rapidly, reducing the capacity of trees to develop a deeper root system to access the water they require. Under these circumstances, supplemental irrigation may be required to reduce the risk of significant tree deaths. If drawdown occurs during cooler winter months, the risk of tree deaths is likely to be reduced. However, application of supplemental irrigation may still be required to prevent tree deaths.

Part of demonstrating the sustainability of discharge into Pilbara river systems as a means of managing excess water is the successful management of a transition to the cessation of discharge. Careful monitoring of vegetation responses to changing water availability in both the saturated and unsaturated profile will facilitate a successful transition. The timing and duration of any supplemental water applications should be based on monitoring and analyses to avoid enhancing foliage cover to unsustainable levels requiring ongoing irrigation.

1.0 Executive Summary

Rio Tinto currently operates the Yandi iron ore mine, located approximately 90 km northwest of Newman in the Pilbara region of Western Australia. The original Yandi deposit, Junction Central, started construction in 1997 with the first shipment of ore occurring in 1999. An expansion to existing mining developments was later proposed in 2005 in the form of the Junction South East (JSE) deposit. A number of other expansions have subsequently occurred, including at the Junction South West (JSW) and Oxbow deposits.

All the deposits at Yandi are Channel Iron Deposits (CID) adjoining, or in close proximity to the Marillana and Weeli Wolli Creek systems. Advance dewatering and groundwater management is required to access the ore as the deposits are mostly situated below the water table. Marillana, Yandicoogina and Weeli Wolli creeks generally only flow naturally and recharge superficial aquifer systems after heavy rainfall events. However, the discharge of dewatered water from neighboring mines since 1992, coupled with discharge from Rio Tinto's operations, has resulted in virtually continuous surface flow through some sections of Weeli Wolli and Marillana Creeks in recent times.

The geology and hydrology of the superficial alluvial aquifers at Yandi are well suited for stygobitic fauna utilisation. Dewatering and groundwater management therefore have the potential to impact stygofauna communities and, as part of related environmental assessments, extensive sampling for stygofauna has been undertaken in the area since 2003.

This report is designed to provide:

- summaries of sampling effort and methodologies for each survey phase from 2003 – 2014;
- an amalgamation of stygofauna data collected from the Yandi operations;
- a summary of conservation significant stygofauna species; and
- an update to taxonomic groups using either genetic or morphological techniques.

Stygofauna sampling at Yandi has been undertaken by Biota since 2003, with 13 phases completed in total, representing a significant and sustained sampling effort. A total of 139 boreholes have been sampled to date, encompassing Junction Central, Junction South-East, Junction South-West, Oxbow and Pocket and Billiards South deposits, together with the adjacent creeklines and also the Billiards North deposit.

Stygobitic fauna sampling was undertaken during all past phases using modified plankton haul nets. Stygofauna sampling nets were lowered to the bottom of the drillholes and bore holes before being slowly hauled to the surface where the contents of the catch jar were collected. Specimens from all taxonomic groups were preserved in 100% ethanol, which allows for both morphological and molecular analysis. Most groups were identified from morphology, with representative amphipod specimens sequenced for variation at the mitochondrial COI gene. These specimens were compared to reference sequences of other Paramelitidae amphipods from the Pilbara, to determine the number of species collected and to assess the relationships of the Yandi specimens to taxa previously collected.

A total of 9,654 specimens of stygobitic fauna have been collected from surveys between 2003 and 2014. The collected specimens represented eight phyla and 12 orders as summarised by taxonomic group below.

- Six specimens of Protozoa were recorded from site DO7YJ138. These specimens were unable to be identified further due to a lack of taxonomic framework for this group in the Pilbara region.
- A total of 832 platyheminth worm specimens were collected from the Yandi area. The specimens were identified to the class Turbellaria, however this group is difficult to identify based on morphology.
- Thirteen specimens belonging to the phylum Nematoda were recorded from the Yandi area, from both Marillana and Weeli Wolli Creeks, but cannot be resolved below phylum.
- A total of 388 specimens of Oligochaeta were recorded during all phases of sampling, representing five families and 13 species.

- A single damaged gastropod shell was recorded from site 99YJWB02 during sampling in 2010. It is currently unclear if this shell represents a surface aquatic form or a stygobitic taxon.
- A total of 3,195 copepod specimens were recorded during all phases of sampling. The order Cyclopoida was the most abundantly collected and the specimens represented 17 distinct species, four of which still remain undescribed.
- A total of 2,775 specimens belonging to the order Ostracoda were recorded from the Yandi area over all phases of sampling. Sixteen distinct species were recorded representing two families (Candonidae and Limnocytheridae). Nine of these species have been formally described.
- A total of 72 specimens of Bathynellacea were recorded from the Yandi area. Seven distinct morphological species were collected, all belonging to the family Parabathynellidae.
- A total of 1,454 specimens belonging to the order Amphipoda were recorded from Yandi over the 13 phases of sampling. Amphipods were mostly identified morphologically, however 146 specimens were identified either genetically or by both methods. A total of eight species have been identified based on morphological characteristics, and genetic analysis also indicates the presence of eight genetic lineages from the 146 specimens successfully sequenced. Lineage WWA2 comprised specimens from the morphologically identified species Paramelitidae sp. B02 and sp. B03, whereas Lineage YB6 included specimens morphologically identified as Paramelitidae sp. B02 and *Pilbarus millsi*. These results suggest that some of the amphipod species represented at Yandi may be morphologically cryptic, as documented elsewhere.
- A total of 686 isopod specimens were collected, with 382 specimens belonging to the species *Pygolabis weeliwolli*, which was recorded from 29 sites from both Marillana and Weeli Wolli Creeks. The species *Pygolabis* sp. B06 was also widely collected.
- A total of 227 specimens of water mite were recorded from Yandi over the 13 phases of sampling. The specimens represented 12 distinct species from eight families.
- Three specimens of Coleoptera were recorded in 2011. These specimens belonged to the species *Boongurrus occidentalis* and were collected from site MNEW1upstream adjacent to Marillana Creek.

The documented fauna now comprises at least 88 stygal taxa, with the greatest abundance of species and specimens recorded from within alluvial and calcrete formations or associated with either Marillana or Weeli Wolli Creek. Sites Marillana07 and MNEW1upstream both yielded the highest abundance and species numbers (1,280 specimens and 1,032 specimens respectively; 23.95% of total records). Six other sites yielded over 31 species, while 53 sites yielded four species or less. These site richness findings should be interpreted with caution, as sampling effort varied by site amongst phases, with any given site sampled between one and 11 times during the study.

With the taxonomic resolution of some groups of stygobitic fauna, it is difficult to definitively assign conservation significance to some of the taxa recorded at Yandi. Thirteen of the taxa collected are undescribed, singleton records, which have been recorded only from within the Yandi study area. A precautionary position then would be to consider these as potentially restricted in distribution, and therefore of higher conservation significance, until otherwise demonstrated. However, given the abundance of other wider ranging Pilbara taxa collected (for example; *Meridiescandona facies, Enchytraeus* Pilbara sp. 2 (PSS) and *Boongurrus occidentalis*), it is unlikely that the recorded singleton species are confined to the Yandi study area. This may suggest that singleton records are more an artefact of sampling rather than reflecting true distributions.

The alluvial geology and superficial, highly transmissive aquifer that extends beyond the Yandi study area is also likely to allow stygobitic fauna dispersal to at least local catchment scale. This alluvial unit is associated with the Weeli Wolli Creek system and extends beyond the Yandi study area to the north and south, with the northern extent meeting the confluence with Marillana Creek and further northwards, opening up into a wide alluvial outwash fan which drains into the Fortescue Marsh. In addition, seasonally variable flooding from cyclonic events are also likely to aid in fauna dispersal. These habitat attributes suggest very small geographic scale restrictions to the Billiards project area, for example, may be unlikely in the stygofauna of the Yandi locality.

2.0 Introduction

Rio Tinto Pty Ltd (Rio Tinto) currently operates the Yandicoogina (Yandi) iron ore mine located approximately 90 km northwest of Newman in the Pilbara region of Western Australia (Figure 2.1). The original Yandi deposit, Junction Central, started construction in 1997 with the first shipment of ore occurring in 1999. An expansion to the existing mining developments was later proposed in 2005 in the form of the Junction South East (JSE) deposit. A number of further expansions have subsequently occurred, including at the Junction South West (JSW) and Oxbow deposits (Figure 2.1).

Rio Tinto plans to sustain the operations at the existing Yandi mine. The proposed sustaining operations include the development of the Pocket and Billiard South (PBS) deposits within the existing Yandi Operations development envelope (MS914; Figure 2.1). All the deposits at Yandi are Channel Iron Deposits (CID) located adjacent to, or in close proximity to the Marillana and Weeli Wolli Creek systems. In order to access the ore within the deposits, advance dewatering and groundwater management will be required, as the deposits are almost entirely below the water table. Such activity has the potential to impact stygofauna communities and as part of environmental assessments, extensive sampling of stygofauna communities has been undertaken in the area since 2003. Historical phases of stygofauna sampling at Billiards and the surrounding tenements have also collected several specimens of troglobitic fauna (or troglofauna) (Biota 2010), though these are not considered in this report.

Environmental Protection Authority (EPA) policy requires Rio Tinto to determine the potential impacts of proposed mining operations on subterranean fauna prior to formal approval and operations commencing (EPA 2013).

2.1 Report Aims

This report is designed to provide:

- summaries of sampling effort and methodologies for each survey phase from 2003 – 2014;
- an amalgamation of stygofauna data collected from the Yandi operations;
- a summary of conservation significant stygofauna species; and
- an update to taxonomic groups using either genetic or morphological techniques.

2.2 Stygofauna Overview

Subterranean fauna in north Western Australia have been recorded for some time from karstic or limestone cave systems on Cape Range and Barrow Island. In the Pilbara, surveys have collected subterranean fauna from other formations such as pisolitic iron formations, channel iron deposits, unconsolidated alluvium and sedimentary basalt (Marmonier et al. 1993, Biota 2004, 2006, 2010, 2011, 2013), indicating that the suitability of a given geology as habitat for subterranean fauna lies more with the availability of habitable space (Marmonier et al. 1993, Humphreys 1999, Biota 2006), than with a specific rock type.

Subterranean fauna habitats are characterised by a suite of physical parameters that include: a lack of light, stable temperatures and humidity, and limited nutrient infiltration from surface environments (Juberthie 2001, Romero 2009). These habitat characteristics have led to the evolution of common body morphology amongst subterranean fauna. Morphological characteristics common to most subterranean fauna include (Culver and Pipan 2009, Romero 2009):

- reduced or lack of pigmentation;
- reduced or lack of eyes; and
- elongate body morphology and appendages adapted for sensory movement.

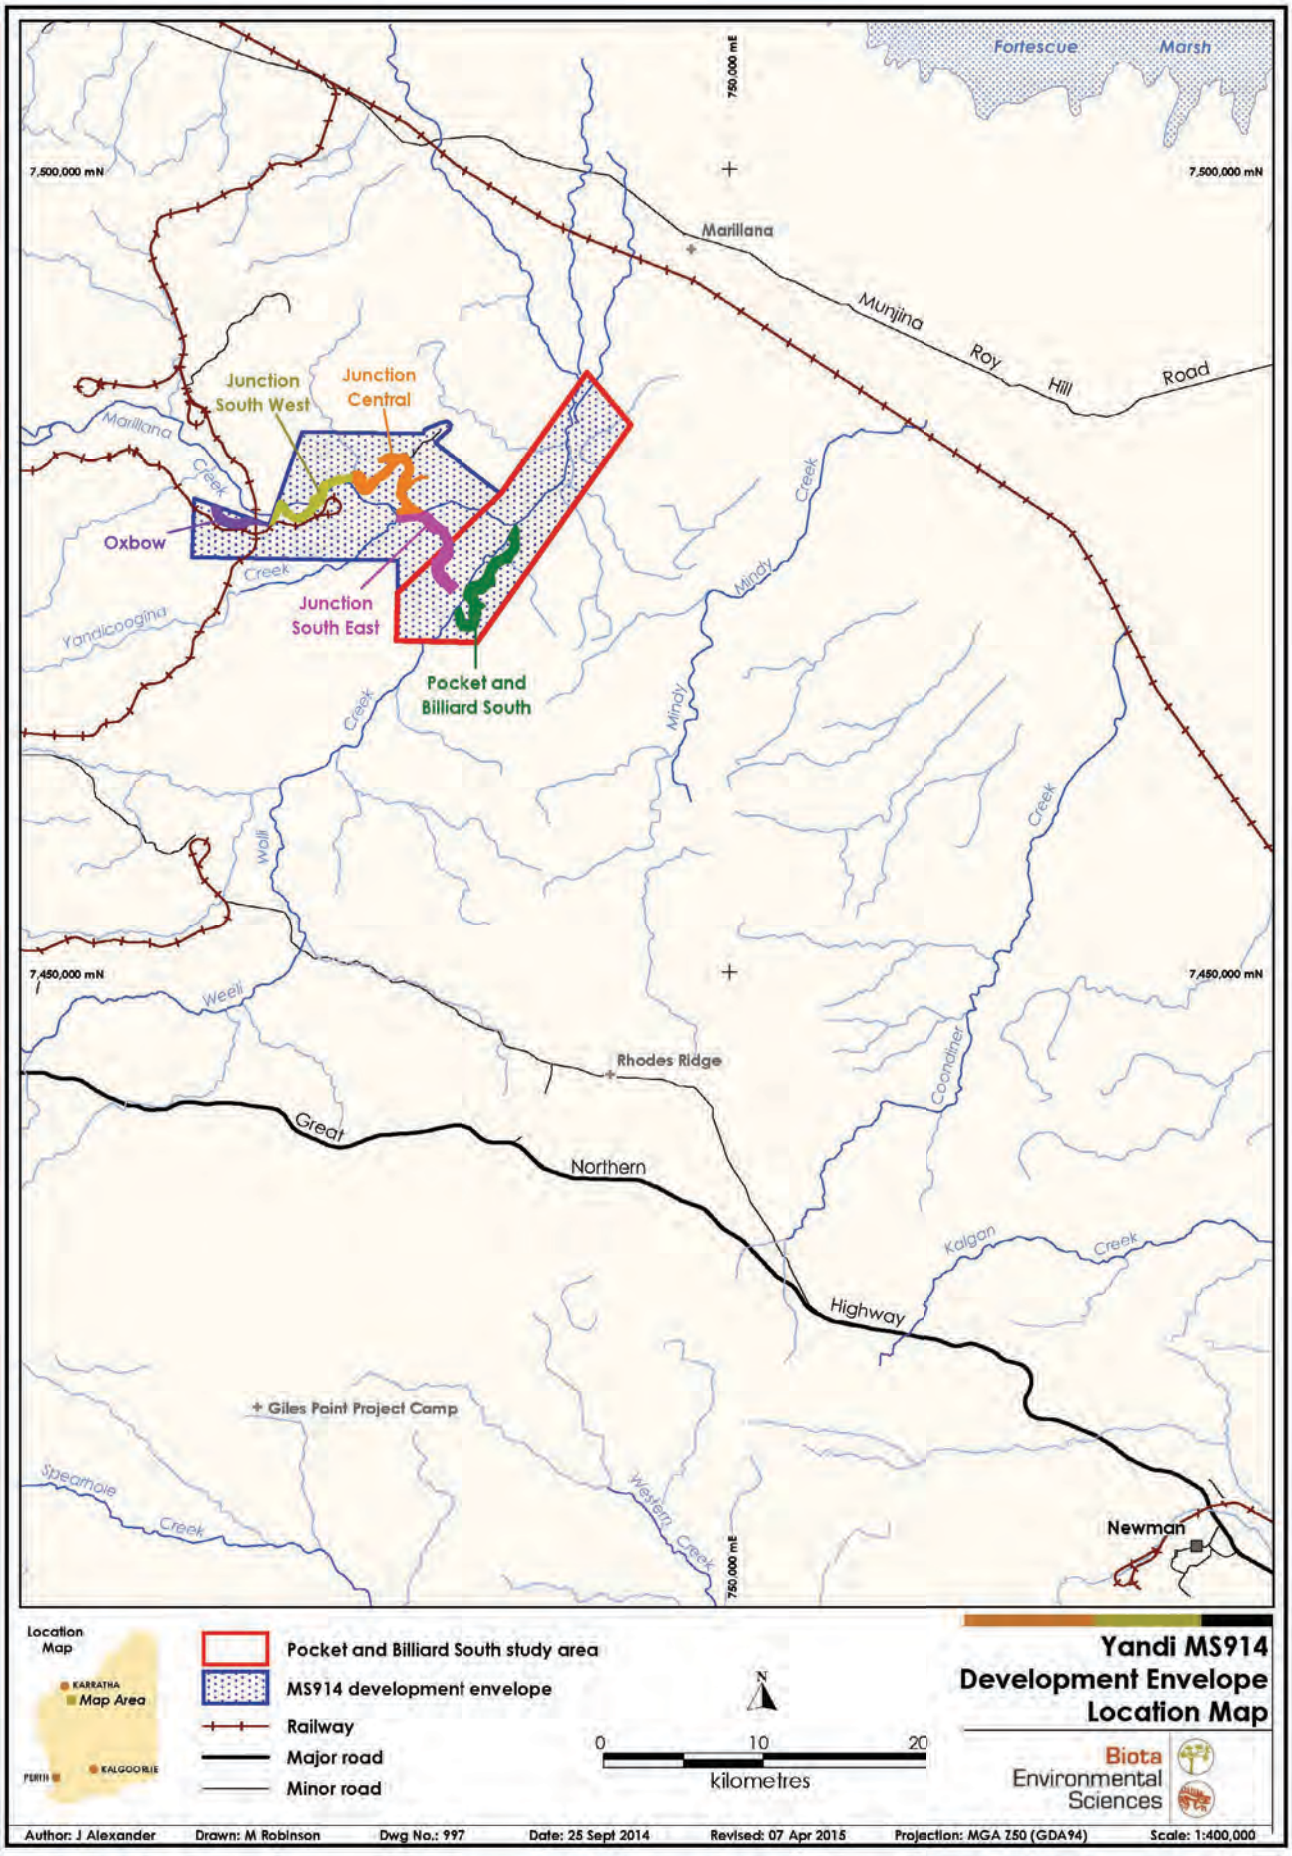

Figure 2.1: Location of the Yandi MS914 development envelope and ore bodies in relation to Newman.

Subterranean fauna can be categorised into two distinct groups based on habitat: troglobitic fauna (troglofauna) and stygobitic fauna (stygofauna). Troglofauna are a suite of fauna that survive only in cavities and interstices between the ground surface and the water table. Stygofauna occupy a similar niche, however are adapted to aquatic conditions and exist in groundwater aquifers and subterranean water bodies. True stygobites are obligatory subterranean habitat dwellers, and while they may occur close to surface environments, are evolved specifically for a subterranean environment, which make it unable, or highly unlikely to survive surface conditions.

Stygal communities in Western Australia are predominantly crustacean (Amphipoda, Isopoda, Decapoda, Syncarida, Ostracoda, Copepoda), however the Annelida (Oligochaeta), Arachnida (Hydracarina) and Platyhelminthes are also commonly collected. Three species of stygal vertebrates have been recorded from Australia, from Barrow Island, Cape Range and the Pilbara. This includes two species of blind gudgeon (*Milyeringa veritas, M. justitia*) as well as a blind cave eel, *Ophisternon candidum*. (Humphreys 2001, DSEWPaC 2008, Foster and Humphreys 2011, Humphreys et al. 2013, Larson et al. 2013).

3.0 Stygofauna Habitat Characterisation

3.1 Climatic Conditions

The climate at Yandi is typified by arid conditions with hot, wet summers and mild, dry winters. Average temperatures for the locality range from 39.0 ºC in January to 8.1 ºC in July (BOM, 2014). The majority of rainfall occurs in the summer months and is driven mostly by cyclonic activity. The average annual rainfall for the area is 310.2 mm, with approximately half of this falling between December and February (Biota 2010).

Marillana and Weeli Wolli creek are ephemeral and generally only flow naturally after heavy rainfall events, however the discharge from neighboring upstream mines since 1992, coupled with discharge from Rio Tinto's operations, has resulted in a virtually continuous flow through sections of Weeli Wolli Creek in recent times.

3.2 Hydrology, Geology and Subterranean Fauna Habitat

The suitability of any geological formation as habitat for subterranean fauna is predominantly determined by the availability of space and potential for nutrient infiltration. In the case of stygofauna, this is further refined to where such rock formations occur below the water table. Several geological units are recognised as being core habitat for subterranean fauna as they characteristically form fractures, caverns and vugs, which allows for a greater rate of fauna dispersal and nutrient penetration. These geologies include limestone karstic systems, calcrete, alluvium, gravels, limonite and dolomite (Marmonier et al. 1993, Humphreys 1999).

The surface geology of the Yandi area (Figure 3.1) includes several units that represent suitable habitat for stygofauna. These comprise alluvium (Qa), colluvium (Qw) and calcrete units (Czk) (Table 3.1), all of which occur as valley fill formations broadly associated with contemporary drainages in the area and have been well sampled during past surveys (Figure 3.1).

Table 3.1: Geological units occurring in the Yandi study area.

Geological Time Scale	Code	Description
Quaternary Period	Qw	Alluvium and Colluvium - red-brown sandy and clayey soil; on low slopes and sheetwash areas.
	Qa	Alluvium - unconsolidated silt, sand, and gravel; in drainage channels and on adjacent floodplains.
	Qc	Alluvium-partly consolidated silt, sand, and gravel; old alluvium dissected by present-day drainage
	Qs	Eolian deposit - sand; in sheets and longitudinal dunes.
Cenozoic Era	Czp	Robe Pisolite: pisolitic limonite deposits developed along river channels.
	Cza	Hematite-goethite deposits on banded iron-formation and adjacent scree deposits
	Czc	Colluvium - partly consolidated quartz and rock fragments in silt and sand matrix; old valley-fill deposits.
	Czr	Hematite-goethite deposits on banded iron-formation and adjacent scree deposits
	Czk	Calcrete - sheet carbonate; found along major drainage lines
Proterozoic Eon	PLHb	Brockman Iron Formation: banded iron-formation, chert, and pelite.
	PLHt	Medium to coarse-grained metadolerite sills intruded into Hamersley Group
	PLHj	Weeli Wolli Formation: banded iron-formation (commonly jaspilitic), pelite, and numerous metadolerite sills.

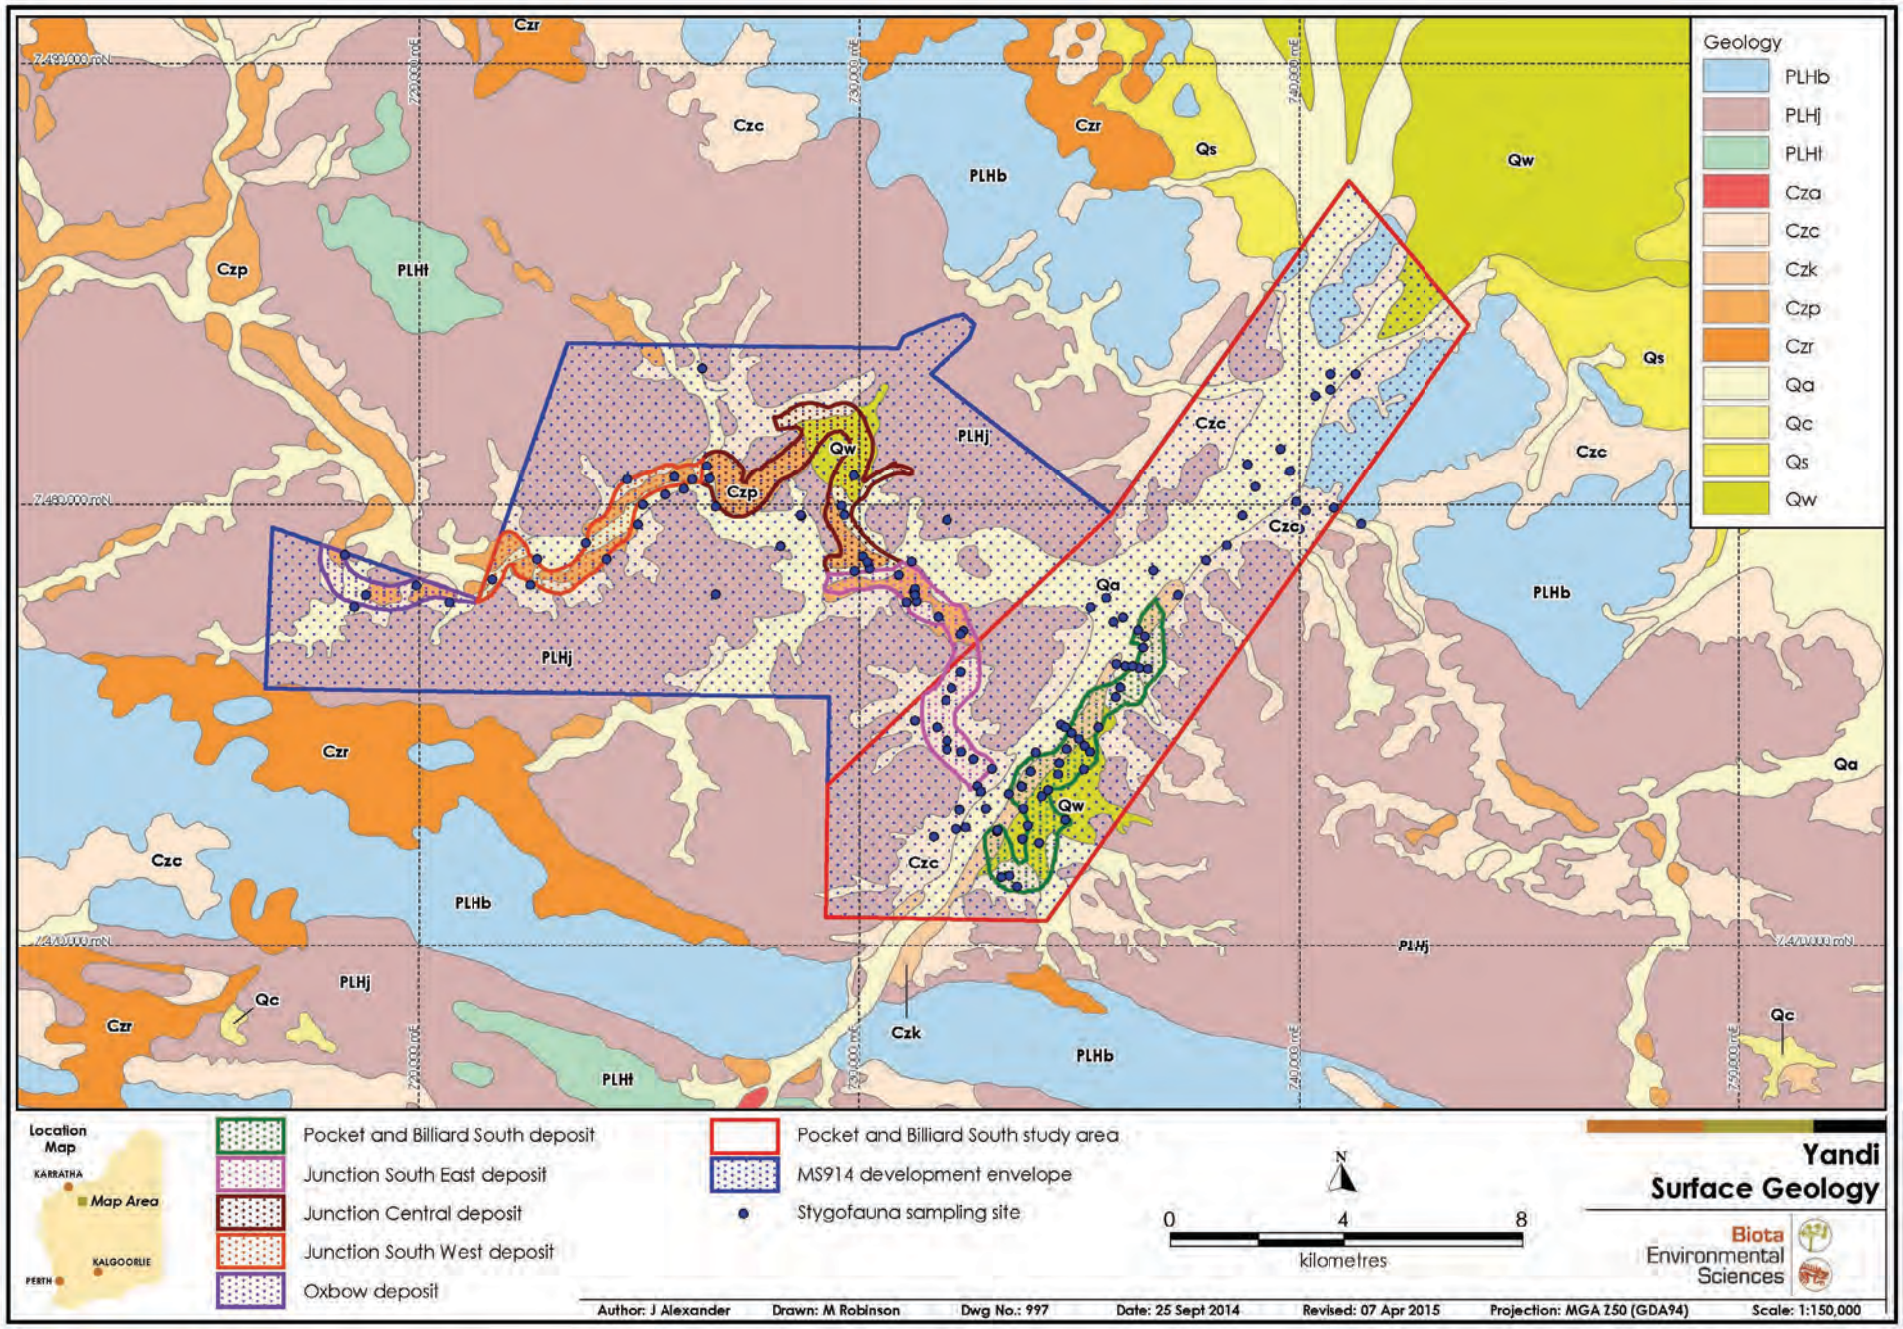

Figure 3.1: Geological units of the study area with stygofauna sampling sites from 2003 – 2014 (see Table 3.1 for geology unit codes and descriptions).

The CID in the Yandi area was eroded into bedrock of shale, dolerite and banded iron formation (BIF) of the Weeli Wolli formation, which overlies the Brockman Iron Formation. The CID is mostly below the water table and is overlain with varying depths of unconsolidated alluvium and colluvium (Rio Tinto 2010). Other units include chert, shale, minor dolerite and occasional CID clasts (Figure 3.2).

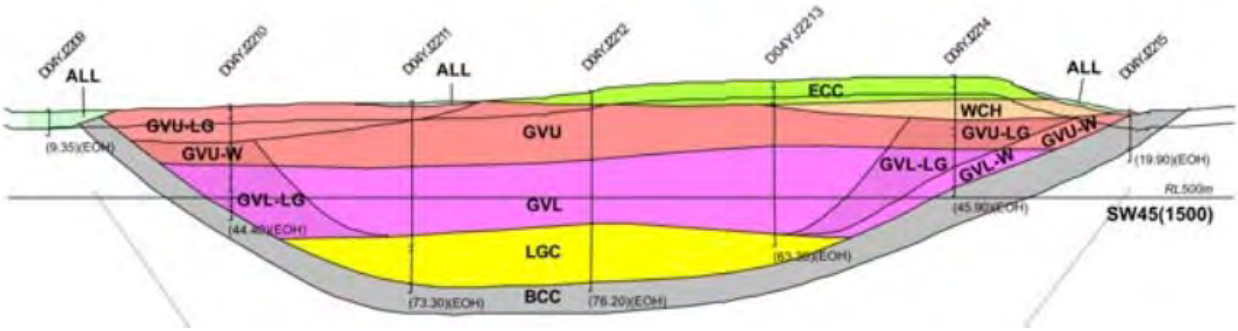

Figure 3.2: Cross-section of the CID at JSW shows relative geological layering (figure supplied by Rio Tinto).

Key	
Basal Conglomerate (BCC)	Pebble conglomerate with varying amounts of cobbles and larger fragments. The BCC is invariably present as the basal channel facies overlying basement
Limonitic Goethite Channel (LGC)	This material forms the footwall of the ore body. Typically hydrated/ altered material with well preserved to weakly preserved relict pisolitic textures and parent mineralogy. Lenses of unaltered to weakly hydrated/ altered material similar to the overlying GVL
Goethite Vitreous Upper (GVU)	Comprises the bulk of the above water table high grade CID. The GVU ranges from hard dense siliceous material that breaks with a conchoidal fracture to an earthy brown porous rock.
Goethite Vitreous Lower (GVL)	Comprises the bulk of the below water table high grade CID.

Alluvial processes have shaped the surface topography of the Yandi locality with the contemporary drainages winding between low-lying mesas and hills. The three major landforms that can be distinguished within the area are the low stony hills, valleys and drainage lines, the latter of which represent prospective habitat for stygofauna when saturated.

The overlying geology of both Marillana and Weeli Wolli Creeks are very similar and schematic cross-sections illustrating the system are shown in Figure 3.3 and Figure 3.4. The CID occurs in two broad configurations: adjacent to the contemporary drainage (Figure 3.3) or underlying it (Figure 3.4). Major rainfall events and subsequent surface creek flows result in recharge of the alluvium (Figure 3.3) and/or directly into the CID (Figure 3.4). Prolonged discharge of dewatering output into the Marillana Creek has, however, caused sections of both Marillana and Weeli Wolli Creek downstream from existing Rio Tinto and BHP Billiton Iron Ore operations to retain water for much a longer duration than normally occurs with seasonal variation. This has resulted in superficial formations remaining saturated for extended periods compared to past conditions.

The geology and hydrology of the superficial aquifer at Yandi is therefore well suited for stygobitic fauna utilisation with a high percentage of the shallow stratigraphy is comprised of saturated alluvium (Figure 3.1,). This shallow alluvial aquifer overlays a deeper aquifer where the CID is situated. These systems are recharged both directly and indirectly by rainfall, groundwater and surface water flow. The CID is primarily recharged by seepage in areas where the creek overlays the CID (Figure 3.4, Figure 3.3 and Figure 3.4) (Rio Tinto 2010). The shallow water table and seasonally variable influx of water from storm events are also likely to aid in fauna dispersal and general hydraulic connectivity of subterranean habitats within the area.

Figure 3.3: Schematic cross-section from Oxbow, illustrating contemporary drainage adjacent to the CID (figure supplied by Rio Tinto).

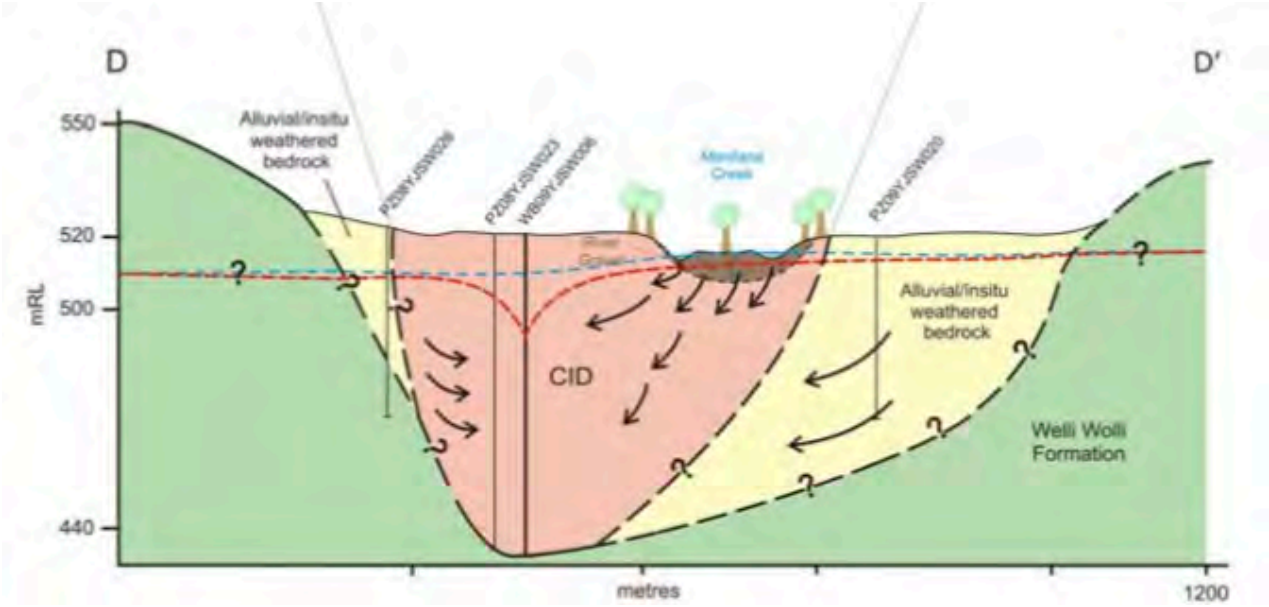

Figure 3.4: Schematic cross-section from JSW, illustrating CID underlying contemporary drainage (figure supplied by Rio Tinto).

4.0 Methodology

The methodology and approach employed during the surveys consolidated in this report were consistent with those outlined in relevant government policy; including:

- Guidance for the assessment of environmental factors; Sampling of Subterranean Fauna in Groundwater and Caves (EPA 2003);
- Guidance for the assessment of environmental factors: Sampling methods and survey considerations for subterranean fauna in Western Australia (EPA 2007); and
- Environmental Assessment Guideline for Consideration of subterranean fauna in environmental impact assessment in Western Australia (EPA 2013).

4.1 Stygofauna Sampling Methodology

Stygofauna sampling during all phases was undertaken using modified plankton haul nets. These sampling nets were constructed from 50 – 70 μm plankton mesh, with 45 – 150 mm apertures, dependent on the site being sampled, attached to a weighted catch jar. Stygofauna sampling nets were lowered to the bottom of the drillholes and boreholes before being slowly hauled to the surface where the contents of the catch jar were flushed into a uniquely labelled container. Each site was sampled in this way five times unless the water sample was very turbid, in which case the site was only sampled two or three times. On the final haul the net was agitated gently, which acts to stir the benthos layer and mobilises any fauna present for more effective specimen collecting. Specimens were stored in a shaded esky in order to preserve the sample prior to sorting and identification.

Following sampling of each drillhole, the nets were thoroughly rinsed with water, inspected and where possible, left to dry before using on another drillhole. This prevented cross-contamination of specimens between sample sites.

Collected stygofauna specimens underwent preliminary identification using dissecting microscopes (Olympus SZ40 and SZ61, magnification up to 40x) to identify specimens as far as possible, most commonly to order level. Fauna specimens were then assigned a unique number based on drillhole name and location and tracked on customised data sheets. Specimens were preserved in 100% ethanol, which allows for both morphological and molecular analysis.

4.2 Molecular Analysis

Select amphipods were sequenced for variation at the mitochondrial COI gene by Helix Molecular Solutions (Helix). The amphipod specimens were compared to reference sequences of members of the same family (Paramelitidae) from the Pilbara, to clarify the number of species collected and to determine the relationships of the Yandi samples to specimens previously collected in the Pilbara. A complete account of the molecular analysis methodology is provided in Appendix 1.

4.3 Survey Design

4.3.1 Personnel and Survey Timing

Stygofauna sampling at Yandi has been undertaken by Biota since 2003, with 13 phases completed in total (Table 4.1). Jason Alexander, Dan Kamien and Phil Runham (all of Biota, managed the projects with Garth Humphreys providing overall direction for the duration of the 13 phases.

Table 4.1: Summary of all field surveys completed by Biota (all personnel were employed directly by Biota unless otherwise indicated).

Year / Phase	Date	Personnel	Trip Focus
2003 Phase 1	3rd – 5th November	Kyle Armstrong, Phil Runham	Baseline stygofauna survey
2005 Phase 2	3rd – 7th April	Phil Runham, Lee Mould	Baseline stygofauna survey
2008 Phase 3	4th – 7th August	Jason Alexander, Jess Delaney (WRM)	Compliance stygofauna monitoring
2009 Phase 4	14th – 17th April	Jason Alexander, Tim Sachse	Compliance stygofauna monitoring
Phase 5	5th – 12th October	Jason Alexander, Jess Cairnes, Jess Delaney, David Keirle	Compliance stygofauna monitoring and targeted Northern Quoll Search
2010 Phase 6	20th – 25th September	Jason Alexander, Jess Cairnes	Compliance stygofauna monitoring
Phase 7	11th – 14th November	Jason Alexander, Jack Tatler	Compliance stygofauna monitoring
2011 Phase 8	20th – 24th June	Jason Alexander, Sylvie Schmidt	Compliance stygofauna monitoring
Phase 9	19th – 15th August	Jason Alexander, Jess Delaney (WRM)	Compliance stygofauna monitoring and Weeli Wolli Amphipod project
2012 Phase 10	3rd – 6th July	Jason Alexander, Andrew Sheppard	Compliance stygofauna monitoring
Phase11	29th October – 2nd November	Jess Cairnes, Jacinta King	Compliance stygofauna monitoring
2013 Phase 12	5th – 9th August	Dan Kamien, Chris Cole	Baseline stygofauna survey for Billiards deposit mine approval
2014 Phase 13	17th – 23rd May	Dan Kamien, Chris Cole	Baseline stygofauna survey for Billiards deposit mine approval

Morphological species level identification was completed by taxonomic specialists, including:

- Jane McRae, Stuart Halse and Mike Scanlon – Bennelongia Environmental Consultants;
- Mark Harvey and Ivana Karonovic – Western Australian Museum (WAM);
- Adrian Pinder - Department of Parks and Wildlife; and
- Russell Shiel – University of Adelaide

Yvette Hitchen of Helix completed molecular sequencing of the Amphipoda (Section 4.2), with Terrie Finston and Oliver Berry (Helix), providing analysis and interpretation of molecular data (Appendix 1).

4.3.2 Sampling Effort

A total of 139 boreholes have been sampled to date, encompassing Junction Central (JC), Junction South-East (JSE), Junction South-West (JSW), Oxbow and Billiards deposits (Table 4.2 and Figure 4.1). Sites were selected in conjunction with Rio Tinto personnel based on bore availability, viability for subterranean fauna and study focus. Many sites were sampled over multiple phases with the two best-sampled sites (99YJWB02 and Marillana06) being sampled during 11 of the 13 phases.

Table 4.2: Summary of sites sampled during all phases completed in the Yandi MS914 development envelope.

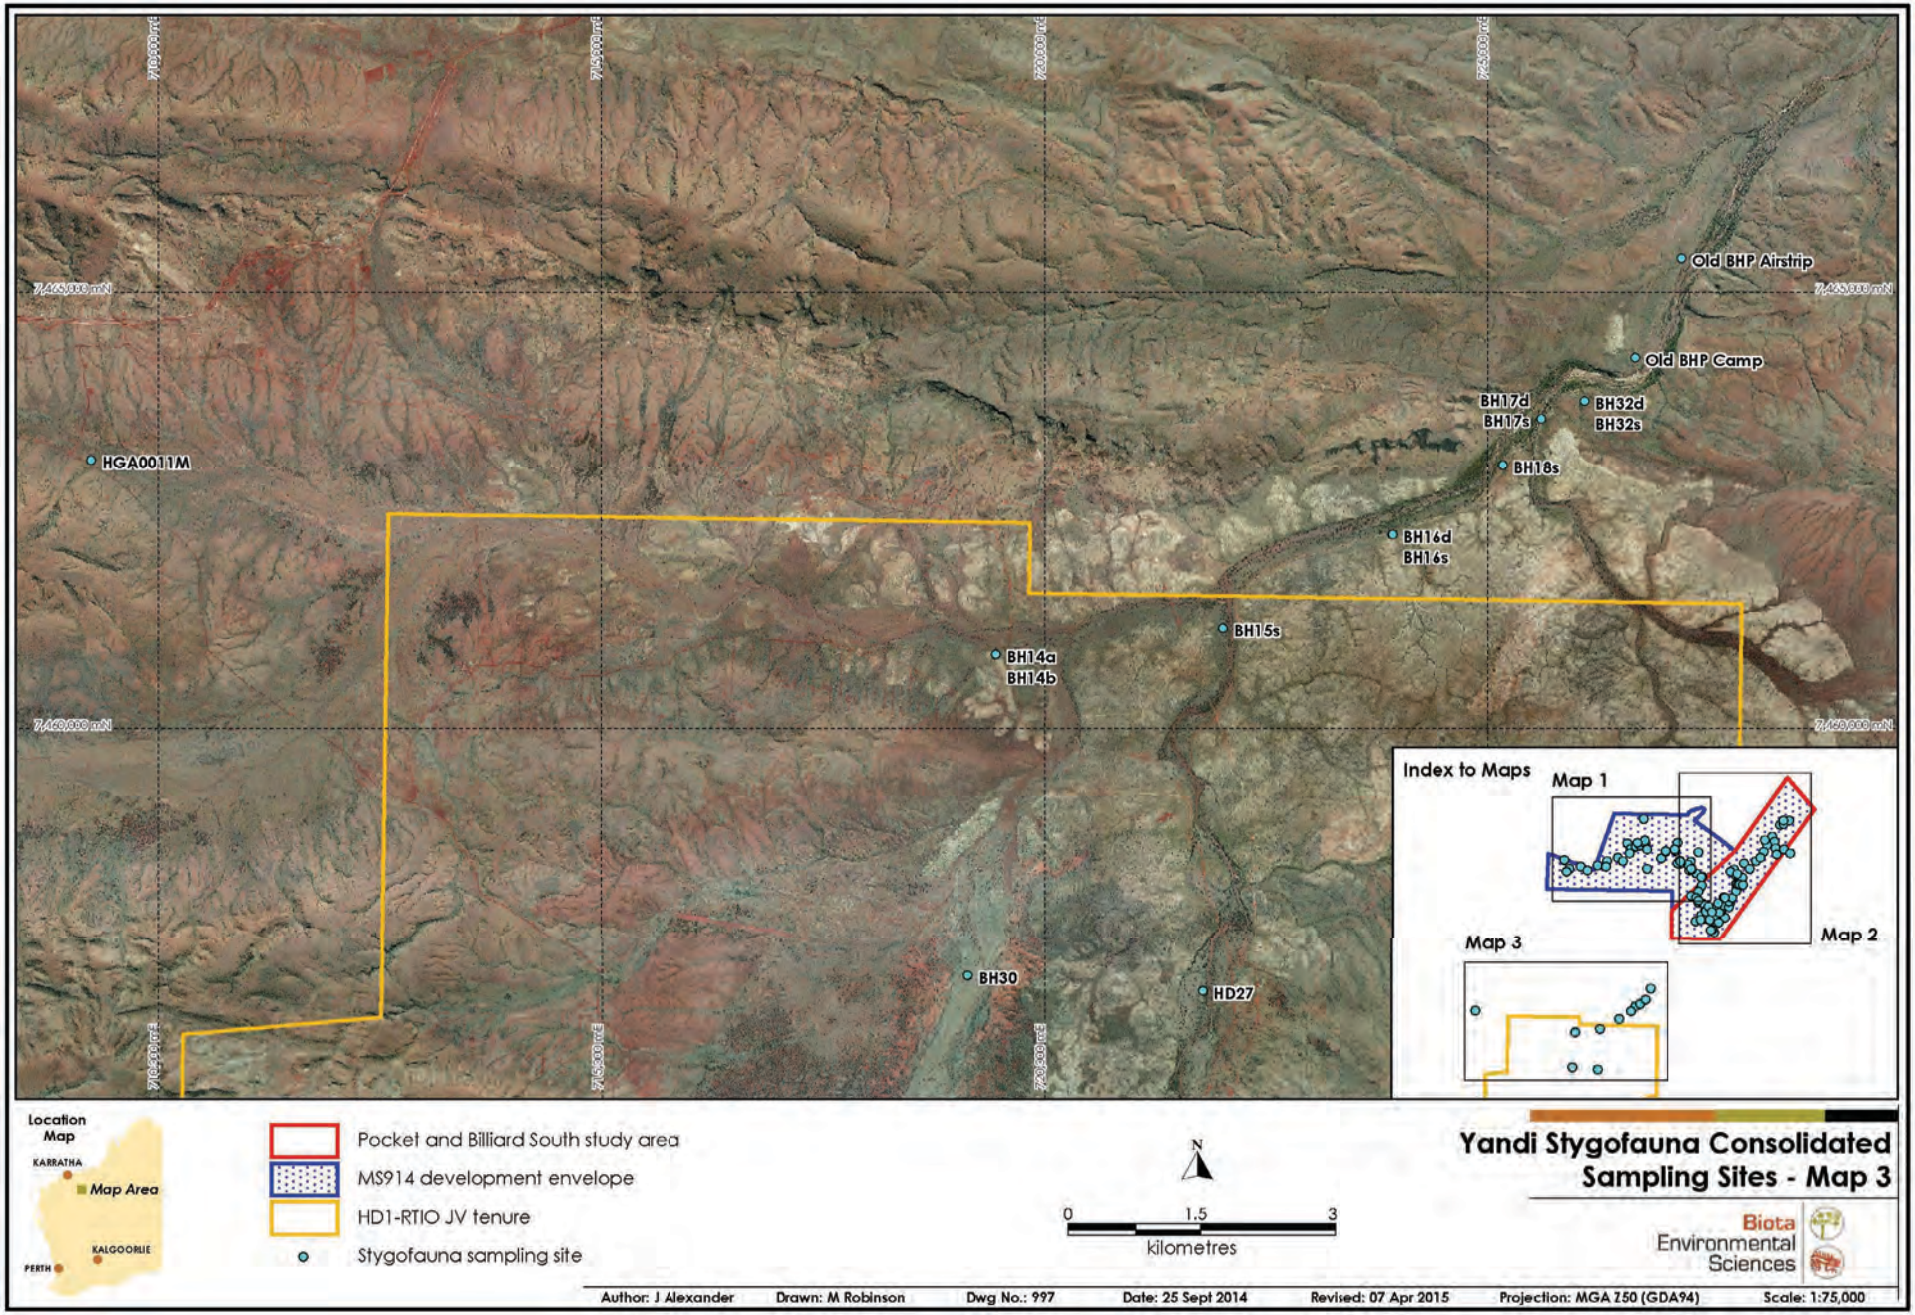

Figure 4.3: Location of all sites sampled for stygofauna in the Yandi MS914 development envelope – Map 3.

4.3.3 Limitations

A common limitation with stygofauna sampling is the limited taxonomic frameworks available for the identification of some groups. The groups collected during this study with limited taxonomic framework include Gastropoda, Nematoda, Platyhelminthes and Protozoa. Without such frameworks it is difficult to infer species distributions and consequently, impacts in relation to mining developments.

Additionally, juvenile and damaged specimens belonging to groups where taxonomy is better resolved are often generally unable to be identified to species level. Indeterminate identifications, or specimens not identified to species level due to specimen damage or age, were excluded from species counts as standard practice, as they potentially belong to already recorded species. Genetic analysis of all historically collected indeterminate, juvenile and damaged specimens would be required to provide additional identifications and confirm this.

The taxonomy of many groups has however been substantially improved since studies began at Yandi in 2003. As a result, not all specimens that were unidentifiable in early phases were able to be assigned to the species recognised in later phases. Recent work has reconciled this for some groups where this has occurred, but there are historical collections of ostracods and copepods that are currently not assigned to current names. In order to apply current taxonomic classification to all groups, all past specimens would need to be re-identified morphologically or genetically. This has not been undertaken as part of the current study as the majority of existing material has been determined to species level.

5.0 Results

5.1 Overview

A total of 9,654 specimens of stygofauna have been collected from surveys between 2003 and 2014 (Table 5.1, Appendix 2). The collected specimens represent eight phyla and 12 orders. Three of the higher taxa, Gastropoda, Nematoda and Protozoa, were unable to be identified below phylum due to a lack of taxonomic framework for these groups in the Pilbara. The flatworms (phylum Platyhelminthes) were similarly unable to be identified beyond class (Turbellaria).

The phylum Crustacea was the most commonly recorded, comprising 85% of the total records. The Copepoda, Ostracoda and Amphipoda were the most abundant, comprising 33% (n= 3,195), 29% (n= 2,775) and 15% (n= 1,454) respectively (Table 5.1). The phylum Gastropoda was least commonly recorded, with only a singleton specimen (Figure 5.1).

A complete breakdown of collected specimens, including distribution, abundance and final identifications from the Yandi area is provided in Section 5.2.

Table 5.1: Summary of higher order taxa collected at Yandi from 2003 – 2013.

Phylum	Class	Order (Common name)	Number Collected
Protozoa	Indeterminate	Indeterminate (Protozoa)	6
Nematoda	Indeterminate	Indeterminate (Nematode)	13
Platyhelminthes	Turbellaria	Indeterminate (Flatworm)	832
Annelida	Clitellata	Oligochaeta (Earthworm)	390
Crustacea	Maxillipoda	Copepoda (Copepod)	3,195
	Malacostraca	Ostracoda (Seed Shrimp)	2,775
		Bathynellacea (Bathynellid)	72
		Amphipoda (Landhopper)	1,454
		Isopoda (Slater)	686
Gastropoda	Indeterminate	Indeterminate (Snail)	1
Chelicerata	Arachnida	Hydracarina (Water Mite)	227
Uniramia	Insecta	Coleoptera (Beetle)	3
		Total	9,654

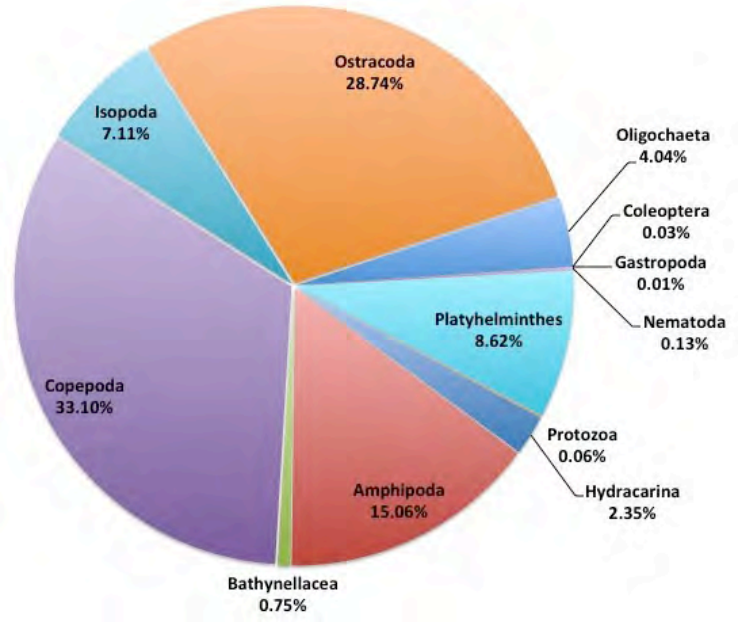

Figure 5.1: Proportional representation of taxa amongst specimens recorded during stygofauna surveys between 2003 and 2014.

5.2 Annotated List of Stygobitic Taxa

5.2.1 Kingdom Protozoa

Six specimens of Protozoa were recorded from site DO7YJ138. These specimens were unable to be identified further due to a lack of taxonomic framework for this group in the Pilbara region. Further genetic studies would be required from contextual specimens from around the Pilbara to determine the species-level distribution of taxa amongst the collected specimens. As little genetic work has been conducted on Protozoa in the Pilbara, this would require many specimens to be analysed.

5.2.2 Phylum Platyhelminthes

Overall, 832 specimens of the phylum platyheminth worms were recorded from the Yandi area (Table 5.2). All recorded specimens belonged the class Turbellaria but specimens from this class are difficult to identify based on morphology as there are few distinguishing features and all specimens possess a similar vermiform body shape. Further genetic studies would be required from contextual specimens from around the Pilbara to determine the species-level distribution of taxa amongst the collected specimens. As little genetic work has been conducted on Platyhelminthes in the Pilbara, this would again require many specimens to be analysed.

Table 5.2: Summary of Platyhelminthes collections and morphological identifications from 2003 – 2014.

Taxonomy		Number	Sites	Notes
Family	Lowest level Identification	Recorded	Recorded	
-	Turbellaria sp. indet.	832	D08YJ050, Discharge, JSE14, Marillana01, Marillana02, Marillana06, Marillana07, MB13YB006, MC10, MNEW1upstream, PZ08YJSW003, PZ08YJSW009, W01YJ15D, YMCCA	Only able to identify to class.
	Total	832		

5.2.3 Phylum Nematoda

Thirteen specimens belonging to the phylum Nematoda were recorded from the Yandi area (Table 5.3). Specimens were recorded from both Marillana and Weeli Wolli Creeks. Specimens were unable to be identified further due to a lack of morphological taxonomic framework for the group. It is technically very difficult to morphologically identify nematodes (this is best done with live animals), and the group is typically not considered in environmental impact assessments (EPA 2007).

Table 5.3: Summary of Nematoda collections and morphological identifications from 2003 – 2014.

Taxonomy		Number	Sites	Notes
Family	Lowest level Identification	Recorded	Recorded	
-	Nematoda sp. indet.	13	D08YJ186, DD09YJ017, Marillana07, MNEW1upstream, RC04YJ2349, RD09YJ114, WW3	Unable to identify further
	Total	13		

5.2.4 Order Oligochaeta

A total of 388 specimens of Oligochaeta were recorded across 13 phases of sampling (Table 5.4). Specimens collected represented five families (Aeolosomatidae, Enchytraeidae, Naididae, Phreodrilidae and Tubificidae) and 13 distinct species. A total of 21 specimens from four families (Enchytraeidae sp. indet., Naididae sp. indet., Phreodrilidae sp. indet. and Tubificidae sp. indet.) were unable to be identified due to specimen damage (Table 5.4).

Three of the collected species (*Pristina longiseta, Pristina aequiseta* and *Dero furcata*) are formally described. The described species *Pristina longiseta* was the most abundant oligochaete species recorded from six sites along Marillana Creek and the confluence of Marillana and Weeli Wolli

Creeks. *Pristina aequiseta* was the only singleton oligochaete record, collected from Weeli Wolli creek in the south of the study area, however is known from elsewhere in Australia and globally.

Two singleton species (*Pristina aequiseta*, and Phreodrilidae sp. indet.) of Oligochaeta were recorded over the 13 phases of sampling (Figure 5.2).

Table 5.4: Summary of Oligochaeta collections and morphological identifications from 2003 – 2014.

	Total	388		

5.2.5 Class Gastropoda

A single damaged gastropod shell was recorded from site 99YJWB02 during sampling in 2010. It is currently unknown if this shell represents a surface aquatic form or a stygobitic taxon. In order to determine the stygobitic status of the gastropod, the specimen would need to be morphologically identified by Winston Ponder of the Australian museum. Stygobitic gastropods are uncommonly collected in the Pilbara and have the potential to display short range endemism (Biota 2013).

5.2.6 Class Copepoda

A total of 3,195 specimens of copepods were recorded across all phases of sampling (Table 5.5). The order Cyclopoida was the most abundantly collected taxon and records comprised 17 distinct species and three indistinct groups (Cyclopidae sp. indet., *Diacyclops* sp. indet., and *Mesocyclops* sp. indet. (juvenile and damaged specimens)) (Table 5.5). Thirteen of the 17 species identified have been recorded previously from the wider Pilbara area. The remaining four species, *Australocamptus* sp. nov., Canthocamptidae sp. B1, *Goniocyclops* sp. and *Parastenocaris* sp. B9, are not yet formally described and are only known from the study area. Two of these (*Australocamptus* sp. nov. and *Parastenocaris* sp. B9) are known from single specimens in Marillana Creek. It is possible these specimens represent existing species but genetic examination would be required to assess this.

The species *Diacyclops humphreysi humphreysi* was the most commonly recorded copepod species, with 2,021 specimens collected from 49 sites over all phases of sampling. Three singleton species (*Australocamptus* sp. nov., *Mesocyclops* sp. indet., and *Parastenocaris* sp. B9) of Copepoda were recorded over the 13 phases of sampling (Figure 5.2).

5.2.7 Order Ostracoda

A total of 2,775 specimens belonging to the order Ostracoda were recorded from the Yandi area over all phases of sampling (Table 5.6). Overall, 69 juvenile specimens were unable to be identified to species level (Ostracoda sp. indet and *Gomphodella* sp. indet).

At least 16 morphologically distinct species were recorded from the remaining 2,706 specimens, representing two families (Candonidae and Limnocytheridae) (Table 5.6). Nine of these species (*Areacandona mulgae, Candonopsis tenuis, Meridiescandona facies, Meridiescandona lucerne, Meridiescandona marillanae, Notacandona boultoni, Notocandona modesta, Gomphodella alexanderi, Gomphodella hirsuta*) have been formally described based on morphological information (Table 5.6).

Table 5.6: Summary of Ostracoda collections and morphological identifications from 2003 – 2014.

Taxonomy		Number	Sites	Notes
Family	Lowest level identification	Recorded	Recorded	
-	Ostracoda sp. indet.	55	BH32s, HD27, Old BHP Airstrip, Old BHP camp, PZ08YJSW003	Not identified past order

	Notacandona boultoni	789	99YJWB02, B1, D08YJ188, Discharge, JSE14, JSE39, Marillana01, Marillana02, Marillana03. Marillana06. Marillana07, MB13YB001, MB13YB007, MNEW1upstream, Plant, PZ08YJSW003, WW2, WW3, WW4, YM119, YMCCA	Plate 5.1
	Notocandona modesta	1	B1	
	Pilbaracandona sp. indet.	11	Discharge, Marillana07, MNEW1upstream	Species being described at time of first collection (2003). Needs to be revisited for updated identification.
Limnocytheridae	*Gomphodella alexanderi*	123	Marillana01, Marillana06, Marillana07, MNEW1upstream, WW2, WW3, YMCCA	Historically *Gomphodella* sp. "yandi". Plate 5.1
	Gomphodella hirsuta	8	Marillana06, Marillana07, WW2, WW3	
	Gomphodella sp BOS200	7	Marillana06, WW2	
	Gomphodella sp. indet.	14	Marillana05, Marillana07, YMCCA	Some juvenile specimens
	Gomphodella sp. BOS334	7	MNEW1upstream	
	New genus sp. BOS333	1	MNEW1upstream	
	Total	2,775		

Ostracod taxonomy has developed significantly since 2003 with many new species described. In accordance with the superseded Ministerial Statement (Condition 695:M11), *Gomphodella* sp. "yandi" was formally described and renamed *Gomphodella alexanderi* (Plate 5.1) (Karanovic and Humphrey 2014). It is likely that many specimens recorded in early surveys, which were unable to be identified to species (such as *Meridiescandona* sp.), may belong to groups described since (such as *Notocandona boultoni*; Plate 5.1). These specimens would need to be revisited to confirm their taxonomic status.

A number of singleton species were recorded from both families. Singleton records include the taxon *Areacandona mulgae* recorded adjacent to Weeli Wolli Creek, and *Candonopsis* ? n. sp. indet., *Notocandona modesta* and New genus sp. BOS333, adjacent to Marillana Creek (Figure 5.2).

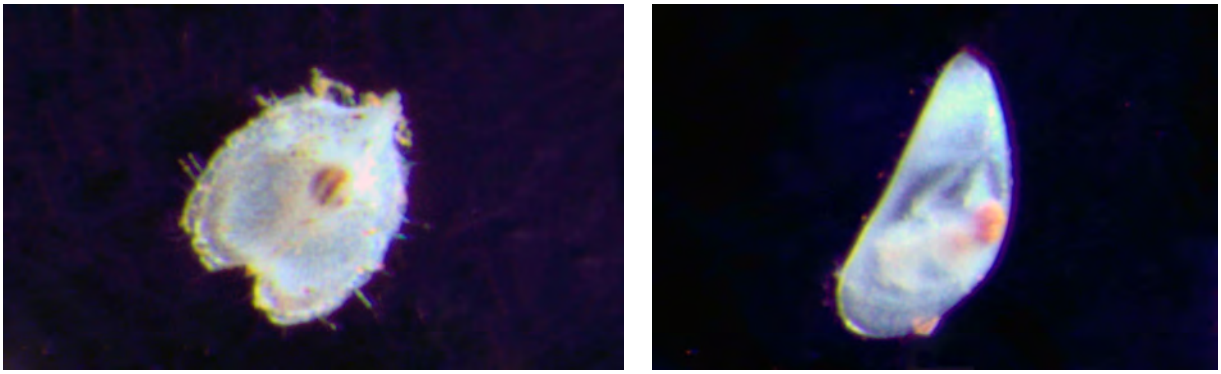

Plate 5.1: *Gomphodella alexanderi* (left) and *Notocandona boultoni* (right) collected from Marillana06.

5.2.8 Order Bathynellacea

A total of 72 specimens of Bathynellacea were recorded from the Yandi area between 2003 and 2014 (Table 5.7). Sixty-two of these specimens belong to the family Parabathynellidae. It is likely that the remaining 10 specimens also belong to the family Parabathynellidae, however they could not be identified to family level as they were either juveniles or damaged specimens. Twenty of the bathynellids collected were identified to eight distinct morphological species. The remaining 52 specimens (Bathynellacea sp. indet. and *Atopobathynella* sp. indet.) were unable to be identified to species level due to either being juvenile specimens or because the specimens were damaged (Table 5.7).

Five singleton species (*Atopobathynella* sp. B07, *Billibathynella* sp. B02, *Billibathynella* sp. B03, *Chilibathynella*? sp. B06, and *Notobathynella* sp.) of Bathynellacea were recorded over the 13 phases of sampling at Yandi (Figure 5.2).

Table 5.7: Summary of Bathynellacea collections and morphological identifications from 2003 – 2014.

Taxonomy		Number Recorded	Sites Recorded	Notes
Family	Lowest level identification			
Indet.	Bathynellacea sp. indet.	10	HD27, Marillana01, Marillana07, MNEW1upstream	Juvenile and damaged

	Chilibathynella? sp. B06	1	WW4	-
	Notobathynella sp.	1	JSE14	-
	Total	72		

5.2.9 Order Amphipoda

A total of 1,454 specimens belonging to the order Amphipoda were recorded from Yandi during 13 phases of sampling (Table 5.8). Of the 1,454 specimens collected, 1,311 were identified based on morphology only. One hundred and forty-three specimens collected from Phases 12 and 13 were subsequently successfully analysed using molecular techniques, 55 of which were also morphologically identified (Table 5.8). The 88 specimens that were successfully analysed using molecular techniques only comprised the majority of amphipods collected from Phases 12 and 13, however three specimens from these two phases were identified morphologically, and three specimens failed to amplify and yield a genetic sequence (Biota 2014).

On further consideration, and in liaison with Rio Tinto personnel, a selection of 89 historically collected, morphologically-identified specimens were subject to molecular analysis. This genetic analysis was completed in an attempt to rationalise inconsistencies in morphological identifications due to historical limitations in the amphipod taxonomic framework. These specimens were selected to represent different described species and working morphotypes. Fifty-five specimens were successfully sequenced however 34 failed to amplify and yield a genetic sequence due to the age of the specimens and related DNA degradation (Appendix 1; Helix 2014).

A total of eight distinct species were identified based on morphological characteristics, excluding indeterminate specimen classifications (Amphipoda sp. indet., Paramelitidae sp. indet., and *Chydaekata* sp. indet.) (Table 5.8). Genetic analysis then indicated the presence of eight genetic lineages from the 143 amphipod specimens successfully sequenced (Table 5.8 and Table 5.9). Of these specimens, 55 had also been identified morphologically. It should be noted Lineage WWA2 and Lineage YB6 contained specimens that were identified as two different morphological species. Lineage WWA2 comprised specimens from the morphologically identified species Paramelitidae sp. B02 and B03, whereas Lineage YB6 included specimens that had been morphologically identified as Paramelitidae sp. B02 and *Pilbarus millsi* (Table 5.8).

Genetic differentiation between lineages within the study area ranged from 11.89 % between Lineages YB3 and YB4, to 25.68 % between WWA2 and YB4 (Table 5.9). Within lineage variation ranged up to just 3.8 % differentiation, considerably less than the between lineage variation, supporting the view that they represent separate species. WWA3 and YB3 contained insufficient specimens to allow for assessment of intra-lineage variation.

Table 5.8: Genetic and morphological analysis and site location for Amphipoda specimens collected during surveys from 2003 – 2014.

Considering both morphological and molecular data, eight distinct species of Amphipoda have been identified morphologically, and eight species using molecular techniques. However, four of the specimens identified using molecular techniques (Lineages WWA2, WWA3, YB1 and YB6) were also identified morphologically, and they corresponded to four of the same species that had already been identified by morphology only. Therefore, the most conservative assessment is that 12 species of Amphipoda have now been identified at Yandi.

5.2.10 Order Isopoda

A total of 686 isopod specimens were collected across all 13 phases of sampling, representing at least six species based on morphological identifications (Table 5.10). This included 32 specimens unable to be identified to species level (Isopoda sp. indet., and *Pygolabis* sp. indet.) due to being either juveniles or damaged specimens. Of the remaining 654 specimens, the majority (382) belonged to the locally widespread species *Pygolabis weeliwolli* (Plate 5.2), which was recorded at 29 sites from both Marillana and Weeli Wolli Creeks. The species *Pygolabis* sp. B06 was also extensively collected (n = 247) however it was only recorded from seven sites from Marillana Creek.

Table 5.10: Summary of Isopoda collections and morphological identifications from 2003 – 2014.

Taxonomy		Number	Sites	Notes
Family	Lowest level identification	Recorded	Recorded

	Total	686		

Plate 5.2: *Pygolabis weeliwolli* collected from sites MNEW1upstream in 2012.

5.2.11 Order Hydracarina

A total of 227 specimens of water mites (e.g. *Arrenurus* sp. 01 (Yandi); Plate 5.3) were recorded across 13 phases of sampling (Table 5.11). The specimens represented 12 distinct species from eight families (Table 5.11). Additionally, three groups (Hydracarina indet., *Arrenurus* sp. indet. and Trombidioidea sp. indet.), were unable to be identified further due to damaged and juvenile specimens (Table 5.11).

The taxon *Recifella* sp. "Yandi" was the most abundantly recorded water mite, being collected from both Weeli Wolli and Marillana Creek. This taxon is yet to be formally described. Three singleton species (*Albia* sp. B1, *Limnesia* sp. B03 and *Mideopsinae penemidopsis*) of Hydracarina were recorded over the 13 phases (Figure 5.2).

Table 5.11: Summary of Hydracarina collections and morphological identifications from 2003 – 2014.

Taxonomy		Number	Sites	Notes
Family	Lowest level identificiation	Recorded	Recorded	
-	Hydracarina indet.	5	Marillana01, Marillana03, Marillana07, Plant	Damaged specimens

	Total	227		

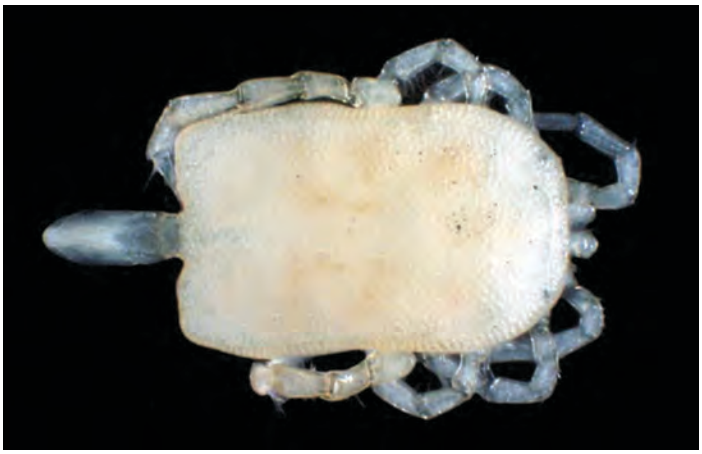

Plate 5.3: *Arrenurus* sp. 01 (Yandi) specimen collected from site MNEW1upstream.

5.2.12 Order Coleoptera

Three beetle specimens were recorded from sampling in 2011. These specimens belonged to the species *Boongurrus occidentalis* (Family Dytiscidae: Watts and Humphrey 2004) and were collected from site MNEW1upstream adjacent to Marillana Creek. This species has been recorded previously and described from outside the Yandi area at Wittenoom Gorge, Killara Station, Moorarie Station and Wagga Wagga Station. The specimens collected at other sites have been collected at the edge of pools in sandy riverbeds and from boreholes. The specimen collected from a borehole at Killara Station was in a calcrete area containing other short-range endemics (Watts and Humphrey 2004).

5.3 Singleton Species

Seventeen singleton species were recorded from five of the orders collected (Table 5.12, Figure 5.2). Singleton species were those recorded from one individual only and in most cases are also currently only known from the Yandi locality. Four of the 17 singletons have previously been described from elsewhere in the region (Table 5.12). It is therefore precautionary to attach higher conservation significance to the remaining 13 species until their wider distribution is demonstrated. The greatest number of singleton species was recorded from Site MNEW1upstream, which is adjacent to Marillana Creek, with five singleton taxa. Sites Marillana06 and WW4 both yielded two singleton species.

Table 5.12: Summary of singleton species collected from the Yandi MS914 development envelope from 2003 – 2014.

Taxonomy			Site Recorded	Notes

6.0 Discussion

Extensive sampling for stygofauna has been completed in the Yandi study area over more than a decade, and the fauna of the locality is now one of the best documented in the Pilbara region. As many as 31 new taxa have now been discovered from the area, and Yandi specimens have also been used as holotypes in formal identifications, such as *G. alexanderi*, and in unfinished descriptions, such as *Recifella* sp. "Yandi". Additionally, eight previously undetected Amphipoda genetic lineages have now been identified in an attempt to resolve this morphologically cryptic group and to provide context to genetic and morphological analysis from the surrounding area.

A total of at least 88 taxa were recorded over the 13 phases of sampling, with the greatest abundance of species and specimens having been recorded from saturated alluvium and calcrete habitats within or immediately adjacent to either Marillana or Weeli Wolli Creek (Figure 6.1 - Figure 6.3). Six sites yielded over 31 species while 53 sites yielded four species or less (Figure 6.1), all of which were associated with calcrete or alluvial units. However this result is likely to have been strongly affected by sampling effort amongst phases, as these richer sites were sampled multiple times during the various surveys. Sites Marillana07 and MNEW1upstream both yielded the highest abundance and species numbers (1,280 specimens and 1,032 specimens respectively; 23.95 % of total records) (Figure 6.1 - Figure 6.3), both of which were situated in calcrete geology.

Thirty-nine of the morphologically-identified species (accounting for 6,183 specimens; or 64.04 % of total records) collected from the Yandi study area have been recorded from elsewhere in Australia or globally. Thirteen of the remaining species documented for the area are singleton taxa that are currently only known from the Yandi locality (Section 5.3). Given the state of taxonomy for some of these stygal groups, it is difficult to definitively assign conservation significance to most of these singleton taxa. A precautionary assessment would treat them as potentially restricted to the area until their wider status can be demonstrated. However, the abundance of other wider ranging Pilbara taxa collected from Yandi (for example; *Meridiescandona facies, Enchytraeus* Pilbara sp. 2 (PSS) and *Boongurrus occidentalis*); and that almost half of the overall assemblage is known from the wider region, may suggest a lower risk of very localised restrictions in species distributions. This may indicate that the recorded singleton species are more an artefact of sampling, rather than reflecting true distributions.

Theses observations are consistent with the nature of the alluvial and calcrete geological units that comprise core stygofauna habitat in the area. The connected nature of these units and the highly transmissive superficial aquifer that extends beyond the Yandi study area, are also likely to promote stygobitic fauna dispersal to at least local catchment scale (Finston and Johnson 2004). These alluvial units are associated with the Marillana - Weeli Wolli Creek system and extend beyond the Yandi study area to the north and south, with the northern extent meeting the confluence with Marillana Creek and extending northwards, opening up into a wide alluvial outwash fan which drains into the Fortescue Marsh. In addition, seasonally variable flooding from cyclonic events are also likely to aid in fauna dispersal. These habitat attributes also suggest very small geographic scale restrictions to the Billiards project area, for example, may be unlikely in the stygofauna of the Yandi locality.

Some of the potentially restricted stygal taxa are predisposed to short range endemism and may truly have small-scale distributions. Subterranean gastropods in particular are infrequently collected in the Pilbara and have been shown to have potential to display such short range endemism (Ponder and Colgan 2002). It would be beneficial to obtain an undamaged specimen of the stygal snail collected from the project area for further analysis. Given the sampling effort to date and infrequency of collection, it is, however, unlikely that additional specimens will be readily forthcoming.

7.0 Glossary

cf.	For Latin *confer*, means "compare with". Identification is not confirmed, but is similar to a particular species.
CID	Channel Iron Deposit.
COI	Mitochondrial cytochrome oxidase subunit I gene.
Cryptic	Two or more species hidden under one species name.
EPA	Environmental Protection Authority of Western Australia.
Epigean	Living or occurring on or near the surface of the ground.
Haplotype	A set of genetic determinants located on a single chromosome.
Lineage	Direct descent from a particular ancestor; ancestry. The descendants of a common ancestor considered to be the founder of the line.
Phylogenetic	Relating to or based on evolutionary development or history.
Stygofauna	Obligate groundwater fauna.
Taxon (plural: taxa)	A taxonomic entity; typically at species level or below.
Taxonomy	Theory and practice of biological classification.
Vermiform	Resembling or having the shape of a worm

Re. Report on the molecular systematics of Amphipoda from the Yandi Billiards region

Dear Dan,

Following is a summary of the results of the Amphipoda study we have completed. Owing to the observed level of sequence divergence between lineages and comparison to reference sequences, it is likely that there are six species of Paramelitidae in your collections. Five of those species have been detected or described previously at Mindy-Coondiner and Marillana and Weeli Wolli Creeks, whereas one appears to be new, based on the material available for comparison.

Sincerely,

Dr. Terrie Finston and Dr. Oliver Berry
Helix Molecular Solutions

Background

The groundwater amphipod fauna of Western Australia is diverse. Since 1995, 27 species of amphipods have been described from north-western Western Australia, including the Pilbara and nearby Barrow Island and Cape Range Peninsula (Barnard and Williams 1995; Bradbury and Williams 1996, 1997a; Bradbury 2000; Finston *et al*., 2008). The majority of these species (19) belong to the family Paramelitidae. Extensive molecular work has been conducted on the amphipod fauna of Western Australia (Helix, 2011). The resulting dataset provides a molecular framework that can be used to provide a regional context for localised sampling. The present study concerns 91 specimens of Amphipoda belonging to the Paramelitidae from the Yandi Billiards site in the Pilbara.

Objective

Ninety-one specimens of Paramelitidae from the Yandi Billiards site in the Pilbara were sequenced for variation at the mitochondrial gene COI. The specimens were compared to reference sequences of Paramelitidae from the Pilbara to estimate the number of species in the collection and determine the relationships of the new samples to specimens previously collected in the Pilbara.

Executive summary

- Ninety-one specimens of Paramelitidae from the Yandi Billiards site in the Pilbara were sequenced for variation at the mitochondrial gene COI.
- Eighty-eight of the 91 specimens yielded a COI sequence.
- A neighbour-joining analysis, which included the 88 specimens analysed here, revealed the presence of six distinct genetic lineages, which represent six species.
- A representative of each species was included in a second phylogenetic analysis, which included 43 reference specimens of Paramelitidae from sites in the Pilbara and voucher sequences of Paramelitidae from the international DNA sequence database GenBank.
- Five of the six species have been detected or described previously at Mindy-Coondiner and Marillana and Weeli Wolli Creeks, whereas one appears to be new, based on the material available for comparison.

Methods

Ninety-one specimens of Paramelitidae from Yandi Billiards in the Pilbara were sequenced for variation at the mitochondrial gene cytochrome oxidase subunit I (COI; Table 1). Primers LCO1490 and HCO2198 (Folmer et al., 1994) were used to amplify a ~700 bp fragment of COI.

Sequences were edited using SEQUENCHER software (Gene Codes Corporation, Ann Arbor, MI, USA). Alignment was performed with CLUSTAL W (Thompson *et al*. 1994) using default parameters. To test that the amplified sequences were the target mtDNA, sequences were translated into proteins and checked for the presence of stop codons. Genetic distances between unique genetic sequences (haplotypes) were measured using uncorrected p-distances (total percentage of nucleotides different between sequences). To account for polymorphism within lineages, the net genetic diversity of Nei (1987) was calculated to give a 'corrected' distance between lineages.

To reduce analysis time, a preliminary neighbour-joining analysis was run to identify the number of distinct genetic lineages among the 91 specimens. One specimen from each of the lineages was included in a second model-based phylogenetic analysis, which included 43 reference specimens of Paramelitidae from sites in the Pilbara outside the study area and voucher sequences of Paramelitidae from the international DNA sequence database Genbank.

MODELTEST software (Posada and Crandall, 1998) was used to determine the model of sequence evolution that best fitted the data. Bayesian analysis was used to construct the phylogenetic tree, incorporating the General Time Reversible (GTR+G) model as identified in MODELTEST. The phylogeny, branch lengths and posterior probabilities were obtained by running two trees simultaneously, each running four simultaneous MCMC chains. The number of cycles needed was determined by the standard deviation of the split frequencies of the two trees. The analysis was paused after every 1 x 10^6 generations and when the standard deviation fell below 0.01, the analysis was stopped. A majority rule consensus tree was constructed after

discarding the first 5000 ("burn-in") trees. The burn-in value was assessed by plotting the posterior probabilities obtained after every generation and identifying the point at which the values reach stationarity (= the asymptote). Trees produced prior to stationarity were discarded. Forty-three specimens of Paramelitidae from the PIlbara were included in the phylogenetic analysis as references, eight of which are lodged with the international DNA sequence database Genbank as follows: *Maarrka etheli* (Genbank accession # DQ838031), *Maarrka weeliwollii* (Genbank accession # DQ838032), *Yilgarus* sp. BES9348 (Genbank accession #EF118228), *Kruptus linnaei* (Genbank accession # GU111906), *Molina pleobranchos* (Genbank accession #DQ255962), *Chydaekata* sp. Marillana (Genbank accession # DQ255989), *Pilbarus millsi* (Genbank accession # DQ490126), *Chydaekata acuminata* (Genbank accession # DQ838024). The remaining 35 specimens were detected in previous surveys of the Pilbara (Helix, 2011). Two species from the Isopoda family Tainisopidae, *Pygolabis paraburdoo* (Genbank accession # EU107628) and *Pygolabis weeliwolli* (Genbank accession # EU107618) were used as outgroups.

Results

Eighty-eight of the 91 specimens yielded a 630 to 716 bp fragment of COI (Table 1). The neighbour-joining analysis revealed the presence of six distinct genetic lineages (YB1 – YB6; Figure 1). The six lineages contained between two and 46 specimens (Table 1; Figure 1).Variation within the six lineages was low, averaging between 0.1 and 0.4% sequence divergence (Table 2). The six lineages differed by between 9.3 and 21.7% mean sequence divergence (Table 3).

A representative from each of the six lineages detected at Yandi Billiards was included in a model-based phylogenetic analysis with the 43 reference specimens. Five of the six representatives from Yandi Billiards were placed in lineages containing reference sequences from Mindy-Coondiner, Marillana and Weeli Wolli Creeks (Figure 2). Specifically, specimen GK56 (representing lineage YB1) was placed in a lineage containing specimen AM9 (Paramelitidae sp. 2C-WW), collected during a previous survey at Weeli Wolli Creek and specimen H28 from Marillana Creek (Figure 2). Specimen GK62 (representing lineage YB2) was placed in a lineage with reference specimen H8 (Paramelitidae sp. H8) from Marillana Creek (Figure 2). Specimen GK91 (representing lineage YB4) was placed in a lineage containing the reference specimen of *Maarrka weeliwolliii* from Weeli Wolli Creek (Figure 2). This species is also known from Marillana Creek (Finston et al., 2011). Specimen GK24 (representing lineage YB5) was placed in a lineage containing specimen G267 (Paramelitidae sp. MC1) from Mindy-Coondiner and specimen G265 (*Maarka* sp MA1) from Marillana Creek (Figure 2). Specimen GK48 (representing lineage YB6) was placed in a lineage with the reference specimen of *Chydaekata sp.* E from Marillana Creek (Figure 2). This species is also known from Weeli Wolli Creek (Finston et al., 2007).

The five specimens that matched reference sequences differed from their nearest reference sequence by between 0.3 and 1.6% sequence divergence (Figure 2; Table 4). The sixth specimen, which showed no close relationship to any of the reference sequences, differed from the reference sequences by between 14.1 and 25.4% sequence divergence (Table 4).

Conclusions

COI is considered by some authors to be a suitable gene for species delineation (Hebert *et al*., 2003a). Based on comparisons between over 1700 crustacean species, Hebert *et al* (2003b) found an average of 15.4 % sequence divergence between species pairs, with nearly 82% of pair-wise comparisons showing greater than 8% sequence divergence. Similar to the Hebert *et al*. (2003b) results, Bradford *et al* (2010) found 11-13% sequence divergence among three lineages of the Amphipoda family Chiltonidae in a single calcrete in the Yilgarn. Reproductive isolation between lineages was confirmed with nuclear (allozyme) markers, indicating that each lineage represented a distinct species.

Owing to the high level of sequence divergence between the six observed lineages in the Yandi Billiards collection (9.3 to 21.7%), it is likely that there are at six species present. Five of the six lineages showed close genetic relationships to reference specimens (0.3 to 1.6% sequence divergence), indicating that they belong to those species. The five were detected previously at Mindy-Coondiner, Marillana and Weeli Wolli Creeks. The sixth species showed no close

relationship to any of the reference sequences and is likely to represent a new species. The six species present at Yandi Billiards are as follows:

1. lineage YB1 =Paramelitidae sp. WW-2C; previously detected at Marillana and Weeli Wolli Creeks
2. lineage YB2 =Paramelitidae sp. H8; previously detected at Marillana Creek
3. lineage YB3 =new
4. lineage YB4 =*Maarka weeliwollii*; previously detected at Marillana and Weeli Wolli Creeks
5. lineage YB5 =Paramelitidae sp. MC1/*Maarka* sp. MA1; previously detected at Mindy-Coondiner and Marillana Creek.
6. lineage YB6 =*Chydaekata sp. E*; previously detected at Marillana and Weeli Wolli Creeks

Further explanation is required for the identification of lineage YB5. The reference specimens to which YB5 was most closely matched (reference specimen G265 from Marillana Creek and G267 from Mindy-Coondiner) were identified on the basis of morphology as Paramelitidae sp. and *Maarka* sp, respectively. As these three specimens cluster with other reference specimens of *Maarka*, they are likely to belong to this genus.

In summary, six species of Paramelitidae were detected at Yandi Billiards. Five of the species (lineages YB1, YB2, YB4 – YB6) have been described or recorded previously, whereas one (lineage YB3) appears to be unrecorded based on the material available for comparison.

Table 2. Mean sequence divergence and standard error (s.e.) between individuals within the six lineages detected in the Yandi Billiards specimens.

Lineage	Distance	s.e.
YB1	0.004	0.002
YB2	0.004	0.001
YB3	0.001	0.001
YB4	0.002	0.002
YB5	0.002	0.001
YB6	0.002	0.001

Table 3. Mean sequence divergence (below diagonal) and standard error (above diagonal) between the six lineages detected in the Yandi Billiards specimens.

Lineage	YB1	YB2	YB3	YB4	YB5	YB6
YB1		0.011	0.011	0.015	0.015	0.017
YB2	0.093		0.012	0.015	0.013	0.016
YB3	0.157	0.137		0.014	0.013	0.015
YB4	0.191	0.202	0.196		0.012	0.015
YB5	0.195	0.191	0.201	0.122		0.015
YB6	0.210	0.205	0.205	0.217	0.199	

Table 4 (attached). Pair-wise sequence divergence (below diagonal) and standard error (above diagonal) between all specimens used in the model-based phylogenetic analysis shown in Figure 2. Distances between the six lineages detected at Yandi Billiards and the reference specimens are highlighted in yellow.

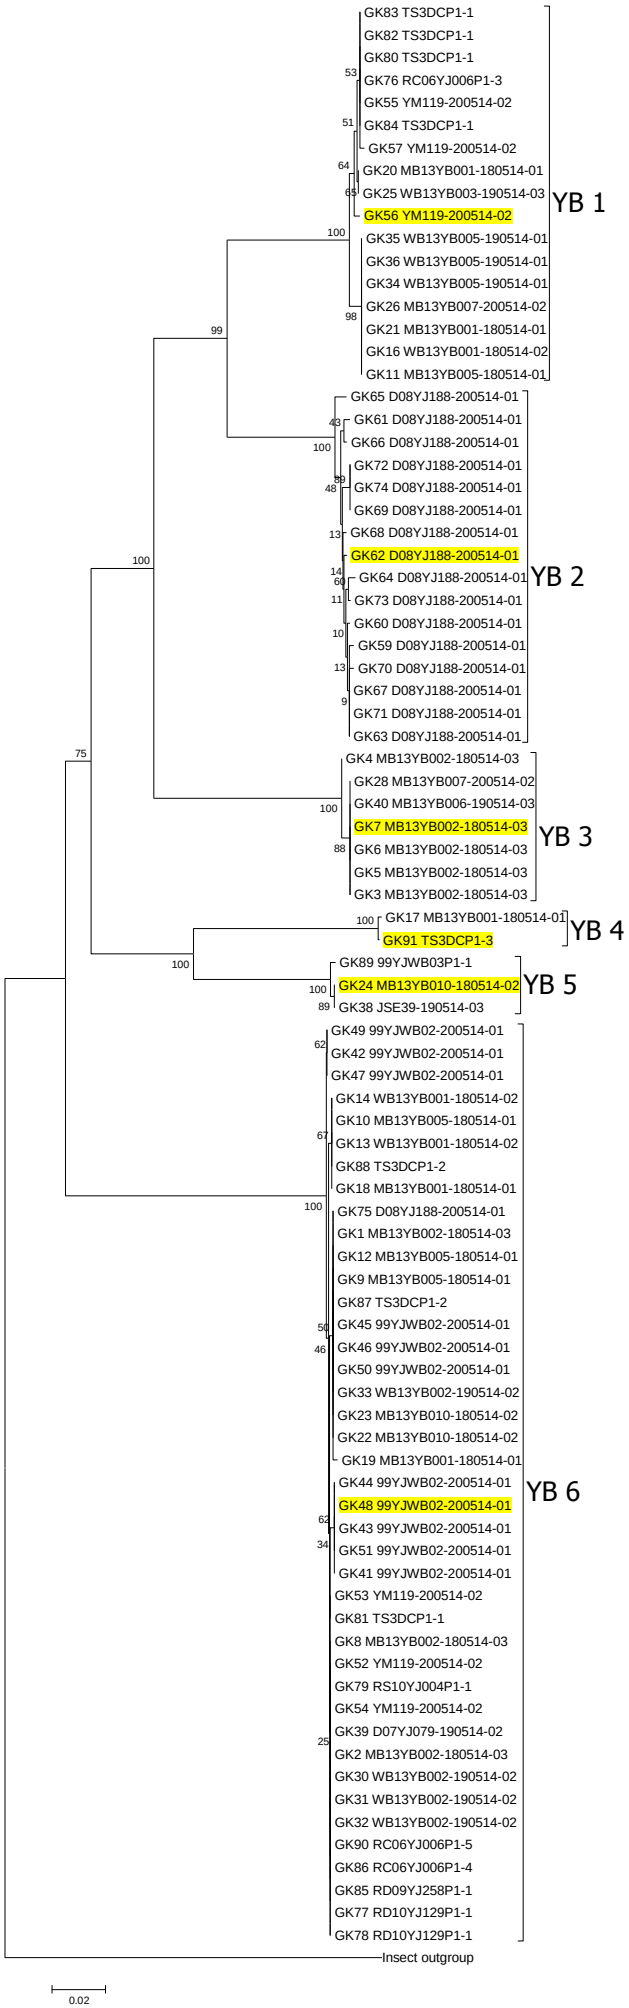

Figure 1. Neighbour-joining analysis of 91 specimens of Amphipoda from Yandi Billiards. Numbers on nodes represent bootstrap support over 100 iterations. The six lineages are labelled YB1 – YB6. Specimens selected to represent each lineage is highlighted in yellow.

Figure 2. Bayesian analysis of COXI haplotypes of Paramelitidae. Numbers on major nodes correspond to posterior probabilities. Specimens from the present study are highlighted in yellow; Scale bar= number of substitutions per site. Red boxes enclose the species detected in the present study. Distances between the Yandi Billiards specimens and the nearest reference sequences are shown next to each pair.

1.0 Introduction

1.1 Project Background

Rio Tinto currently operates the Yandi iron ore mine as part of its Pilbara Iron operations. Yandi is located approximately 75 km northwest of Newman in the Pilbara region of Western Australia. The original Yandi mine, Junction Central, started construction in 1997 with the first shipment of ore occurring in 1999. The Yandi operations are approved under *Environmental Protection Act 1986* Ministerial Statement 914 (MS914; see Figure 1.1).

Rio Tinto is currently undertaking a 'Pre-feasibility Study' for development of two channel-iron deposits at Yandi Billiards, Pocket and Billiards South, located approximately 7 km east of the existing Yandi mine.

It is anticipated that the future development of Yandi Billiards will be formally assessed under the State *Environmental Protection Act 1986* and potentially the Commonwealth *Environment Protection and Biodiversity Conservation (EPBC) Act 1999*. Any potential impacts on fauna species listed as Threatened under the *EPBC Act 1999* constitutes a Matter of National Environmental Significance (MNES) and requires referral under the Commonwealth act.

Numerous biological surveys have been completed in the Yandi locality, and although some of these overlap Yandi Billiards, they do not provide full coverage of the anticipated development area. A desktop review and gap analysis of the surveys completed in the Yandi Billiards area was recently conducted (Biota 2013a), in order to determine further work required to bring the information for the area to a level suitable to support environmental impact assessment under both State and Commonwealth legislation.

Biota Environmental Sciences (Biota) was commissioned to undertake a Level 2, seasonal fauna survey and a targeted survey in the Yandi Billiards area to address the recommendations of the desktop review and gap analysis report (Biota 2014a, 2014b). Currently, only Phase 1 of the Level 2 survey has been conducted, with Phase 2 fieldwork scheduled for September 2014. A targeted survey for the Threatened Northern Quoll (*Dasyurus hallucatus*) was also completed in July 2014. The Yandi Billiards survey area is approximately 8,640 ha in size and is hereafter referred to as the 'study area' (see Figure 1.1).

1.2 Scope and Objectives of this Study

The objective of this report is to provide up to date information on conservation significant fauna at Yandi Billiards that are relevant to the terms of the *EPBC Act 1999*. To this end, this report will act as a supporting document for referral of the Yandi Billiards development to the Department of the Environment (DotE). The fauna relevant to the referral comprise MNES species listed as Critically Endangered, Endangered or Vulnerable under the *EPBC Act 1999.*

Investigation of records from previous studies in the vicinity of Yandi billiards has been conducted, including fauna recorded at Yandi Billiards from the first phase of the Level 2 study (Biota 2014a) and recent Northern Quoll (*Dasyurus hallucatus*) targeted surveys (Biota 2009a, 2014b).

1.3 Relevant MNES Fauna Species

Reviews of previous surveys (Biota 2013a), database and literature searches have identified that five MNES fauna species may potentially occur in the study area (Table 1.1).

Table 1.1: MNES fauna species potentially occurring in the study area based on database searches.

Scientific name	Common name	Conservation Status	
		State	Federal
Pezoporus occidentalis	Night Parrot	S1	Critically Endangered
Dasyurus hallucatus	Northern Quoll	S1	Endangered
Liasis olivaceus barroni	Pilbara Olive Python	S1	Vulnerable
Macrotis lagotis	Bilby	S1	Vulnerable
Rhinonicteris aurantia	Pilbara Leaf-nosed Bat	S1	Vulnerable

A current account of survey effort expended to detect these species in the study area and results to date are presented in Section 2.0 and 3.0 respectively. Additional reviews of relevant databases were also conducted to supplement the existing knowledge base in regards to MNES species in the study area (see Section 2.4).

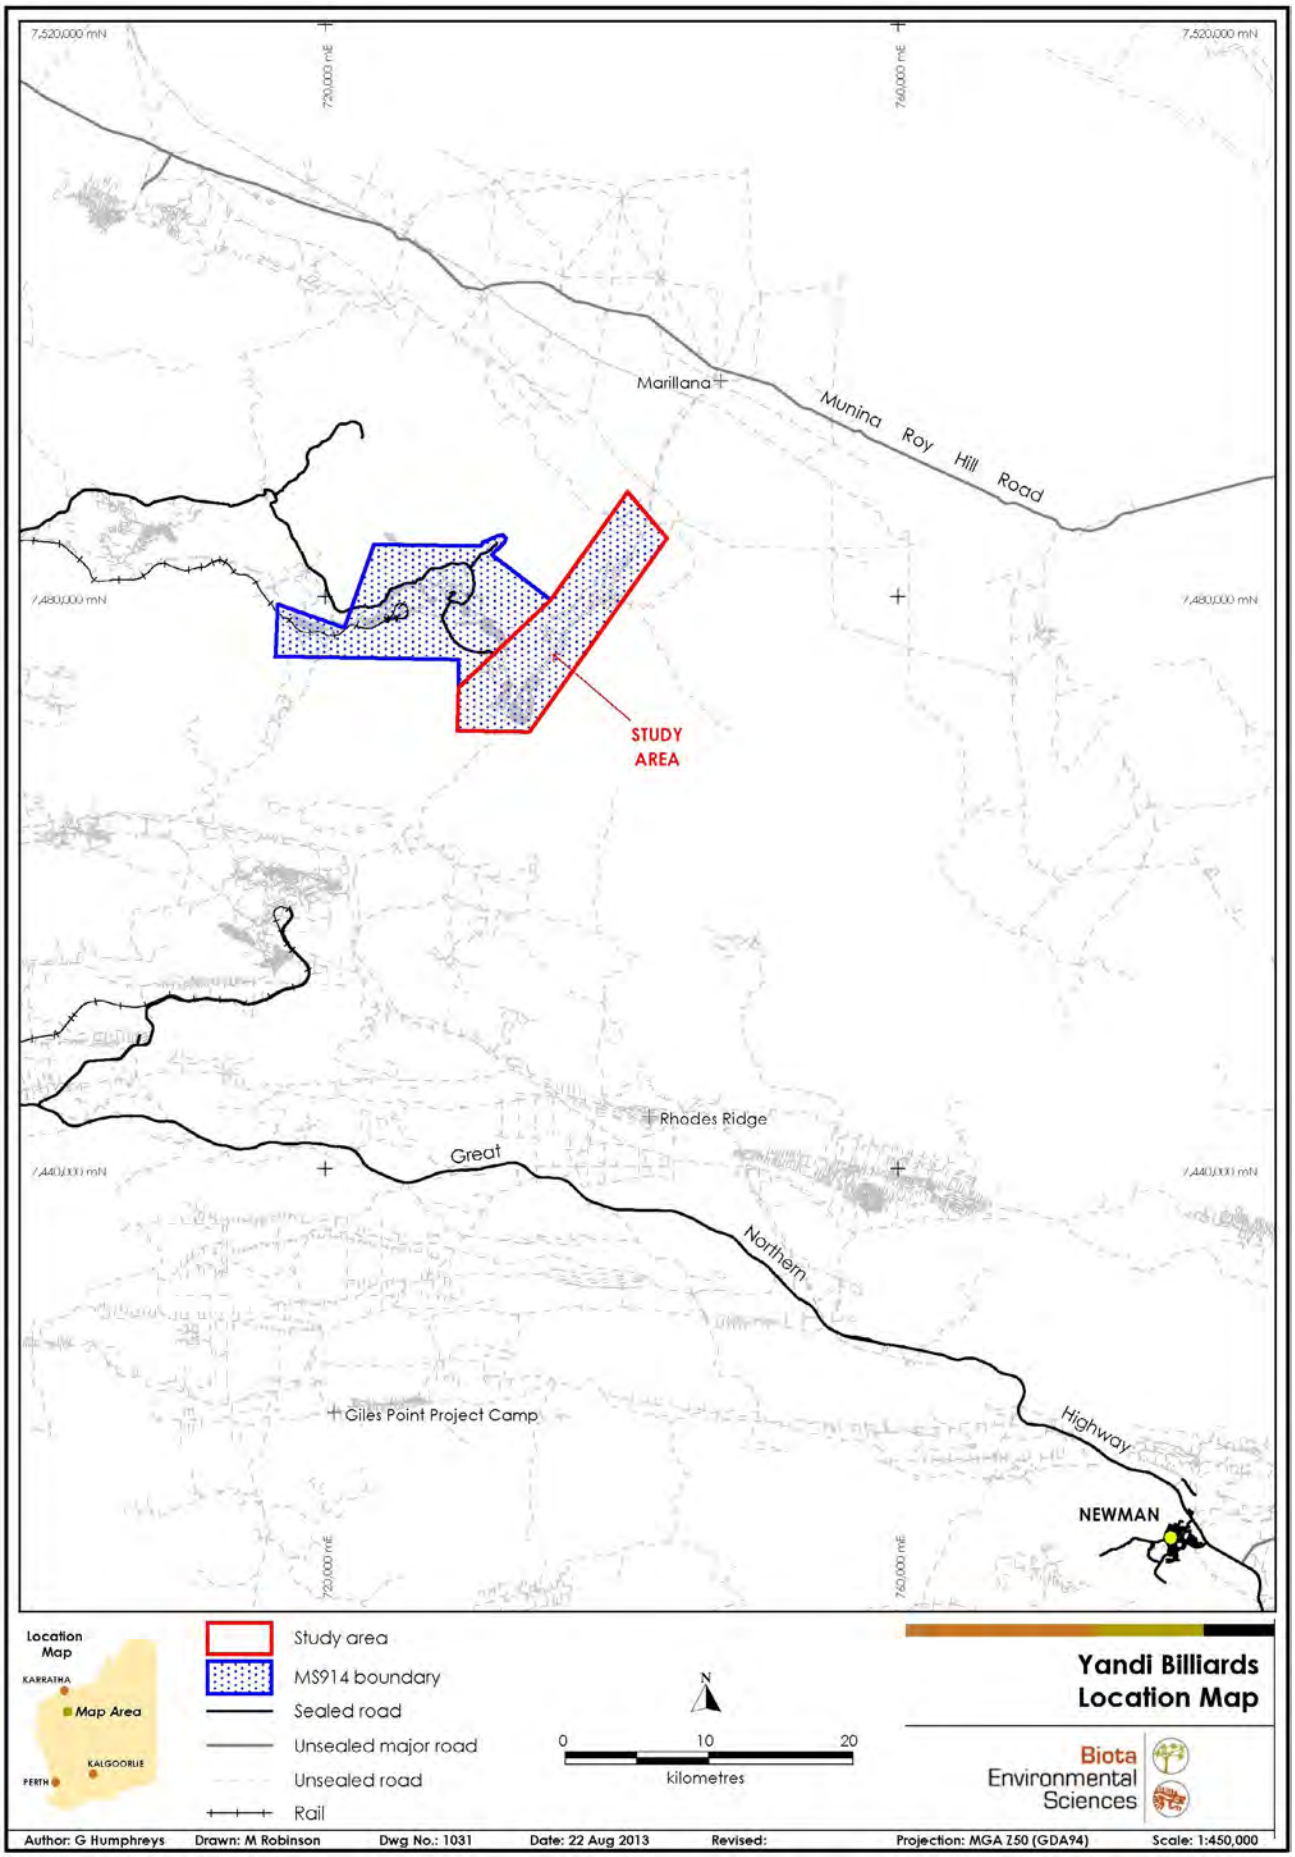

Figure 1.1: Location of the study area and the MS914 boundary.

2.0 Summary of Survey Effort and Methodology

2.1 Overview of Fauna Sampling

Phase 1 of the Level 2 fauna survey consisted of systematic baseline trapping combined with opportunistic and targeted searching for conservation significant vertebrates. The survey was completed over a 10-day period, from March 8th to 18th, 2014 (Biota 2014a) (Section 2.2). In addition, a targeted Northern Quoll survey was also conducted within the study area in August 2014 (Biota 2014b) (Section 2.3).

2.2 Level 2 Fauna Survey (Phase 1)

The fauna survey consisted of baseline trapping combined with opportunistic and targeted searching for conservation significant vertebrates (Biota 2014a). Systematic terrestrial fauna sampling was carried out at 11 sites located in land systems that were not sampled, or sampled at lower intensity, during previous surveys in the study area (based on findings of Biota 2013).

Systematic trapping sites comprised:

- Five pitfall trapping grids, consisting of a single row of ten pit-fall traps (alternating 20 litre buckets and PVC tubes), spaced at approximately 10 m intervals and connected with a 100 m single length of 30 cm high flywire fence.
- Four funnel trapping grids, consisting of 8-10 pairs of funnel traps (i.e. 16-20 traps) placed adjacent to a 100 m single length of 30 cm high flywire fence.
- Two Elliott trap transects, consisting of ten large Elliott box traps, four cage traps and 25 medium Elliott traps (sampling for Northern Quoll (*Dasyurus hallucatus*)).

Sampling of avifauna was conducted using a combination of techniques including:

- unbounded, habitat-specific area searches (30 minute duration) conducted at each of the systematic trapping sites; and
- opportunistic observations of birds while traversing the study area.

A minimum of two systematic avifauna surveys was conducted at each of the systematic sites. These surveys provided a total of 11.5 person hours of systematic avifauna survey for the study area.

Bats were sampled at five sites from echolocation call recordings using SongMeter SM2BAT bat detector units, which detect and record ultrasonic echolocation calls emitted by bats during flight. This methodology is appropriate to detect the Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) if present.

Non-systematic sampling targeting vertebrate conservation significant species and other cryptic or additional species that are not likely to be trapped systematically was conducted at 11 locations. Non-systematic sampling techniques were included:

- motion camera trapping (suitable for Northern Quoll (*Dasyurus hallucatus*) and Pilbara Olive Python (*Liasis olivaceus barroni*) if present);
- nocturnal searches (suitable for Pilbara Olive Python (*Liasis olivaceus barroni*) and Night Parrot (*Pezoporus occidentalis*) if present);
- searches for evidence and secondary signs in habitat potentially containing fauna of conservation significance (all potential MNES fauna species); and,
- audio recording for night birds and amphibian calls using SM2 SongMeter bat detector units configured to record audible noise (suitable for Night Parrot (*Pezoporus occidentalis*) if present).

2.3 Targeted Northern Quoll Survey

Targeted trapping for the Northern Quoll (*Dasyurus hallucatus*) was carried out by two Biota zoologists in accordance with the federal referral guidelines (DSEWPaC 2011). Sites were chosen within the study area to represent a range of habitats with the best potential to be utilised by Northern Quolls including drainage lines and breakaways. Transects comprising of 20 large Elliott traps and four cage traps were deployed at each of five trapping locations for a minimum of seven nights (Biota 2014b).

In addition, timed track and scat searches were conducted and baited remote cameras were deployed for a minimum of three days at each systematic trapping site. The survey was undertaken from 5th to 13th August 2014, consistent with the timing identified in DSEWPaC (2011).

While this survey primarily targeted the Northern Quoll, the opportunity was also taken to deploy four SM2 SongMeter bat detection units over the course of the survey and to include searches for evidence of Pilbara Olive Pythons during traverses for the Northern Quoll.

2.4 Database Searches and Likelihood Assessment

In addition to the survey effort outlined in Sections 2.1 to 2.3, the following databases were searched to further inform the likelihood of MNES species occurring in the study area:

1. The Commonwealth *EPBC Act 1999* Protected Matters Database was searched to identify MNES fauna species that may occur in the locality.
2. NatureMap[1] was then used to review records of the MNES fauna species identified from the *EPBC Act 1999* Protected Matters Database. NatureMap is the most comprehensive source of information on the distribution of the State's fauna, and comprises records from the Fauna Survey Returns Database(maintained by the Department of Parks and Wildlife (DPaW)), the WA Museum Specimen Database, and BirdLife Australia's Atlas of Australian Birds.

The MNES species identified as potentially occurring in the study area were then assigned a likelihood ranking based on the criteria detailed in Table 2.1.

Table 2.1: Ranking system used to assign the likelihood that a species would occur in the study area.

Rank	Criteria
Recorded	1. The species has been previously recorded in the study area.
Likely	1. There are existing records of the species in close proximity to the study area, or from the locality; and • the species is strongly linked to a specific habitat, which is present in the study area; or • the species has more general habitat preferences, and suitable habitat is present.
May potentially occur	1. There are existing records of the species from the locality, however • the species is strongly linked to a specific habitat, of which only a small amount is present in the study area; or • the species has more general habitat preferences, but only some suitable habitat is present. 2. There is suitable habitat in the study area, but the species is recorded infrequently in the region.
Unlikely	1. The species is linked to a specific habitat, which is absent from the study area; or 2. Suitable habitat is present, however there are no existing records of the species from the locality despite reasonable previous search effort in suitable habitat; or 3. There is some suitable habitat in the study area, however the species is very infrequently recorded in the region.
Would not occur	1. The species is strongly linked to a specific habitat, which is absent from the study area; and/or 2. The species' range is very restricted and would not include the study area.

[1] http://naturemap.dec.wa.gov.au

3.0 MNES Fauna in the Study Area

3.1 Recorded MNES Fauna

To date, the Pilbara Olive Python (*Liasis olivaceus barroni*) (Plate 3.1) is the only MNES threatened fauna species recorded within the study area (Figure 3.1). Two avifauna species listed as Migratory under the *EPBC Act 1999* have also been recorded, but neither is of conservation concern in regards to the proposed development of the Yandi Billiards project.

Pilbara Olive Python *Liasis olivaceus barroni* (State: Schedule 1, Federal: Vulnerable)

A single Pilbara Olive Python was observed in Weeli Wolli Creek during a nocturnal search YBLNoct04 (22º50'39"S, 119º15'56"E; Figure 1.1). The species has also been previously recorded in the immediate vicinity of the study area, with several sightings made at the existing Yandi operations at Marillana Creek.

The Pilbara Olive Python appears to be relatively common in the wider locality with additional nearby records from Koodaideri (38 km northwest; Biota 2012), and Flat Rocks (37 km west; Biota 2013b) and Hope Downs (21 km southwest; Biota 2009a), which lie within the same catchment.

Plate 3.1: Pilbara Olive Python *Liasis olivaceus barroni*.

Regarded as a Pilbara endemic, the Pilbara Olive Python has a known distribution that coincides roughly with the Pilbara bioregion (Environment Australia 2000). Core habitat for the species includes gorges, escarpments, rocky outcrops and water holes where it may find suitable prey that utilise these environments (DotE 2014). It seeks shelter in caves, beneath boulders, in pools of water and occasionally in trees overhanging water (Bush and Maryan 2011).

Within the study area, its core habitat is likely to be consistent with that described above; comprising the major riverine systems of Marillana and Weeli Wolli Creeks and the limited rocky breakaway landforms present (see Figure 1.1). The great majority of this habitat, and the current record, occur outside of areas that may be affected by the planned mine pit and waste dump locations for the development (Figure 1.1), but within the zone of potential hydrological impact.

Fork-tailed Swift, *Apus pacificus* (State: Schedule 3, Federal: Migratory)

An opportunistic observation of nine Fork-tailed Swift individuals flying over the study area was made during the Biota (2014a) survey. This species is expected to be a transient visitor to the study area and is unlikely to rely on any terrestrial habitats present, as it is entirely aerial in Australia, occurring only as a non-breeding visitor (Johnstone and Storr 1998).

Rainbow Bee-eater, *Merops ornatus* (State: Schedule 3, Federal: Migratory)

This species has been recorded on numerous occasions opportunistically and whilst conducting systematic avifauna surveys in the study area (Biota 2014a). This species, which is very common and widespread in the Pilbara bioregion (Biota 2013c), is likely to be a breeding resident or non-breeding visitor to the region, with Weeli Wolli Creek providing attractive wetter habitat with ample tall trees from which to forage (Johnstone and Storr 1998).

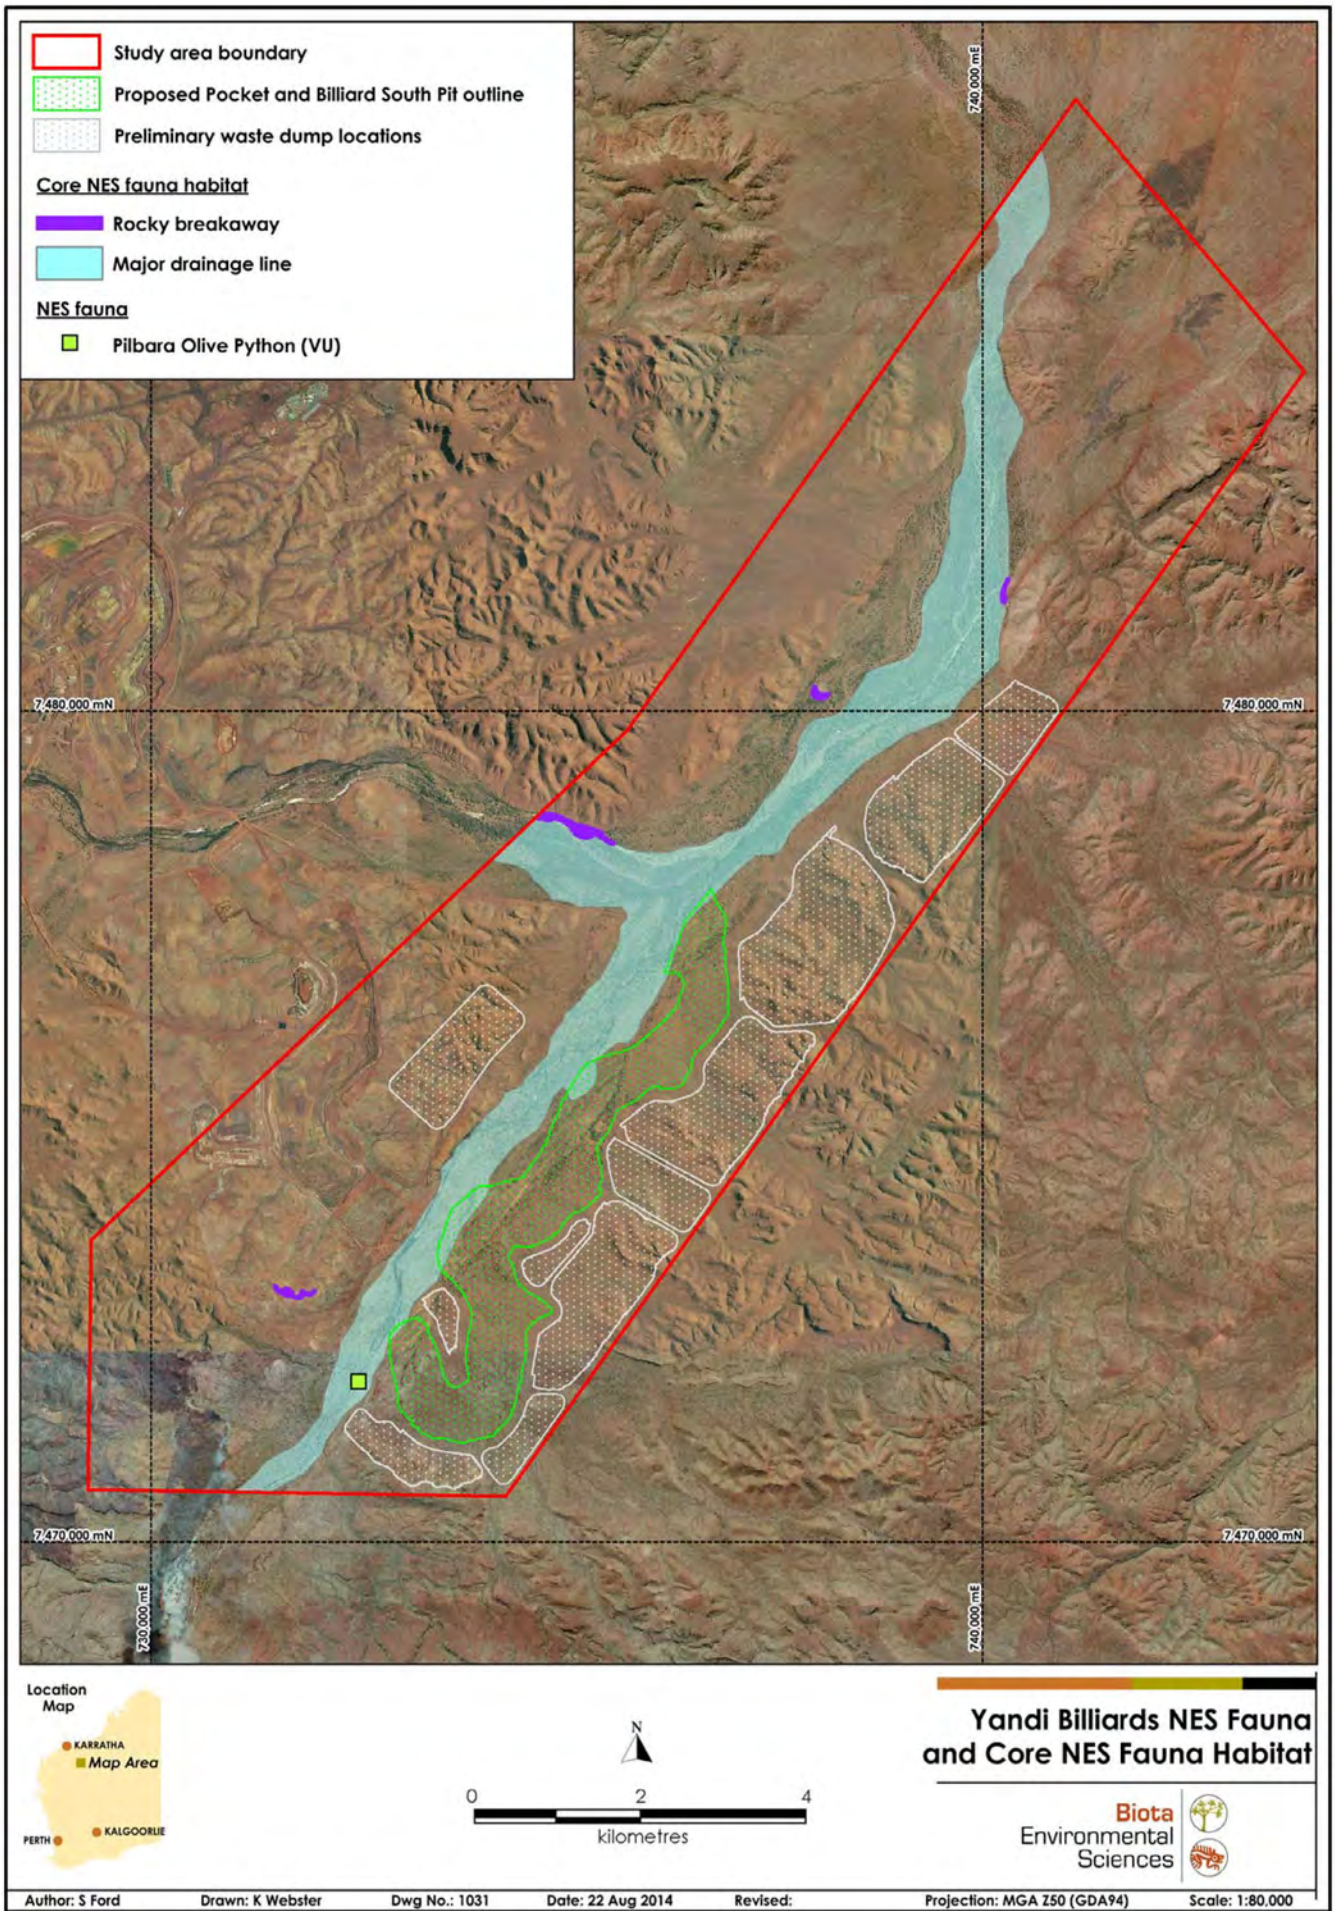

Figure 3.1: Locations of recorded MNES fauna and MNES core habitat, showing conceptual mine pit and waste dump design.

3.2 MNES Fauna that May Potentially Occur in the Study Area

Five of the remaining MNES species yielded by database searches (Table 1.1; Appendix 1) may potentially occur in the study area but have yet to be confirmed.

Northern Quoll *Dasyurus hallucatus* (State: Schedule 1, Federal: Endangered)

The Northern Quoll is considered to primarily occur along rocky gorges, rocky free faces and hills, usually of high relief; and secondarily along drainage lines, which are used for denning purposes (DEWHA 2010, DSEWPaC 2011). Adjacent plains and vegetated areas provide habitats suitable for foraging and dispersal of young (Van Dyck and Strahan 2008), but are considered to be of less importance for the purpose of the species' conservation.

There has been anecdotal sighting of Northern Quoll individuals at the existing Yandi warehouse (Biota 2009a, 2010) and camp (M. Brand, Rio Tinto, pers. comm. 2014). However, these represents the only evidence from the Yandi vicinity in the past 19 years and come from a higher relief area containing landforms more suitable for the species than the current study area. With a total trap effort of over 10,000 Elliott trap nights spread over a number of years and seasons in the Yandi operational mine area, it is considered extremely unlikely that a significant population of this species occurs within the study area (Biota 2010). The species may potentially occur in the study area, but the recent targeted Northern Quoll survey at Billiards detected no evidence of its presence (Biota 2014b) and suitable core habitat is limited to a few rocky breakaways, all of which are outside conceptual mine pit and waste dump locations (Figure 3.1).

Pilbara Leaf-nosed Bat *Rhinonicteris aurantia* (State: Schedule 1, Federal: Vulnerable)

The occurrence of this species is influenced by the availability and proximity of suitable roost caves (Churchill 1998); that is, deep caves offering suitable humidity and a stable temperature.

In the Pilbara, they are thought to be restricted to caves where at least semi-permanent water is nearby (Bob Bullen, Bat Call WA, pers. comm. 2013). The habitats of the study area may provide foraging opportunities for this species, but no suitable roost caves are currently known to occur in the vicinity. The closest known roost is situated at Koodaideri, some 43 km to the northwest, which is outside of the maximum documented foraging range of individual Pilbara Leaf-nosed Bats (approximately 30 km from the roost; Biota 2013c). It is possible another currently unknown *Rhinonicteris aurantia* roost occurs in the locality but the probability of this is relatively low and no echolocation calls of the species have been recorded to date during any of the field surveys.

Other Migratory Species.

The *EPBC Act 1999* search results list three other migratory species that may occur in the study area, comprising the Great Egret *Ardea alba*, Cattle Egret *Ardea ibis* and Oriental Plover *Charadrius veredus* (Appendix 1). None of these avifauna have been recorded during recent systematic surveys of the study area (Biota 2014a).

All of these species may potentially occur in the study area on a periodic basis, with recent records for all three from within 40 km of the study area on NatureMap. However, these migratory taxa are likely to utilise the habitats of the study area on a transitory or intermittent basis only, if they do occur. There are no records of breeding activity or other data that suggest these migratory species are reliant on the habitats of the study area.

3.3 MNES Fauna Unlikely to Occur in the Study Area

Three of the MNES fauna species identified by database searches are considered unlikely to occur and no evidence of their presence has been detected during recent surveys.

Night Parrot *Pezoporus occidentalis* (State: Schedule 1, Federal: Critically Endangered)

There is a confirmed Night parrot record from Minga Well, north of the Fortescue Marsh (Davis and

Metcalf 2008), and an unconfirmed sighting from the southern edge of the Fortescue Marsh (Roy Teale, Biota, pers. obs.). However, no evidence of this species has been observed within the study area and the majority of the habitat is not suitable.

The study area lies in the vicinity of the Fortescue Marsh (approximately 26 km at its closest point), where the most recent Night Parrot observations in Western Australia have been made. Although the Night Parrot has potential to occur in the study area, the likelihood is low due to the rare nature of this species and lack of suitable habitat.

Bilby *Macrotis lagotis* (State: Schedule 1, Federal: Endangered)

This species has been documented as holding temporary home ranges and showing relatively rapid changes in distribution in response to variation in habitat resources (Johnson 1995).

Two individuals were recorded approximately 50 km northeast of the study area in 1997 (NatureMap database). While these records came from the opposite side of the Fortescue Marsh to the study area, there is a small potential for this species to occur within the study area, particularly on the plains in the most northwestern section. However, to date no evidence of this species has been noted despite ground searches for burrows. The species is considered unlikely to be present.

Australian Painted Snipe *Rostratula australis* (State: Schedule 1, Federal: Vulnerable)

The Australia Painted Snipe is a very rarely recorded species that utilises shallow inland wetlands and swamps (Johnstone and Storr 1998). There is a single record of the species on NatureMap from the Fortescue Marsh, some 40 km east of the study area. This is consistent with Johnstone and Storr (1998) who consider the species a rare summer visitor with only three individuals recorded from the Pilbara bioregion in the last century. Given its scarcity, and the lack of recent evidence it occurs in the study area, it is considered unlikely to occur.

3.4 MNES Fauna not Occurring in the Study Area

The remaining species yielded from the *EPBC Act 1999* database search (Appendix 1), would not occur in the study area.

Northern Marsupial Mole *Notoryctes caurinus* (State: Schedule 1, Federal: Endangered)

The Northern Marsupial Mole occurs in soft red sand dunes and other suitable sandy habitats in the Great Sandy Desert and Little Sandy Desert (Benmesh and Aplin 2008). It is apparently absent from even dune swales, as these are too compacted, and does not occur in harder substrate topography. Given that no dune landforms occur in the study area, and as NatureMap indicates the nearest reliable record is from 230 km east within the Little Sandy Desert, it is reasonable to conclude the species would not occur in the study area.

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 15/09/14 15:58:53

Summary
Details
- Matters of NES
- Other Matters Protected by the EPBC Act
- Extra Information

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Areas:	None
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	8
Listed Migratory Species:	6

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place and the heritage values of a place on the Register of the National Estate.

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	6
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Commonwealth Reserves Marine	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

Place on the RNE:	None
State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	8
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Matters of National Environmental Significance

Listed Threatened Species		[Resource Information]
Name	Status	Type of Presence
Birds		
Pezoporus occidentalis Night Parrot [59350]	Endangered	Species or species habitat likely to occur within area
Rostratula australis Australian Painted Snipe [77037]	Endangered	Species or species habitat may occur within area
Mammals		
Dasyurus hallucatus Northern Quoll [331]	Endangered	Species or species habitat likely to occur within area
Macrotis lagotis Greater Bilby [282]	Vulnerable	Species or species habitat likely to occur within area
Notoryctes caurinus Kakarratul, Northern Marsupial Mole [295]	Endangered	Species or species habitat likely to occur within area
Rhinonicteris aurantia (Pilbara form) Pilbara Leaf-nosed Bat [82790]	Vulnerable	Species or species habitat likely to occur within area
Plants		
Lepidium catapycnon Hamersley Lepidium, Hamersley Catapycnon [9397]	Vulnerable	Species or species habitat likely to occur within area
Reptiles		
Liasis olivaceus barroni Olive Python (Pilbara subspecies) [66699]	Vulnerable	Species or species habitat likely to occur within area

Listed Migratory Species		[Resource Information]
* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.		
Name	Threatened	Type of Presence
Migratory Marine Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Migratory Wetlands Species		
Ardea alba Great Egret, White Egret [59541]		Species or species habitat likely to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat may occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species		[Resource Information]
* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.		
Name	Threatened	Type of Presence
Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba Great Egret, White Egret [59541]		Species or species habitat likely to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat may occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat may occur within area

Extra Information

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Mammals		
Camelus dromedarius Dromedary, Camel [7]		Species or species habitat likely to occur within area
Equus asinus Donkey, Ass [4]		Species or species habitat likely to occur within area
Equus caballus Horse [5]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Cenchrus ciliaris Buffel-grass, Black Buffel-grass [20213]		Species or species habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World Heritage and Register of National Estate properties, Wetlands of International Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

For species where the distributions are well known, maps are digitised from sources such as recovery plans and detailed habitat studies. Where appropriate, core breeding, foraging and roosting areas are indicated under 'type of presence'. For species whose distributions are less well known, point locations are collated from government wildlife authorities, museums, and non-government organisations; bioclimatic distribution models are generated and these validated by experts. In some cases, the distribution maps are based solely on expert knowledge.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Acknowledgements

This database has been compiled from a range of data sources. The department acknowledges the following custodians who have contributed valuable data and advice:

1.0 Executive Summary

Rio Tinto plans to sustain the operations at the existing Yandicoogina (Yandi) mine, located approximately 90 km northwest of Newman, Western Australia. The proposed sustaining operations include the development of the Channel Iron Deposits (CID) at Pocket and Billiard South (PBS) within the existing Yandi Operations development envelope (MS914).

Following earlier survey work, Biota was commissioned to undertake a second phase of troglobitic fauna sampling within the study area. Troglobitic fauna, or troglofauna, are considered to be of conservation significance, given species often display extreme short-range endemism and may be affected by relatively small-scale developments such as mining and construction.

Phase 2 of troglofauna sampling was completed under "Licence to Take Fauna for Scientific Purposes" No. SF009624. Methodology and approach were consistent with those outlined in Environmental Protection Agency (EPA) Guidance Statement No. 54a and EPA Environmental Assessment Guideline (EAG) No. 12.

Two phases of troglofauna sampling have now been completed in the wider Yandi tenure to date. A total of 52 sites were sampled in 2009, Phase 1, incorporating 58 traps installed. Thirty-four of these sites, 46 traps, were located within the current Yandi Billiards study area, and were considered in this report. Phase 2 was completed in 2014, with a total of 32 sites sampled with 58 troglofauna traps. Additionally, troglofauna were collected as by-catch from four sites during past stygofauna sampling within the wider Yandi tenure. All troglobitic fauna records from the broader Yandi tenure are included in the results of this report, however this assessment focused on those collected within the Billiards study area.

Several geological units within the study area are recognised as being suitable for troglobitic fauna as they characteristically incorporate interstitial spaces, vugs or fractures that provide habitat space when above water table. The relevant units present in the study area included alluvium, colluvium, calcrete and banded iron formation. These habitats combined comprise 86.1% of the surface geology units of the Billiards study area.

Six troglobitic fauna specimens have been recorded in the wider Yandi tenure. Taxa collected comprise:

- the spider *Myrmopopaea* sp. nov – collected from Billiards study area site WW2;
- the beetle Pselaphinae sp. indet – collected from Billiards study area site RC13YBR0037;
- a pauropod, Pauropoda sp. indet. - collected from Billiards study area site D07YJ218;
- the schizomids *Draculoides* sp. 'Lineage WWS1' (site RC13YBR0038) and *Draculoides* sp. indet. (site WW3) – both collected from Billiards study area; and
- the pseudoscorpion *Lagynochthonius* sp. nov. - collected from JSW deposit, site MNEW1upstream (outside of the Billiards study area).

Four of the five specimens recorded from within the Billiards study area were collected from sites outside the PBS deposit itself. The taxon *Myrmopopaea* sp. nov. was the only specimen recorded from within the PBS deposit. Given the geology where this specimen was recorded, continuous and interconnected calcrete and alluvium, it is unlikely that this species is restricted to this site, and it is more probable that the single record is a sampling artefact. These geological units run in a generally connected extent adjacent to the course of Weeli Wolli Creek and contain sufficient interstitial spaces and cavities to allow movement of troglobitic fauna. This habitat continuity suggests that *Myrmopopaea* sp. nov. is likely to occur more widely than the current record and its distribution probably extends beyond the study area.

Given the limited returns from sampling completed to-date, both via troglofauna habitat traps and via stygofauna haul nets, it is unlikely that troglobitic fauna inhabit the PBS Deposit in high density. Additional sampling targeting surrounding geologies would be required to better

determine potential core troglofauna habitats within the Billiards study area as the primary habitat for the fauna in the area is currently poorly defined. The long-term persistence of the fauna in this riverine habitat setting also suggests these habitats are well connected with other older geological units that do provide core habitat over longer timeframes.

2.0 Introduction

Rio Tinto Pty Ltd (Rio Tinto) currently operates the Yandi iron ore mine located approximately 90 km northwest of Newman in the Pilbara region of Western Australia (Figure 2.1). The original Yandi deposit, Junction Central, started construction in 1997 with the first shipment of ore occurring in 1999. An expansion to existing mining developments was later proposed in 2005 in the form of the Junction South East (JSE) deposit. A number of other expansions have subsequently occurred, including at the Junction South West (JSW) and Oxbow deposits (Figure 2.1).

Rio Tinto plans to sustain the operations at the existing Yandicoogina (Yandi) mine, located approximately 90 km northwest of Newman, Western Australia. The proposed sustaining operations include the development of the Channel Iron Deposits at Pocket and Billiard South (PBS) within the existing Yandi Operations development envelope (MS914; Figure 2.1). Approximately 99% of the PBS deposit lies below the water table. Historical phases of stygobitic fauna (or stygofauna) sampling at Billiards and the surrounding tenements collected several specimens of troglobitic fauna (troglofauna) (Biota 2010a). Mining operations have the potential to impact on troglobitic fauna communities and as such, Environmental Protection Authority (EPA) policy requires Rio Tinto to determine potential impacts on subterranean fauna prior to operations commencing (EPA 2013).

2.1 Troglobitic Fauna Background

Australia was historically thought to lack habitat suitable for subterranean fauna. Studies in recent decades however, mostly with an emphasis on environmental impact assessment, have revealed Australia to be highly diverse in subterranean fauna with numerous areas of interest throughout the continent (Guzik et al. 2010). In Western Australia these zones of subterranean biodiversity can be found at the Nullarbor, Yilgarn, Cape Range, Barrow Island and the Pilbara bioregion (Humphreys 2001, Page et al. 2008, Guzik et al. 2010).

Subterranean fauna can be categorised into two distinct ecological groups based on habitat, troglobitic fauna (troglofauna) and stygobitic fauna (stygofauna). Troglofauna are a suite of fauna that survive only in air-filled cavities and interstices between the surface and the water table. Troglobites are obligatory subterranean habitat dwellers, and while they may occur close to surface environments, are strongly adapted to subterranean environments. This makes such fauna unable or highly unlikely to survive surface conditions. A range of similarly adapted fauna occur that opportunistically use subterranean habitats but are able to survive outside these stable environments. Studies from the Pilbara bioregion have demonstrated that these latter suites of fauna; troglophiles, trogloxenes and edaphobites, are not similarly restricted in range and therefore unlikely to be impacted at taxon level by small scale developments (Biota and Helix 2011, Helix 2012).

Troglofauna in northern Western Australia have been known for some time from karstic limestone systems on Cape Range and Barrow Island. Surveys in the Pilbara over the past decade or more have collected subterranean fauna from other geological units such as banded iron formations, channel iron deposits, unconsolidated alluvium and sedimentary basalt (Marmonier et al. 1993, Biota 2004, 2006a, 2010a, 2011a, 2013a), indicating that the suitability of a formation as habitat for troglobitic fauna is mostly a function of the availability of habitable space (Marmonier et al. 1993, Humphreys 1999, Biota 2006a), rather than a specific rock type.

Subterranean habitats are characterised by shared physical parameters that include a lack of light, stable temperature, limited nutrient infiltration from surface environments and a constant humidity (Juberthie 2001, Romero 2009). These habitat characteristics have resulted in convergence in body morphology evolution amongst many subterranean fauna.

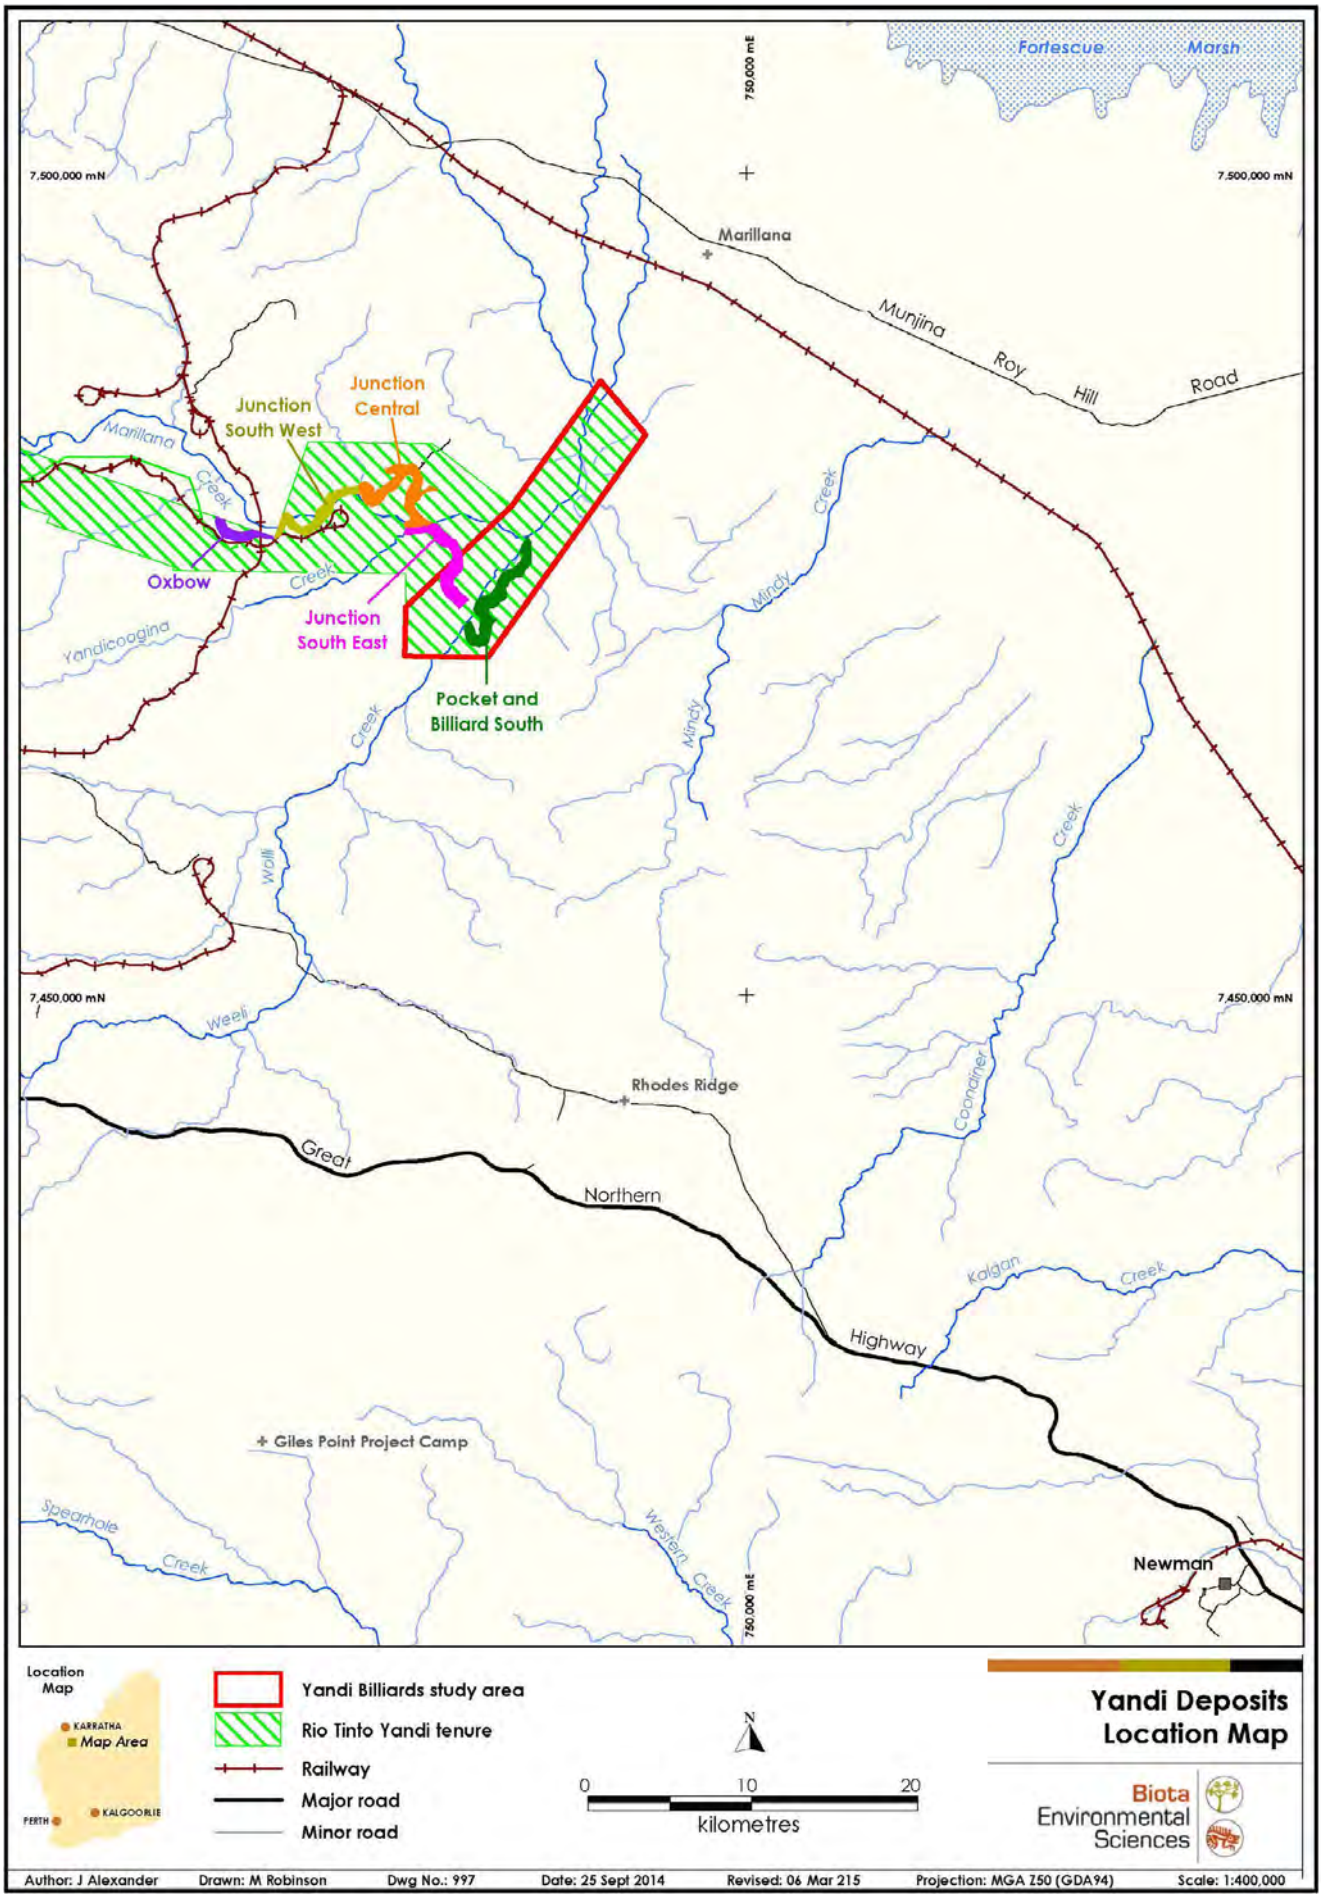

Figure 2.1: Location of Yandi mine areas in relation nearby Newman townsite.

Morphological characteristics common to most subterranean fauna include reduced or lack of pigmentation, reduced or lack of eyes, and elongate body morphology and appendages adapted for sensory movement (Culver and Pipan 2009, Romero 2009).

Troglofauna in semi-arid Australia are thought to be relictual rainforest fauna. Fauna adapted to humid environments, which retreated underground to subterranean environments during the aridification of Australia (in the late Miocene; Humphreys 1993). This is inferred from affinities of the taxonomic groups represented amongst the troglofauna with other extant taxa in tropical climates. Some invertebrate groups with troglobitic representatives include the Arachnida (e.g. Schizomida, Pseudoscorpiones and Araneae), Chilopoda (e.g. Scolopendrida), Diplopoda (e.g. Polydesmida and Haplodesmida), and Insecta (e.g. Diplura, Thysanura, Coleoptera and Blattodea). A single troglobitic vertebrate species of blind snake (*Ramphotyphlops longissimus*) is known from Australia, collected from Barrow Island (Aplin 1998, Humphreys et al. 2013)

Due to their dependence on constant humidity, dispersal and distribution of troglobitic fauna species tends to remain limited to individual blocks of inter-connected habitat, leading to long periods of population isolation and localised speciation. As a result, troglobitic fauna are considered to be of conservation significance, given species often display extreme short-range endemism and species may therefore be affected by relatively small-scale developments such as mining and construction.

2.2 Study Scope and Objectives

Biota Environmental Sciences (Biota) was commissioned to undertake a single-phase troglobitic fauna survey targeting the proposed PBS deposit expansion and wider Yandi tenure, which encompasses 8,639 ha (Table 4.1). The scope of this study was to sample for additional troglobitic fauna specimens from within the Billiards study area to support the environmental assessment of the project.

The objectives of this study included:

- the implementation of a second, single-phase troglobitic fauna survey focussing on the Billiards study area;
- morphological identification of groups thought to display short range endemism or troglomorphism;
- potential genetic analysis of specimens of interest, such as Schizomida; and
- the production of a single report outlining the results of the current phase of sampling.

The aim of this report is to provide a summary of the recent phase of sampling and amalgamate historical and current data within the wider Yandi tenure, with emphasis on the Billiards study area.

2.3 Historical Sampling

Extensive sampling for stygobitic fauna has been completed in the Rio Tinto Yandi tenements. Biota has completed 13 stygofauna surveys in the Yandi locality, encompassing all operations and deposits including the PBS study area. These surveys were completed between 2003 and 2014, and have included nine monitoring surveys for the purposes of regulatory compliance (Biota 2010a, 2011b, 2011c, 2013b). While these studies do not specifically target troglobitic fauna, four specimens have been collected as by-catch from the following sites (all coordinates in zone 50, GDA94):

- D07YJ218 (732924 mE, 7471648 mN);
- MNEW1upstream (726009 mE, 7480355 mN);
- WW2 (733149 mE, 7472618 mN); and
- WW3 (733405 mE, 7473428 mN).

As a result of troglobitic fauna collections during stygofauna surveys, Biota was commissioned to completed a targeted troglobitic fauna survey, Phase 1, in 2009 (Biota 2010a). A total of 52 sites were sampled incorporating 58 traps installed. Thirty-four of these sites, comprising 46 traps, were located within the current Yandi Billiards study area, and will be focussed on in this report.

The results of this sampling are summarised in Section 5.0.

3.0 Methodology

Troglobitic fauna sampling was completed under "Licence to Take Fauna for Scientific Purposes" No. SF009624 issued to Dan Kamien (Appendix 1). Methodology and approach were consistent with those outlined in the EPA Guidance Statement No. 54a (EPA 2007) and EPA Environmental Assessment Guideline (EAG) No. 12 (EPA 2013).

3.1 Troglobitic Fauna Sampling Methodology

Troglobitic fauna were sampled by means of custom-built litter colonisation traps suspended within drillholes located within the study area. Traps were constructed from 60 mm internal diameter PVC irrigation pipe cut to a length of 180 mm. Each trap had a series of 20 mm holes drilled into the side, and traps remained open at the upper end. Up to three traps were installed to provide greater vertical coverage of the stratigraphy.

Leaf litter was gathered locally from the ground surface in the study area, particularly from the bases of *Acacia* shrubs. The collected litter was soaked in water and irradiated in a microwave oven for two minutes on maximum power setting. This killed any surface invertebrates present and assisted in the breaking down of organic matter. Wet litter was added to the traps, which were kept in sealed containers until immediately prior to insertion into the drillholes to avoid desiccation of leaf litter. After the installation of traps, the opening of each drillhole was sealed to maintain humidity and to avoid entry of surface fauna.

Traps were recovered from each drillhole after seven weeks and stored in labelled zip lock bags in order to maintain humidity and prevent desiccation of potential troglofauna specimens during transportation to Perth.

Fauna specimens were recovered from the traps using specially designed Tullgren funnel units. Leaf litter from each trap was placed in a sieve under an aluminium lamp containing a 25-watt globe. This created a temperature of approximately 30°C at the surface of the leaf litter. A funnel situated below the leaf litter collected the fauna as they fell, directing them into an attached vial of 100% ethanol. Leaf litter was left in the Tullgren funnels for a period of 24 hours, or until dry, after which time the bulked invertebrate sample was removed.

Fauna specimens collected via Tullgren funnels were identified to order level using dissecting microscopes (Olympus SZ40 and SZ61, magnification up to 40x). Fauna specimens were assigned a unique number based on drillhole name and location and tracked on customised data sheets. Specimens were preserved in 100% ethanol, which allows for both morphological and molecular analysis.

3.2 Survey Design

3.2.1 Timing and Personnel

The Yandi Billiards troglobitic fauna assessment project was managed by Jason Alexander, with directional input from Garth Humphreys of Biota. Dan Kamien, Jason Alexander, Chris Cole and Andrew Sheppard, all of Biota, completed troglofauna sampling. Sampling was completed between 17th of May and 10th of July 2014 (Table 3.1).

Table 3.1: Summary of Yandi Billiards troglofauna field survey.

Dates	Purpose	Personnel
21/05/14 – 22/05/14	Troglobitic fauna habitat trap installation	Dan Kamien, Chris Cole
9/07/14 – 10/07/14	Troglobitic fauna habitat trap recovery	Jason Alexander, Andrew Sheppard

Preliminary and final morphological identification of troglofauna specimens to order level was completed by Dr Mieke Strong of Biota. Collected schizomid specimens were handed onto Helix Molecular Solutions for genetic analysis (Appendix 2). Melissa Robinson and Kylie Webster of Biota prepared maps for field surveys and reporting purposes.

3.2.2 Sampling Effort

3.2.2.1 Phase 2 Sampling Effort

A total of 32 sites, incorporating 58 traps, were sampled during the single-phase survey in 2014 (Table 3.2, Figure 3.1). These sites were selected in liaison with Rio Tinto personnel based on accessibility and drillhole viability.

Table 3.2: Summary of location and sampling effort for troglofauna survey within the Billiards study area in 2014.

Site Name	Easting (m E)	Northing (m N)	Traps Installed	Traps Recovered	Trap depths (m)

		Total	58	58	

(Coordinates in GDA94, Zone 50)

Three of the sites were sampled in both Phases of sampling in 2009 and 2014. These sites include D07YJ218, D08YJ050 and RD09YJ163.

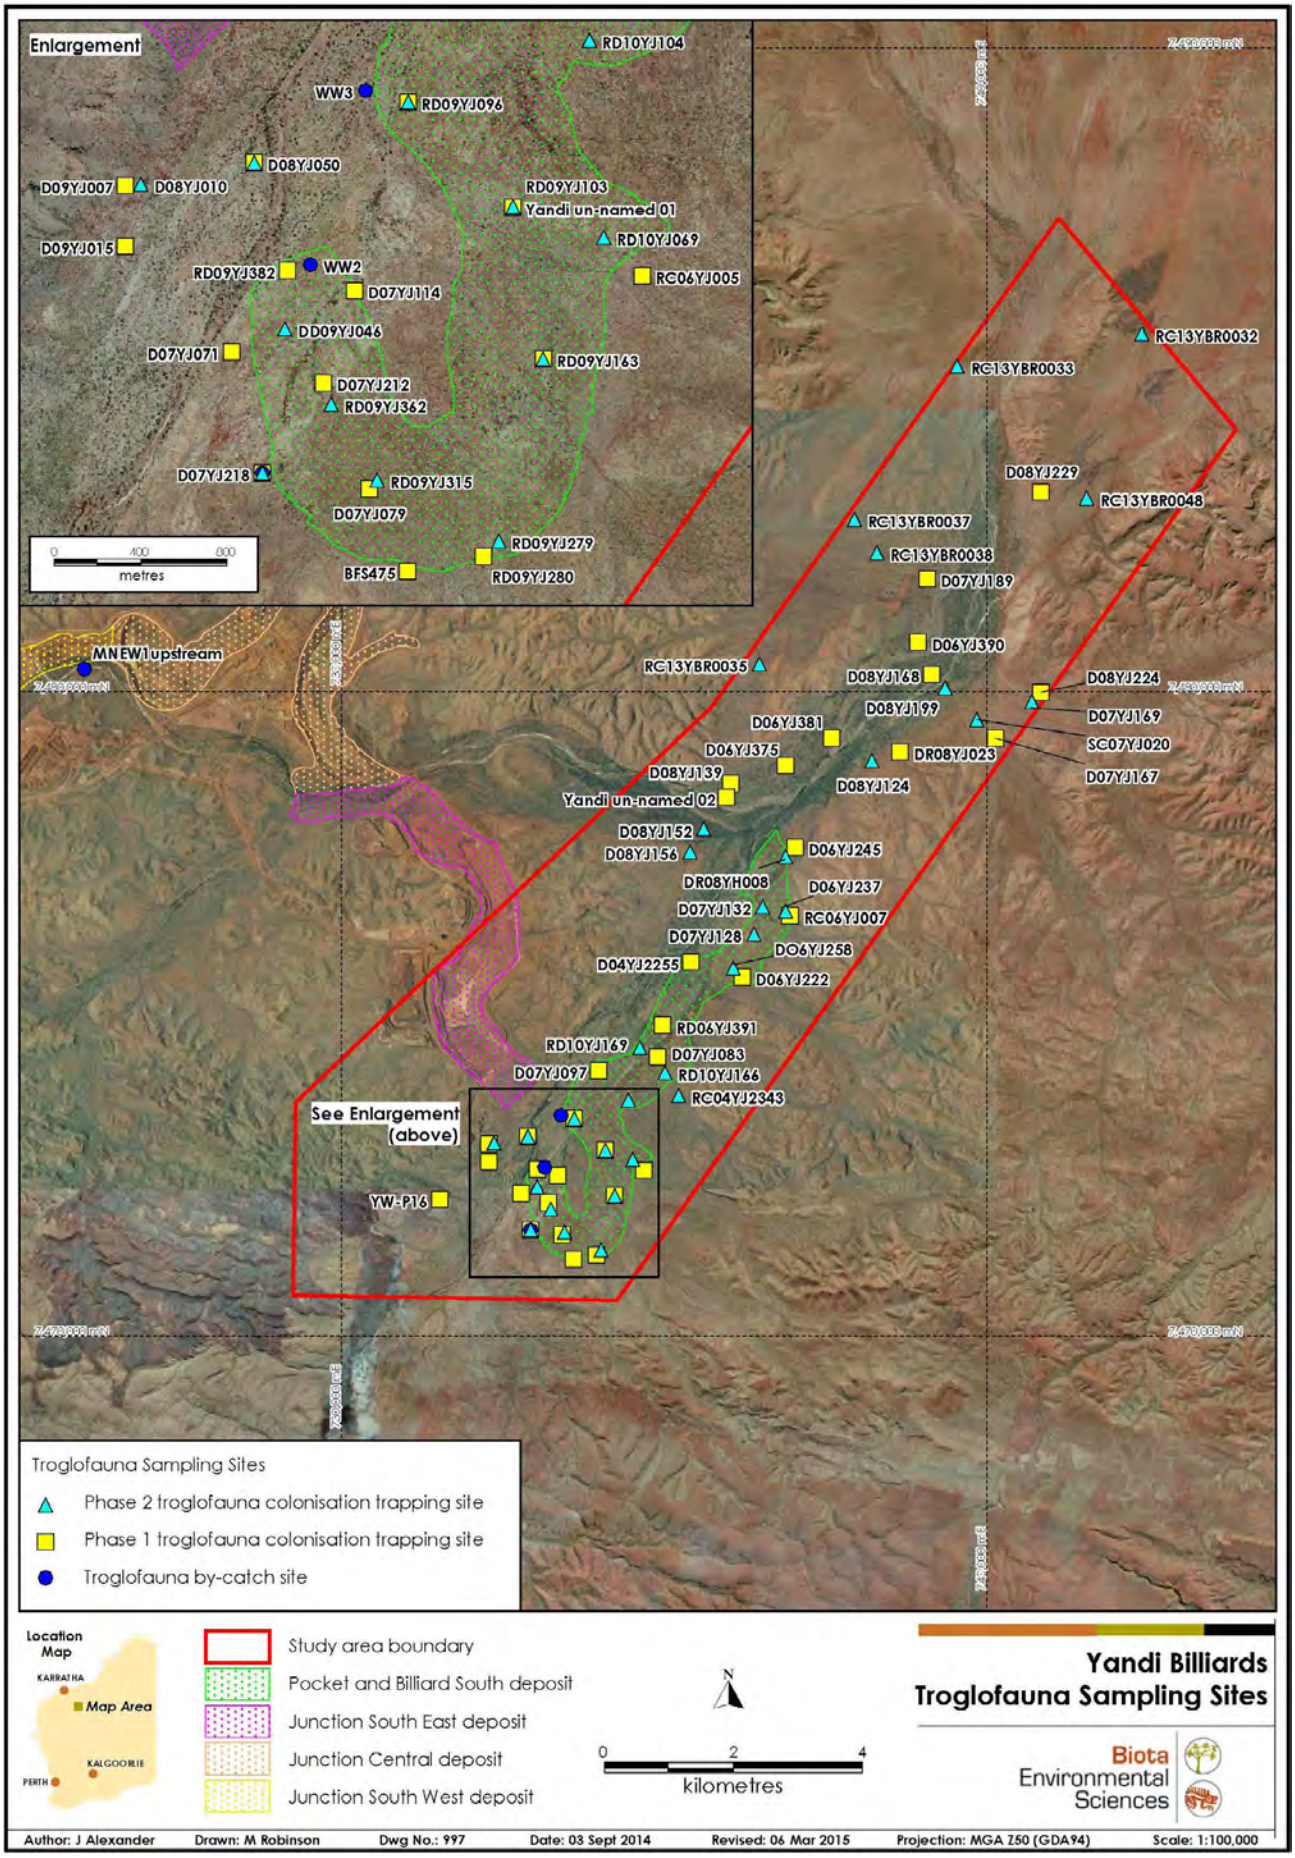

Figure 3.1: Location of sites sampled using habitat colonisation traps within the Billiards study area as well as locations of opportunistic collections.

3.3 Limitations

A number of limitations apply to the troglobitic fauna surveys completed within the Yandi Billiards study area. A specimen of Schizomida unable to be identified due to DNA degradation and as a result no further information can be provided on this specimen (distribution or conservation status).

Two of the taxa, Pauropoda and Coleoptera, were unable to be identified due to poor resolution of their wider taxonomic framework. This limited the conclusiveness of some of the findings on some taxa in regards to both taxonomic placement and ecological status. Further studies would be required to determine the conservation status of these groups.

Troglobitic fauna sampling at Yandi has been limited to existing drill holes, which are focused on the CID and the surrounding alluvium. As the alluvium is subject to seasonal inundation it is unlikely to constitute core habitat for troglobitic communities. Surveys targeting surrounding geologies above inundation level (such as surrounding hills) would be beneficial to determine core troglofauna habitat for conservation.

4.0 Geological Habitat Characterisation

The suitability of potential subterranean fauna habitat is predominantly a function of availability of space, potential for nutrient filtration from surface sources and the ability of the substrate to maintain a stable humidity. Several geological units are recognised as being suitable for troglobitic fauna as they characteristically incorporate interstitial spaces, which provide these attributes and allow for fauna dispersal. These geologies include limestone karstic systems, calcrete, alluvium (particularly when associated with paleochannel aquifers), gravels, limonite and dolomite (Marmonier et al. 1993, Humphreys 1999, Biota 2006b).

The CID in the Yandi locality forms part of the palaeodrainage of the Marillana Formation CID (Ramanaidou et al. 2004) and was formed by the erosion of shale bedrock, dolerite and Banded Iron Formation of the Weeli Wolli Formation, which overlies the older Brockman Iron Formation. The CID is mostly below the water table and is overlain with varying depths of unconsolidated alluvium and colluvium, with areas of calcrete development associated with the contemporary drainage lines.

The study area encompasses eight major surface geology units, as outlined in Geological Survey of Western Australia (2002) (Table 4.1 and Figure 4.1). These predominantly comprise Qa "Alluvium", Czc "Colluvium" and PLHj "Weeli Wolli Formation", each representing approximately 27% of the study area (Table 4.1). Most of the sites sampled during this study were located in the Qa "Alluvium", Qw "Alluvium and Colluvium" and Czk "Calcrete" geological units.

The Weeli Wolli Creek system within the study area consists of a superficial layer of alluvial aquifer overlaying CID deposit. A cross-section schematic of the PBS deposit provided in Figure 4.2.

Table 4.1: Geological units occurring in the Yandi Billiards study area.

Geological Period	Code	Description	Area (ha)	% of Study Area	Potential for Troglofauna Habitat
Quaternary Period	Qw	Alluvium and colluvium - red-brown sandy and clayey soil; on low slopes and sheetwash areas.	557	6.5	Low
	Qa	Alluvium - unconsolidated silt, sand, and gravel; in drainage channels and on adjacent floodplains.	2,413	27.9	Medium
	Qs	Eolian deposit - sand; in sheets and longitudinal dunes.	1	<0.1	Low
Cenozoic Era	Czp	Robe Pisolite: pisolitic limonite deposits developed along river channels.	5	0.1	High
	Czc	Colluvium - partly consolidated quartz and rock fragments in silt and sand matrix; old valley-fill deposits.	2,337	27.1	Medium
	Czk	Calcrete - sheet carbonate; found along major drainage lines	341	3.9	High
Proterozoic Eon	PLHb	Brockman Iron Formation: banded iron-formation, chert, and pelite.	638	7.4	High
	PLHj	Weeli Wolli Formation: banded iron-formation (commonly jaspilitic), pelite, and numerous metadolerite sills.	2,349	27.2	Medium
		Total	8,641		

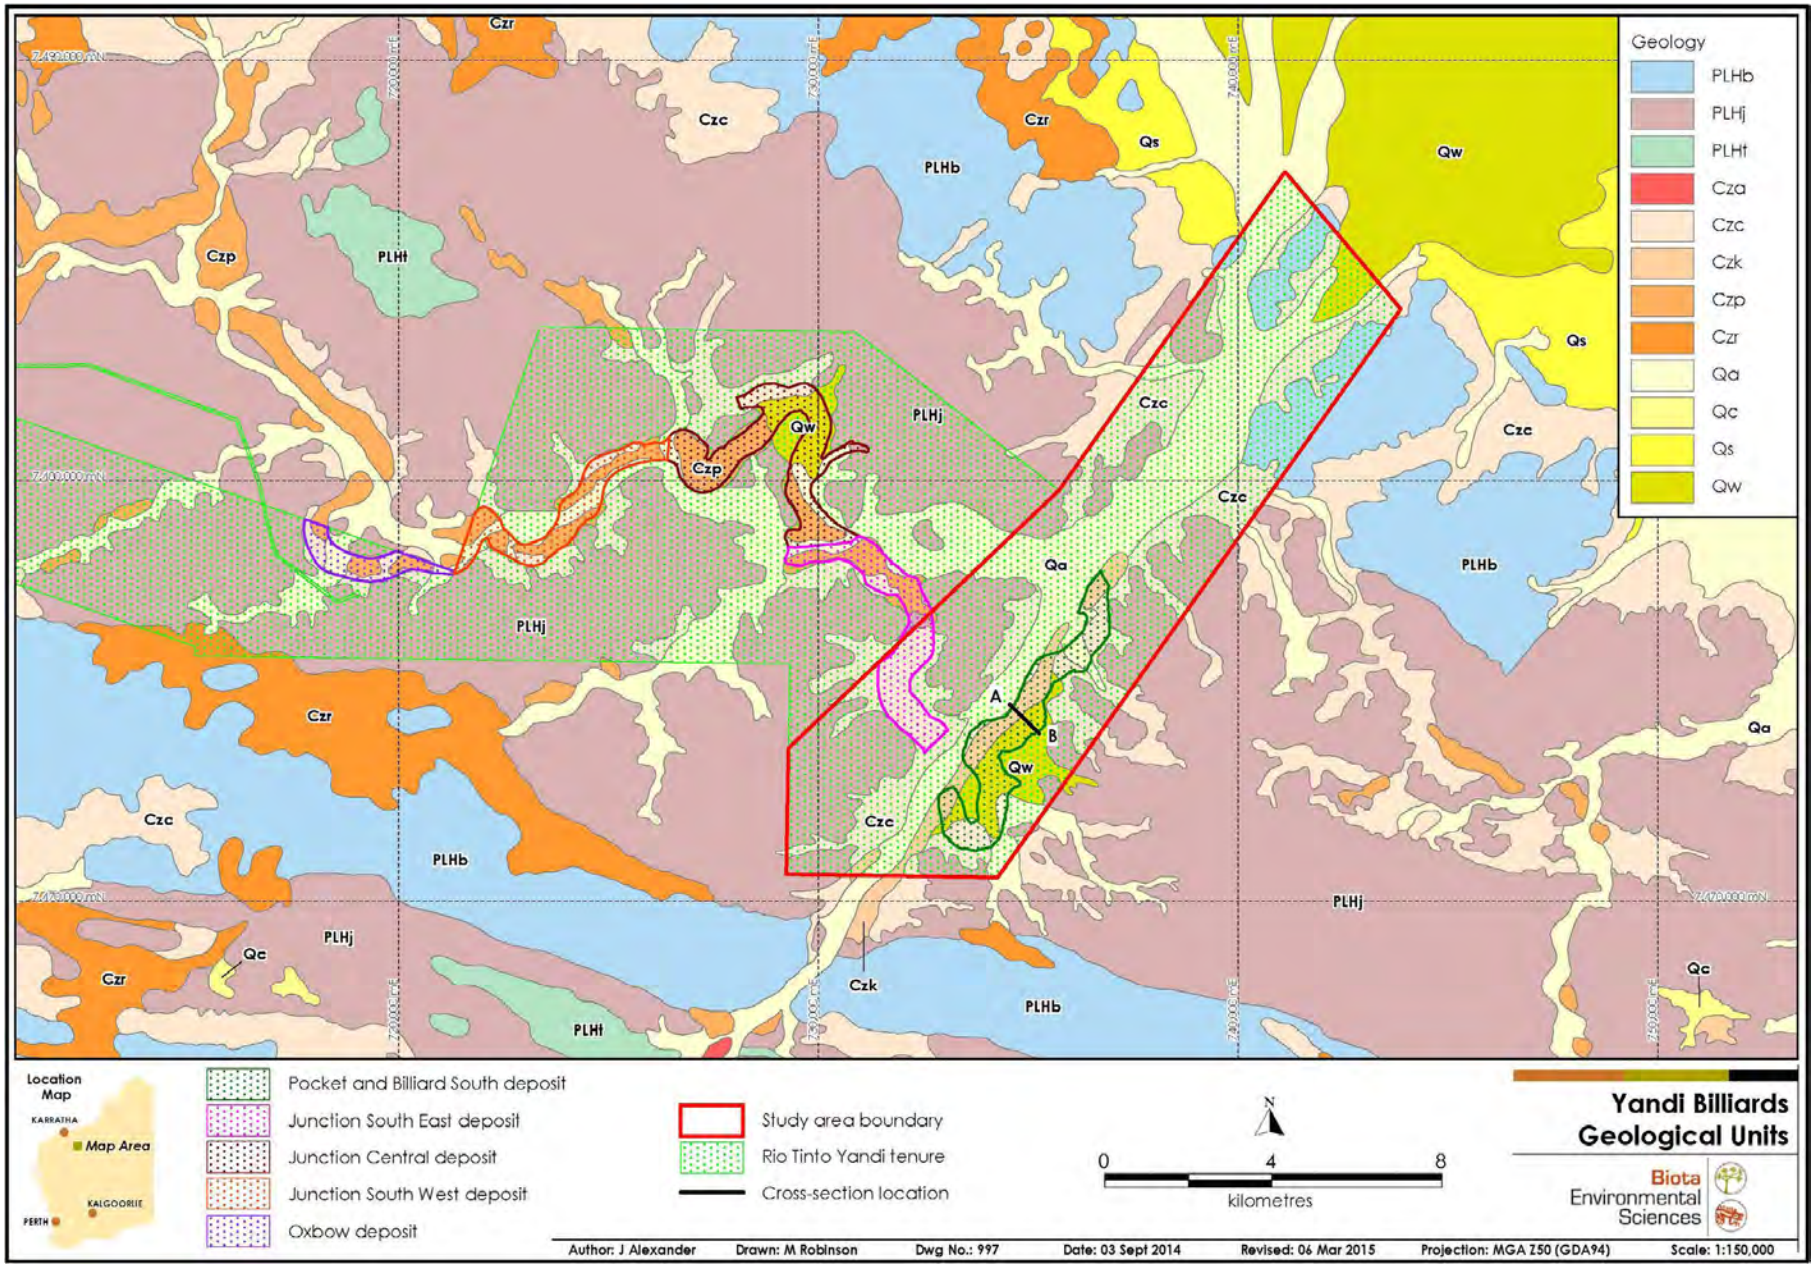

Figure 4.1: Geological units of the study area (see Table 4.1 for unit codes and descriptions).

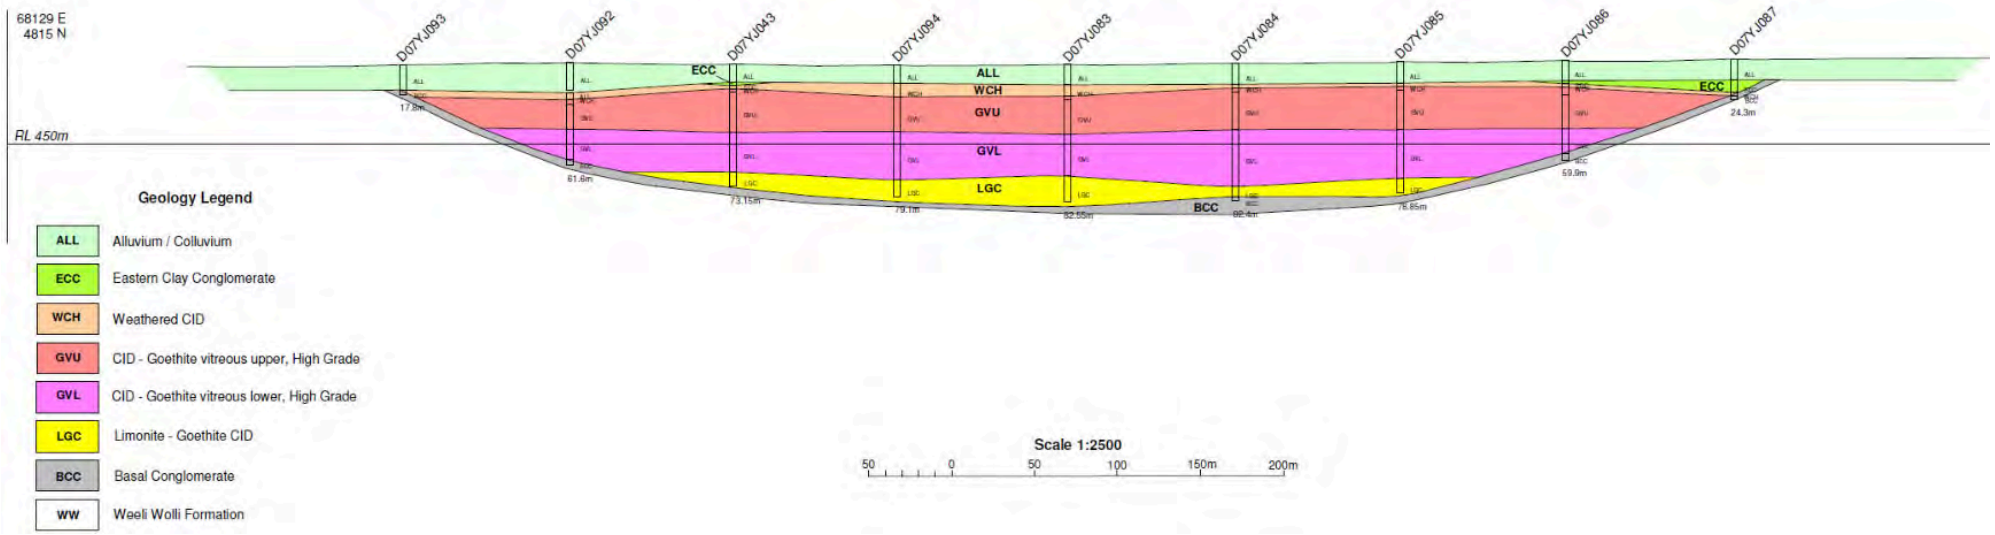

Figure 4.2: Cross-section of the PBS deposit (figure supplied by Rio Tinto).

The prospectivity of the various geological units present for troglobitic fauna is outlined in Table 4.1 based on findings of past surveys in the region. Troglobitic fauna have previously been recorded in low-lying alluvium and colluvium formations, including during extensive subterranean fauna sampling at the Bungaroo Valley (Biota 2013a). Previously completed studies have determined that troglobitic fauna potentially occur in areas where superficial alluvium and colluvium are common (Robe Headwaters, Western Hill, Mt Ella and Arrowhead; Biota 2013c). Calcrete also represents a known habitat for troglofauna as, like karst systems, provides large cavities required for movement and dispersal (Biota 2009a, 2011d, 2013c).

The geological units on the higher elevation margins of the study area include Brockman Iron formation and Weeli Wolli formation (Figure 4.1), both of which contain Banded Iron Formation (BIF) and have the potential to contain habitat for troglofauna. Brockman Iron formation, in particular, has yielded troglobitic fauna records, including in settings where adjacent to or overlain by alluvium or colluvium during various studies throughout the Pilbara, including Koodaideri, Hope Downs 4 and West Turner Syncline (Biota 2009b, 2014a, 2014b). Troglofauna habitat within these formations predominantly appears to be associated with hydrated zones, where the interaction of downward percolating groundwater and a fluctuating water table leads to cavities habitable by subterranean fauna. Hydrated zones in BIF have been identified as potential troglofauna habitat in at Koodaideri, Hope Downs 1 (Biota 2006c) and 4 (Biota 2009b) and Marandoo (Biota 2008). Hydrated zones also occur in contact with more superficial colluvial deposits (Biota 2014a), which may facilitate movement between geological units.

5.0 Survey Results

5.1 Phase 1 / Stygofauna By-Catch - Results Overview

Four specimens of troglofauna were collected using stygofauna haul nets in 2008 and 2009 (Section 2.3) throughout the wider Yandi tenure. No troglofauna were recorded from Phase 1 of troglofauna colonisation trap sampling in 2009.

Table 5.1: Summary of potential troglobitic fauna recorded as by-catch from stygofauna haul nets from the wider Yandi study tenure

Taxon			Total Individuals	Notes
Subphylum	Class	Order (Common Name)		
Chelicerata	Arachnida	Aranea (Spider)	1	Collected during stygofauna sampling in 2009.
		Pseudoscorpiones (Pseudoscorpion)	1	Collected from site MNEW1upstream, in the JSW tenement. Collected in 2009.
		Schizomida (Schizomid)	1	Collected during stygofauna sampling in 2008. Specimen partially decayed.
Uniramia	Pauropoda	Pauropod (Pauropods)	1	Collected from habitat trap in 2009
		Total	4	

Note that while polyxenid millipedes were historically collected from the area and thought to display short-range endemism, recent evidence has indicated that members of this order in the Pilbara are not SREs and are therefore not likely to be troglobites (Biota and Helix 2011). Therefore, past records of Polyxenida have not been considered as troglobitic for the purposes of this report.

5.2 Phase 2 - Results Overview

A total of 1,850 specimens were collected from troglofauna colonisation traps in 2014 (Appendix 3). As is common in troglobitic fauna sampling, many of the specimens collected were not troglobitic, but were surface (epigean) or soil (edaphobitic) fauna. This included Acarina (mites), Collembola (springtails), Diptera (flies) and Psocoptera (Booklice) (Berry 2005, Biota 2006a, 2010b). These groups are not considered at high risk of limited species distributions and are therefore at a reduced risk of impact to their conservation status from developments. For the purposes of this report no further consideration is given to these groups.

Two specimens of troglobitic fauna were collected from the Billiards Study area in 2014. These specimens represent two classes, Arachnida (order Schizomida) and Insecta (order Coleoptera). Both specimens were recorded from the north of the study area (Figure 5.2).

Table 5.2: Summary of collections from recent sampling at the Billiards study area.

Taxon			Total Individuals	Site
Subphylum	Class	Order (Common Name)		
Chelicerata	Arachnida	Schizomida (Schizomid)	1	RC13YBR0038
Uniramia	Insecta	Coleoptera (Beetle)	1	RC13YBR0037
		Total	2	

5.3 Account of Troglobitic Fauna

5.3.1 Order: Araneae (Spiders)

A single mature, female spider specimen was collected from sample site WW2 while sampling for stygofauna in April 2009 (Figure 5.2). This specimen was identified as a previously undescribed taxon (M. Harvey, W.A. Museum, pers. comm. 2009) belonging to the genus *Myrmopopaea* (*Myrmopopaea* sp. nov.).

5.3.2 Order: Coleoptera (Beetles)

A single specimen of troglobitic beetle was collected in 2014 (Plate 5.1). This specimen was recorded from site RC13YBR0037 (Figure 5.2). The specimen, belonging to the subfamily Pselaphinae (Family: Staphylinidae), was unable to be identified morphologically to species level due to a lack in taxonomic framework on the group. Pselaphinae specimens have been recorded from caves, leaf litter and ant nests and the group is very diverse in the tropics (Brian Hanich, W.A. Museum, pers. comm. 2014).

It is currently unclear if this specimen represents a troglobitic or SRE species, or is troglophilic and likely not to display restricted distribution at species level. This specimen has residual eyes which may indicate a recent adaptation to subterranean environment, or that this species inhabits both subterranean and surface environments (i.e. a trogloxene).

Prior studies completed on Coleoptera specimens from the Kimberley region in Western Australia indicates that these specimens have the potential to display short range endemism (Helix 2011).

Plate 5.1: Pselaphinae sp. indet. collected from site RC13YBR0037 at Billiards study area, dorsal (above) and lateral (below) view.

5.3.3 Order: Pauropoda (Pauropods)

These arthropods are rarely collected and the Western Australian Museum collection has only a handful of specimens from widely scattered locations (Framenau and Harvey 2009). A single pauropod specimen was collected from sample site D07YJ218, within the PBS deposit (Figure 5.2).

The status of specimen from Yandi is uncertain. It is possible that some pauropod species in Western Australian represent SRE species, but other pauropod species are widely distributed around the world, suggesting that short- range endemism is not prevalent in this group (Scheller 1960). A full taxonomic treatment of the Western Australian specimens is necessary by a specialist before their status can be properly assessed.

5.3.4 Order: Pseudoscorpiones (Pseudoscorpions)

A single troglobitic pseudoscorpion specimen belonging to the genus *Lagynochthonius* was collected from alluvial substrate at site MNEW1upstream. This mature, male specimen (*Lagynochthonius* sp. nov) is a new species collected from the JSW tenement (Figure 5.2), and is thought to represent an SRE taxon (M. Harvey, W.A. Museum, pers. comm. 2009). Further specimens would be beneficial prior to the formal description of this species.

5.3.5 Order: Schizomida (Schizomids)

Two specimens of the order Schizomida have been collected from the Billiards study area (Table 5.3, Figure 5.2). The first specimen, collected in 2008 via stygofauna haul net, was unable to be identified morphologically past genus level due to specimen degradation. Given the level of degradation, genetic analysis was also not feasible. The specimen, recorded from site WW3 within the PBS deposit, was identified as belonging to the genus *Draculoides*.

The second, juvenile schizomid specimen, collected via habitat trap in 2014, was identified to *Draculoides* sp. however again was unable to be identified further morphologically (Plate 5.2). This specimen was forwarded onto Helix for molecular analysis. This analysis placed the collected specimen in genetic lineage WWS1 (Table 5.3), distinct from reference specimens, indicating that this lineage represents a species currently unrecorded (genetically) from the Pilbara (Figure 5.1). This specimen was recorded from a reference site, RC13YBR0038, outside the PBS deposit (Figure 5.2).

Table 5.3: Summary of Schizomida collections and identification at Billiards study area.

Taxonomy			Number Collected	Site
Order	Family	Identification / Genetic Lineage		
Schizomida	Hubbardiidae	*Draculoides* sp. 'Lineage WWS1'	1	RC13YBR0038
		Draculoides sp. indet	1	WW3
		Total	2	

Plate 5.2: *Draculoides* sp. 'Lineage WWS1' collected from site RC13YBR0038 at Billiards study area, dorsal (above) and lateral (below) view.

Lineage WWS1 differed from other specimens included in the genetic analysis by between 10.2 % and 15.3 % genetic divergence (Appendix 2). Lowest sequence divergence occurred between the Yandi specimen and nearby Koodaideri specimens (between 10.2 – 10.7 % divergence) (Figure 5.1), indicating that these species share a common ancestor.

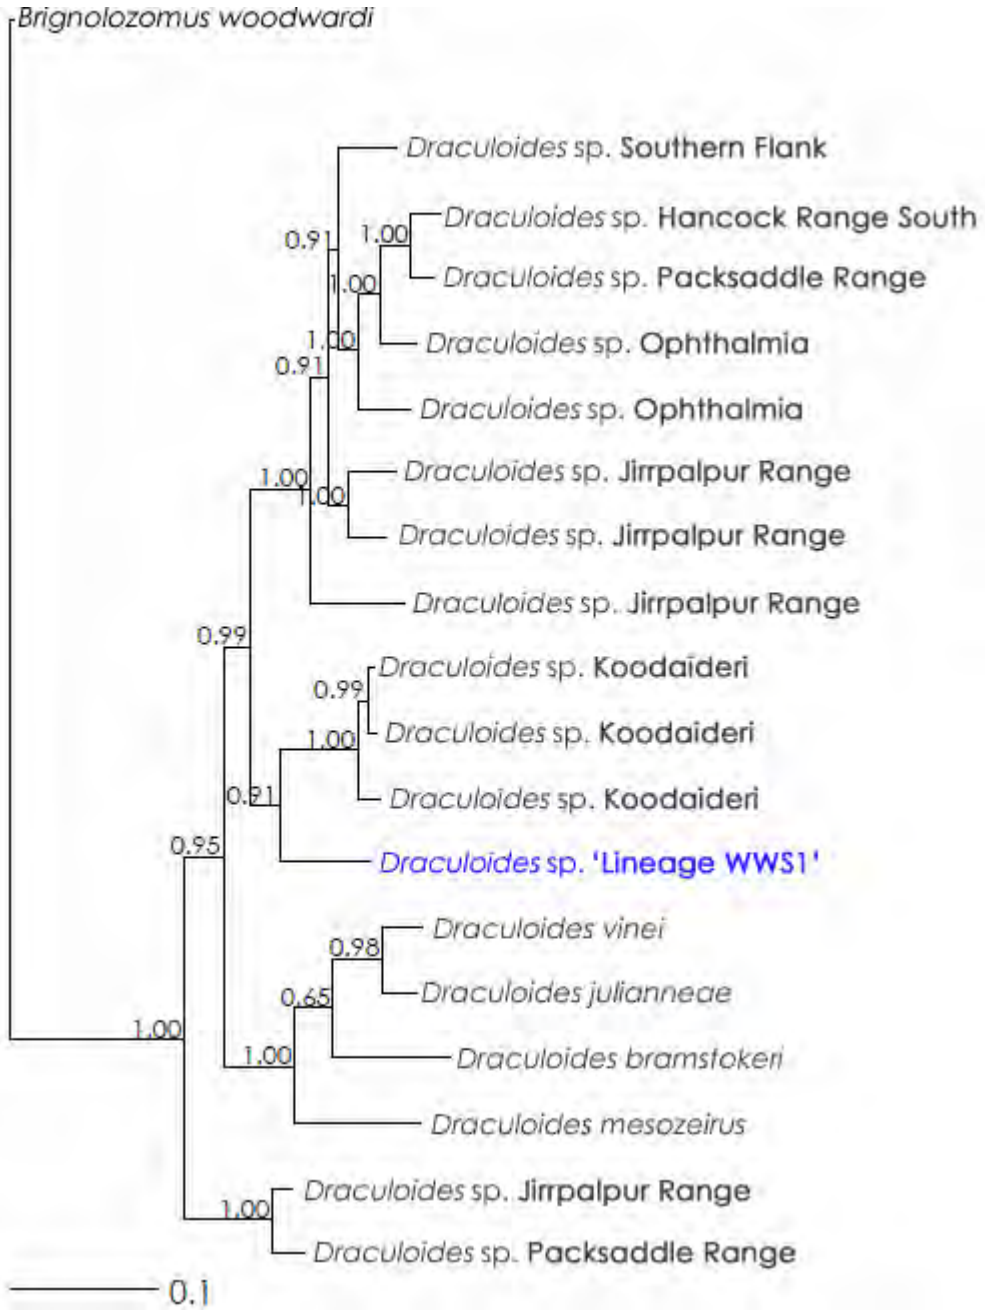

Figure 5.1: Phylogenetic tree based on Bayesian analysis of CO1 haplotypes of recorded Yandi Schizomida, and reference data from the Pilbara region.
(Yandi specimen labelled blue, specimens from other localities labelled black)

6.0 Discussion

6.1 Conservation Significance

Six potential troglobites have been recorded from the wider Yandi tenure over two phases of troglofauna sampling and 13 stygofauna surveys, all represented by single specimens. Five of these were recorded within the current Billiards study area (Table 6.1). Four are confirmed troglobites with the ecological status of the remaining two specimens unconfirmed. Additional specimens and wider spatial scale molecular analysis would be necessary to better determine species-level distribution and thereby further infer dispersal characteristics. Table 6.1 provides a summary of the taxa recorded, their likely conservation significance and notes on the geological units from which they were collected.

Table 6.1: Conservation significance of specimens from the Yandi area.

Specimen	Conservation Significance	Notes
Myrmopopaea sp. nov.	Confirmed troglobitic / SRE species	Recorded from calcrete, site WW2, within the boundary of the PBS deposit. Limited distribution but may not be restricted to this geological unit.
Pselaphinae sp. indet.	Troglobitic status unconfirmed.	Recorded from colluvium, site RC13YBR0037 outside the PBS deposit within the study area. Distribution unknown.
Pauropoda sp. indet.	Troglobitic status unconfirmed.	Recorded from calcrete, site D07YJ218, outside of the PBS deposit within the study area. Distribution unknown.
Lagynochthonius sp. nov.	Confirmed troglobitic / SRE species	Recorded from alluvium at MNEW1upstream at the JSW tenement (Figure 5.2). Likely to be of limited distribution.
Draculoides sp. 'Lineage WWS1'	Confirmed troglobitic / SRE species	Recorded from colluvium, site RC13YBR0038, outside the PBS deposit within the study area. Likely to be of limited distribution.
Draculoides sp. indet.	Confirmed troglobitic / SRE species	Recorded from calcrete, site WW3, outside the boundary of the PBS deposit. Likely to be of limited distribution but molecular and morphological analysis not possible. Specimen potentially belongs to *Draculoides* sp. 'Lineage WWS1'.

Lagynochthonius sp. nov. was recorded from JSW area adjacent to Marillana Creek and is not directly relevant to the current Billiards troglofauna environmental assessment. Of the five specimens recorded from the Billiards study area, four were recorded from sites outside the PBS deposit (*Draculoides* sp. 'Lineage WWS1', *Draculoides* sp. indet., Coleoptera sp. indet. and Pauropoda sp. indet; Table 6.1). It should be noted however that *Draculoides* sp. indet and Pauropoda sp. indet. were recorded from sites less than 50 m from the deposit boundary and may therefore still be affected by the proposed mining operations. These impacts, while not resulting in direct loss of habitat, could include secondary tier ecological changes due to clearing and mining infrastructure (water, nutrient and sediment infiltration) and alterations to the aquifer due to dewatering, which may alter the frequency and level of habitat inundation.

The remaining taxon, *Myrmopopaea* sp. nov., has been recorded only from within the PBS deposit and was collected from calcrete habitat (see Section 6.2).

6.2 Troglofauna Habitat in the Study Area

The majority of the troglofauna specimens recorded at Yandi have been collected from shallow alluvium, colluvium and calcrete drill holes with less than 10 m to water table. The surface geology units therefore generally characterise the habitats that the fauna were using at that time, given that other geological formations at depth were below water table.

All troglofauna specimens were recorded from three surface geological units, Alluvium (Qa), Colluvium (Czc) and Calcrete (Czk) (Section 4.0, Figure 6.1) and these represent habitats that the

fauna currently utilise within the Billiards study area. It should be noted, however, that the unconsolidated alluvium, colluvium and calcrete geological units, which lie adjacent Weeli Wolli Creek, are subject to seasonal inundation. This process of seasonal flooding may periodically render areas of habitat unsuitable for use by troglofauna. Brockman Iron and Weeli Wolli formations, which adjoin the alluvium, colluvium and calcrete, form part of higher elevation landforms and may act as refuge from inundation, potentially representing core troglofauna habitat over longer timeframes. Brockman Iron formation, in particular, has recorded troglobitic fauna in hydrated zones at Koodaideri and other locations in the bioregion (Biota 2014a).

At present it is therefore unclear what constitutes the longer-term core habitat for troglobitic animals in the study area, but the fauna does occur at apparently low density in relatively recent and lower elevation valley-fill and alluvial units.

The species, *Myrmopopaea* sp. nov., while recorded only from within the impact area of the deposit, was recorded from a surface geology unit which is effectively continuous throughout the Billiards study area and adjacent areas (Figure 6.1). This calcrete habitat contains sufficient inter-connected interstitial spaces and cavities to allow movement of troglobitic fauna and this suggests the risk of the species being restricted at small spatial scale would be relatively low.

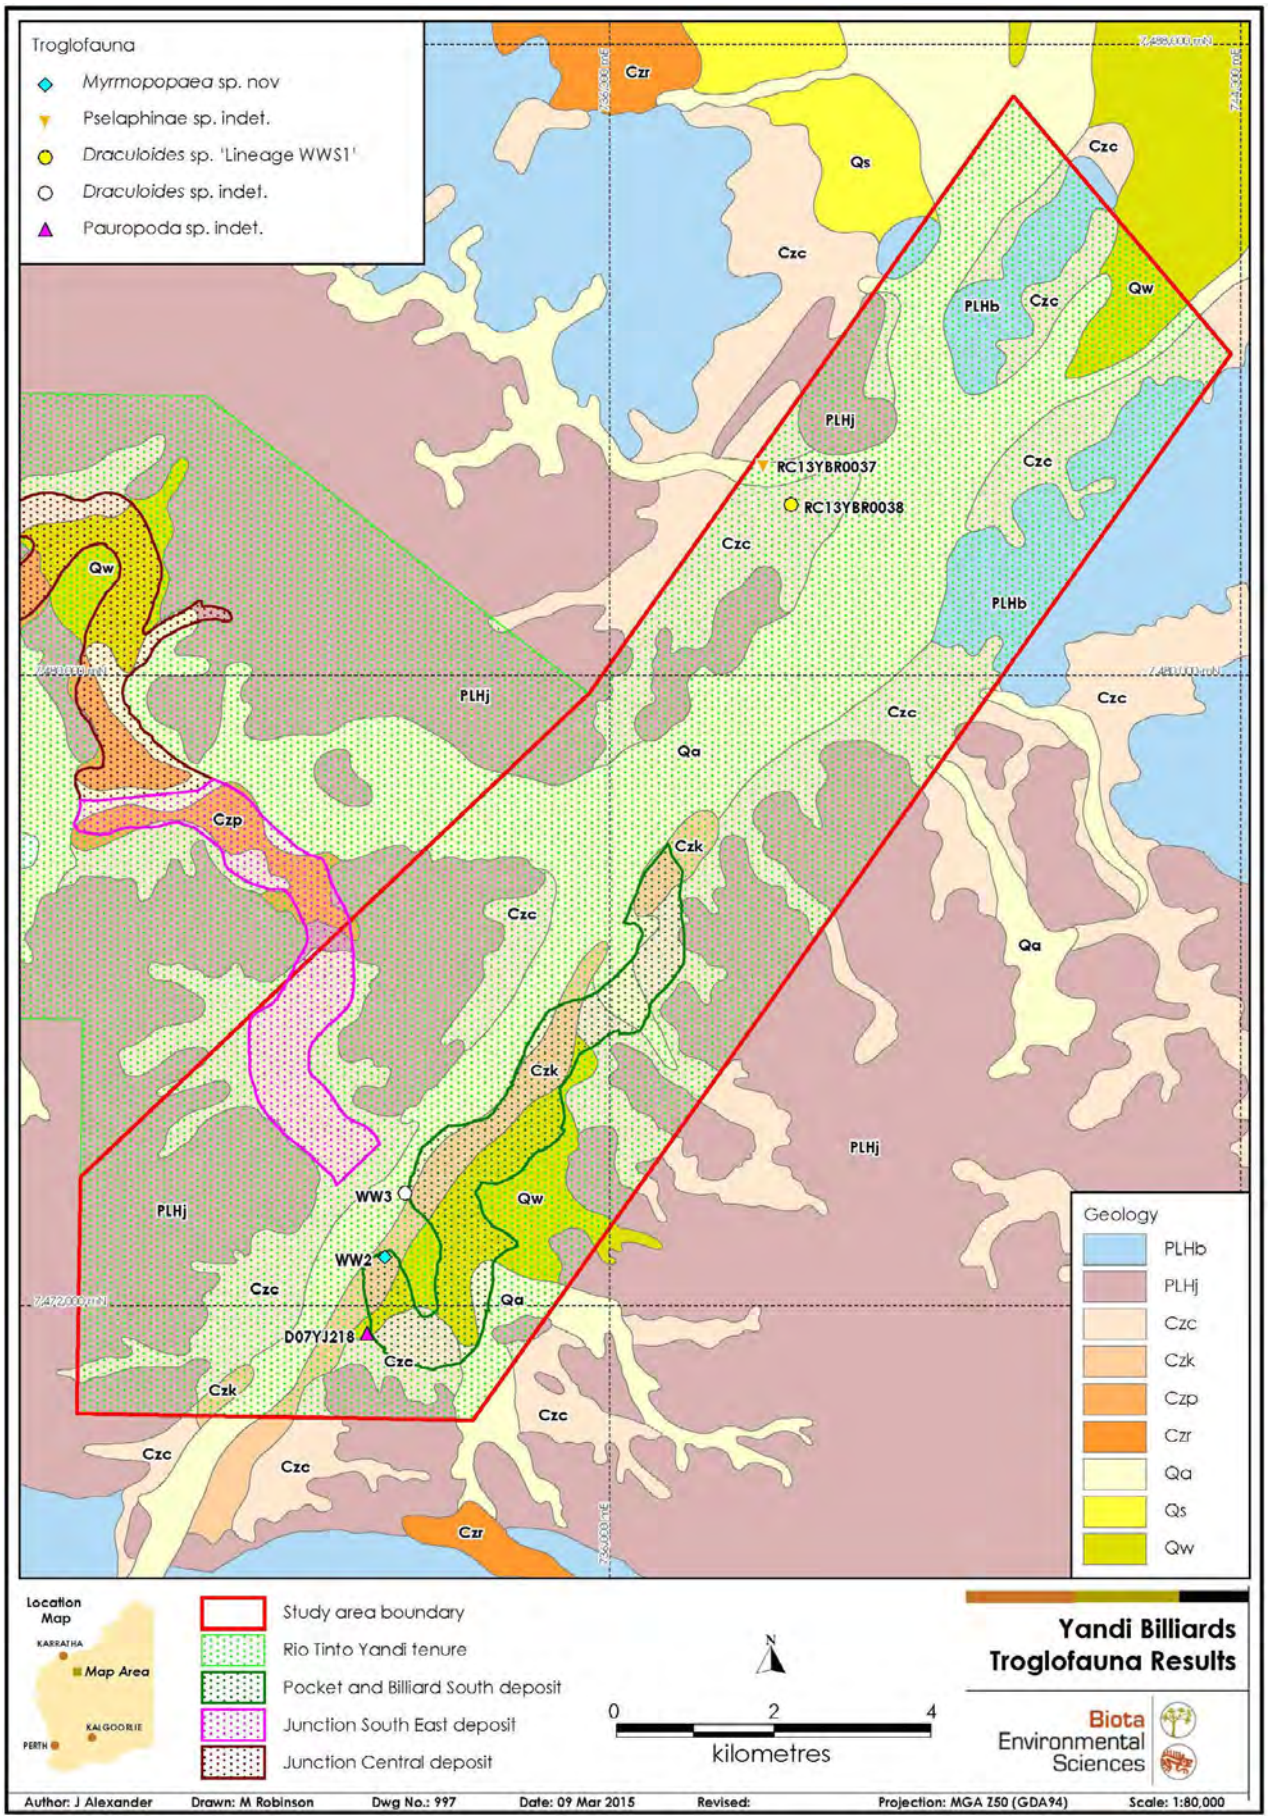

Figure 6.1: Troglofauna records from the Billiards study area in relation to surface geology.

This page intentionally blank.

7.0 Glossary

Edaphobitic / Edaphobite	Soil dwelling fauna that can often display troglomorphic characteristics. Edaphobites are unlikely to have limited distributions and therefore unlikely to be classified as short-range endemics.
EPA	Environmental Protection Authority.
Haplotype	A group of alleles of different genes on a single chromosome that are closely enough linked to be inherited, usually as a unit.
Interstices	An opening or space, especially a small or narrow one between mineral grains in a rock or within sediments or soil.
Karst	Soluble-rock landscape; terrain with distinctive hydrology and landforms arising from a combination of high rock solubility and well-developed secondary porosity (Goodall et al. 2000).
Short-Range Endemic (SRE)	A species that has a naturally small distribution and is often characterised by having poor dispersal capabilities, confinement to disjunct habitats and low fecundity.
Taxonomy	Theory and practice of biological classification.
Troglomorphic	Pertaining to morphological, behavioural and physiological characters that are convergent in subterranean populations (Christiansen 1962).
Troglophilic / Troglophile	Species able to live and reproduce underground as well as in the epigean environment (Goodall et al. 2000).
Troglobite / Troglofauna	Species living obligatory in caves; also blind, depigmented and often having an elongate body morphology.
Trogloxene	Organisms that can come and go from a cave environment but use it during certain periods of their life cycles, such as nesting and hibernation.
Stygobite / Stygofauna	Obligate groundwater fauna.

This page intentionally blank.

WILDLIFE CONSERVATION ACT 1950
REGULATION 17

LICENCE TO TAKE FAUNA FOR SCIENTIFIC PURPOSES

THE UNDERMENTIONED PERSON MAY TAKE FAUNA FOR RESEARCH OR OTHER SCIENTIFIC PURPOSES AND WHERE AUTHORISED, KEEP IT IN CAPTIVITY, SUBJECT TO THE FOLLOWING AND ATTACHED CONDITIONS, WHICH MAY BE ADDED TO, SUSPENDED OR OTHERWISE VARIED AS CONSIDERED FIT.

DIRECTOR GENERAL

CONDITIONS

1 THE LICENSEE SHALL COMPLY WITH THE PROVISIONS OF THE WILDLIFE CONSERVATION ACT AND REGULATIONS AND ANY NOTICES IN FORCE UNDER THIS ACT AND REGULATIONS.

2 UNLESS SPECIFICALLY AUTHORISED IN THE CONDITIONS OF THIS LICENCE OR OTHERWISE IN WRITING BY THE DIRECTOR GENERAL, SPECIES OF FAUNA DECLARED AS LIKELY TO BECOME EXTINCT, RARE OR OTHERWISE IN NEED OF SPECIAL PROTECTION SHALL NOT BE CAPTURED OR OTHERWISE TAKEN.

3 NO FAUNA SHALL BE TAKEN FROM ANY NATURE RESERVE, WILDLIFE SANCTUARY, NATIONAL PARK, MARINE PARK, TIMBER RESERVE OR STATE FOREST WITHOUT PRIOR WRITTEN APPROVAL OF THE DIRECTOR GENERAL. NO FAUNA SHALL BE TAKEN FROM ANY OTHER PUBLIC LAND WITHOUT THE WRITTEN APPROVAL OF THE GOVERNMENT AUTHORITY MANAGING THAT LAND.

4 NO ENTRY OR COLLECTION OF FAUNA TO BE UNDERTAKEN ON ANY PRIVATE PROPERTY OR PASTORAL LEASE WITHOUT THE CONSENT IN WRITING OF THE OWNER OR OCCUPIER, OR FROM ANY ABORIGINAL RESERVE WITHOUT THE WRITTEN APPROVAL OF THE DEPARTMENT OF INDIGENOUS AFFAIRS.

5 NO FAUNA OR THEIR PROGENY SHALL BE RELEASED IN ANY AREA WHERE IT DOES NOT NATURALLY OCCUR, NOR BE HANDED OVER TO ANY OTHER PERSON OR AUTHORITY UNLESS APPROVED BY THE DIRECTOR GENERAL, NOR SHALL THE REMAINS OF SUCH FAUNA BE DISPOSED OF IN SUCH MANNER AS TO CONFUSE THE NATURAL OR PRESENT DAY DISTRIBUTION OF THE SPECIES.

6 THIS LICENCE AND THE WRITTEN PERMISSION REFERRED TO AT CONDITIONS 3 & 4 MUST BE CARRIED BY THE LICENSEE OR AUTHORISED AGENT AT ALL TIMES FOR THE PURPOSE OF PROVING THEIR AUTHORITY TO TAKE FAUNA WHEN QUESTIONED AS TO THEIR RIGHT TO DO SO BY A WILDLIFE OFFICER, ANY OTHER STATE OR LOCAL GOVERNMENT EMPLOYEE OR ANY MEMBER OF THE PUBLIC.

7 **********ANY INTERACTION INVOLVING GAZETTED THREATENED FAUNA THAT MAY BE HARMFUL AND/OR INVASIVE MAY REQUIRE APPROVAL FROM THE DEPT OF SUSTAINABILITY, ENVIRONMENT, WATER, POPULATION & COMMUNITIES PH 02 6274 1111. INTERACTION WITH SUCH SPECIES IS CONTROLLED BY THE COMMONWEALTH GOVERNMENT'S "ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION ACT 1999" & "ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION REGULATIONS 2000" AS WELL AS DPaW'S WILDLIFE CONSERVATION ACT & REGULATIONS.**********

8 NO BIOPROSPECTING INVOLVING THE REMOVAL OF SAMPLE AQUATIC AND TERRESTRIAL ORGANISMS (BOTH FLORA AND FAUNA) FOR CHEMICAL EXTRACTION AND BIOACTIVITY SCREENING IS PERMITTED TO BE CONDUCTED WITHOUT SPECIFIC WRITTEN APPROVAL BY THE DIRECTOR GENERAL OF DPaW.

9 FURTHER CONDITIONS (NUMBERED 1 TO 9) ARE ATTACHED.

PURPOSE SUBTERRANEAN FAUNA SURVEY TARGETING STYGOFAUNA AND TROGLOFAUNA, USING MODIFIED PLANKTON HAUL NETS IN 30 EXISTING DRILL HOLES AND HABITAT TRAPS FILLED WITH LEAF LITTER AT THE YANDI BILLIARDS PROJECT AREA, 90KM NORTHWEST OF NEWMAN, FOR RIO TINTO. SPECIMENS TO BE LODGED WITH THE WA MUSEUM.

WILDLIFE CONSERVATION REGULATIONS 1970

Regulation 17:- Licence to Take Fauna for Scientific Purposes

FURTHER CONDITIONS (OF LICENCE NUMBER SF00 9624)

1. The licensee shall take fauna only in the manner stated on the endorsed Regulation 17 licence application form and endorsed related correspondence.

2. Except in the case of approved lethal traps, the licensee shall ensure that measures are taken in the capture and handling of fauna to prevent injury or mortality resulting from that capture or handling. Where traps or other mechanical means or devices are used to capture fauna these shall be deployed so as to prevent exposure of trapped animals to ants and debilitating weather conditions and inspected at regular intervals throughout each day of their use. At the conclusion of research all markers etc and signs erected by the licensee and all traps shall be removed, all pitfalls shall be refilled or capped and the study area returned to the condition it was in prior to the research/capture program. During any break in research, cage traps should be removed and pitfalls either removed, capped or filled with sand.

3. No collecting is to be undertaken in areas where it would impinge on pre-existing scientific research programs.

4. Any form of colour marking of birds or bats shall only be undertaken in accordance with the requirements of the Australian Bird and Bat Banding Scheme.

5. Any inadvertently captured specimen of fauna which is declared as likely to become extinct, rare or otherwise in need of special protection is to be released immediately at the point of capture. Where such a specimen is injured or deceased, the licensee shall contact Department of Parks and Wildlife licensing staff at Kensington (08 9219 9831) for advice on disposal. Records are to be kept of any fauna so captured and details included in the report required under further condition 6 below.

6. Within one month of the expiration of this licence, the holder shall submit an electronic return detailing the locality, site, geocode, date and number of each species captured, sighted or vouchered during the currency of the licence, into the Department of Parks and Wildlife Fauna Survey Database (FSD). A copy of any paper, report or thesis resulting from the research shall on completion be lodged with the Director General. If a renewal of this licence is required, the licensee shall submit a written progress report for activities undertaken during this licence period prior to the expiry of this licence.

7. Not more than ten specimens of any one protected species shall be taken and removed from any location less than 20km apart. Where exceptional circumstances make it necessary to take large series in order to obtain adequate statistical data the collector will proceed with circumspection and justify their actions to the Director General in advance.

8. All holotypes and syntypes and a half share of paratypes of species or subspecies permitted to be permanently taken under this licence shall be donated to the Western Australian Museum. Duplicates (one pair in each case) of any species collected which represents a significant extension of geographic range shall be donated on request to the Western Australian Museum.

9. To prevent any unnecessary collecting in this State, all specimens and material collected under the authority of this license shall, on request, be loaned to the Western Australian Museum. Also, the unused portion or portions of any specimen collected under the authority of this license shall be offered for donation to the Western Australian Museum or made available to other scientific workers if so required.

Re. Report on the molecular systematics of Amphipoda and Schizomida from the Weeli Wolli region

Dear Jason,

Following is a summary of the results of the Paramelitidae and Schizomida study we have completed. Owing to the observed level of sequence divergence between lineages and comparison to reference sequences, it is likely that there are four species of Paramelitidae in your collections. Three of those species have been detected or described previously at Munjina and Marillana and Weeli Wolli Creeks, whereas one appears to be new, based on the material available for comparison. The one specimen of Schizomida you provided appears to be a new species that has not yet been detected in the Pilbara, based on the material available for comparison.

Sincerely,

Dr. Terrie Finston and Dr. Oliver Berry
Helix Molecular Solutions

Paramelitidae

Background

The groundwater amphipod fauna of Western Australia is diverse. Since 1995, 27 species of amphipods have been described from north-western Western Australia, including the Pilbara and nearby Barrow Island and Cape Range Peninsula (Barnard and Williams 1995; Bradbury and Williams 1996, 1997a; Bradbury 2000; Finston *et al*., 2008). The majority of these species (19) belong to the family Paramelitidae. Extensive molecular work has been conducted on the amphipod fauna of Western Australia (Helix, 2011). The resulting dataset provides a molecular framework that can be used to provide a regional context for localised sampling. The present study concerns 89 specimens of Amphipoda belonging to the family Paramelitidae from the Weeli Wolli catchment in the Pilbara.

Objective

Eighty-nine specimens of Paramelitidae from the Weeli Wolli catchment in the Pilbara were sequenced for variation at the mitochondrial gene COI. The specimens were compared to reference sequences of Paramelitidae from the Pilbara to estimate the number of species in the collection and determine the relationships of the new samples to specimens previously collected in the Pilbara.

Executive summary

- Eighty-nine specimens of Paramelitidae from the Weeli Wolli catchment in the Pilbara were sequenced for variation at the mitochondrial gene COI.
- Fifty-four of the 89 specimens yielded a COI sequence; many of the specimens were old and did not yield high-quality DNA.
- A neighbour-joining analysis, which included the 54 specimens analysed here, revealed the presence of four distinct genetic lineages, which represent four species.
- Representatives of each of the four species detected at Weeli Wolli were included in a second phylogenetic analysis, which included 49 reference specimens of Paramelitidae from sites in the Pilbara and voucher sequences of Paramelitidae from the international DNA sequence database GenBank.
- Three of the four species have been detected or described previously at Munjina and Marillana and Weeli Wolli Creeks, whereas one appears to be new, based on the material available for comparison.

Methods

Eighty-nine specimens of Paramelitidae from the Weeli Wolli area in the Pilbara were sequenced for variation at the mitochondrial gene cytochrome oxidase subunit I (COI; Table 1). Primers LCO1490 and HCO2198 (Folmer et al., 1994) were used to amplify a ~700 bp fragment of COI. The specimens were collected between 2008 and 2011 and were examined morphologically and assigned to the lowest taxonomic level possible (J. Alexander, pers. comm.).

Sequences were edited using SEQUENCHER software (Gene Codes Corporation, Ann Arbor, MI, USA). Alignment was performed with CLUSTAL W (Thompson *et al*. 1994) using default parameters. To test that the amplified sequences were the target mtDNA, sequences were translated into proteins and checked for the presence of stop codons. Genetic distances between unique genetic sequences (haplotypes) were measured using uncorrected p-distances (total percentage of nucleotides different between sequences).

To reduce analysis time, a preliminary neighbour-joining analysis was run to identify the number of distinct genetic lineages among the 54 specimens. Specimens from each of the lineages were included in a second model-based phylogenetic analysis, which included 49 reference specimens of Paramelitidae from sites in the Pilbara within and outside the study area and voucher sequences of Paramelitidae from the international DNA sequence database Genbank.

MODELTEST software (Posada and Crandall, 1998) was used to determine the model of sequence evolution that best fitted the data. Bayesian analysis was used to construct the phylogenetic tree, incorporating the General Time Reversible (GTR+G) model as identified in MODELTEST. The phylogeny, branch lengths and posterior probabilities were obtained by

running two trees simultaneously, each running four simultaneous MCMC chains. The number of cycles needed was determined by the standard deviation of the split frequencies of the two trees. The analysis was paused after every 1 x 10^6 generations and when the standard deviation fell below 0.01, the analysis was stopped. A majority rule consensus tree was constructed after discarding the first 5000 ("burn-in") trees. The burn-in value was assessed by plotting the posterior probabilities obtained after every generation and identifying the point at which the values reach stationarity (= the asymptote). Trees produced prior to stationarity were discarded. Forty-nine specimens of Paramelitidae from the Pilbara were included in the phylogenetic analysis as references, eight of which are lodged with the international DNA sequence database Genbank as follows: *Maarrka etheli* (Genbank accession # DQ838031), *Maarrka weeliwollii* (Genbank accession # DQ838032), *Yilgarus* sp. BES9348 (Genbank accession #EF118228), *Kruptus linnaei* (Genbank accession # GU111906), *Molina pleobranchos* (Genbank accession #DQ255962), *Chydaekata* sp. Marillana (Genbank accession # DQ255989), *Pilbarus millsi* (Genbank accession # DQ490126), *Chydaekata acuminata* (Genbank accession # DQ838024). The remaining 41 specimens were detected in previous surveys of the Pilbara (Helix, 2011). Two species from the Isopoda family Tainisopidae, *Pygolabis paraburdoo* (Genbank accession # EU107628) and *Pygolabis weeliwolli* (Genbank accession # EU107618) were used as outgroups.

Results

Fifty-four of the 89 specimens yielded a 533 to 727 bp fragment of COI (Table 1). The neighbour-joining analysis revealed the presence of four distinct genetic lineages (WWA1 – WWA4; Figure 1). The four lineages contained between one and 21 specimens (Table 1; Figure 1).Variation within the four lineages was low, averaging between 0.4 and 1.4% sequence divergence (Table 2). The four lineages differed from one another by between 18.0 and 20.5% mean sequence divergence (Table 3).

Representatives from each of the four lineages detected at Weeli Wolli were included in a model-based phylogenetic analysis with the 49 reference specimens. Two representatives were included from lineage WWA1 (WWA1a, WWA1b), to reflect the variation detected within the lineage (Figure 1). The representatives from WWA1, WWA2 and WWA4 were placed in lineages containing reference sequences from Munjina and Marillana and Weeli Wolli Creeks (Figure 2). Specifically, specimens GO29 and GO45 (representing lineage WWA1) were placed in a lineage containing specimen AM9 (Paramelitidae sp. 2C-WW), collected during a previous survey at Weeli Wolli Creek and specimen H28 from Marillana Creek (Figure 2). Specimen GO21 (representing lineage WWA2) was placed in a lineage with reference specimen 'camp a' (Paramelitidae sp. 'camp') from Marillana Creek as well as specimens from Munjina and Weeli Wolli Creek (Figure 2). Specimen GO42 (representing lineage WWA4) was placed in a lineage containing the reference specimen of *Chydaekata sp.* E from Marillana Creek (Figure 2). This species is also known from Weeli Wolli Creek (Finston et al., 2007).

The Weeli Wolli specimens that matched reference sequences (lineages WWA1, WWA2, WWA4) differed from their nearest reference sequence by between 0.0 and 3.8% sequence divergence (Figure 2; Table 4). The final specimen, lineage WWA3, which showed no close relationship to any of the reference sequences, differed from the reference sequences by between 19.7 and 25.9% sequence divergence (Table 4).

Conclusions

COI is considered by some authors to be a suitable gene for species delineation (Hebert *et al*., 2003a). Based on comparisons between over 1700 crustacean species, Hebert *et al* (2003b) found an average of 15.4 % sequence divergence between species pairs, with nearly 82% of pair-wise comparisons showing greater than 8% sequence divergence. Similar to the Hebert *et al*. (2003b) results, Bradford *et al* (2010) found 11-13% sequence divergence among three lineages of the Amphipoda family Chiltonidae in a single calcrete in the Yilgarn. Reproductive isolation between lineages was confirmed with nuclear (allozyme) markers, indicating that each lineage represented a distinct species.

Owing to the high level of sequence divergence between the four observed lineages in the Weeli Wolli collection (18.0 to 20.5%), it is likely that there are four species present. Three of the

four lineages showed close genetic relationships to reference specimens (0.0 to 3.8% sequence divergence), indicating that they belong to those species. The three were detected previously at Munjina and Marillana and Weeli Wolli Creeks. The fourth species showed no close relationship to any of the reference sequences and is likely to represent a new species. The four species present at Weeli Wolli are as follows:

1. lineage WWA1 =Paramelitidae sp. WW-2C; previously detected at Marillana and Weeli Wolli Creeks
2. lineage WWA2 =Paramelitidae sp. 'camp'; previously detected at Marillana Creek, Weeli Wolli, and Munjina
3. lineage WWA3 =new
4. lineage WWA4 =*Chydaekata sp. E*; previously detected at Marillana and Weeli Wolli Creeks

In summary, four species of Paramelitidae were detected at Weeli Wolli. Three of the species (lineages WWA1, WWA2, WWA4) have been described or recorded previously, whereas one (lineage WWA3) appears to be unrecorded based on the material available for comparison. High quality DNA could not be obtained from many of the specimens, likely due to their age and exposure to heat and light during morphological examination.

Schizomida

Executive summary

- A single specimen of *Draculoides* from Weeli Wolli was sequenced for the COI gene.
- The specimen was analysed with a reference data set of Schizomida from the Pilbara.
- In a phylogenetic analysis, the specimen was placed in a distinct genetic lineage that did not contain any other reference specimens.
- The Weeli Wolli specimen differed from the reference specimen by between 10.2 and 15.3% sequence divergence.
- Owing to the high level of sequence divergence between the Weeli Wolli specimen and the reference specimens, the Weeli Wolli specimen is likely to represent a new species of *Draculoides* that has not so far been detected in the Pilbara, based on the material available for comparison.

Methods

A single specimen of Schizomida from Weeli Wolli, identified on the basis of morphology as belonging to the genus *Draculoides* (Table 1) was sequenced for COI and compared to a reference collection of schizomids from the Pilbara in a similar manner to the Paramelitidae, with the following exceptions: the specimen from Weeli Wolli was included in a model-based phylogenetic analysis along with a sub-set of reference specimens of schizomids that were selected based on the criteria that they showed ≤ 15% sequence divergence from the new specimen. One hundred seventy-eight reference sequences were tested (including the four described species of *Draculoides*), and of those, 13 were detected that differed by ≤ 15% sequence divergence from the new Weeli Wolli specimen. The 13 individuals represented 11 distinct lineages (haplotypes of groups of closely related haplotypes that differ from other such groups by >3% sequence divergence) that are likely to represent 11 presumptive species. The four described species of *Draculoides* were also included in the phylogenetic analysis.

Results

The specimen of *Draculoides* from Weeli Wolli was placed in a distinct genetic lineage (WWS1) that did not contain any of the reference specimens (Figure 3). It formed a relatively well-supported clade with three specimens of *Draculoides* from Koodaideri (Figure 3).

The specimen of *Draculoides* from Weeli Wolli differed from the reference specimens by between 10.2 and 15.3% sequence divergence (Table 5). It differed from the closest reference specimens (three specimens from Koodaideri) by between 10.2 and 10.7% (Table 5).

Conclusions

Owing to the high level of sequence divergence between the new specimen from Weeli Wolli and the reference specimens (>10%), it is likely that the Weeli Wolli specimen belongs to a new species that has not yet been detected in the Pilbara, based on the material available for comparison. It does however appear to share a common ancestor with a species of *Draculoides* detected at Koodaideri.

Table 2. Mean sequence divergence and standard error (s.e.) between individuals within the four lineages of Paramelitidae detected in the Weeli Wolli specimens. n/c= not calculated because n=1 for the group.

lineage	D	S.E.
WWA1	0.014	0.003
WWA2	0.007	0.002
WWA3	n/c	n/c
WWA4	0.004	0.002

Table 3. Mean sequence divergence (below diagonal) and standard error (above diagonal) between the four lineages of Paramelitidae detected in the Weeli Wolli specimens.

Lineage	WWA1	WWA3	WWA4	WW5
WWA1		0.015	0.016	0.018
WWA2	0.186		0.015	0.018
WWA3	0.180	0.189		0.017
WWA4	0.205	0.205	0.202	

Table 4 (attached). Pair-wise sequence divergence (below diagonal) and standard error (above diagonal) between all Paramelitidae specimens used in the model-based phylogenetic analysis shown in Figure 2. Distances between the four lineages detected at Weeli Wolli and the reference specimens are highlighted in yellow.

Table 5. (attached). Pair-wise sequence divergence (below diagonal) and standard error (above diagonal) between all Schizomida specimens used in the model-based phylogenetic analysis shown in Figure 3. Distances between the species detected at Weeli Wolli and the reference specimens are highlighted in yellow.

Figure 1. Neighbour-joining analysis of 54 specimens of Amphipoda from Weeli Wolli. Numbers on nodes represent bootstrap support over 100 iterations. The four lineages are labelled WWA1 – WWA4. Specimens selected to represent each lineage are highlighted in yellow.

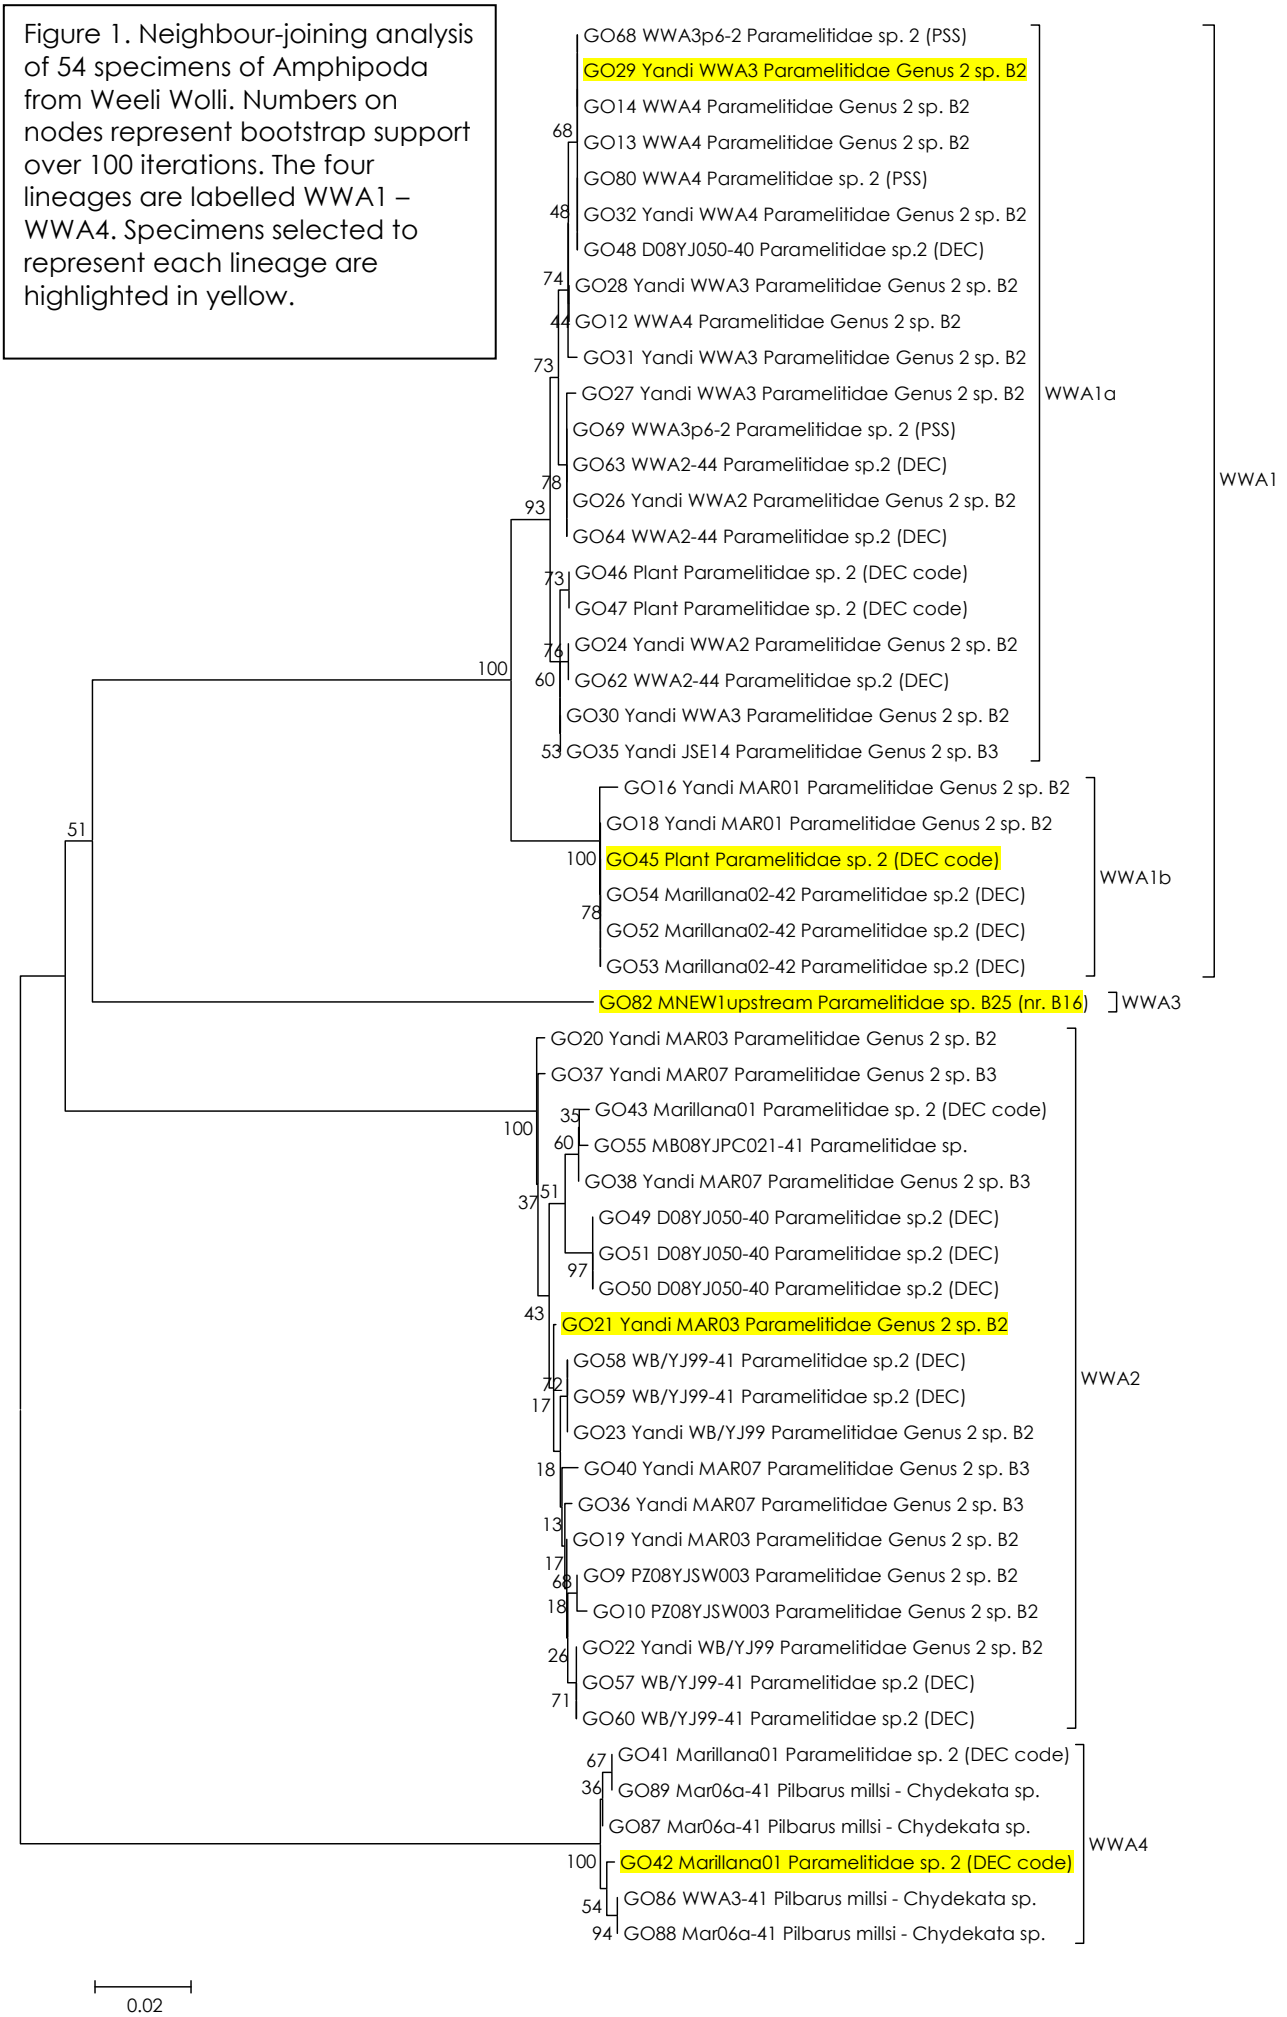

Figure 2. Bayesian analysis of COXI haplotypes of Paramelitidae. Numbers on major nodes correspond to posterior probabilities. Specimens from the present study are highlighted in yellow; Scale bar= number of substitutions per site. Red boxes enclose the species detected in the present study. Distances between the Weeli Wolli specimens and the nearest reference sequences are shown next to each pair.

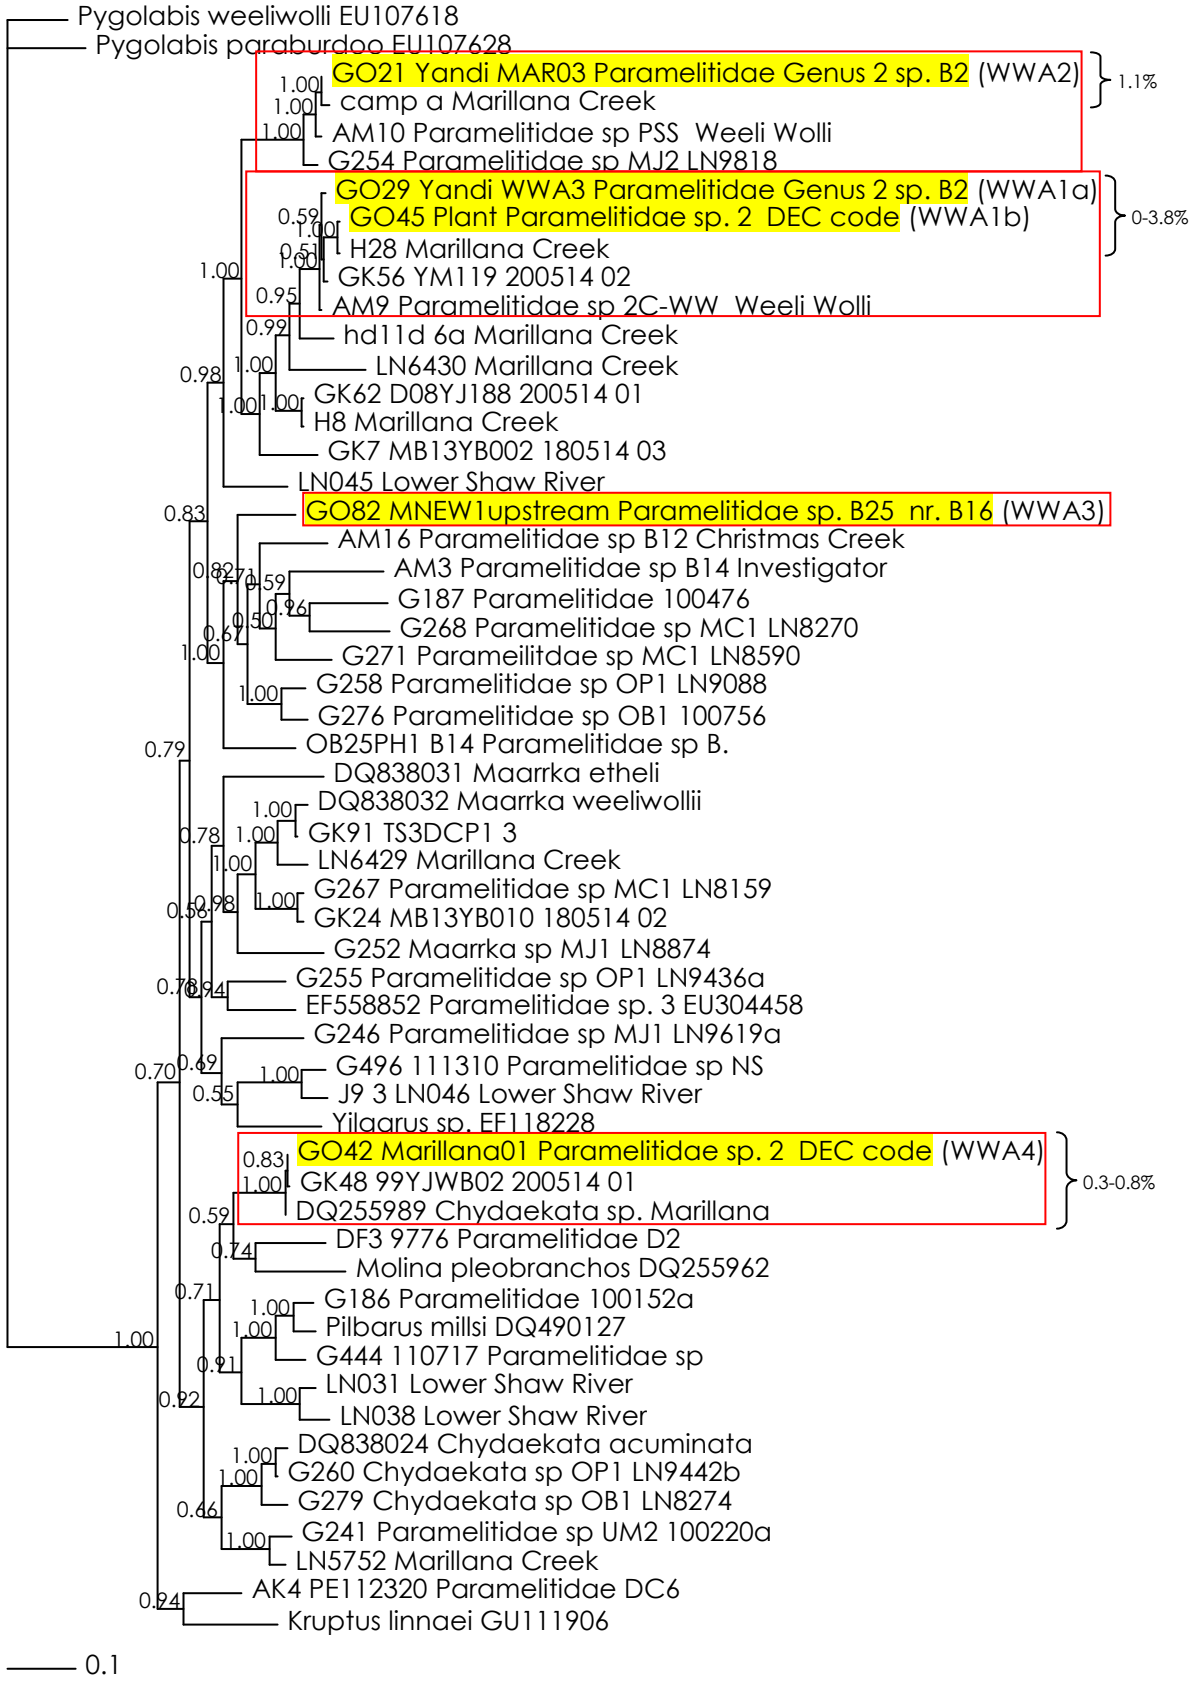

Figure 3. Bayesian analysis of COI haplotypes of Schizomida. Numbers on major nodes correspond to posterior probabilities. The specimen from the present study is highlighted in yellow; Scale bar= number of substitutions per site. Distances between the Weeli Wolli specimen and the nearest reference sequences are shown next to the clade.

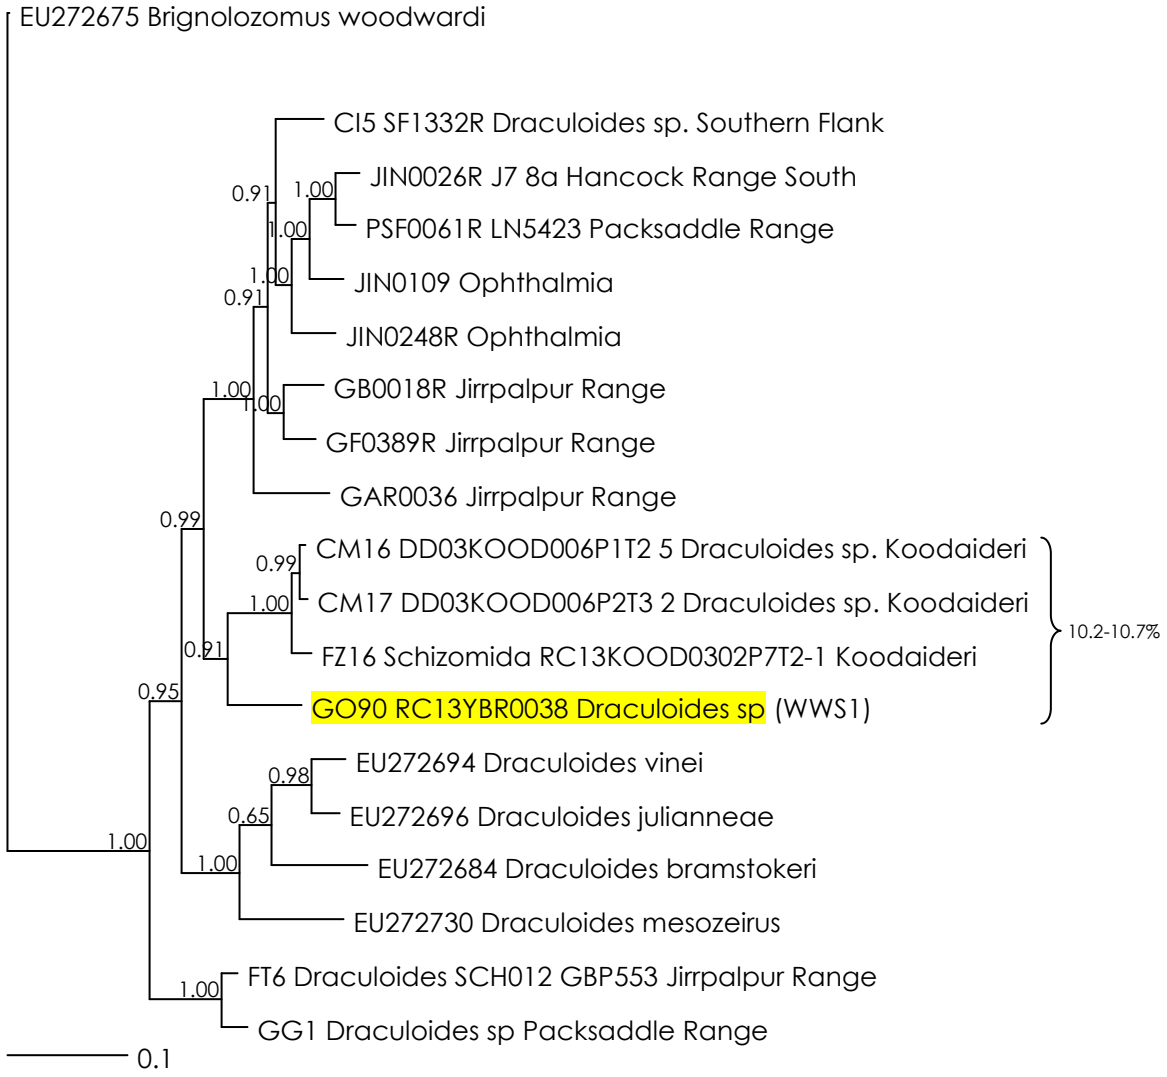

Appendix 3

1 INTRODUCTION

In the East Pilbara of Western Australia, two relatively large creek systems (Marillana Creek and Weeli Wollli Creek) form part of a broader catchment which ultimately drains into Fortescue Marsh. The historic paleo-channel of these two creek systems has created Channel Iron Deposits of significant economic value. In the process of recovering these resources, the ecological values of these creek systems have been altered, but overall (in the vicinity of the Rio Tinto Yandicoogina Project area), they appear to have been maintained. As development continues in this area a complex interaction of potential impact sources, particularly with respect to hydrological changes, and resultant spatial distribution and scale of potential ecological impacts is occurring. In addition to current impacts, the respective spatial distribution and significance of the ecological values present are of key interest to support environmental impact assessments. In many cases; the finer details on the local scale and timing of ecological impacts are enormously difficult to determine. By comparison, the ability to gain increased clarity and spatial resolution about the location and significance of the values under threat is much more achievable. In light of this fact; work is being undertaken to identify the knowledge gaps, associated spatial resolution issues, scales of significance and historical context surrounding the key ecological values of the study area.

Vegetation mapping is one of the primary tools for identifying key ecological values; their spatial location within a creek system; and their inherent sensitivity to perturbations. Current riparian monitoring/management is limited to the scale of previous vegetation mapping within the riparian zone. However when considering in detail the potential for complex hydrological impacts, a more detailed scale of mapping is required for accurate, measured and more meaningful management and mitigation. Furthermore recent monitoring has determined that some of the most significant and sensitive communities mapped within the study area have been augmented by development impacts (namely surplus-dewater discharge), and in some cases may not have existed in the pre-impact environment.

Two key focuses of this study are to increase the spatial, structural, and compositional resolution of the vegetation mapping within the riparian zone, while gaining greater understanding of the significance of communities in the riparian zone and their distribution pre-impact.

The following study outlines the work undertaken within the stretches of Marillana and Weeli Wolli Creeks surrounding the Rio Tinto Project area to:

- Refine the vegetation mapping within the riparian zone of Marillana and Weeli Wolli Creeks (within the vicinity of their confluence - the study area), with the aim of increasing the scale, accuracy and detail of vegetation mapping and associated community descriptions.

- Classify and map the age structure of Melaleuca argentea co-dominated riparian communities (“obligate phreatophytic vegetation”) within the study area.

- Provide an interpretation of the presence and distribution of present day communities in the Pre-discharge (pre-mining) environment.

- Incorporate the determined community age structure, or maturity of phreatophytic vegetation and use this information to develop inferences about their presence in the pre-discharge environment: provide interpretations of the significance of riparian communities in

the study area, based on their distribution, composition, structure, sensitivity (to hydrological changes), and associated biological values.

1.1 STUDY AREA

The study area determined to be the focus of this work incorporates a stretch of Marillana Creek from its confluence with Weeli Wolli Creek to approximately 19 km upstream. The zone along Weeli Wolli Creek includes a stretch 6 km downstream and 13 km upstream from its point of confluence with Marillana creek. Lying within the Marillana Pastoral station these stretches of both creek systems are herein to be known as the "study area" and the boundaries of this study area are presented in Figure 1-1.

1.2 COMPLEXITY OF OVERLAPPING IMPACTS TO BOTH CREEKS

Key potential impact sources active on riparian communities and ecosystems of Weeli Wolli and Marillana creeks area:

- direct impact from infrastructure clearing and transport; and
- drawdown effects on groundwater and surface water availability:
  - In some areas communities and select species experiencing drought stress and fatality due to reduced sub-surface access to groundwater sources
- effects of increased surface water (perennial flow regimes) from mining discharge:
  - in some areas communities and select species experiencing stress and fatality due to excess water presence (waterlogging);
  - in some areas communities and select species undergoing artificial augmentation due to additional water presence (increased recruitment and cover/abundance); and
  - in some areas augmented vegetation experiencing stress and fatality as discharge regimes are altered.

Throughout the Yandicoogina development area there is variability in the distribution, magnitude, spatial extent and degree of overlap of each of these potential impact factors. As a consequence, determining the resulting potential impact profile is considerably complicated, especially once coupled with the underlying environmental variability (in areas such as geology, slope, sediment characters, creek profile etc.) of the area. In some cases impacts are multiplied due to spatial overlap of impact factors, and in cases impacts are somewhat ameliorated or neutralised due overlap of offsetting impact factors. Whatever the case may be, it is clear that the potential to accurately predict impacts is heavily reduced by the spatial complexity of their interaction. Therefore, beyond broad spatial impact predictions, the key course of action for management and mitigation is to become clear on the exact location and significance of key values, to be aware of which ones are most susceptible to change, and in light of potential sensitivities determine where the most relevant impacts might occur.

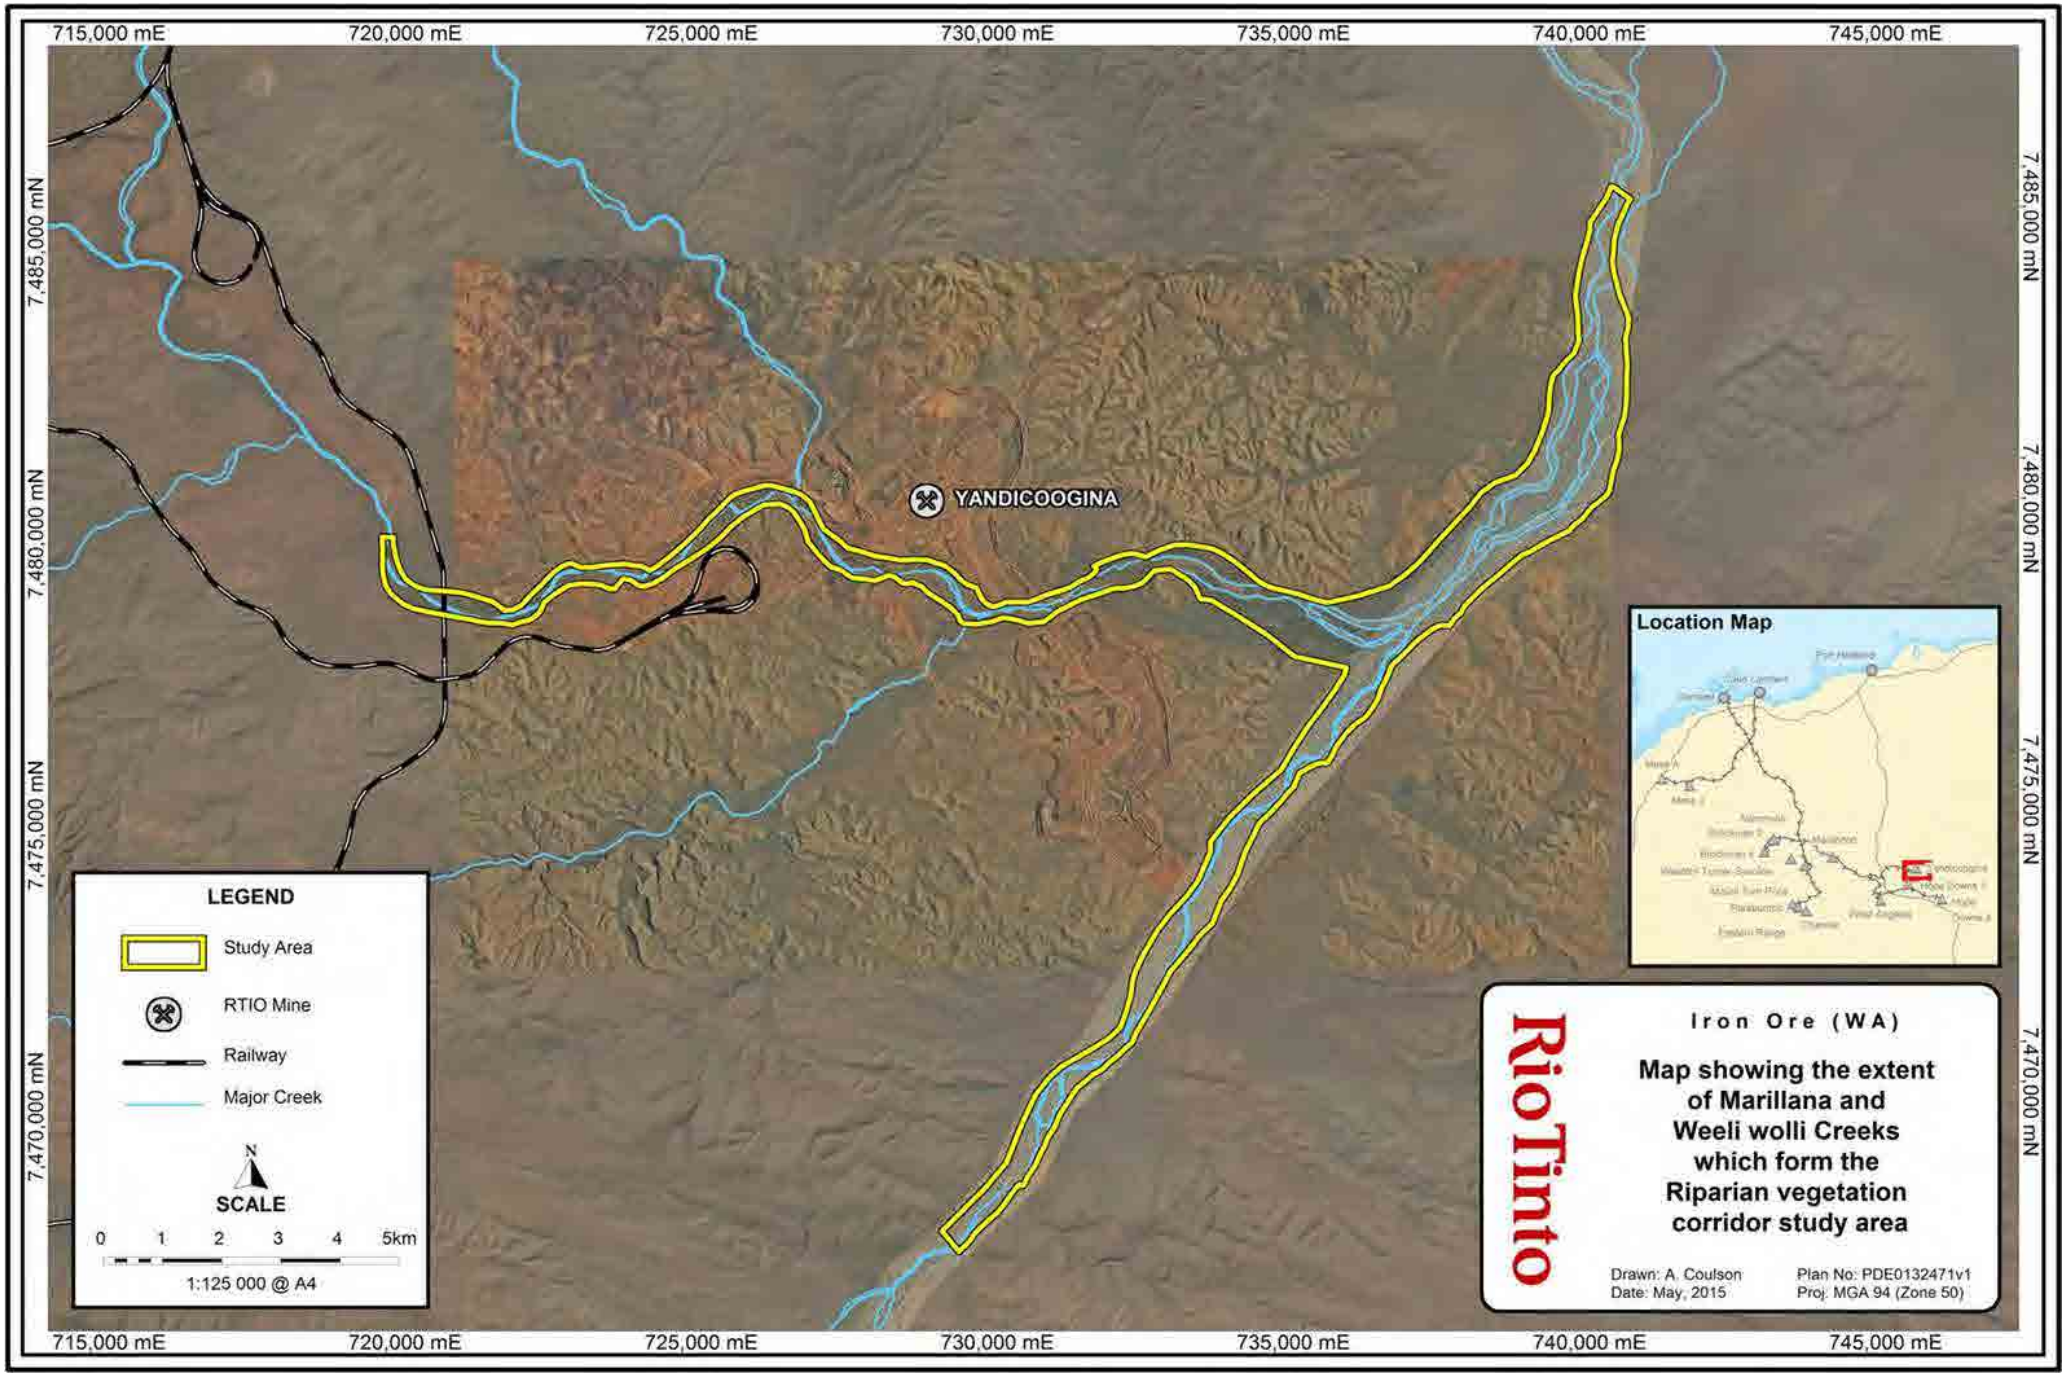

Figure 1-1: **Extent of Marillana and Weeli Wolli Creeks which form the Riparian Vegetation Corridor Study Area**

2 BACKGROUND

2.1 LARGE CREEK SYSTEMS OF THE HAMERSLEY SUB-REGION

The Hamersley subregion of the Pilbara bioregion is essentially represented by those areas occurring on and adjacent to the ranges, valleys, and plateau formations of the Hamersley Ranges. These ranges are unique in the Pilbara due to their size, relatively vast expanses of upland area, and associated large and extremely rugged and rocky habitats.

Rainfall patterns in the Hamersley Ranges, when compared to the reminder of the Pilbara region, are also different with higher annual rainfall over the Hamersley Range (up to 500 mm). This higher average rainfall is known to be a product of advection and convergence of moist sea breezes together with uplift from orography and heating associated with the steep and rocky features of the Hamersley Range (Charles *et al* 2013)).

Within the Hamersley subregion these factors combine to produce a significant number of large and relatively unique creek systems. The number and spread of these large creek systems, along with the spatial boundaries of their respective catchments, are depicted in

Figure 2-1. To provide a comparative look at the size of each of these creek systems the areal extent of the catchment of each is provided below in Table 2-1.

Table 2-1: Major Creeks of the Hamersley Range

Creek	Approximate Catchment Size (Km^2)
Mindy Mindy Creek	372
Joffre Creek	539
Giles creek	598

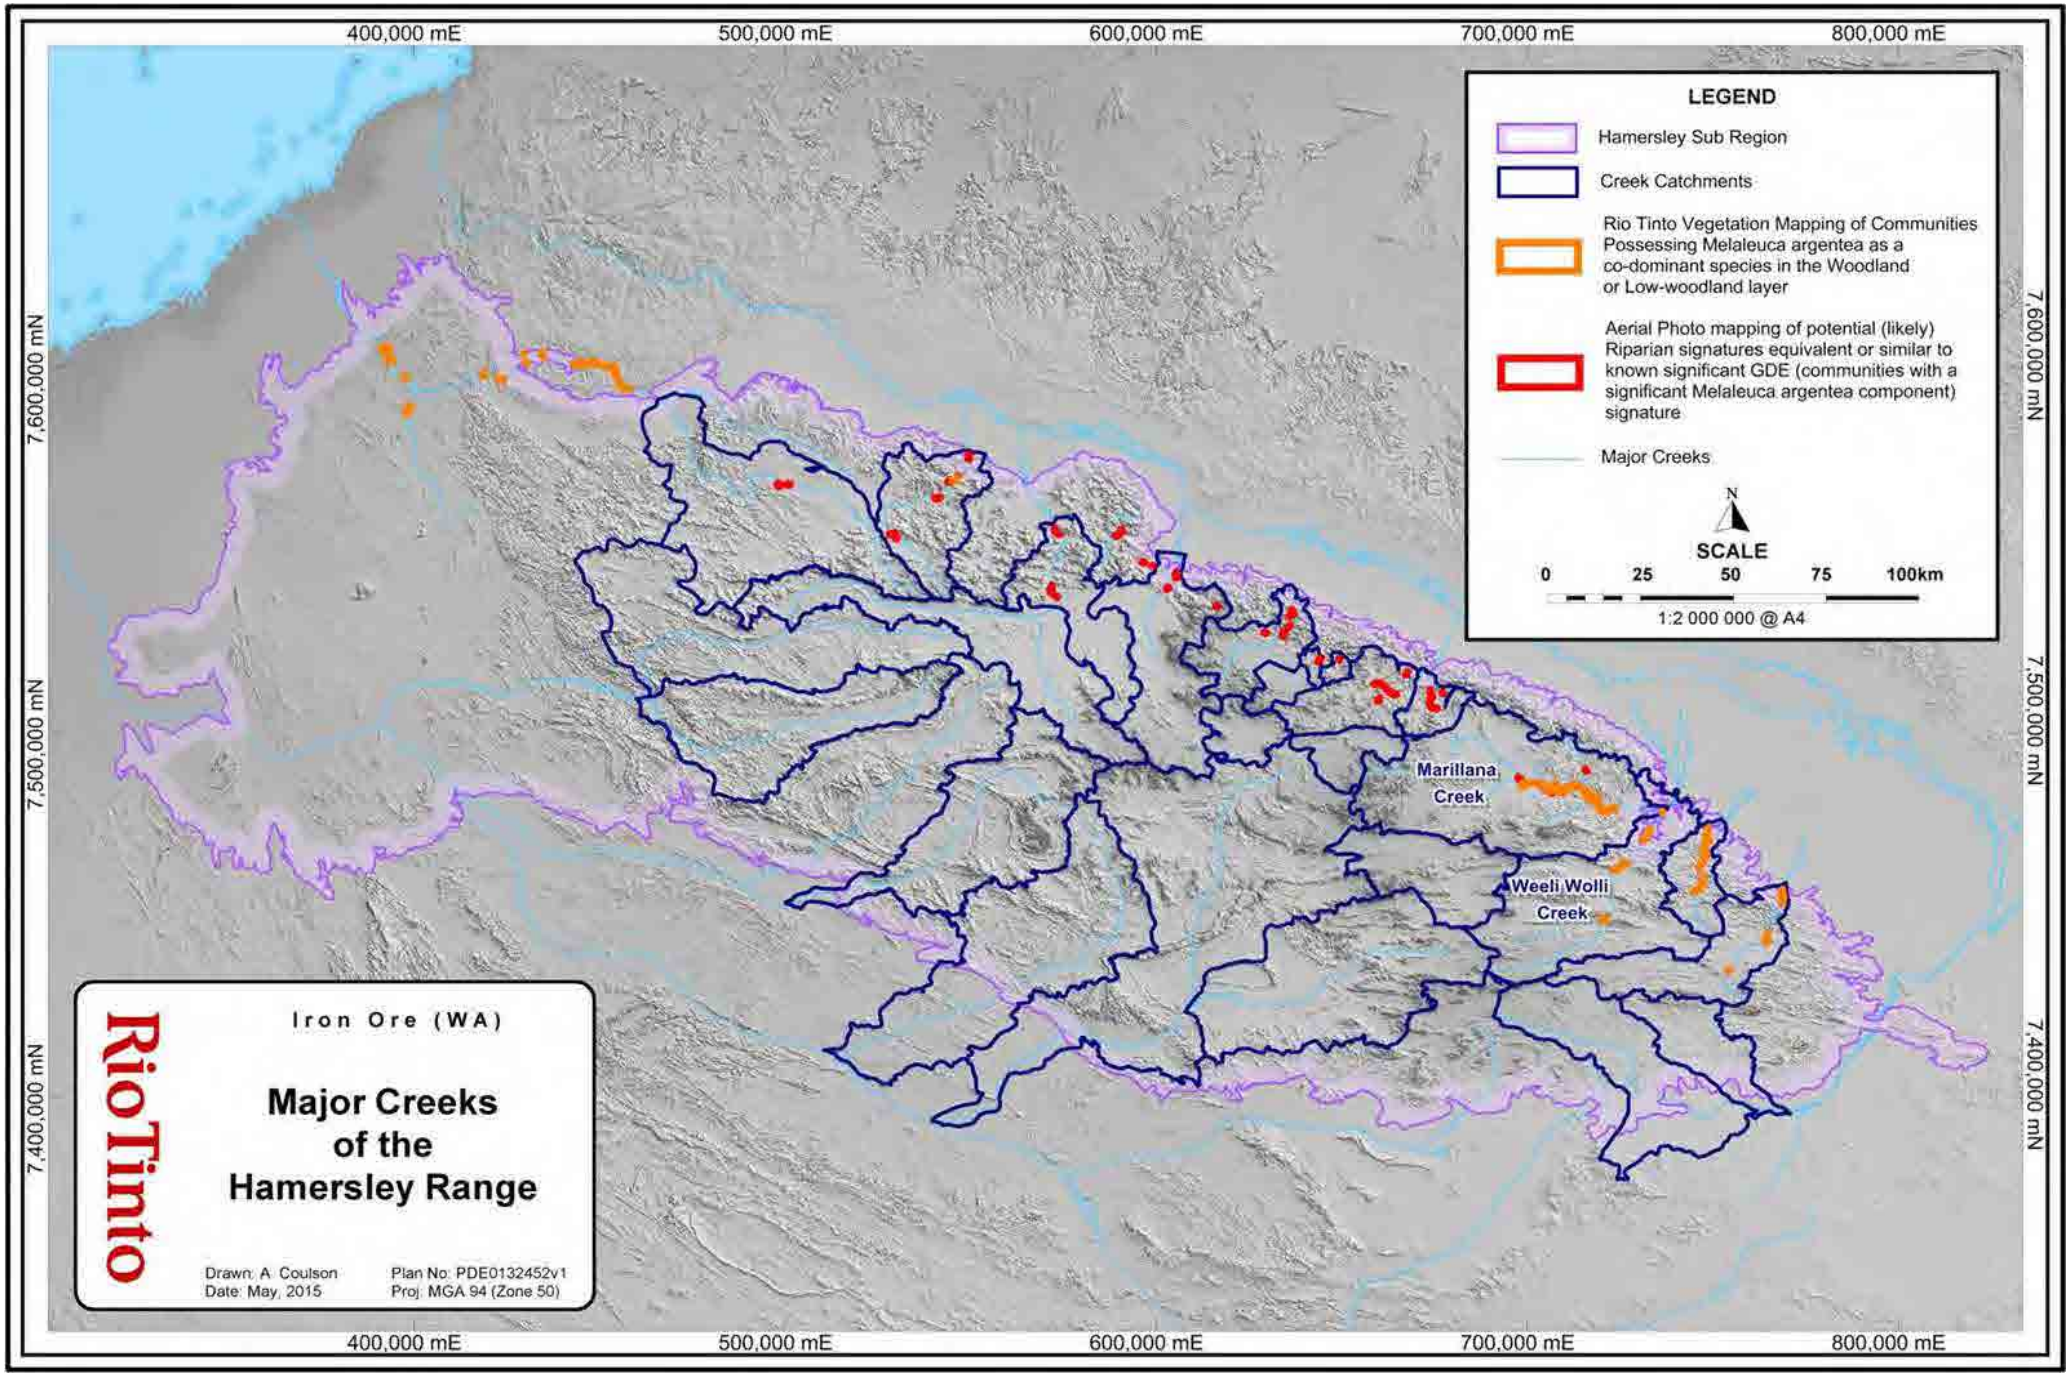

Figure 2-1: Major Creeks of the Hamersley Range

2.2 THE MARILLANA AND WEELI WOLLI CREEK SYSTEMS

2.2.1 Marillana Creek

The Marillana Creek catchment covers approximately 2200 km^2, with the creek flowing in an easterly direction between ranges of Brockman Iron Formation. The mid to upper catchment comprises a broad alluvial plain with several large areas of calcrete, and some clay pan zones. In the lower catchment, the drainage is well-defined due to topographical constraints, with the creek merging with Yandicoogina Creek and Weeli Wolli Creek prior to entering the Fortescue Marsh. The creek is generally ephemeral and only flows between 30 and 60 days per year. The Marillana Creek catchment contributes approximately 50% of the flow into the Fortescue Marshes from the Weeli Wolli Creek system (Aquaterra 2001). Marillana Creek therefore contributes approximately 5% of the surface water inputs to the Fortescue Marsh.

Marillana Creek typically comprises a gravel and calcrete aquifer that subparallels and meanders across the Channel Iron Deposit (**CID**) palaeodrainage at several locations. The CID or pisolitic limonite aquifer is aligned with the eroded keel of the Yandicoogina Syncline and is underlain by the Weeli Wolli Formation. The Marillana Creek CID forms a strip aquifer with a total length of 70 km, width of 800 m and saturated thickness of 60 m. The Marillana Creek CID aquifer merges with the Weeli Wolli Creek CID aquifer, which together contribute groundwater flow northward into the Fortescue Valley.

Marillana Creek is gauged by the Department of Water (DoW) at Flat Rocks (WRC number 708001) which is approximately 27 km west of the existing Rio Tinto Yandicoogina Project and upstream of the BHPBIO operations. Daily flow data for the gauging station is available from August 1967 to the present with occasional missing data. Before mining commenced in the Rio Tinto Yandicoogina locality in the early 1990s, stream flow in Marillana Creek was intermittent and largely dependent on rainfall. From 1975 to 2008 the annual number of flow days ranged between 10 and 365 (with a mean of 212) at the Flat Rocks gauging station. Continual flow at this location was recorded between 2000 and 2004 mainly due to saturated catchment conditions from abnormally high rainfall in 2000 (970 mm recorded at Flat Rock station) and the influence of the Munjina Clay pan (DoW 2015). Flat Rocks is an atypical stretch of Marillana Creek (as indicated by the name) in that the geology of the area appears to be influencing the patterns of surface water expression. The proximity of geological substrates and associated alluvial profiles in the vicinity of the Rio Tinto operations are significantly different, and are likely to determine that surface expressions of water moving through the catchment occur less frequently. Evidence of this can also potentially be attributed to the significant mature *Melaleuca argentea* woodlands which naturally occur in and upstream of the flat rocks vicinity, and which were sighted as part of field work completed for this study.

2.2.2 Weeli Wolli Creek

The Weeli Wolli Creek catchment, including Marillana Creek and Yandicoogina Creek, represents a significant surface water flow (10%) into the Fortescue Marshes (Aquaterra 2001). Weeli Wolli Creek is generally an ephemeral creek system which can be divided into three zones: an upper catchment (above Weeli Wolli Springs); a lower catchment (trunk drainage between Weeli Wolli Springs and the Hamersley Ranges escarpment); and broad outwash on the Fortescue Plain. The entire Weeli Wolli

catchment (including Marillana Creek) equals approximately 4,000 km^2, but without the Marillana Creek component equates to approximately 1800 km^2. The upper catchment comprises a number of tributaries that flow between east-west trending ranges before flowing through a narrow gorge in the Packsaddle Range at Weeli Wolli Springs. Weeli Wolli Spring has formed by the concentration of flow through a relatively narrow gap in the Brockman Formation outcrop and changes in topographic gradient. This 'damming' effect of groundwater flow results in an apparent "underground reservoir" that discharges over the shallow basement forming the spring. The spring is a permanent water feature that is supported by groundwater discharge. Surface water flow disappears about 2 km downstream of the spring as a result of seepage and evaporation. The area often experiences periodic heavy rainfall during summer because of both monsoonal effects and cyclones. Although the average surface flow is 2.8 GL/year it has been as high as 22 GL during an exceptional flood year. The pisolite and calcrete, where present below the water-table, constitute a significant aquifer which is recharged via direct rainfall infiltration and creek-line infiltration (Johnson & Wright 2001).

Weeli Wolli Creek continues its path downstream into the lower Weeli Wolli Creek catchment where it joins with Marillana Creek to the west and then drains onto a wide alluvial floodplain 20 to 30 km across in the Fortescue Valley. The reach of Weeli Wolli Creek which emerges from the Packsaddle Range north of the springs, and continues to the vicinity of the confluence with Marillana Creek, is generally represented by a relatively incised creek channel (with a consistently favoured low flow channel pathway), flanked by a clear and broad open floodplain. Downstream of the confluence with Marillana Creek, the incised channel zone of Weeli Wolli becomes much broader with multiple low flow channels emerging in a braided arrangement to provide a much greater area of meandering creek bed habitat. In addition, this reach possesses a less consistent and clearly formed adjacent floodplain to that present south of the confluence. The flows of Weeli Wolli Creek terminate at the Fortescue Marsh, an internally draining basin of the Upper Fortescue River catchment.

Weeli Wolli Creek is currently gauged by DoW at two locations: Waterloo Bore; and Tarina. The Tarina station sits on the upstream boundary of the study area within Weeli Wolli Creek, while Waterloo bore sits just downstream of the study area boundary. This station's proximity to Weeli Wolli springs (4km downstream) means its data is somewhat influenced by perennial flows in and immediately downstream of the spring. Despite this, data from both Tarina and Waterloo suggest flows in Weeli Wolli Creek downstream of the springs is generally ephemeral, with an annual number of flow days in the same range but with a lower average of flow days.

2.3 PREVIOUS SURVEYS

A significant amount of survey work has been conducted in the Yandicoogina locality since mining development began in the 1990's. Table 2-2 outlines the flora and vegetation surveys which have been conducted in the area since this time. The majority of the recent survey work has been conducted by Biota Environmental Sciences. This body of work has essentially sampled/surveyed a riparian environment which had already seen some degree of impact from mining/pastoralism and particularly from surplus dewater discharge and historical grazing. The group of surveys conducted by Mattiske and including Integrated Environmental Services (1981), were generally conducted in a pre-mining development scenario (although within an environment already exposed to extensive grazing influence), and as such can provide useful insight to the pre-discharge environment.

Figure 2-2 illustrates the survey boundaries of the key pre and post-discharge flora and vegetation surveys conducted in the vicinity of the study area.

Table 2-2: Summary of vegetation and flora surveys contributing to the previous vegetation mapping dataset

Study (Reference)	Area Surveyed Within Study Area	Survey Description Survey Timing (Conditions for Plant Growth4)	Available Data
Yandicoogina Vegetation and Flora Integration Report (Biota 2014a)	19,351 ha	Integration of existing data with a further botanical survey to provide additional information on the values associated with the complete development envelope for the HI Yandi project.	– Quadrats/relevés/mapping notes. – Conservation significant flora and weeds. – Vegetation mapping. – Vegetation condition assessment. – Species list.
Yandicoogina Billiards – Phase 1 and Phase 2 (Yandi PBS) (Biota 2014b)	8,640 ha (8,640 ha)	Two phase (seasonal) vegetation and flora survey of the PBS survey area to expand the existing data for the area to a Level 2 standard. 8 – 20 March 2014 (favourable); 7 – 11 July 2014 and 14 July 2014 (favourable).	– Quadrats/relevés/mapping notes. – Conservation significant flora and weeds. – Vegetation mapping. – Vegetation condition assessment. – Species list.
Yandicoogina JSW/Oxbow Vegetation and Flora Integration Report (Biota 2014c)	2,133 ha (2,192 ha)	Integration of existing data with a further botanical survey to provide additional information on the values associated with the JSW and YOX survey areas. 27 February – 4 March 2012 (favourable).	– Quadrats/relevés/mapping notes. – Conservation significant flora and weeds. – Vegetation mapping. – Vegetation condition assessment. – Species list.
Yandicoogina Additional Areas (Biota 2014d)	2,807 ha (2,828 ha)	Establish additional quadrats to validate vegetation mapping of additional areas around the JSW and YOX deposits to match the project footprint. 12 – 18 June 2012 (favourable).	– Quadrats/relevés/mapping notes. – Conservation significant flora and weeds. – Vegetation mapping. – Vegetation condition assessment. – Species list.
Yandicoogina Additional Vegetation Mapping (Biota 2011a)	2,806 ha (3,030 ha)	Mapping of additional areas around the JSW and YOX deposits to match the project footprint. 29 November – 3 December 2010 (unfavourable).	– Mapping notes. – Vegetation mapping. – Conservation significant flora and weeds. – Vegetation condition assessment. – Species list.

2.3.1 Resultant Vegetation Mapping and Inherent Issues

Previous vegetation mapping covering the study area has been completed at a resolution commensurate with the environmental impact assessment (**EIA**) objectives for which it was commissioned. Generally, flora and vegetation surveys conducted for the purpose of EIAs are commissioned with the aim of sampling and documenting all values present. Consequently sampling effort is spread widely and the level of detail attained is typically proportionate to the size of the area, number of landforms present, and the extent of areas of elevated ecological value.

Previous surveys conducted by Biota, and summarised in the "Yandicoogina Vegetation and Flora Integration Report" (2014), provide a well-integrated vegetation model for area. This mapping provides an important platform for the current study however the objectives of this study determined that mapping at a much finer resolution was required.

Despite the significant number of surveys conducted over Marillana and Weeli Wolli Creeks the detail of the vegetation mapping acquired has essentially been relatively broad. In the case of development at Yandicoogina, potential impacts to the riparian zone as a result of hydrological changes remains the key area of focus. As a consequence it was identified that improving the detail of riparian vegetation mapping would help increase knowledge in the riparian zone and increase the understanding of the environmental values, and hence increase the effectiveness of environmental management. The key area of vegetation refinement required to meet the objectives of this study, is the separation of areas of Obligate Phreatophytic Vegetation (**OPV; defined in section 2.4**) from non-OPV and to differentiate areas containing different size-classes of *M. argentea*.

A key distinction relating to OPV vegetation and the previous mapping provided by Biota (2014) relates to the C1 vegetation unit. Previous mapping by Biota within the study area described the C1 community to be present (Biota 2014a) and described this community to be represented by *Eucalyptus camaldulensis* subsp. *refulgens*, *E. victrix* woodland over *Melaleuca argentea*, *M. glomerata, Acacia coriacea* subsp. *pendens* low open woodland. Biota identified this community to inhabit scoured creek beds and channels of the wetter parts of Marillana and Weeli Wolli Creeks throughout the study area. As discussed later, this community appears to be an amalgamation of two separate communities (associations) occurring in this same area but possessing significantly differing distributions. It is this difference in distribution which is an important distinction required for the adequate consideration of the significance and distribution of OPV within the study area.

2.4 PHREATOPHYTIC VEGETATION AND SPECIES, AND GROUNDWATER DEPENDENT ECOSYSTEMS IN THE PILBARA

Riparian systems of the Pilbara bioregion are subjected to extremely seasonal and variable hydrologic regimes in which stream flow typically occurs following cyclonic rainfall events (Ruprecht and Ivanescu 2000). Large flow events can result in the formation of isolated pools, replenish floodplain soil moisture and recharge groundwater within the riparian system.

In creeks and rivers of the Pilbara, groundwater is typically contained within shallow, unconsolidated sedimentary aquifers close (<20 m) to the surface (Landman 2001). In some instances, groundwater reaches the surface and natural springs are formed, maintaining permanent surface water pools. These shallow aquifers and springs often support groundwater dependent ecosystems (**GDE's**); natural ecosystems that require access to groundwater to meet some or all of their water

requirements to maintain their communities of plants and animals, and ecological processes (Sommer and Froend 2011).

GDE's comprise plant species that, in the absence of rainfall, rely directly on groundwater (and associated surface expressions) but may also contain grass and herbaceous species relying on recent precipitation (Sommer and Froend 2011). Plant species which draw water from the saturated zone (the phreatic zone) or capillary fringe of the water table are known as phreatophytes and the presence of GDE's is often inferred from the presence of such species (Eamus *et al.* 2006). Phreatophytes can usually be found along streams where there is a steady flow of surface or groundwater, or consistent still pools in areas where the water table is near the surface.

At the opposite end of the scale is a "xerophyte", which is essentially a species of plant which has adapted to survive in an environment with little access to water (Salisbury and Ross 1991). Terms used to describe the water use strategies of plants occupying various positions within the Phreatophyte to Xerophyte scale are: "Obligate Phreatophyte"; "Facultative Phreatophyte"; and "Vadophyte".

It is generally considered that any vegetation that uses groundwater is potentially at risk of impact if it occurs in a location where the groundwater would be lowered beyond assumed natural groundwater variation. However, the impact on vegetation from lowering the groundwater table is likely to be relative to the species' dependence upon groundwater, and on the alternative sources of moisture available to it in any one situation. For example, plants that rely on water sourced directly from the groundwater table (phreatophytes) are more likely to show signs of decline or be lost than those that can rely on sources of soil moisture (i.e. vadophytes) such as precipitation and soil pore moisture anomalies from other sources. An assessment of the groundwater dependence of species present within the study area has been informed by a desktop literature review, with specific reference to previous vegetation association mapping and an understanding of the surface water and underlying groundwater environment.

Not all phreatophytic species display the same degree of dependency on groundwater and the dependency within species has been shown to vary both spatially and temporally (Eamus and Froend 2006). Obligate phreatophytes are those species for which access to groundwater is critically important to their presence in the landscape. Such species can only inhabit areas where they have access to groundwater in order satisfy at least some proportion of their environmental water requirements (**EWR**) (Eamus *et al.* 2006). Facultative phreatophytes, on the other hand, are plant species for which access to groundwater is not necessarily important to their presence in the landscape. Facultative phreatophytes may utilise groundwater to satisfy a proportion of their EWR but, if required, may also satisfy their total EWR via stored soil water reserves (Eamus *et al.* 2006).

The tree species *Eucalyptus camaldulensis subsp. refulgens* Brooker & M.W. McDonald (River Red Gum), *Eucalyptus victrix* L.A.S.Johnson & K.D.Hill (Coolibah) and *Melaleuca argentea* W.Fitzg (Silver Cadjeput – historically identified as *M. leucadendra*) are the three most common phreatophytic species within riparian systems of the Pilbara bioregion. The presence of these species is often used to infer the presence of a Groundwater Dependant Ecosystem. The three species vary in their degree of dependence on groundwater and this variation has a strong influence on their patterning and abundance within riparian systems.

Melaleuca argentea is a tree which grows to approximately 20 meters and is found along larger watercourses of the Pilbara. *Melaleuca argentea* is thought to be depend on groundwater almost

exclusively to meet its water requirements and is therefore considered to be an obligate phreatophyte (Lamontagne *et al.* 2005, Graham *et al.* 2003, Landman *et al.* 2003, O'Grady *et al.* 2006). Due to its dependence on groundwater, this species is typically found in parts of creeks and rivers characterised by permanently inundated pools and springs or where the water table is permanently close to surface (McLean *et al.* 2013). *Melaleuca argentea* is generally considered to be the plant taxon within the Hamersley Ranges at highest risk of impact through changes to groundwater availability associated with mining drawdown. *Melaleuca argentea* has previously been recorded within the study area at varying quantities and while certain parts of the study area are considered to possess occurrences of shallow groundwater or consistent surface water features, in many cases these levels or sources have been increased and decreased as a result of development in the area. Consequently, it is considered that while vegetation associations at high risk from groundwater drawdown are present in the study area, it appears that not all were present pre-development, and many are not showing influence from draw down due to consistent surface water inputs from surplus water discharges. Table 2-3 presents the different classes of groundwater dependence (water use strategies) relevant to plant groups in the Pilbara, and the most relevant species considered being attributable to each.

Table 2-3: Tree species dependence on groundwater

Species dependence on Groundwater	Plant Physiology/water use strategy	Relevant Species in the Pilbara
High	Phreatophyte	*Melaleuca argentea*
Moderate	Facultative phreatophyte (sometimes a vadophyte)	*Eucalyptus camaldulensis, Melaleuca glomerata*
Low to Moderate	Vadophyte (in anomalous cases can be a Facultative phreatophyte	*Eucalyptus victrix and Eucalyptus xerothermica*
Low (virtually negligible)	Xerophyte	E.g. Eucalyptus leucophloia, *Corymbia hamersleyana*, Corymbia deserticola. Etc…

Vegetation associations occurring along the main drainage channel and associated flood plains within the study area support three native tree species that are considered to be at moderate risk from groundwater drawdown: *Eucalyptus camaldulensis* subsp. *refulgens*; *Eucalyptus victrix* (moderate risk); and *Eucalyptus xerothermica* (minimal risk). These tree species are classified as vadophytes or facultative phreatophytes. *Eucalyptus camaldulensis subsp. refulgens* is the most widespread of Australian Eucalypt species and is known to tolerate an apparently wide range of water regimes (Colloff 2014). River Red Gum is considered a facultative phreatophyte as it obtains its water for transpiration via three main sources: groundwater, river flooding (which over tops creek and river banks thereby replenishing floodplain soil moisture), and rainfall (Wen *et al*. 2009). The degree to which River Red Gum depends on groundwater and soil moisture has been found to vary both spatially and temporally (Mensforth *et al*. 1994, O'Grady *et al*. 2009, Wen *et al*. 2009, O'Grady *et al*. 2010).

E. camaldulensis typically occurs along inland rivers and may be dependent on shallow groundwater for survival, although the root system may penetrate considerably deeper than 10 m. Studies in the Pilbara indicate that *E. camaldulensis* occurring along the larger drainage lines may have access to groundwater up to 21 m below the surface (AGC 1992). Investigations at Marillana Creek found the vigour of large *E. camaldulensis* trees (>10 m tall) declined in response to lower groundwater levels caused by test pumping of water, while the vigour of smaller *E. camaldulensis* remained unchanged

(Onshore Environmental 2013). This observation suggests that the species is capable of being both a vadophyte and a phreatophyte, using the former strategy when young and the latter strategy when mature (Halpern Glink Maunsell 1999). Muir environmental (1995) indicates that River red gum (*E. camaldulensis*) and Coolibah (*E. victrix*) are generally not restricted in their occurrences along Marillana Creek and thus cannot be considered as being true phreatophytes, but as vadophytes (i.e. primarily unsaturated soil dependent). In the case of *E. camaldulensis*, general observations in the Pilbara by Rio Tinto Botanists suggests that there is some degree of restriction to the distribution of this species along large creeks, and so the concept that this species can be both a phreatophyte and a vadophyte (depending on the circumstances) is probably most accurate.

Eucalyptus victrix is a small to medium sized eucalypt which typically occurs on smaller creeklines and floodplain habitats throughout semi-arid Western Australia. Like River Red Gum, *E. victrix* is also considered to be a facultative phreatophyte. This species has been shown to access groundwater in areas where the depth to groundwater is low (O'Grady *et al.* 2009) but in non-riparian habitats, has also been shown to exploit shallow soil water to meet is transpiration needs (Grigg *et al.* 2008). *Eucalyptus victrix* is known to inhabit an ephemeral wetland (i.e. Mount Bruce Flats, Karijini National Park) despite the absence of a permanently saturated regolith (Rio Tinto 2011a). Comparisons of groundwater and stem xylem water stable isotope compositions as well as pre-dawn and midday leaf water potential measurements suggest that *E. victrix* within the Mount Bruce Flats in Karijini National Park uses water drawn from the unsaturated soil profile during extended dry (Rio Tinto 2011a). Further to this, *Eucalyptus victrix* and *Eucalyptus xerothermica* are generally considered to be examples of vadophytes being relatively drought tolerant but susceptible to decline when groundwater becomes limiting (Muir Environmental 1995).

The water use characteristics of *E. camaldulensis, E. victrix* and *M. argentea* may also influence their response to mining related impacts such as dewatering and discharge. Dewatering, which causes localised lowering of groundwater levels, may be expected to have a significant impact on the health of *M. argentea* but lesser impacts on *E. victrix* or *E. camaldulensis*, provided adequate soil moisture is maintained from periodic, rainfall-generated stream flow. On the other hand however, artificial discharge of surplus groundwater along ephemeral creeks and rivers may favour *M. argentea* (resulting in increased recruitment and vigour) by creating a perennial hydrologic regime. Change from a steady-state ephemeral hydrologic regime to a more perennial one may adversely impact *E. victrix* and to a lesser extent *E. camaldulensis*. Florentine (1999) found that *E. victrix* exhibits some tolerance to waterlogging (e.g. production of adventitious roots) but overall growth, transpiration rate and net photosynthesis are negatively affected under waterlogged conditions. By contrast, *E. camaldulensis* is considered to be one of the most waterlogging-tolerant eucalypt species (Bell 1999; van der Moezel *et al.* 1988), though empirical studies of River Red Gum waterlogging tolerance in the Pilbara bioregion are lacking and may be somewhat dependent on subspecies. At the local scale the impacts of excess water will differ depending on the substrate and channel morphology and thus the relative position of trees (particularly on a vertical plane) to available water.

Probably the most important point to consider when classifying the water use of plant species by attributing particular species to one of the above described water use strategies, is that typically plants and their associated environments do not always behave in definite manners. While the physiological constraints and demands of the plant tend to be quite definite, the way in which the environment provides for this physiology and the way in which the plant acquires its needs from the environment can vary quite considerably in time and space (O'Grady *et al*. 2009). The most relevant area of variability in relation to the risk of death from changes in water availability is represented by

a plants ratio of resource allocation between its canopy and root systems. The size and distribution of a plants root system (and conversely the size of its canopy and associated water demands) has a direct link to its ability to acquire sufficient moisture when soil conditions change (Salisbury and Ross 1991). The rate of water availability change therefore has important consequences for the ability of a plant to re-allocate these resources in time and therefore potentially to transition between the bounds of a phreatophyte and a vadophyte.

Another important point to consider when assigning species or communities to phreatophytic water use strategies is the source of moisture. While phreatophytic species are considered to be dependent on groundwater this is not always accurate in the context of the typical definition for groundwater. Groundwater is often considered to be defined as the underlying water table, but in the case of plant water use it is more accurately any source of water on, in or under the ground as long as its presence remains fairly consistent. For example; phreatophytic species can establish because stream morphology and/or underlying geology are such that specific areas sustain consistent alluvial water bodies or surface water pools and patches of moisture which are perched well above the underlying groundwater table. Subsequently these communities can be sustained by consistent fluvial flows regardless of the behavior of deeper groundwater bodies. The reason such distinctions are important, is that in an impact assessment scenario potential changes to clearly detectable and therefore more broadly evident groundwater aquifers often comprise the measurable features of hydrological influence acting on riparian systems. However despite such a focus, changes to broad scale groundwater features can often occur with little or no influence on small scale aquifers and surface water features consistently present in certain fluvial situations.

The resounding message which becomes apparent when considering phreatophytic species is that not all phreatophytic species are equal. Each species considered has evolved in a different habitat, and each habitat has varying degrees of water availability. An additional layer of complexity is represented by the various niches which these species have adapted to take advantage of within each habitat. Consequently species like *Eucalyptus victrix* and *E. camaldulensis* have quite different adaptive capabilities and as such can survive and prosper in quite different water availabilities.

GDE's and their associated species and landforms represent features of elevated ecological value. Phreatophytic species often represent fast growing pioneers which are highly resistant to disease. They also provide, shelter, specialised foraging grounds, and nesting/denning areas for native fauna. Phreatophytes are also known to be indicators of potable groundwater, and to provide water purification services, as their roots are known to fix heavy metals via the provision of bacteria driven filtration (World heritage Encyclopedia 2014).

GDE's, generally represent areas with relatively permanent water, and as such tend to support relatively dense and diverse vegetation communities. Such vegetation tends to contain an above average proportion of mesic perennial and ephemeral species diversity, and so represents repositories of genetic diversity which are often restricted in their distribution and areal extent. Coupled with the diversity of fauna species (particularly avifauna, and nocturnal invertebrate fauna) which they support, their value is generally accepted to be high. It is for this reason that those species which are considered obligate phreatophytes, and therefore most dependent on water permanence, are those species which are the best indicators for the presence of these high value ecosystems. In the Pilbara, that species is known to be *Melaleuca argentea*, and consequently the distribution, abundance and age structure of this species in the environment is often the best available measure for the presence and quality of high value groundwater dependent ecosystems.

However, communities which occur in generally ephemeral habitats, and which do not possess an obligate phreatophytic species such as *Melaleuca argentea*, but instead only possess facultative phreatophytes such as *Eucalyptus camaldulensis* can also be described as groundwater dependent Communities or GDE's. For this reason it becomes important to make the distinction between general groundwater dependent ecosystems/vegetation, and those which are more specifically highly groundwater dependent, or "truly phreatophytic".

In the Pilbara, *M. argentea* is widely considered a strict obligate phreatophyte, and because of the potentially variable water use strategies of some of the other phreatophytic species in the Pilbara (namely facultative phreatophytes), *M. argentea* clearly represents the best indicator for true groundwater dependence. Therefore to provide a term which can be used to make the distinction between the less significant often facultative types of phreatophytic vegetation (general GDE's) and those possessing "true" or obligate phreatophytes, the term "Obligate Phreatophytic Vegetation" (OPV) is proposed.

For the purpose of this study, the term "Obligate Phreatophytic Vegetation" is defined as representing communities which:

> *Encompass vegetation associations and sub-associations, whose structure is at least co-dominated by one obligate phreatophyte, namely Melaleuca argentea (i.e. possesses vegetation described as being dominated by one or more species within the tree or tall shrub stratum and which includes the species Melaleuca argentea as one of these described dominant species). Note: this is not an well recognized term, and has been created for the purpose of this study from associated, well accepted terms such as "Obligate Phreatophytes" & "Groundwater Dependent Vegetation").*

The distinction this term makes is important for this study, as communities which this species comprises a significant component of, are best placed to indicate perennial water availability, and therefore indicate the distribution of ecological values associated with permanent water availability. By making this distinction this study can then differentiate between OPV and the more commonly distributed GDE's represented by facultative phreatophytic vegetation such as *Eucalyptus camaldulensis* woodlands which tend to surround OPV. Consequently, for the purpose of this study, and to aid in the process of assessing riparian significance and the distribution of significant riparian communities in the study area; we will consider communities and vegetation associations/sub-associations within which *Melaleuca argentea* forms a co-dominant species, to be called OPV (Obligate Phreatophytic Vegetation). The remaining communities possessing other phreatophytic species, and including those possessing *M. argentea* as an associated species only, are from here on in to be termed "Facultative Phreatophytic Vegetation" (**FPV**).

2.5 FACTORS CONTRIBUTING TO BIOLOGICAL SIGNIFICANCE

The set of statutory listings for vegetation communities and ecosystems by the WA State or Commonwealth Government are not exhaustive and are generally based on a system of nomination, such that they do not represent a systematic treatment of features of high value or significance. Therefore unlisted flora and vegetation may be locally or regionally significant for similar reasons to those features chosen or nominated for listing.

Based on Guidance Statement 51 (Terrestrial Flora and Vegetation Surveys for Environmental Impact Assessment in Western Australia)(EPA 2004), and other sources; vegetation may be significant because its areal extent is below a threshold level and a range of other reasons, including:

- scarcity;
- high diversity;
- high diversity within special functional plant groups (e.g. mesic species, ephemeral taxa, xerophytic taxa etc.);
- unusual species, or range extension species;
- novel combinations of species (associations);
- a role as a refuge;
- a role as a key habitat for threatened species or large populations representing a significant proportion of the local to regional total population of a species;
- being representative of the range of a vegetation association (particularly; a good local and/or regional example of an association in "prime" habitat, at the extremes of known range, recently discovered range extensions, or isolated outliers of the main range);
- of restricted distribution or occupying a rare landform; and
- exceptional condition.

Vegetation communities are often considered locally significant if they contain multiple Priority Flora species or contain a range extension of a particular taxon outside of the previously known distribution. They may also be locally significant if they are restricted to one or two locations or occur as small isolated communities. In addition, vegetation communities that exhibit unusually high structural and species diversity are also locally significant.

Vegetation communities are regionally significant where they are limited within the bioregion to specific and relatively rare landform types, are generally very uncommon or restricted plant community types within the regional context, or support significant populations of threatened flora. Communities can also be rated at the sub-regional scale for the same reasons but confined to certain areas within one or multiple sub-regions. Determination of significance for flora and vegetation may be applied at various scales, for example, a vegetation community may be nationally significant and governed by statutory protection as well as being locally and regionally significant (EPA 2004).

2.6 RELEVANT HIGH-VALUE RIPARIAN VEGETATION COMMUNITIES WITHIN THE HAMERSELY'S AND THEIR ASSOCIATED DISTRIBUTION

The climate of the Pilbara is essentially classified as arid-tropical possessing an average precipitation to evaporation ratio of less than 0.2 (McKnight 2000). With precipitation generally falling within the range of 250-450 mm the Pilbara can be mistaken for being semi-arid, but with high average temperatures and an average evaporation rate in the vicinity of 2000 mm per year, the effective precipitation in the region is minimal. Because of such climatic factors, water gaining sites which are exposed to surface water supply from larger catchments and which can lock away significant amounts of water from evaporation, become quite important. Such fluvial systems create riparian corridors which provide refuge for a diversity of moisture loving species which wouldn't otherwise be present in areas possessing a similar climate classification. Consequently these features provide

value to the region as custodians of biological diversity through their provision of ecological services and habitat diversity/complexity.

Beyond the general importance and functions of large creek systems in hot and often dry climates such as that of the Pilbara; drainage systems which provide the right catchment size and environmental conditions (generally related to underlying geology, elevation, slope, meander shape and creek profile etc.) to create surface or groundwater permanence are considered most valuable because of the restricted vegetation communities they can sustain, and by association the fauna assemblages they support. The permanence of the water present ensures the landforms ability to create and sustain obligate phreatophytic species (e.g. *Melaleuca argentea*), vegetation of a high structural and species diversity, and potentially associated conservation significant fauna assemblages. These attributes in turn create value and therefore significance due to the restricted distribution of these perennial habitats. With respect to conservation significance, features such as this tend to possess elevated conservation significance as they are generally few in number, restricted to small areal extents, and sensitive to perturbation.

2.6.1 The Role of Phreatophytic Vegetation/Groundwater Dependent Ecosystems

Within the Pilbara, riparian habitats which provide permanent surface or groundwater are commonly present along sections of the regions large river systems. While these systems are not common, they are large, and OPV is generally common along parts of their length. Beyond the river systems of the Pilbara, the remaining representations of OPV are quite restricted to parts of those large creek systems which provide the right catchment and substrate conditions to maintain perennial surface and groundwater sources. In the Hamersley Range subregion such areas are often restricted to the rocky uplands and perched valleys of the Hamersley plateau. The unique landforms and geological substrates of these riparian examples also provide another distinction to which significance can be attributed given their restricted distribution.

As discussed earlier; in the Pilbara obligate phreatophytes such as *Melaleuca argentea* are essentially dependant on moisture permanence to survive. Without it, they will almost certainly die, and as a result of this dependence this species is considered one of the best indicators of water permanence in the Pilbara. In general the structure and composition of creekline vegetation tends to be driven by the degree of moisture present, and so vegetation is an important indicator of surface water permanence, potentially providing insight into the degree of permanency and therefore associated value and significance. This means of insight is important as there are often no good alternatives (at a finer scale) for establishing water permanence in an area. Human records are generally not extensive or detailed enough to truly determine if a site actually possesses surface or groundwater permanency. Furthermore, climatic factors can have a strong influence from year to year, and the underlying water table heights established from an often limited array of bores are hard to accurately interpolate. Generally the best and often only true indicator is the composition and structure of vegetation present.

In the Pilbara, a list of sub-perennial to perennial water indicating species might contain the following list of species in order of importance (Western Australian Herbarium 2015). Consequently, riparian zones or water gaining sites which contain Melaleuca argentea and varying proportions of the following species are considered to provide good evidence of water permanence (bold species indicated best indicators):

- ***Melaleuca argentea***
- *Samolus spp.*

- ***Acacia ampliceps***
- ***Eucalyptus camaldulensis***
- ***Typha domingensis***
- ***Muehlenbeckia spp.***
- *Melaleuca glomerata*
- *Melaleuca bracteata*
- *Atalaya hemiglauca*
- *Sesbania formosa*
- *Cyperus vaginatus/iria*
- *Imperata cylindrica*
- *Marsilea spp.*
- *Potamogeton spp.*
- *Acacia coriacea subsp. pendens*
- *Eucalyptus victrix*
- *Melaleuca linophylla*
- *Acacia citrinoviridis*
- *Acacia sclerosperma*
- *Gossypium robinsonii/sturtianum*
- *Lobelia spp.*
- *Stylidium spp.*
- *Sesbania spp.*
- *Stemodia spp.*
- *Sorghum spp.*

So while it is clear that the species composition of vegetation provides a significant insight into water permanency, an additional level of detail about water permanency is provided by the structure of vegetation. This essentially involves making inferences about the degree and extent of permanency based on the age structure of any obligate phreatophytic species which might be present. It is postulated that if water remains permanently available to these phreatophytic species then at least a percentage of the population is likely to be present as "semi-mature" to "mature" individuals of approximately 40-100 cm diameter (see Table 3-1 for trunk diameter definitions of the semi-mature and mature size class terms used for this report). While environmental perturbations such as floods and similar peak flow events will have an influence on the age structure, it is still considered likely that mature trees (older large individuals) will remain to provide insight into the stability of the moisture conditions present over reasonable temporal scales.

In the Pilbara evidence of such an age structure can be seen at the well-known and long studied Weeli Wolli springs. This spring is well known for its permanent surface water expression by both more recent land-managers and the long term traditional owners of the area who indicate that the spring has been used for hundreds of years. A report by Gavin Jackson P/L, dates many sites at hope downs (right beside the spring) as thousands of years old, and also provides an in-depth justification for inland Pilbara (particularly near the spring) as being settled near the last glacial maximum (Jackson P/L 2003). The spring is represented by a stretch of creek possessing generally permanent surface water as a result of and groundwater being forced to the surface by geological and topographical features. In the wetter parts of the spring the vegetation is broadly comprised of a *Melaleuca argentea* and *Eucalyptus camaldulensis* woodland (to open forest in places). A woodland is defined as being comprised of trees from 10-30 m tall and having a combined cover abundance of 10-30% (open forest being 30-70%) (Aplin 1979). Given this structure, and the observed size/age structure of this community, it is clear that a significant proportion of the obligate phreatophytic trees (*Melaleuca argentea*) in this area are considered to be mature and large in size. Such structure combined with recognition of long-term perennial water availability at Weeli Wolli Spring supports the concept that there is a direct relationship between the maturity of age structure shown by obligate phreatophytes in a community and the degree of moisture permanency present. Additional evidence for this relationship can be seen by the reducing maturity of age structure and more restricted distribution (restricted to minor populations lining the low flow channel) of *Melaleuca argentea* moving downstream and away from the permanent water source of Weeli Wolli spring.

In the case of the Marillana and Weeli Wolli creek systems and other similar systems in the Hamersley's, the most significant riparian communities are those containing a substantial *Melaleuca argentea* component such as:

- Weeli Wolli springs PEC;
- parts of some of the larger gorge systems flowing north out of Karijini National Park (e.g. Munjina Creek or Joffre Creek);
- some of the lesser known sections of Marillana creek (upstream of the study area) such as at and upstream of Flat Rocks; and
- small patches of other east and north western Hamersley Range Creek systems such as Mindy Mindy, Coondiner, and Southern Fortescue Creeks.

What all these areas have in common is the presence of varying sized representations of large mature *M. argentea* and *E. camaldulensis* woodland (similar to vegetation identified in the C1AA community). What these areas also have in common, is that in most cases the woodland is not represented by a sometimes very thin (almost single tree width) strip of this woodland which often forms on the banks of some permanent-to near permanent surface pools. Instead the relevant vegetation is spread across a broader lateral range of the creek indicating more general groundwater permanence through a larger proportion of the creek profile, and thus providing greater habitat and structural diversity values. Broader (laterally) representations like this appear quite restricted in their distribution within the Hamersley subregion, and consequently they can be considered sub-regionally significant.

Recent aerial photo interpretation (by Rio Tinto Botanical specialist Jeremy Naaykens) of most large creek systems in the Northern zone of the Hamersley sub-region (See figure 2-1) recognised and mapped relevant aerial signatures and some DMSI (where available) signatures likely to represent GDE's similar to or equivalent to this community (after comparison with signatures of known representations). By combining this recent aerial photo signature mapping with previous Rio Tinto vegetation mapping, a conservative figure for the current areal extent of similar representations of *M. argentea* and *E. camaldulensis* woodlands was created. From this mapping it was estimated that only 1/5 of the aerial signatures mapped are likely to accurately represent this community, and consequently no more than 10 km^2 or 0.0002% of the sub-region is represented by it.

Beyond these more extensive and significant stands of *M. argentea/Eucalypt* spp. woodland, where water availability is generally perennial; surface and groundwater availability in the remaining sections of the larger Hamersley Range creek systems are generally more variable. However at the smaller scale, landforms and features such as creek bends & corners, constricted channels and small scale geological anomalies can combine to more consistently retain surface water (or close proximity groundwater and small perched alluvial aquifers) than the majority of the general creek bed. In such cases, narrow isolated patches of OPV (similar to association C1AA) can be found lining large pools or occupying low points. However, such vegetation is more typically represented by a less significant community similar to the previously recognised C1 community (Biota 2014a). This comparatively less significant community tends to be a woodland to open woodland of *Eucalyptus camaldulensis* and *E. victrix* with *M. argentea* co-dominating in the low woodland or tall shrubland layer with other moisture loving species such as *Melaleuca glomerata*, *Acacia coriacea subsp. pendens*, *A. ampliceps*, *Atalaya hemiglauca* etc. Within the creek profile, this community is comparatively more restricted,

often concentrated around low flow channels and other consistently moist zones within the creek profile. This community is generally only considered locally significant, with a reduced suite of ecological values, and a slightly more widespread distribution. Recent desktop mapping exercises estimated that, excluding representations on major river systems, there is likely to be approximately 50km^2 of similar vegetation within the Hamersley subregion (0.0009% of the sub-region). This is purely an estimate, but as can be seen in Figure 2-1 this vegetation type is scattered throughout the Northern Half of the Hamersley's, and likely to be represented by isolated patches in the southern half of the Hamersley sub-region.

The remainder of the phreatophytic vegetation and generally significant but well represented units of the study area are essentially represented by; an open woodland (to woodland in places) of *E. camaldulensis* and *E. victrix* over patches of mixed low open woodland/tall open shrubland scattered throughout anna-branching channels and broad open creek bed zones. This vegetation community is typically one of the more common of the larger more topographically confined riparian systems within the Hamersley ranges (i.e. those dissecting significant range systems rather than occupying the finer soils of plains and broad alluvial valleys). The other more common and least significant community on systems such as these is represented by low open woodland (to scattered low trees) of *Eucalyptus victrix* over mixed *Acacia* spp. tall open shrublands (broadly equivalent to the previously mapped C3 unit mapped throughout the area (Biota 2014)).

2.7 SENSITIVITY OF LOCAL RIPARIAN COMMUNITIES TO HYDROLOGICAL IMPACTS

When considering development and associated impacts, it is pertinent that a measure of sensitivity/resilience be considered and attributed to features of significance so that an element of risk can be attributed to their ultimate significance.

While *Melaleuca argentea* co-dominated communities generally represent the most significant of the Marillana and Weeli Wolli Creek riparian communities because of their associated values and perennial water availability, it is this dependence on a perennial water source which makes them the most sensitive to anthropogenic hydrological changes. Despite the inherent sensitivity of these communities the age structure and distribution of the respective sub-associations of *M. argentea* co-dominated communities present in the Marillana and Weeli Wolli creek has some degree of influence on their sensitivity to impact. The most significant and mature representations of *M. argentea/Eucalypt spp. woodland* are likely to be most sensitive to change due to their generally higher water demands, broader lateral distribution within the creek profile, and mature age structure. At the other end of the scale is the community which possesses a youth dominated *Melaleuca argentea* age structure which is generally restricted in its distribution to lining key surface water features and low flow channel margins. Assuming a relatively regular regime of surface water flows, this community should be comparatively resilient to changes in groundwater availability when compared to the mature woodland community. *Melaleuca argentea* communities which fall in between these two ends of the scale of sensitivity will generally possess sensitivities commensurate to their water demands, predominant age and maximum distance from low flow channels.

2.8 FRAMEWORK FOR SIGNIFICANCE

For the purpose of incorporating a sense of "quantification" to the process of attributing significance to riparian communities within the study area, the following "framework for Significance" is proposed as a means of providing a systematic qualitative assessment of significance:

Key steps for considering the relevant factors/attributes are:

1. Part one - consider the number and magnitude of ecological values associated with or provided by a biological feature.

2. Part two - determine the distribution and therefore degree to which it is restricted in the environment, the degree of representation (the degree to which a vegetation unit is represented by other communities outside of the study area), and potential rarity of this feature within local, sub-regional, and regional scales.

3. Part three – consider the condition of the biological feature, and its inherent resilience to perturbation.

Once determined, the combined consideration of these three key attributes is used to determine a significance rating. The inherent sensitivity or resilience of a feature to perturbation will tend to increase or decrease the likelihood of impact, as well as the consequences of the impact. In addition, the current condition of the feature at the time of consideration will have an influence on its significance. In order to incorporate sensitivity/resilience and locally known potential anthropogenic impacts into the resultant significance, it is proposed that for this study, the term "Development Significance" will be created and used to attribute an alternative and only locally relevant significance to the biological features of the study area. In addition this term will incorporate the condition of the feature as well and the inherent risks and consequences of development on this feature into the attributed significance. The "Development Significance "will in turn provide more measured guidance to management and mitigation as development is undertaken or continued.

The resultant significance is to be attributed to one of the levels in the following scale, via the process of assigning a measure of the factors presented for each level below:

1. Low (generally common and well represented, and with no additional values identified and commonly highly resilient to perturbation).

2. Minor (generally common and well represented, but with additional values identified).

3. Minor-Moderate (Somewhat restricted or uncommon, or possessing some key local values).

4. Moderate, (Locally restricted, and possessing some key local values).

5. Moderate-High, (Local to broader scale degree of restriction and possessing key ecological values (often along with and some degree of reduced resilience or sensitivity)).

6. High, (At least sub-regional scale degree of restriction and possessing multiple key ecological values and often a degree of sensitivity to perturbation).

7. Very-High (Potentially regionally restricted, multiple key ecological values identified, and often possessing a well-known social-biological value or proven to support key populations of Threatened flora/fauna, and often with an inherent degree of sensitivity to perturbation).

Importantly it should be noted at this point, that the above is a relative scale, and while it presents a system for defining the different levels in the scale, some of the factors presented to determine if a biological feature is attributed to a level may be perceived as arbitrarily assigned. What is important

is that it provides a scale of enough detail to allow for the various available combinations of those factors described as influencing the determined significance (i.e. degree of restriction, values etc.).

This report does not attempt to deal with the term conservation significance; this is an additional level of subjectivity which is not proposed in the context of this study. However, it is noted that in many flora and vegetation assessments the most significant features (potentially equivalent to the High to Very-High significance ratings presented in this report) are often determined to be conservation significant. As a consequence, avoiding direct impacts to features of high significance is generally important, while avoiding or minimising significant indirect impacts should at least be an objective where practicable.

2.9 HISTORY OF DEWATER DISCHARGE IN THE VICINITY OF THE STUDY AREA

Discharge of surplus dewater from the BHPBIO Yandicoogina mine operation into Marillana Creek began in May 1991 (see Figure 3-5 to 3-11 for the location of the various surplus water discharge locations). In 1998 Rio Tinto started releasing surplus dewater into Marillana Creek and by December 2006 the combined operations were discharging at an average rate of 34 ML/day-1. Release of surplus dewater directly into Weeli Wolli Creek began in 2006 (pre-mining discharge from Hope Downs and intermittent discharges from JSE), with expansion of the Rio Tinto JSE mine and development of the Hope Downs 1 operation, approximately 20 km upstream of Yandicoogina. In addition to this, an array of re-injection bores were brought on-line in 2007 re-injecting surplus-discharge into the local aquifer immediately to the east of Weeli Wolli Creek in the vicinity of the proposed PBS project area (this ceased in late 2014). In 2009, approximately 49 GL of surplus dewater was discharged into Marillana and Weeli Wolli Creeks, consisting of:

- ~14 GL into Marillana Creek from the Hamersley Yandicoogina operations;
- ~5 GL into Marillana Creek from the BHPBIO Yandicoogina operations; and
- ~30 GL into Weeli Wolli Creek from Hope Downs 1 mining operations (~20 km upstream from the Marillana Creek confluence).

The combined discharges of the various mining projects in the catchment have resulted in continuous (perennial) stream flow and potential saturated creek bed conditions in the downstream sections of the Marillana and Weeli Wolli Creek systems (the study area). Since 2008, the surface water discharge footprint, defined as the extent of surface water expression, extends to up to ~8 km beyond the confluence of the Marillana and Weeli Wolli Creeks. The surface wetting front fluctuates over a distance of approximately 5-9km, depending on climatic conditions and surplus water discharge rates.

Sub-catchment areas in the vicinity of the Rio Tinto and BHPBIO operations have been modified by the construction of diversion structures, mine pits and haul/access road crossings. Changes to the direction and pattern of surface flows have resulted, with an overall reduction in flow contributions to Marillana Creek compared with the pre-disturbance regime. Hydrological modelling undertaken by Rio Tinto indicates that the existing operations have caused only minor reductions in flow contributions to Marillana Creek; in the order of 1% of the pre-disturbance flow volumes (Rio Tinto 2010).

2.10 SURPLUS DEWATER DISCHARGE, VEGETATION AUGMENTATION AND PHREATOPHYTIC VEGETATION DISTRIBUTION IN THE STUDY AREA

For riparian vegetation communities present in the study area, the resultant scale of significance attributed to these communities is largely a product of scales of water availability, such that the more perennial surface and groundwater becomes the more significant the vegetation, flora and associated habitats tend to become. An unavoidable outcome of this is that 'significant' vegetation communities will establish where development artificially increases the availability of water. Assigning significance to such vegetation communities, as they are artificially augmented by altered hydrological conditions, can be problematic.

Evidence on Marillana Creek, in the vicinity of the Rio Tinto Yandicoogina operations, suggests that surplus dewater discharge can and has facilitated the establishment of abundant *Melaleuca argentea* populations in certain highly restricted creek zones. However, if *M. argentea* is the species most sensitive to groundwater changes, and it is observed to be flourishing in an environment where groundwater tables are heavily reduced (i.e. locations surrounding the mining pits), it is most likely being sustained and established by surface water discharges, which in effect irrigate these trees. While this surface water discharge is likely to maintain a shallow depth to groundwater within close lateral proximity to surface flows, in general the distribution of this groundwater appears highly restricted. These observations suggest that *M. argentea* it is more accurately highly moisture dependent rather than reliant on the presence of local groundwater aquifers. Therefore in general, the source of water (i.e. regional or local aquifer groundwater, perched aquifer or alluvial pore-water or surface water flows) is likely to be less important than the consistency of its availability and the ability of obligate phreatophytic components of the vegetation to access it. In the case of patches of OPV immediately downstream of discharge points on Marillana creek such as the BHPBIO discharge, it is postulated that:

> *If this vegetation was a product of natural historical groundwater presence it is most likely that its distribution within the creek system would be less laterally restricted to the low flow channel and spread more laterally within the broader incised creek channel (such as is present in other stretches of Marillana Creek and at well-known examples like Weeli Wolli spring).*

However this concept should not be overstated and it is possible the available surface and ground water in certain pre-discharge circumstances was confined to the immediate low-flow channels and therefore not available across the broader channel under baseline conditions. However the assumption is that in general, under baseline conditions, areas of perennial water availability are most often associated with laterally broader subsurface water availability than that generally apparent within stretches of the study area being artificially irrigated via surface water discharge.

Weeli Wolli spring is characterised as a GDE with significant stands of OPV supported by the surface expression of the local groundwater table. In the vicinity of the spring a significant proportion of OPV possesses a relatively broad lateral distribution within the creek profile, a more evenly distributed age structure and the common presence of large/old trees.

Based on observations at Weeli Wolli Spring and other known areas of groundwater dependent OPV, it would be expected that the majority of GDE vegetation established under baseline groundwater and surface water conditions, would exhibit an age structure similar to that observed at Weeli Wolli Spring; that is, an even frequency distribution of size classes from saplings to large mature trees. In

addition it would also be expected to see a reduced degree of lateral restriction in the distribution of OPV within the typical creek profile. By extension, GDE vegetation which occurs mainly as thin strips lining the low flow channel, and dominated by a young unevenly distributed age structure, is likely to have established following the onset of discharge. Comparison of flora and vegetation surveys before and after commencement of discharge, interpretation of temporal changes in aerial imagery and observations of present day riparian ecology generally support this interpretation.

What is observed in many cases along Marillana and Weeli Wolli creeks, are thin strips of OPV lining the low flow channel and possessing an age structure, which is disproportionately represented by young individuals. Furthermore, within such representations of OPV in the study area, the distribution patterns of larger/older individuals (while typically still quite young by comparison with other known representations) appear to show a positive correlation with proximity to discharge points, such that decreasing and relatively minimal to negligible numbers of older individuals are seen as distance downstream from discharge points increases.

Differing aerial photo signatures shown in photography acquired from the area before and after surplus water discharge commenced in the study area show apparent trends in vegetation augmentation surrounding the key low flow features evident within the creek profiles of Weeli Wolli and particularly Marillana Creek. Best available aerial photography from Marillana creek around the time when discharge was initiated in that area (1994-1995 from the BHPBIO discharge point) shows a distinct lack of similar dense-vegetation signatures surrounding low flow features when compared to present day aerial photos. Furthermore, vegetation mapping from the 8 km stretch of creekline downstream of the BHPBIO discharge point channel completed by Mattiske in 1995, did not indicate the presence of OPV lining the low flow channels of the riparian corridor (Mattiske 1995a). In addition to this evidence, photos taken along this same stretch from a helicopter recconnaisance of the area in 2010 provide addiitonal temporal information. These photos show a thickening strip of vegetation along the low flow channel which appeared to contain populations of young *M. argentea* individuals, but also shows a lack of this species in the remainder of the adjacent vegetation occuring within the broader creek bed and associated secondary channels.

The pattern of evidence available, suggests that the pre-impact distribution of OPV communities in the study area, communities similar to the C1 association identified as part of Biota's post-discharge surveys (Biota 2014a), was highly restricted, such that its presence in Marillana and Weeli Wolli creeks was quite uncommon and generally very small in spatial extent.

The potential that a substantial proportion of the significant riparian communities of the area are artificially augmented, and previously absent from the majority of the development area is an important insight when considering the potential impacts of anthropogenic hydrological changes. It appears likely that the surplus water discharge associated with development can provide the conditions necessary to promote and establish OPV in areas where the natural generally ephemeral water availability of the existing environment is unlikely to have supported OPV. This raises the question; if a community is established to be artificially augmented such that it is now considered to represent OPV, is the potential Impact to it now considered significant (beyond the values of the pre-discharge community) given the values and significance generally associated with OPV. To answer this, the first step is to establish that the original community was one that was significantly less mesic, was supported by generally ephemeral water availability, and therefore did not possess a substantial *Melaleuca argentea* component. Once this is established then the logical conclusion would be that regardless of the significance of the resultant community; if the pre and post mining

environment cannot support it (i.e. it did not provide perennial water availability) then impact to the community is inevitable. In such cases the important distinction is that those impacts defined as inevitable are confined to impacts associated with the removal of the additional values/significance attributed to the augmented community. Furthermore; while these impacts may extend to those community changes resulting from the successional processes likely to occur in the transition to ephemeral water availability (e.g. high mortality rates likely among recruitment etc.), the final or climax community which results should be quite similar to the community which existed pre-discharge.

Given the historical influence of development in the area, a key goal of this study is to attempt to establish the location and actual significance of the higher value riparian communities in the area. As a result a significant part of the following study is aimed at gaining detailed information about the composition and distribution of vegetation in the present riparian environment so that it can be used in conjunction with other sources of information to shed light on the composition of the pre-discharge environment. Once this is done, it is predicted that the path to determining the baseline riparian values of the area and the true consequences of impacting the present environment as a result of mining-related impacts will become clear.

2.11 GROWTH RATE PROJECTIONS AND THE DISTRIBUTION OF OPV IN THE PRE-DISCHARGE ENVIRONMENT

An important objective of this study is to contextualise the significance of vegetation communities both currently and historically present, but also contextualising the potential impacts from proposed development on these communities. A key concept requiring exploration is the concept that in some cases, the presence of highly sensitive groundwater dependant species such as *Melaleuca argentea,* and associated OPV communities, may essentially be a product of vegetation augmentation by surplus-water discharge. What this suggests in certain areas is that; historically the generally ephemeral water availability is unlikely to have sustained OPV, and it is only since the provision of perennial surface water-flows (from continuous surplus-water discharge) that the associated fluvial environment has enabled their establishment.

To explore this concept further and demonstrate whether the provision of perennial surface water flows are likely to have significantly influenced the distribution of OPV in the study area, the key question requiring exploration is:

> *Which present day patches of Melaleuca argentea co-dominated community (OPV) if any, present a "young" age structure of consistently uneven frequency distribution, such that it could easily be inferred to have established since mining discharge has provided perennial water?*

Consequently to determine in any particular area whether present-day populations of *Melaleuca argentea* indicate their likely pre-discharge presence, the following questions must be addressed:

1. Using tree trunk size as a proxy for age, how is an individual/population likely to grow in 9 (Weeli Wolli Creek) and 15 years (Marillana Creek) post seedling establishment? (Measured in average DBH change of *Melaleuca argentea* individuals present in the Pilbara and growing under near-optimal conditions).

2. With this figure in mind; what average DBH for the larger individuals of a resident population of this species would represent the upper limit of DBH considered likely to have only established since discharge commenced?

By answering the first and then the second question, a DBH figure which can be compared to the data collected in the study area can be attained. This comparative DBH figure then provides cut-off figure for use in demonstrating which potentially discharge augmented OPV patches are likely to have been absent in the pre-discharge environment.

The following detailed vegetation mapping refinement exercise and associated field data will form the framework with which to answer these questions and make inferences about the distribution and historical significance of local riparian communities.

3 METHODOLOGY

3.1 MAPPING REFINEMENT

3.1.1 Introduction

The vegetation mapping refinement component of this work focused on addressing apparent disparities in the previous mapping of vegetation units consistent with and associated with phreatophytic vegetation (or GDE's), and with a particular emphasis on those most sensitive to surface and groundwater hydrological changes associated with mining (i.e. OPV). As discussed earlier, within the Pilbara it is generally accepted that the most hydrologically sensitive communities are those possessing a significant component of *Melaleuca argentea*. With awareness of this point, an initial review was undertaken to identify tools suitable for identifying the likely distribution of such OPV communities at a desktop level. A field plan capable of ground-truthing the predicted and potential spatial distribution markers for OPV communities in the study area was developed following completion of the desktop mapping process. This field plan was also developed with the aim of compiling additional fine scale information about the spatial distribution and composition of other less sensitive/significant vegetation communities (FPV) within the study creek systems, for the purpose of supplementing the vegetation mapping refinement process.

Together the desktop work and field plan would allow for a more comprehensive refinement of the spatial distribution (mapping) of key riparian vegetation communities throughout the study area. Quite importantly this desktop/field-based work would also be designed in a way which collected information which would provide a framework for contextualising and incorporating historical changes into the resultant vegetation model.

It should be noted that the refinement of vegetation boundaries and descriptions was only conducted on riparian units occurring within the major creek system riparian habitats of the study area (essentially the "C" coded units). As a result of this refinement some of the original riparian vegetation codes (C1, C2, and C3 coded vegetation - Biota 2014a) have been slightly altered to help them fit within the new vegetation-mapping framework. In an effort to maintain the logic and intent of previous mapping unit delineation and coding, the original codes and the hierarchy of significance which they attempt to convey have been maintained as much as possible while still allowing them to reflect the new findings and resultant structure.

The vegetation and flora field survey conducted as part of this study was undertaken in accordance with the requirements outlined in the EPA guidance documents (EPA 2002, 2004a). With respect to data collection methods; this survey acknowledged the large amount of Quadrat/Relevé based data collection which has previously been conducted within the study area. Coupled with knowledge that riparian species composition can both stay relatively consistent and vary significantly over small spatial scales, it was concluded that the degree of information on the associated floristic composition of riparian communities already captured within the study area was sufficient to meet the objectives of this study. Following this conclusion, it was identified that "mapping Traverses" was the data collection tool most effective for the purpose mapping refinement and the tool which hitherto had been used to a lesser extent in the riparian zone of the study area. Mapping traverses, generally comprise walking through the target area and regularly taking notes and spatial information on the apparent vegetation associations/sub-associations present and the location and pattern of boundaries which separate them. By aligning these traverses to maximise their potential

to regularly test the spatial position of these boundaries, such a technique quickly establishes an effective database with which to correlate these patterns with similar patterns in aerial imagery. It is for these general reasons that this is one of the most effective techniques for refining vegetation mapping. The use of mapping traverses oriented to repeatedly intersect vegetation boundaries allowed a focus on the establishment of vegetation boundaries and hence development of robust fine scale vegetation mapping for the areas investigated.

It should be noted that typical vegetation mapping is essentially a model, such that the spatial validity of boundaries and the vegetation associations depicted to lie within is only true a portion of the time. In general the proportion of time which the model is correct is directly correlated to the amount of ground-truthing which is done per unit area of the model, and the scale of the community descriptions created. The third influencing factor is generally considered to be the complexity of environmental factors influencing vegetation ecology, but for the surveyor this is an uncontrolled factor and is therefore not generally considered in detail. For the vegetation mapping model presented as a part of this study, it was a requirement that it provide a very high degree of accuracy in relation to the spatial location and distribution of OPV communities. As a consequence the degree of ground-truthing effort planned and conducted within the riparian zone (particularly the incised channel zone) was very high, such that the mapping is considered to be significantly more accurate than typical vegetation mapping undertaken in typical flora and vegetation surveys within WA. Despite this spatial confidence, and despite the spatial scale and detail within vegetation associations descriptions having increased (become finer) the vegetation map is still a model, and so the accuracy of the vegetation descriptions modelled to be present at any one point in the map is still variable to some degree. However in the case of the model presented, it is considered to be significantly more accurate than previous models due to the additional modelling effort which has been conducted.

3.1.2 Tools Developed at a Desktop Level for use in the Field

Photosynthesising vegetation cover on both Marillana and Weeli Wolli creeks was assessed using Normalised Difference Vegetation Index (NDVI) images generated from high resolution (0.5 – 1 m pixel) remotely sensed digital multispectral imagery (**DMSI**). NDVI relies on the fact that photosynthetic organisms have the unique characteristic of reflecting nearly all infra-red electromagnetic radiation, and absorbing significant amounts of the red visible wavelength of electromagnetic radiation (used for photosynthesis)(Specterra Services 2010). As a result an index calculating the ratio between the intensity of the two wavelength ranges provides a simple measure of vegetation cover/density. NDVI imagery of the relevant creek stretches were visually assessed by a specialist botanist for occurrences of high-density vegetation signatures (i.e. areas where a comparatively high degree of vegetation cover was evident in comparison to surrounding riparian vegetation cover signatures) likely to indicate presence of mesic conditions and therefore potentially GDE's. GDE's such as OPV are recognized to be associated with a high degree of groundwater presence, thus given the consistent presence of moisture, combined vegetation cover associated with these areas is often relatively dense (i.e. canopy cover, combined with cover related to shrub and groundcover strata combine to provide aerially dense cover signatures) and often possesses a comparatively denser canopy cover in relation to surrounding more widespread riparian vegetation. Consequently areas of the creek system showing comparatively higher measures of vegetation cover are often the areas where groundwater is close to the surface and species such as *M. argentea* are present in significant numbers. Plate 1 shows one example of a high density NDVI signature and one example of a sparse NDVI signature. High vegetation cover signatures were identified and

mapped throughout the study area. Plate 2 and Plate 3 show two examples of the PCD signature mapping which was conducted across the study area for the purpose of ground-truthing. Figure 3-1 to 3-5 present the NDVI imagery and distribution of high PCD signatures present across the study area, which was used as a supporting tool for the GDE interpretation and ground-truthing process.

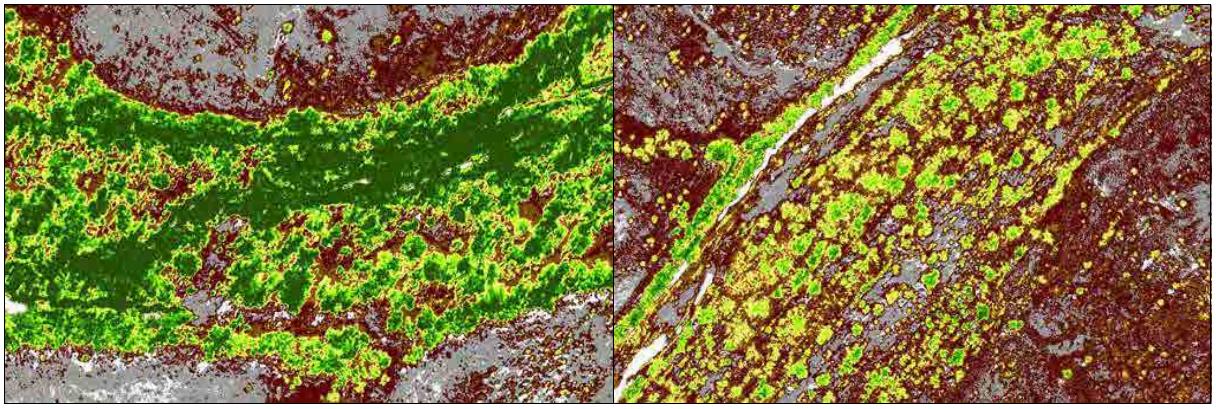

Plate 1: Samples of NDVI image showing a high density NDVI (vegetation cover) signature on the left and a sparse cover NDVI signature on the right

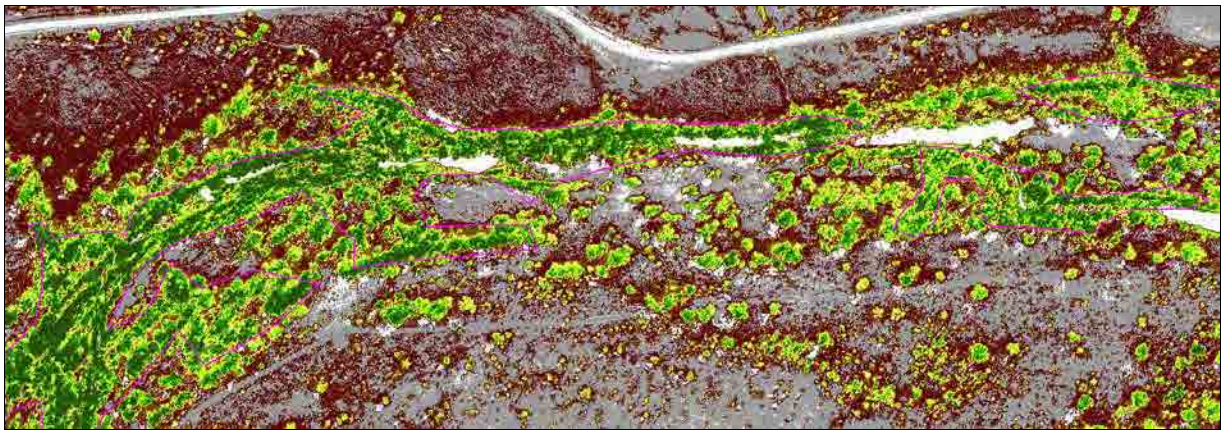

Plate 2: Example 1 of dense cover NDVI signatures digitised (pink bordered polygons) and delineated from more typical creek vegetation densities/canopy covers along two sections of creek

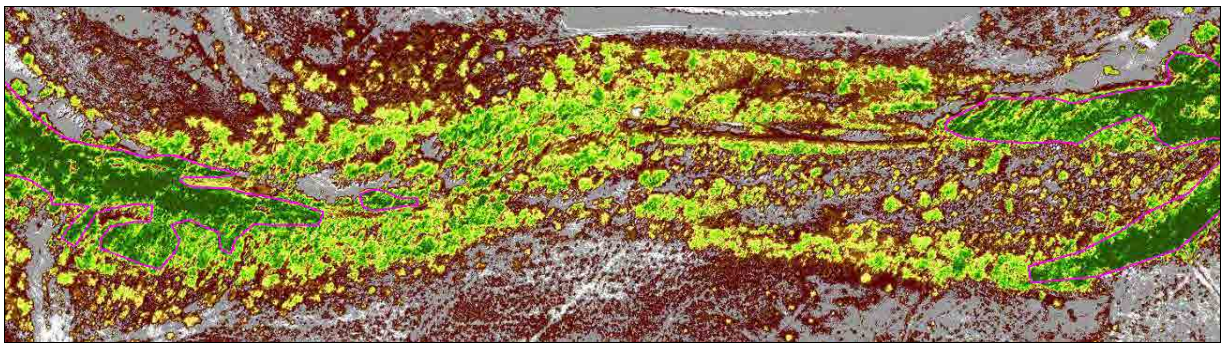

Plate 3: Example 2 of dense cover NDVI signatures digitised (pink bordered polygons) and delineated from more typical creek vegetation densities/canopy covers along two sections of creek

In addition to the high cover NDVI signature mapping, pre-discharge impact historical aerial photography was visually assessed to identify and map areas of dense vegetation and consistently formed canopy cover. Through an analysis of available aerial photography by an experienced Pilbara botanist, dense vegetation signatures were mapped to create digital polygons identifying general areas of elevated vegetation-density/canopy-cover. In addition, and as part of this process, an

alternative set of digital polygons were produced which represented the “particularly dense and more anomalous swathes of historical vegetation” detected.

Polygons digitised from both NDVI images and historical aerial photography were uploaded to GPS as transparent polygons and overlaid onto the actual NDVI image. In addition to this, polygons of previous mapping of significant riparian vegetation units were also uploaded to GPS as transparent polygons. To facilitate the effective use of ground-truthing tools in the field, separate GPS units were used in the field to avoid clutter and obstruction on the GPS screen while traversing the creek system. Three separate GPS units were used; one for ground-truthing (the NDVI map and associated digitised polygons), one for waypoint creation (approximately 1400 waypoints were created during this exercise), and another for navigation throughout the area (tracks, infrastructure, and riparian zone delineation).

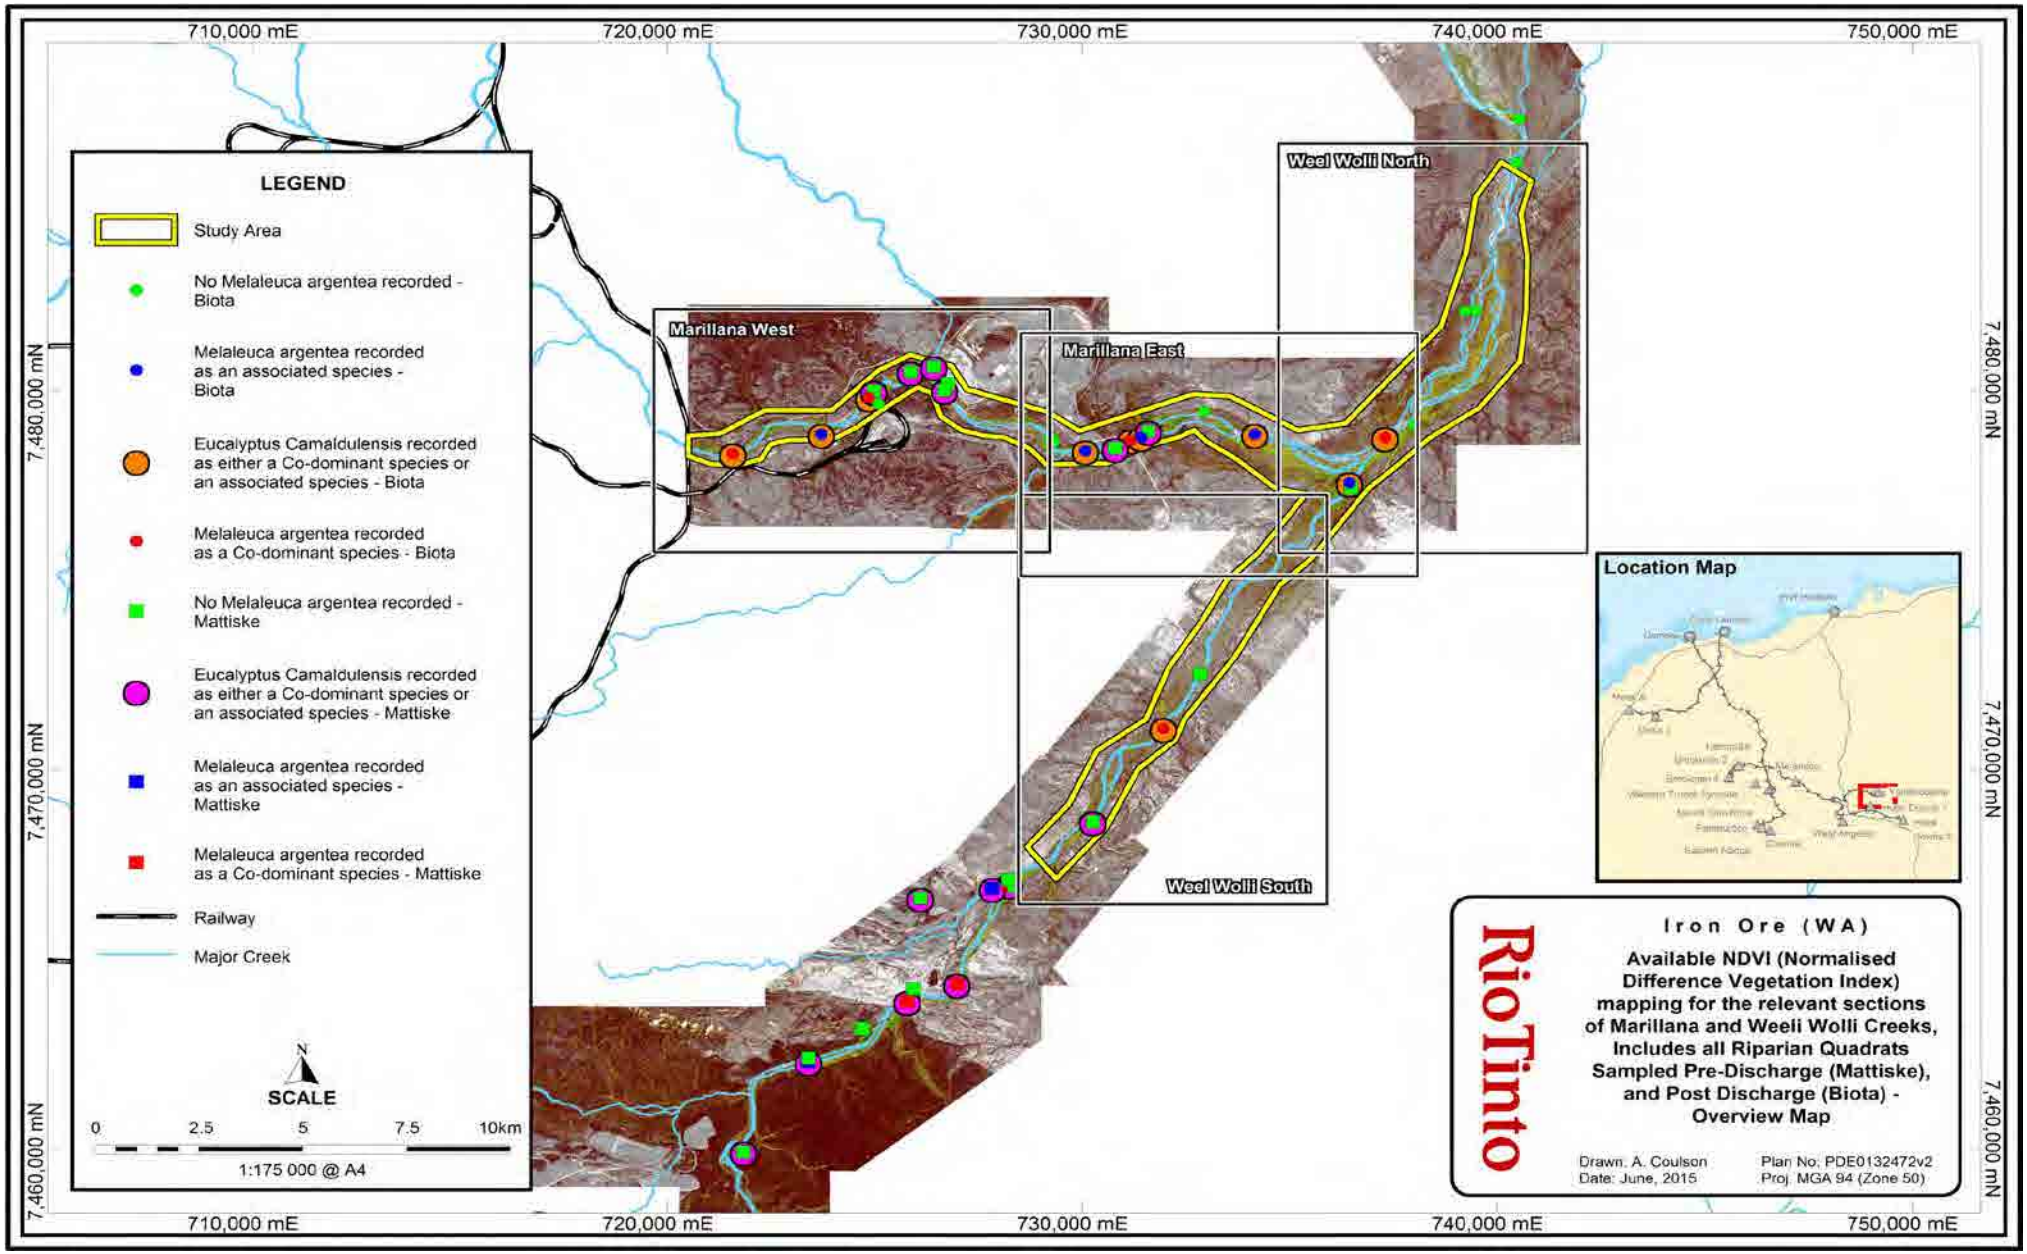

Figure 3-1: Overview map showing available NDVI imagery maps for Marillana, Weeli Wolli North, and Weeli Wolli South study area reaches

These maps also display the location of the most relevant riparian quadrats sampled as part of previous flora and vegetation survey work conducted in the study area. Labelling of these quadrats indicates the presence/absence of Melaleuca argentea and Eucalyptus camaldulensis at the time of survey, and the timing of sampling based on a pre and post discharge timeline. NDVI imagery from Nov 2010

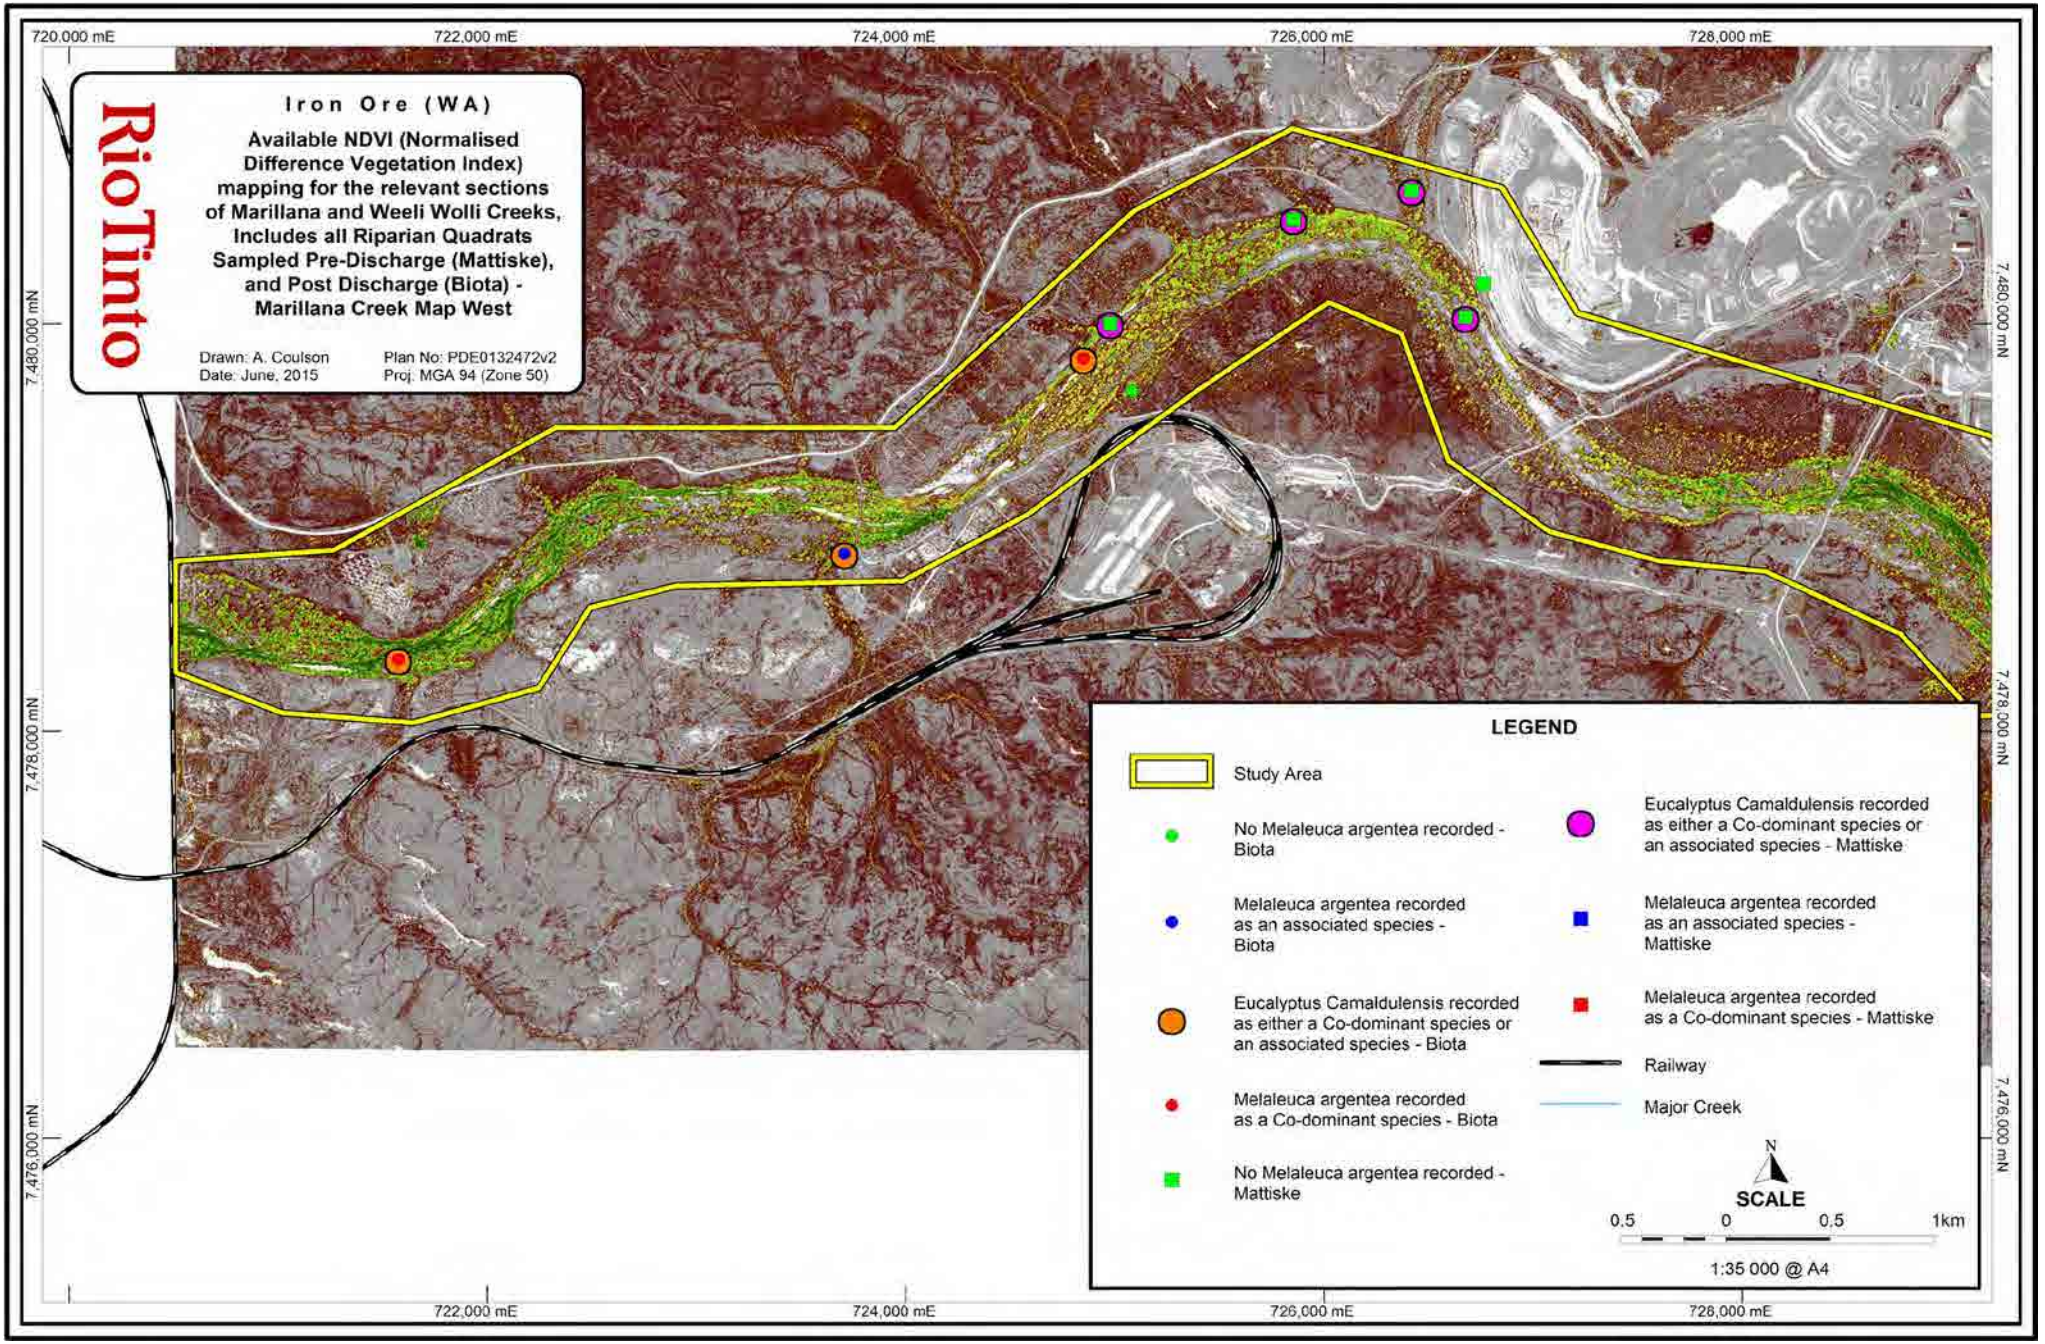

Figure 3-2: NDVI imagery map for the Marillana Creek reach of the study area. Includes riparian quadrats previously sampled and an indication of key phreatophytic species presence

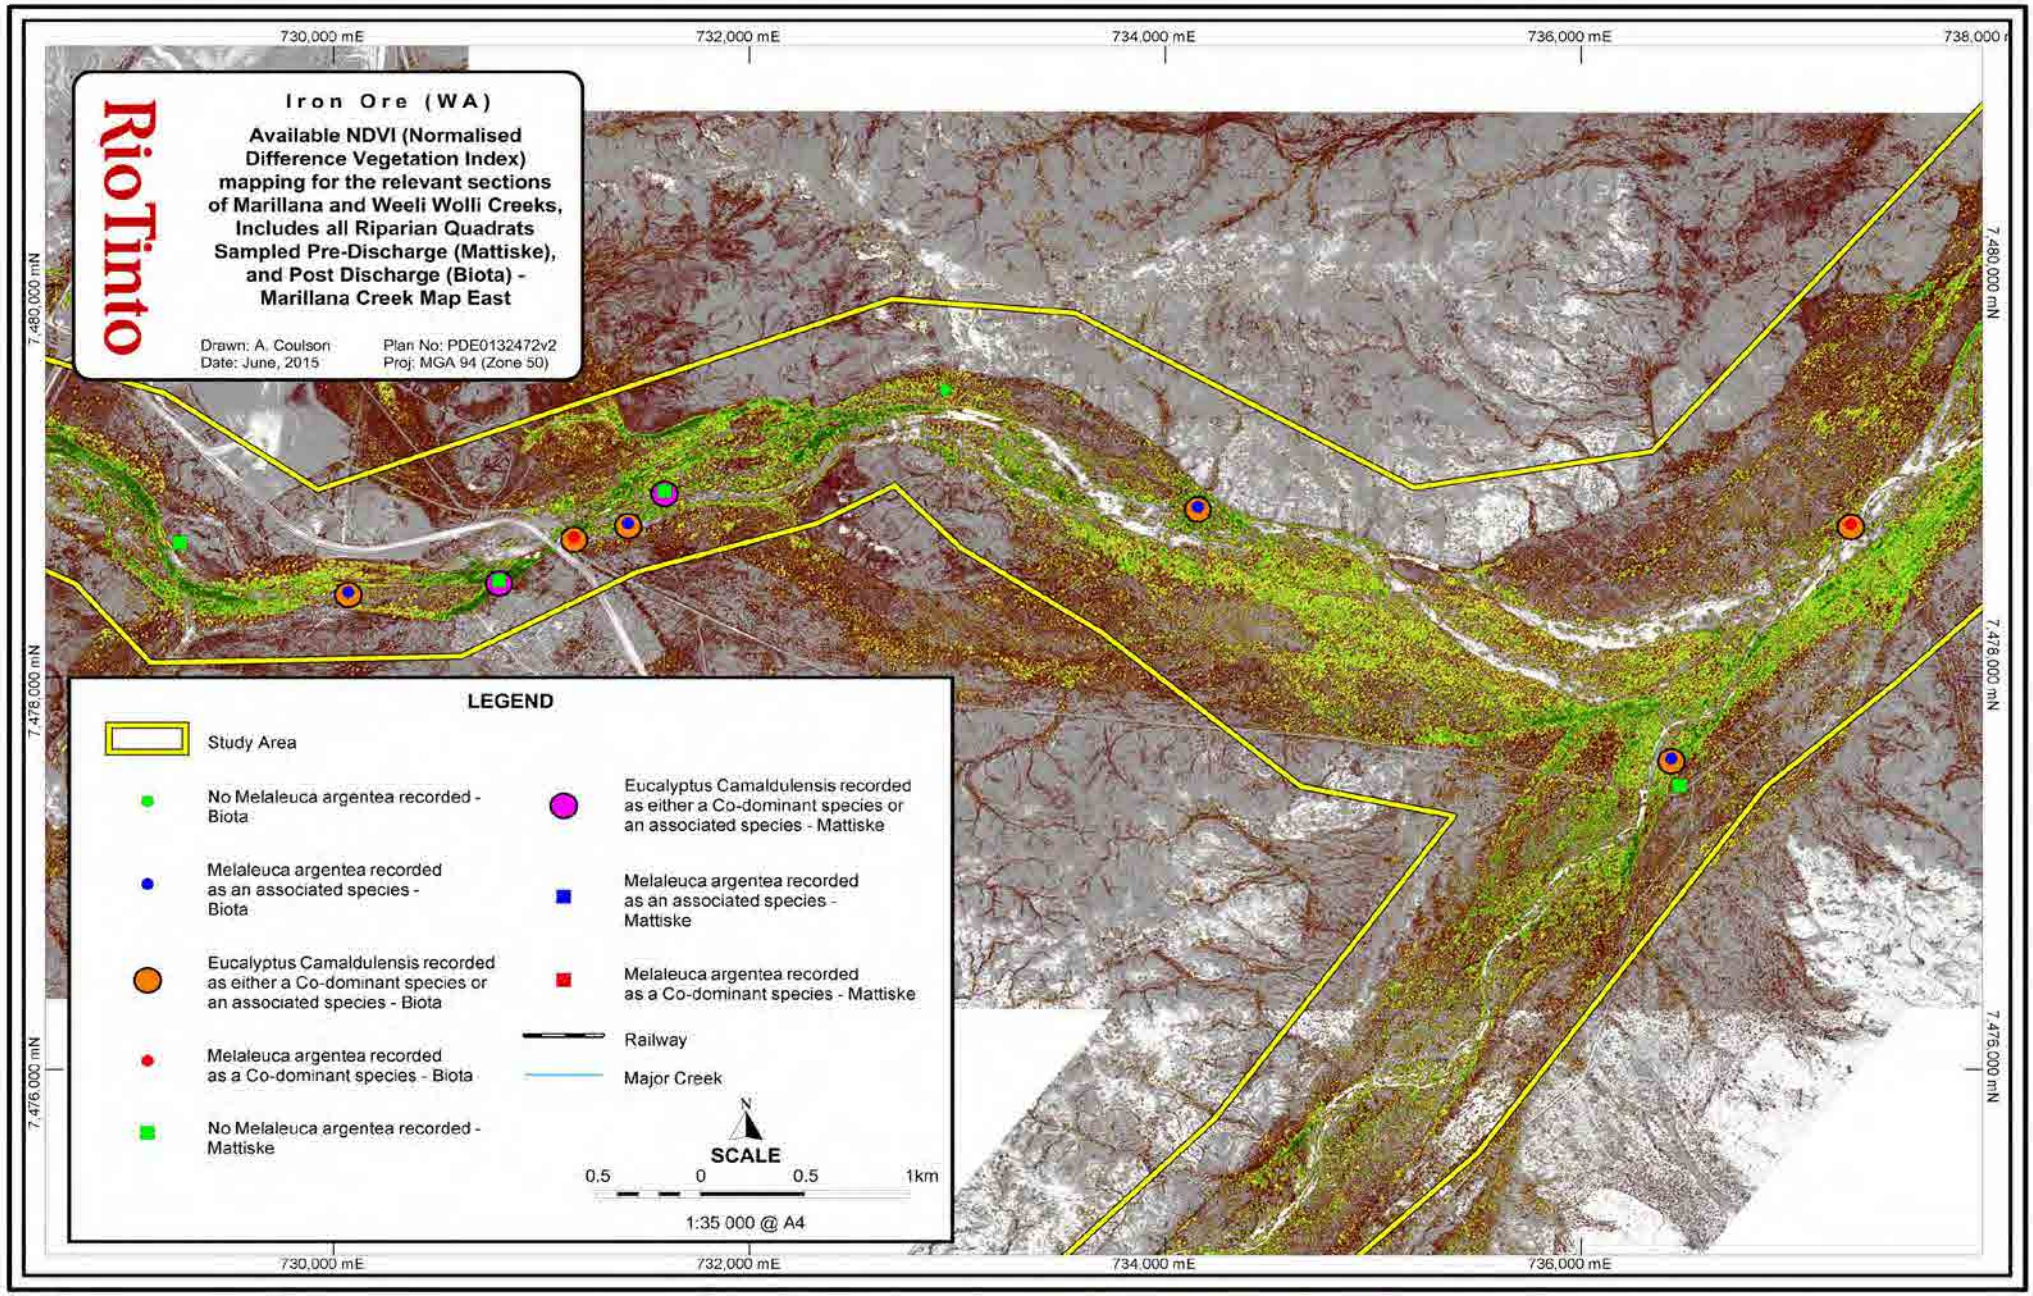

Figure 3-3: NDVI imagery map for the Weeli Wolli Creek North study area reach. Includes riparian quadrats previously sampled and an indication of key phreatophytic species presence

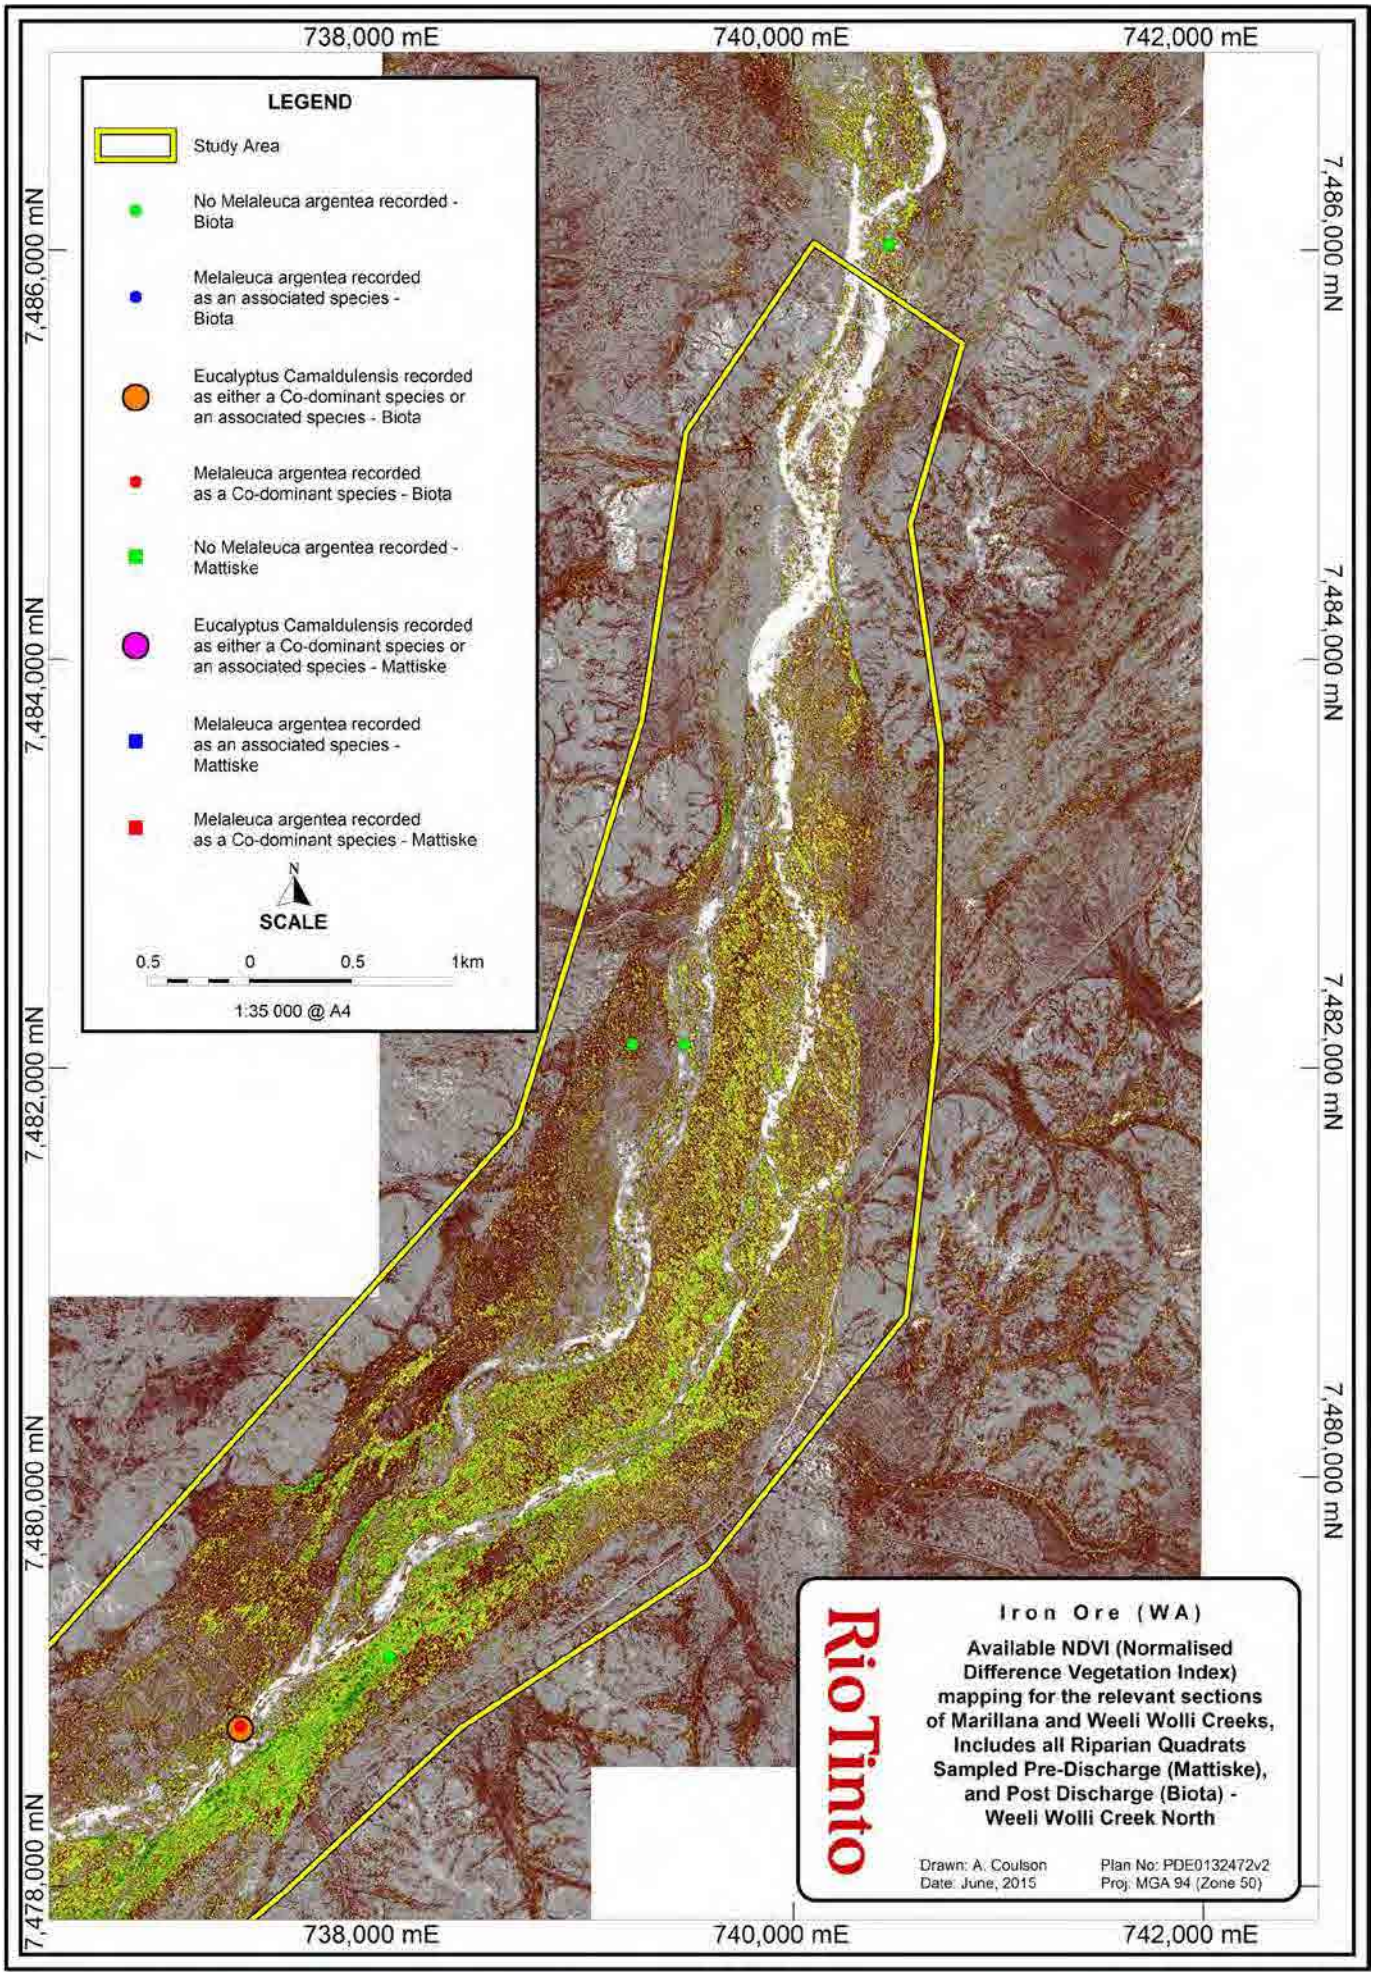

Figure 3-4: NDVI imagery map for the Weeli Wolli Creek North study area reach. Includes riparian quadrats previously sampled and an indication of key phreatophytic species presence

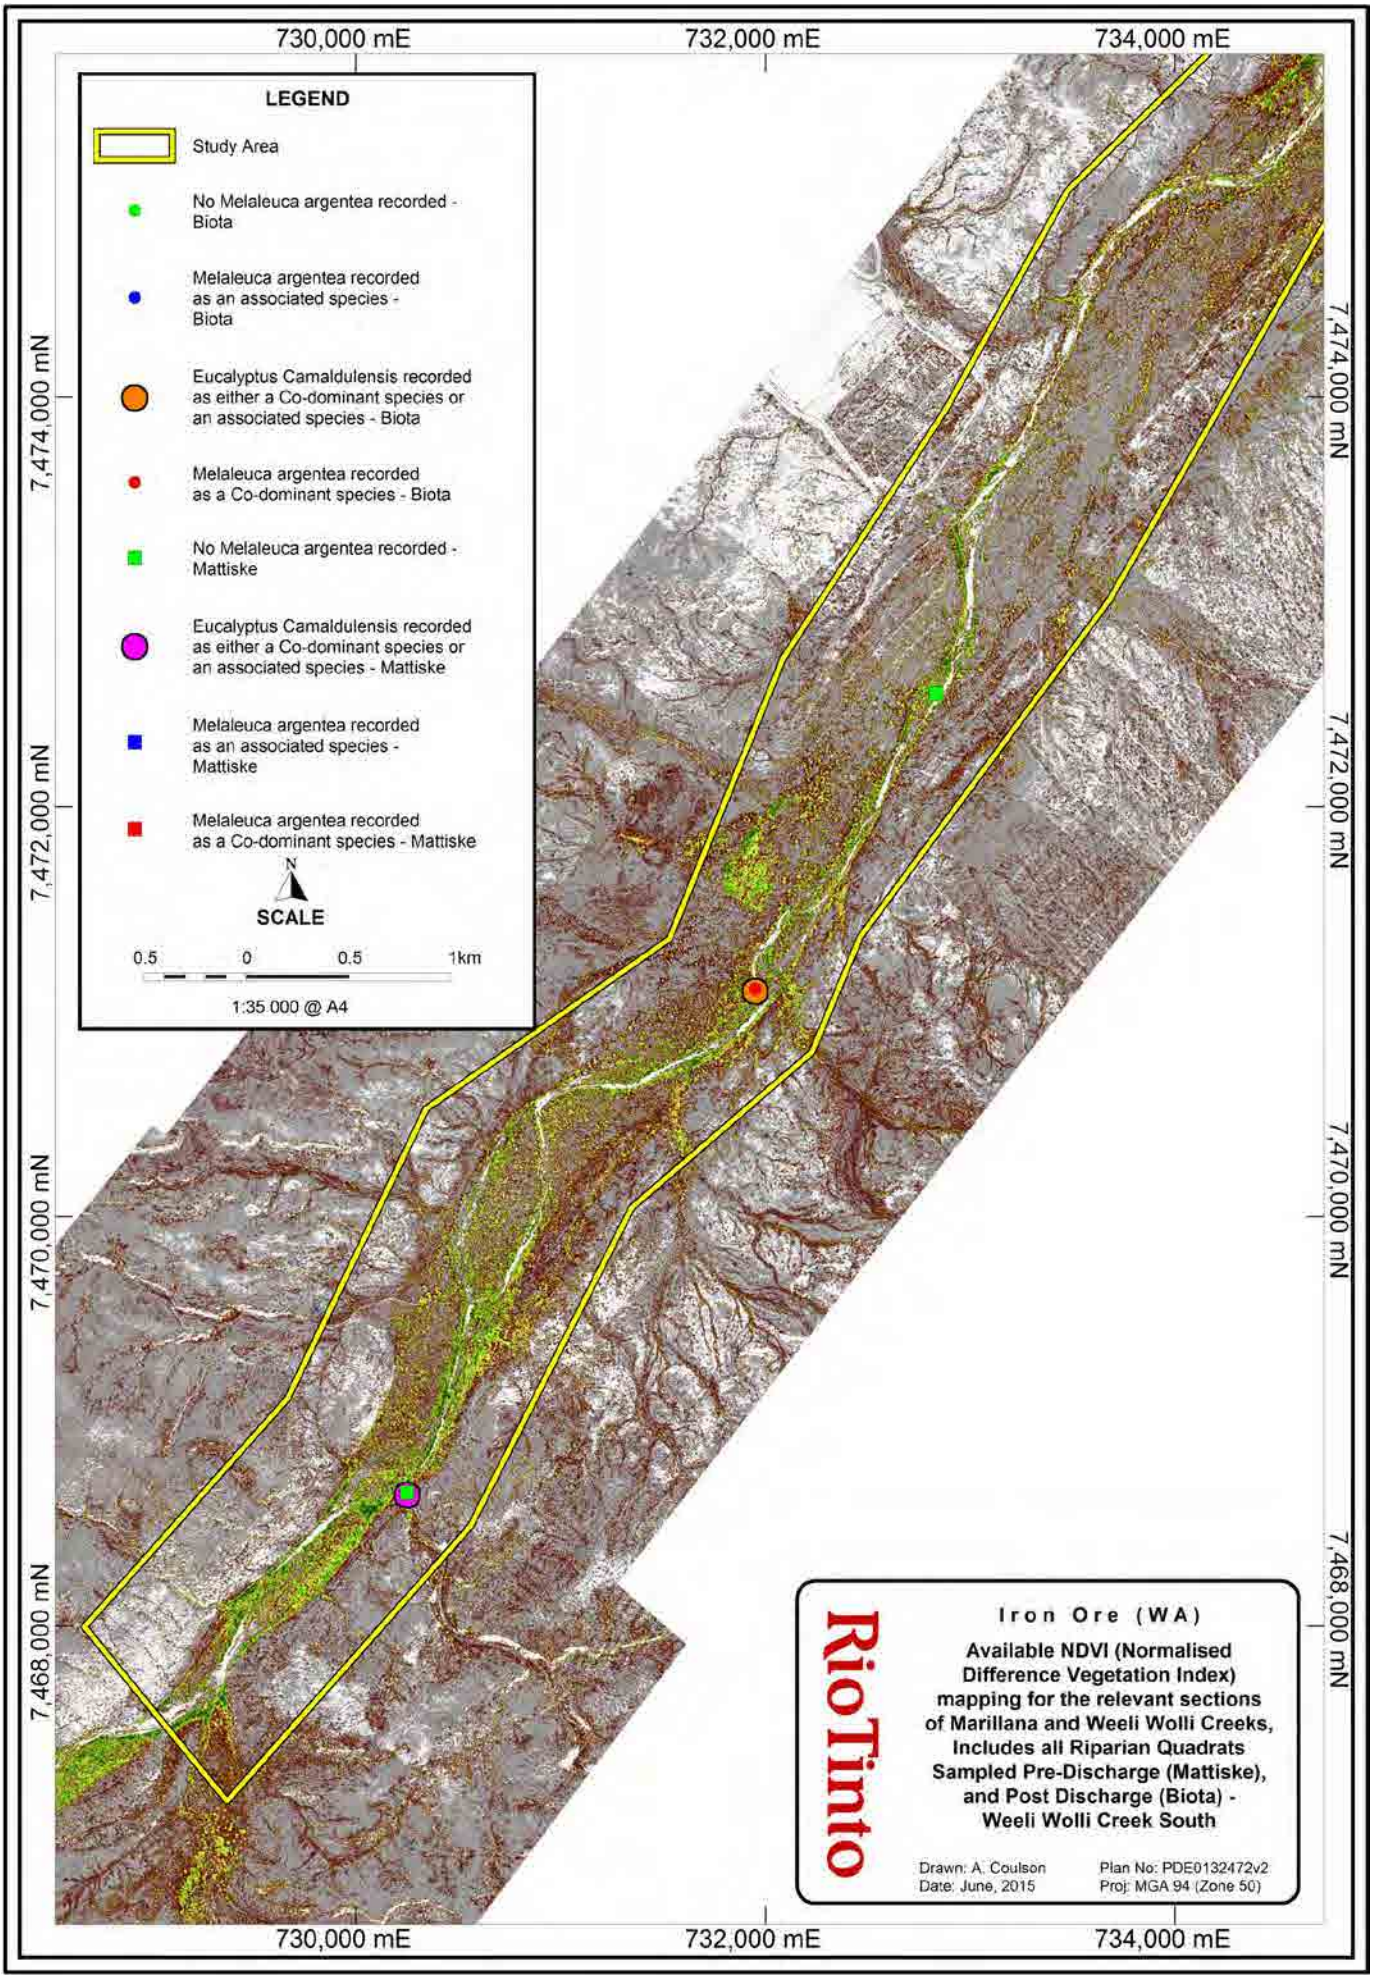

Figure 3-5: NDVI imagery map for the Weeli Wolli Creek South study area reach. This map also includes riparian quadrats previously sampled and an indication of key phreatophytic species presence

3.1.3 Ground-truthing and Mapping Refinement Field Work

With the above tools in place a field data collection framework was devised and focused on the following key tasks:

Within the study area (local stretches of Marillana and Weeli Wolli creeks):

1. Traverse the entire length of the incised creek profile (while periodically intersecting the inner portion of the adjacent floodplains) to gain an understanding of the ecology and distribution of significant communities present within its boundaries. In addition to this; gaining an overarching awareness of the variability, morphology and spatial distribution of the different creek profiles and associated substrates present throughout.

2. The ground-truthing of identified NDVI signatures, and historical aerial photo mapping of dense-vegetation to confirm the presence/absence of phreatophytic species (namely *Melaleuca argentea*, and to a lesser extent useful GDE indicator species such as *Eucalyptus camaldulensis, Acacia ampliceps* and *Typha domingensis*).

3. Record specific data about the spatial boundaries/distribution and age structure of *Melaleuca argentea* populations encountered throughout while searching for and way-pointing any old/large mature individuals present.

Note: the "incised channel zone" is defined by URS (2015) as the zone between the main lower elevation channel banks. According to URS, the incised channel width is variable but assumed to be in the order of 100 m wide, and inundated by 1-year and 2-year ARI stream flow events. This zone is described to be flanked by the riparian zone floodplain, which is assumed to be approximately 400 m wide and inundated by 2-year to 5-year ARI stream flow events (URS 2015).

It was anticipated that these key tasks would be carried out by directing field effort in a way which ultimately was a product of the interaction of four key drivers to traverse pattern:

1. Firstly; it was determined that typically vegetation distribution patterns were likely to be aligned in a linear fashion parallel to the direction of flow and along and adjacent to associated primary/secondary and minor flow channels. In acknowledgment of this fact, a traversing pattern which intersected these perceived boundaries in a perpendicular fashion was deemed most appropriate to ground-truth digitised polygons and collects the best spatial data for vegetation unit extrapolation at a fine scale. Therefore a zig-zag traverse pattern was determined the best technique to use when traversing the creek.

2. The second process was the use of the NDVI image and desktop NDVI and aerial photo signature mapping to influence the surveyor's fine scale traversing movements when zig-zag traversing the creek profile. Essentially this meant continuing to generally move in a zig-ag fashion while aiming successive meanders across the creek to intersect vegetation features of most relevance identified using the desktop tools described above or particular NDVI image patterns identified while in the field.

3. The density of the vegetation present would determine that not every part of the creek could be viewed and assessed for the presence of phreatophytic vegetation, so the direction and

path of successive meanders would be influenced by the visual cues to these communities which were assessed each time the surveyor moved through sections of the creek which allowed view of vegetation over longer distance (typically the open low flow channel zones and scoured bed creek portions).

4. The final driver to traverse pattern was the general morphology and variability of the creek profile. Of the two creeks surveyed, Marillana was generally much broader in its incised channel zone and narrower in its floodplain zone, while Weeli Wolli was the opposite. Consequently it was perceived (and observed in the field) that OPV (and to a lesser extent FPV) in Marillana Creek would at times be more widely distributed around multiple low flow channels within the incised channel zone, and in Weeli Wolli creek they would be narrowly distributed around a single low flow channel within the incised channel zone. Therefore in Weeli Wolli creek much smaller wavelength zig-zag traverse patterns were generally employed, meaning lateral traverse distances were typically much smaller allowing a much greater degree of focus on particular portions of the incised channel zone. In Marillana creek the opposite was true.

As a consequence of the key tasks and the additional drivers to traverse pattern, the resultant traverse pattern and data capture array realised in the field is presented in Figures 3-6 to 3-13 below, as track logs and data points recorded via GPS. Throughout this traverse pattern the following data was recorded at the resultant array of waypoints within the Riparian zone of the study area.

1. "Present" or "Structurally Absent" of *Melaleuca argentea* – "**Presence**" equating to a cover/abundance considered as comprising a dominant structural component of the stratum which it occupies (within vegetation in the vicinity of the surveyor; approximately 20-30m radius), and not generally representing a cover/abundance below 1-2 %. "**Structurally Absent**" represents either not detected within the vicinity of the record whatsoever or only present as an associated species. For the purpose of this work, and more generally; associated species are defined as not comprising a dominant structural component of vegetation and not generally representing a cover/abundance below 1-2 % max.

2. If *M. argentea* was noted as "Structurally absent", but where this species was not strictly absent and instead was present as an associated species; the record was prefixed with an "N" cover/abundance so that its cumulative distribution could be considered spatially.

3. The intersected boundary location of any populations deemed to represent a "Presence". This at times included (where appropriate) the surveyor purposefully walking along the perceived boundary and making multiple boundary waypoints for a portion of the boundary length, so as to provide data on its length, orientation and variability.

4. The position (and where able to be easily conveyed; the dimensions) of any sizeable "Patches", "strips", or "thin strips" of riparian vegetation where *M. argentea* was considered to be a co-dominant/dominant component of the vegetation present. In most cases, where appropriate, the close alignment/association of such "patches" with bodies of water on the Low Flow channel was noted in the data recorded.

5. Areas where *M. argentea* was "present" on the bank directly opposite to that of the recorder (where access was restricted).

6. The cover/abundance of any *M. argentea* populations recorded as a "presence" (i.e. representing a dominant/co-dominant member of the vegetation).

7. The size class (as a proxy of age) and location of any individuals identified to possess a trunk diameter at Knee to waist height of approximately 30 cm and above. These individuals would form a database of "mature" individuals (not strictly from a reproductive sense, and as opposed to populations).

8. The size class (as a proxy of age) of any populations recorded as a "presence" (where appropriate) – In all cases the recordings were for the population in the vicinity of the recorder such that the size class recorded was a classification of the size range of many individuals (i.e. the entire population visible). In the vicinity of the recorder was defined as generally a 20-40m radius, but at times a larger area where vegetation density or movement by the surveyor allowed assessment of greater radius. These size classes were inferred based on a visual assessment of the average trunk diameter, or the average range of trunk diameters present within the population in sight. The size class/range determined at data points was allocated to populations (and individuals) via the use of terms which represented the various size classes used. In many cases (where appropriate – i.e. the size structure showed minimal variability) an average size class was recorded (such as Young), and in other areas where size structure was more variable a range was given (i.e. Young to Semi-Mature-minus). The size class terms used were:

    - 'Mature' (M);
    - 'Semi Mature Plus' (SM+);
    - 'Semi Mature' (SM);
    - 'Semi Mature Minus' (SM-);
    - and 'Young' (Y).

    The definition of each of these size classes and the representative terms used in the field are presented in Table 3-1.

9. Mapping notes – general notes on vegetation present at point locations. This often involved purely assigning vegetation to pre-captured associations/sub-associations or previously identified and mapped riparian communities/units.

10. Photo points – points where multiple photos (minimum 4) were taken of the vegetation surrounding the record.

The above data collection framework was used to collect data in the field over two field trips conducted by Rio Tinto Botanist Jeremy Naaykens and with the assistance of RTIO Environment staff Greg Richter and Ken Kennedy. The first field trip focused on Marillana creek and was conducted from the 30th of March till the 3rd of April, while the second field trip focussed on Weeli Wolli Creek and was conducted from the 9th till the 12th of April.

Table 3-1: **Definitions for the size classes used to classify the average trunk diameter (or range of trunk diameters) of *Meleleuca argentea* populations encountered in the field, and allocate these populations to a percieved age class (or age class range). Also included are inferences made about the degree to which individuals/populations of each size class would be expected to be present in the Pre-discharge Riparian environment. These inferences are presented based on comparative assesments of monitoring based growth projections presented in Table 4-4.**

Inferences which have been interpreted to be relevant to populations of *Melaleuca argentea* which possess an average size range (and associated age structure) broadly classified as equivalent to one of more of the following age classes (listed in the columns below) are presented below in the far right column and assume that: 		Within riparian vegetation of large creek systems exposed to long term discharge (see above durations), the present day existence (representing a cover/abundance beyond that of an associated species) of *Melaleuca argentea* individuals or populations equivalent in size to the age classes below to the left; **suggests the following about pre-impact vegetation and the likely inclusion of obligate phreatophytes within this vegetation at that time:**
Size classes (as a proxy for age)	***Melaleuca argentea* individuals/populations which were visually estimated to possess:**	**Vegetation which contained individuals/populations of this size (but not larger) scattered within or at greater cover/abundances were considered to :**
M - Mature trees	Trunk diameter(s) at knee to waist height in the **Range of 50cm and above**	Represent areas which would have historically supported vegetation with *M. argentea* as a co-dominant species within the woodland to low-woodland stratum (over-storey stratum).
SM(+) - Semi Mature plus	Trunk diameter(s) at knee to waist height in the **Range of 30-45cm**	Represent areas which would have historically supported vegetation with *M. argentea* as a co-dominant species within the low-woodland stratum and as an associated species in the woodland stratum.
SM - Semi Mature	Trunk diameter(s) at knee to waist height in the **Range of 20-30cm**	Represent areas which would have historically supported vegetation with *M. argentea* as either an associated species or in some cases a co-dominant (minor) in the low-woodland stratum.
SM(-) - Semi Mature minus	Trunk diameter(s) at knee to waist height in the **Range of 10-20cm**	Represent areas which would have historically only supported vegetation with *M. argentea* as an associated species in the Low-woodland or lower strata.
Y - Young	Trunk diameter(s) at knee to waist height in the **Range of less than 10cm**	Represent areas which at best and potentially only on occasion; historically supported vegetation with *M. argentea* as an associated species in the Low woodland or lower strata.

Note: *M. argentea* populations were allocated to size classes in the field based on visual estimates of trunk diameter and as such there is some potential for inaccuracy. In all cases the recordings were for the entire population in view of the recorder. In many cases (where appropriate - ie. the size structure showed minimal variability) an average size class was recorded (such as Young), and in other areas where the size structure was more variable a range was given (ie. Young **to** Semi-Mature-minus). Throughout the creek and wherever encountered; trees which were visually deemed to be consistent with an individual of diameter at least equal to the upper end of the Semi mature age class (30cm and above) were recorded individually (to establish a database of "Mature" trees) and assigned to the Semi-mature or above size classes. Diameter estimates are based on the diameter at knee to waist height of the observer, as the majority of individuals were relatively young and of a branching habit making it impractical to estimate diameter at breast height – a more commonly used standard for tree diameter measurements.

The relevant creeks to which this table is applied have been exposed to surplus water discharge for the following durations:

- **Weeli Wolli Creek:** approximately 9 years from 2006 (upstream of the Marillana-Weeli Wolli confluence)
- **Marillana Creek:** approximately 18-20 years from 1995 (15 years used for the growth projection relevant to this creek stretch)

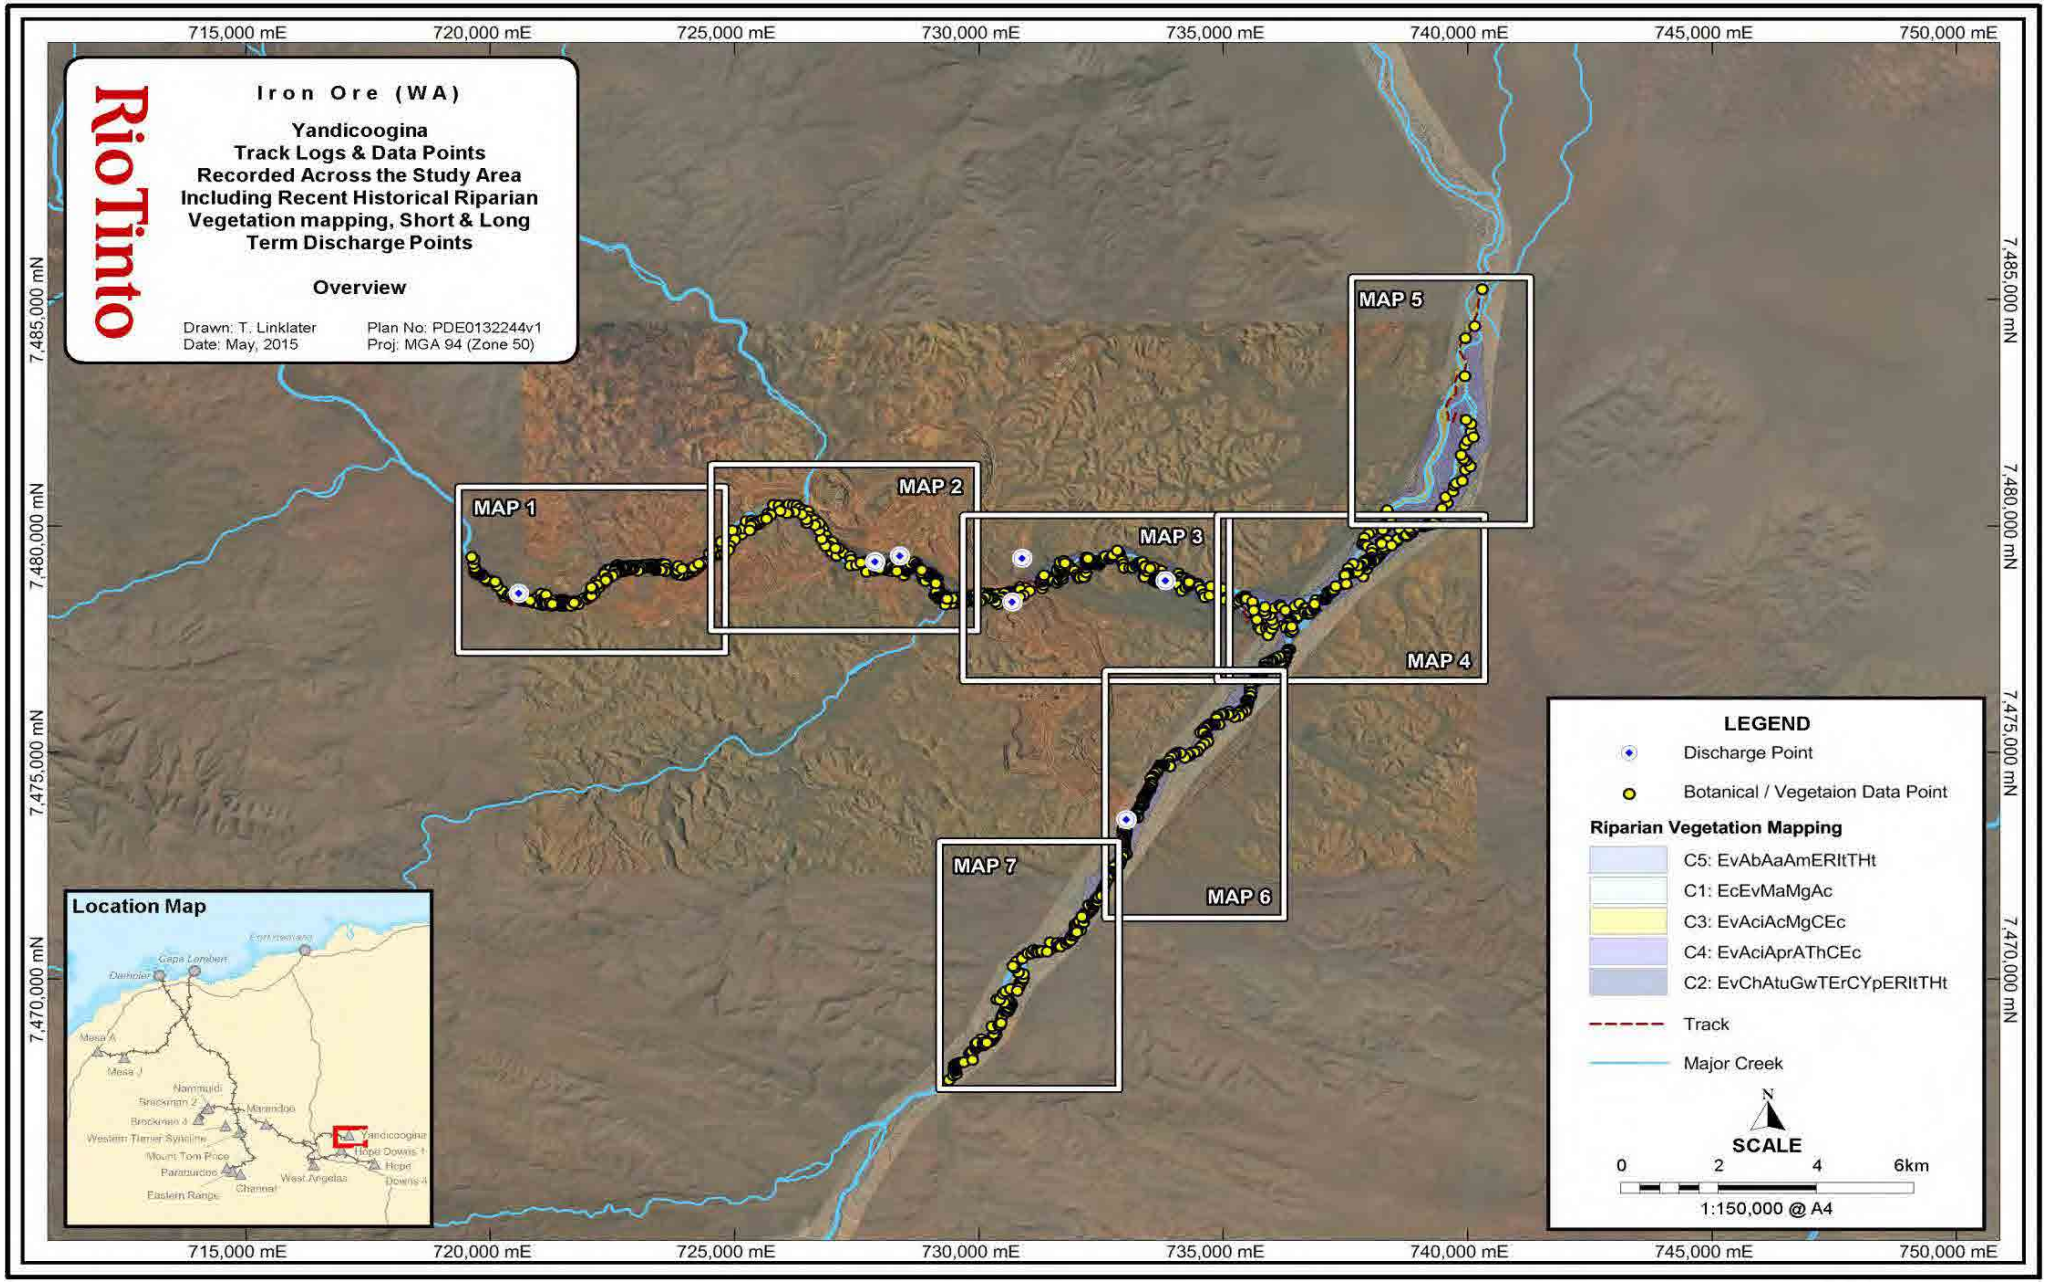

Figure 3-6: Overview of survey effort maps 1 to 7. Maps 1 -7 depict the survey effort conducted within the study area by showing the track logs and data points collected throughout using a GPS. This map also shows the previous riparian vegetation mapping across the study area (Biota 2014a) as well as the relevant discharge points influencing surface water in the study area

3.1.4 Post Field Work Mapping Refinement

Classification and assessment of the average size and inferred age structure of *Melaleuca argentea* populations

Following field acquisition, data was entered within Excel and uploaded to a GIS (Mapinfo Pro, Encom Discovery 2011). This GIS data was initially analysed to gain a broad understanding of the distribution of *M. argentea* within the study area. Once general distribution patterns were established and considered in relation to the location of discharge points and broad patterns of creek morphology, all data points which had a size class recorded for the population which they represented, were classified to the following ranges and displayed across the creek system (including all individual "mature" trees way-pointed). The size ranges (as a proxy for age) separately created for this task were "Young", "Young to SM(-)", "SM and older". This process enabled a broad scale size class map for *Melaleuca argentea* within the study area to be created, thus representing a proxy for the spatial distribution of different age classes and their associated age structures for obligate phreatophytes across the study area.

Using the complete dataset and commonly accepted data point correlation and extrapolation techniques, the spatial boundaries of all OPV communities encountered in the study were mapped at a fine scale. Correlation and extrapolation techniques generally involve the correlation of vegetation data with aerial photo signatures and the subsequent extrapolation of that data across the extent of the relevant aerial signature. These polygons were mapped to represent areas where the cover/abundance of *M. argentea* was deemed to comprise a significant component of the resident community's structure and therefore represent a co-dominant/dominant member as opposed to merely an associated species. Once boundaries were established for all mappable occurrences of OPV, the previously produced broad size class map was then used in conjunction with all of the actual (non-grouped) size class data to determine the dominant size class, and therefore inferred age of each patch of this community. This was generally done based on four factors:

1. The variability/range of the inferred age structure present (inferred based on trunk size classes) within a mapped vegetation patch.

2. The average maximum inferred size for each representative vegetation patch.

3. The presence/absence and number of individual "mature" trees recorded in any representative patch/area.

4. The general structure and composition of the vegetation within which the *M. argentea* occurred. For example; in general, younger communities possessed a particular understorey and over-storey vegetation structure, such that their allocation to this size class was reinforced if such characteristic structure/composition was present as well. Various structural/compositional characteristics were typically observed within vegetation possessing certain *M. argentea* size classes and these were consequently taken into account (where noted) in the allocation process.

The four distinct *M. argentea* community "size class ranges" (inferred to broadly represent age structures) determined to be of most relevance, from a current and historical significance perspective, to OPV communities in the study area were established to be:

- M-SM^{plus} populations, (mapped as red class – Mature to semi-mature at times SM+);
- Y-SM(+)* populations (orange class – Young to semi-mature plus*);
- Y-SM(-)*(yellow class – Young to semi-mature minus*); and
- Y* populations (green class – Young*).

See Table 4-3 for complete definitions of these distinct community "size class ranges" for resident *Melaleuca argentea* populations.

In addition to the above population factors two other spatial/historical factors were used to help in the process of attributing each patch of *Melaleuca argentea* co-dominated OPV to a "size class range" (and associated community structure). This attribution process often had to summarise multiple size class data points for each patch of vegetation being considered (often over quite small spatial distances), such that in many cases multiple and sometimes contradictory size classes/ranges needed to be summarised into the corresponding representative size range for the patch. It was in these cases that the following factors played a small part in determining whether; certain data points were anomalies, whether patches needed to be split based on spatial anomalies in size distribution, whether historical aerial photo indicators supported the anomalous size class trends present in certain patches, or whether apparent influence from such factors supported the recorded variations in size class.

1. The proximity or correspondence of the vegetation patch in question to/with the dense historical vegetation polygons (mapped at the desktop phase from pre-discharge aerial photography) previously mapped and classed as representing the "particularly dense and more anomalous swathes of historical vegetation" layer created as part of the desktop assessment.

2. The position of the community/patch in relation to key creek profile/morphology characters. This factor was used in situations such as; where an obvious bend in the creekline occurred at the end of a straight (and at the termination of a large pool), or where surrounding hills confined the creek profile to a much smaller lateral width. Or where the low flow channel transitioned from the far edge of one bank to the other (within the incised channel zone) in a near right angle fashion. All of these situations were postulated to provide more consistent surface and sub-surface water presence along with the mechanical processes associated with running water (as opposed to relatively stagnant surface water).

Mapping refinement of the riparian communities present in the study area

Once all patches of OPV were attributed to one of the four communities "size class ranges" created, vegetation descriptions were formulated for each resulting community sub-association based on mapping data acquired. Following this process; the remaining riparian associations (potentially FPV) co-occurring with and often surrounding the *M. argentea* co-dominated sub-associations (OPV) were refined based on mapping notes, photo points and additional data points collected as part of the field component.

The key task of this final mapping component was to establish, and spatially delineate, a riparian community which is generally represented by a woodland of *Eucalyptus camaldulensis* and *E. victrix (FPV)*, but which does not contain *Melaleuca argentea* as a co-dominant species. Previous mapping along Marillana and Weeli Wolli creeks did not include such a community. Instead, for the purpose of simplification, previous (post-discharge) mapping merged this type of community with occurrences of OPV. It appears that this is the reason the original C1 community was spatially distorted with respect to the distribution of OPV. It should be noted at this point, that the amalgamation described above and the resultant influence this had on the spatial accuracy of OPV in the previous mapping of the study area, is a common product of the inherent decisions to lump or split vegetation associations which the vegetation mapping process requires. For this reason the distinctions hade herein are in no way a criticism, but rather an explanation of the problems of scale occurring between mapping projects undertaken for different objectives.

Along with establishing and delineating the above mentioned community/association the task of refining the remaining generally facultative phreatophytic vegetation (FPV) represented a substantial piece of mapping work. This process was aided significantly by the use of recent high resolution aerial photography. The high resolution imagery enabled individuals/populations of *Eucalyptus camaldulensis* to be identified on aerial photography and therefore accurately mapped. Consequently, mapping was conducted using the combination of field data (point based notes and photos) and aerial photo interpretation. Individuals or groups of *Eucalyptus camaldulensis* within the riparian environment were distinguished from *E. victrix* on the basis of:

1. the generally larger (spatial extent) canopy footprint of *E. camaldulensis*;

2. the generally denser canopy cover signature of *E. camaldulensis*;

3. the generally dissimilar branch signature of *E. camaldulensis* canopy architecture; and

4. the generally darker green canopy colour signature *E. camaldulensis*.

The available aerial photography was considered to be of a quality suitable for the application of the above described visual assessment and was found to be robust when ground-truthed using field data. Some more obvious and presentable examples of the aerial signature of *E. camaldulensis* trees are provided below in Plate 4. The examples presented in plate 15 were generally chosen due to their location on an open floodplain, where canopy density is reduced and as such surrounding canopy species don't inhibit the display of the above described characters, thus making them easier for the reader to appreciate/visualise (for those not versed in making such assessments).

Once the key riparian vegetation units which were the focus of this work were refined, they were overlain on previously mapped riparian vegetation units (C1-C5 – Biota 2014a). The new units were integrated into the old mapping by superseding the mapping they spatially intersected and now represented. The resulting map was then cleaned and refined so as to remove any artefacts of scale produced during the intersection of the two models.

All vegetation communities whose structure was refined as part of this study, were described using Aplins' (1979) framework for "Vegetation Structural Classes". This framework is presented in Appendix 1, along with the Vegetation condition scale of Trudgen (1988), which is used in this study. As such all communities (those presented in Table 4-1 with a Bolded new vegetation code) established as part of this study are generally considered to represent sub-associations. Community

descriptions were created by identifying dominants (where present) for all strata available, rather than restricted to the three traditional strata, such that they represent complex vegetation descriptions, approximately equivalent to level 6 mapping within the National Vegetation Information System (NVIS). It should be noted that while the remaining vegetation communities, which are maintained from previous vegetation mapping (Biota 2015), and which tend to occur outside of the study area; more generally represent complex vegetation units of the sub-association scale, some are more accurately described as associations, and as such the scale presented is somewhat variable. Such apparent variability in vegetation description scale is typical of Pilbara vegetation surveys, and in many ways is a product of the inherent patterns in vegetation structure which are generally present.

Plate 4: Aerial photos showing *Eucalyptus camaldulensis* canopies (inside orange polygon) on parts of Weeli Wolli Creek

Beyond the more obvious shrub features, the majority of the remaining eucalypt canopies present in these plates are considered to be *E. victrix* as indicated by the obvious white branch and trunk colouration, open branching habit and lighter foliage colour

3.2 GROWTH RATE PROJECTION CALCULATIONS FOR *MELALEUCA ARGENTEA* UNDER 2 TEMPORAL DISCHARGE REGIMES

3.2.1 Deductive Process and Assumptions Made

One of the key secondary aims of this study was to determine which present day *Melaleuca argentea* co-dominated communities/patches if any, present a trunk size structure consistent enough and young enough that it could easily be inferred to have established since surplus-water discharge ensured perennial water availability. To enable this to be determined, the first task is to determine the annual growth rate of this species under favourable conditions (in a Pilbara creek system with perennial water availability), and compare this to the growth realised by populations present in the study area.

The average range of trunk sizes, visually approximated in the field for any *M. argentea* population, was created as a proxy for the age and the relevant associated age structure characters. Once fine scale knowledge of resident size structure is acquired via field work, the next step in the process is to determine the average amount of 2-dimensional (i.e. a horizontal cross-section) trunk biomass (growth) added by this species each year. This figure would be represented by a cm^2 increase in trunk cross-sectional area per year. Once such a figure is attained the next step is determining a "reasonable maximum average trunk diameter" which would be likely to establish/grow over either a 9 or 15 year time scale in a scenario where:

> **A generally ephemeral creek habitat** (likely to be comprised mainly of vegetation equivalent to the C2A or C2Asb community), **which likely only (at best) contained *Melaleuca argentea* as an associated species** (i.e. no more than isolated to scattered small populations or individuals of generally young size and structure), **was then provided perennial surface water input representing ideal growth conditions for initiating and sustaining the germination and establishment of larger more substantial populations of *M. argentea*** (constituting the inclusion of this species as a co-dominant in a developing OPV) **as long as discharge was maintained.**

This "reasonable maximum trunk diameter" was created to represent a relatively conservative "cut-off figure" whereby:

> **If present day populations possessed at least regular** (on average at least scattered individuals i.e. 1-2% within the resident sighted population) **individuals of equivalent or greater diameter then; that population** was considered to presently possess an upper size-class or old enough age structure to indicate that *M. argentea* was potentially present as a co-dominant component (in various structural forms) of the resident pre-discharge community.

Once attained, the "reasonable maximum trunk diameter" (from herein referred to as the "Cut-off figure") would be used to compare with the "size class range" of the various patches of *M. argentea* co-dominated riparian community recorded throughout the study area. For patches which possessed

a relatively narrow trunk diameter range and an upper size class below that of the cut-off figure, it would be inferred that this present day OPV community was:

> **Unlikely to have been present in the pre-discharge riparian environment, and instead a FPV community which at best only contained *M. argentea* as an associated species was present in its place.**

For example: if the "reasonable maximum trunk diameter" equals a diameter of 25 cm, and a population of *M. argentea* within a present day patch of OPV was attributed a "size class range" of Y-SM(-), then the upper size class is SM(-), which equates to a 10-20 cm field estimate, and which is below the "cut-off figure" (reasonable maximum trunk diameter) of 25 cm. Consequently this patch of present day OPV is unlikely to have possessed *M. argentea* as a co-dominant component of the pre-discharge vegetation.

The above described process of deduction relies on a cut-off value (the reasonable maximum trunk diameter), and therefore making decisions on which side of the cut-off mark certain patches of present day OPV communities will fall. Because of this, it is important to note that there may be cases where the upper size class of the OPV patch being considered may fall either side of the cut-off, or just below, such that a "grey-area" becomes evident. It is this 'grey-area' and the potential issues associated which influenced the community "size class ranges" created for the refined OPV communities.

The field data acquired appeared to support the production of four general size and physical structure groupings. The spread of the data meant that 2 levels of age structure sat either side of the cut-off mark. Having communities representing key intermediate age structures sitting either side of the cut-off enabled the conclusions to incorporate some conservative conclusions in relation to the pre-discharge environment.

The methodology described above and the proposed data sources used to calculate the projected growth rates assumes the following things about the populations they are proposed to project growth for:

1. That the perennial surface water conditions, general climate, and direct impact scenario they occupied represented fairly favourable growth conditions.

2. That growth rates while somewhat influenced by winter temperatures were not limited by water or nutrient availability given the typical conditions within a large perennial Pilbara creek system.

3. The larger individuals are often the ones which have managed to get off to a better start due to them by chance being; less shaded than others, less influenced by adjacent competition, positioned such that they are protected from flood damage, etc.. Therefore these individuals are most likely to possess growth rates closer to that representative of ideal conditions. It is these individuals which are deemed most important when considering the maximum age of a population rather than some of the small, outcompeted or stunted individuals which are likely to be inconsistent in their associated size to age ratios.

4. That populations assumed to establish after surplus-water discharge commenced, have begun establishing almost immediately (following commencement of discharge), from either; young

isolated to scattered in-situ individuals, in-situ, seedlings, germination of propagules in-situ, or germination of propagules transported from other populations upstream.

Despite the inherent assumptions and limitations associated with this process of deduction, it is considered the best available technique for interpreting the pre-discharge environment from short term field data collection within the present day environment. In addition, the field data being used in the process is considered sound and highly detailed, such that it is considered to represent an appropriate set of ground-truthed data with which to make informed and conservative enough judgements about the pre-discharge environment.

3.2.2 *M. argentea* Growth Projection Calculations

For the purpose of this study, annual growth rates for *Melaleuca argentea* are required so that this growth rate can be projected over the two temporal discharge regimes relevant to Marillana and Weeli Wolli creeks. It is determined that the best way to do this (in a short time scale) is to gather field based monitoring data which provides recordings of trunk DBH of *M. argentea* (or similar *Melaleuca* species) individuals at different time intervals for varying sized individuals Five sources of available data were found: 2 from unpublished Rio Tinto Melaleuca argentea monitoring sites (Unpublished data collected for Rio Tinto by Mattiske consulting along East Pilbara creeks including Marillana and Weeli Wolli (Mattiske 2014), and Unpublished data from one Rio Tinto monitoring site in the Kimberley (Rio Tinto 2013)), 1 from a study of Melaleuca argentea patterns of water use in the Pilbara (Mclean, 2013), and two from forest or cultivation based data indicating growth rates for cultivated or forest based populations of Melaleuca quinquinervia (as a final DBH for particular ages; generally 40 years) (Benson and McDougall 1998; Conde 1979).

All of these data sources provided either two temporal monitoring points with DBH for both and an associated time interval, or in the case of Benson & McDougall (1998), and Conde (1979), an average or upper-percentile diameter after a 40 year time span. Given that the key metric of concern is the increase in 2 dimensional trunk biomass over a particular unit of time (i.e. the change in cross-sectional area over a year) the most appropriate way to calculate an average increase in this measure of biomass per year is to convert all DBH figures to a cross sectional area. The key reasoning for this is that for example: a 5cm increase in DBH on a 10cm diameter tree results in a change in cross sectional trunk area of 390 cm^2 while a 5cm increase in DBH to a 30cm diameter tree equates to a 1020 cm^2 change in cross-sectional area DBH. For this reason changes in DBH compared between trees of different size are not equivalent with regards to change in trunk Biomass and so converting to a cross sectional area provides an equivalent measure when comparing between different sized trees.

Consequently the steps required for this calculation were.

1. Convert DBH for each tree at both the start and end monitoring times to a cross sectional area in cm^2. **Using: $A=Pi*r^2$**.

2. Calculate the difference in cross sectional area over time by subtracting the start time cross-sectional area from the end time cross-sectional area. **Using: Area B – Area A** (where “B” is the later (end) monitoring time and “A” is the earlier (start) monitoring time).

3. Convert this cross sectional difference to a change in cross sectional area per year, by dividing the Change in area by the number of years between the start and end monitoring points. **Using: Change-in-area / (number of months/12).**

4. Times this change in area per year by the number of years over which discharge active (one figure for 9 years discharge and a separate one for 15 years). This gives us the amount of biomass in cross sectional trunk area which the tree projected from would likely grow in 9 and 15 years. **Using: (Delta-Area)*(Discharge years).**

5. Convert this resultant cross sectional area to a resultant DBH. **Using: DBH = 2*(Square root of (Area/Pi)).**

6. To allow for likely differences in the potential for an individual to add trunk biomass per year which could result from age and therefore size (root and canopy resources), group the resultant individual projected biomass figures (in DBH) by the ranges evident in the spread of the original DBH figures of the monitoring trees.

7. For each range of original monitoring tree DBH (eg.1-3cm, 3-6cm, 6-9cm DBH, etc.) calculate the average projected DBH for each range and for the two discharge time spans (9 and 15 years). **Using: Sum(DBH)/(#-of-trees)** (#-of-trees = Number of individual monitoring trees in relevant original DBH range).

8. Determine the most relevant average projected DBH for the discharge time span by analysing the spread of the data in relation to the DBH of the original trees. Determine an average figure for each time span.

9. To be conservative and to allow for differences in growth rate due to competition, climatic variability and local impacts/perturbations - Subtract 25% from this figure to provide a more conservative figure. **Using: 0.75 * DBH.**

Once all the above calculations were made a comparative figure would be produced. The results of this process are presented below in section 4.3.2.

3.3 REMOTE SENSING TOOLS USED TO COMPARE VERTICALLY VISIBLE VEGETATION SIGNATURES AND TEMPORAL SIGNATURE CHANGES IN AND BETWEEN THE PRE AND POST DISCHARGE ENVIRONMENTS

Two key remote sensing tools were used as part of this study to observe the vegetation signatures present within the riparian zone of the pre and post discharge temporal environment of the study area. In addition one remote sensing tool was used to provide a quantitative measure of vegetation changes which have gone on in the respective riparian zones between 2006 and 2014.

The first is represented by visible spectrum “aerial photography”. Aerial photography acquired in 1994 for Marillana Creek, and 2006 for Weeli Wolli Creek was used to observe the pre-discharge environment of the respective riparian creek habitats. This was compared with aerial photography for the entire study area which was acquired in 2014.

The second tool is represented by DMSI change detection Imagery. This type of imagery is explained as being created by, and representing:

Digital Multispectral Imagery (**DMSI**) is a remote sensing tool used to provide maps of indicative change in vegetation condition, health and cover over time and across extended areas of interest. DMSI samples reflected electro-magnetic energy in fixed wavelength bands, providing spectral information for all vertically visible ground features. Healthy vegetation has unique spectral properties, with its high chlorophyll content absorbing a large proportion of red energy and its structure strongly reflecting infra-red energy. This spectral characteristic can be exploited to provide information on the relative density and health of vegetation via the calculation of a "vegetation index"; the simple ratio of the infra-red and red reflectance. This index is known as the Simple Vegetation Index or the Plant Cell Density (**PCD**) Index.

Where multiple acquisitions of DMSI with minimal solar angle variation are co-registered spatially, the change in PCD index can be calculated for each pixel and displayed for visual interpretation as a Composite Change Detection Image. In these images vegetation which has lost or gained density and health between the two acquisition periods is displayed in hues of red to blue respectively; such that the deeper the hue of red or blue, the greater the magnitude of change that has occurred.

In this study DMSI change detection imagery is used to determine the distribution of positive (and negative) vegetation change anomalies within the riparian zone, and then establish whether correlations exist between the distribution of this positively anomalous vegetation change and the distribution of different types of OPV within the study area. The principle DMSI change detection imagery used for this study is represented by an image which depicts vegetation change from 2006 to 2014, based on yearly acquired 1m pixel imagery. This image is perfect for consideration of this influence of discharge on the study area stretch of Weeli Wolli creek. Surplus-water discharge initially commenced within Marillana Creek in approximately 1995, and as such this image has reduced application within this creek system. Issues with the acquisition of DMSI and production of change detection imagery around this time led to the decision to rely on the 2006-2014 imagery.

During the late 1990's and early 2000's issues pertaining to the low reliability of image calibration and spatial correlation from year to year determined that the use of change detection imagery was problematic. In addition, this period represented a time when the acquisition and application of DMSI was in its infancy, and as such the resolution and spatial extents of acquisition were quite variable from year to year. The inherent and local issues relating to DMSI imagery acquired in the period 1995-2005, become apparent when analysing and comparing local NDVI imagery, change detection, and true and false colour imagery, from this time period. Consequently it was determined that using the 2006-2014 change detection imagery was the safest and most spatially extensive option for presenting trends in vegetation cover within the study area.

3.4 LIMITATIONS OF THIS STUDY

Overarching

- The survey area was easily accessed
- Rainfall/seasonal conditions, and flowering/fruiting conditions were favourable for conducting this type of survey.

Desktop and Field Data Acquisition Tools

- Size classes attributed to *M. argentea* populations are only an estimate, so potentially inaccurate in some cases.
- Some issues became apparent when using NDVI as a marker for GDE presence, as the NDVI signature for OPV communities of old age (mature) were hard to distinguish from that of more common mature *Eucalypt* spp. FPV communities. In these cases relatively comprehensive creek coverage was relied on to make sure such representations were not missed.

Ground Truthing and Mapping Refinement Field Work

- Amount of flowing-water in the creek at the time of survey restricted movement across creek in some situations
- All species of interest were in good condition, with key eucalypt species fruiting in many cases at the time of survey, making identification in the field easy

Post Field Work Mapping Refinement Process

- Data quantity and resolution was more than adequate
- Coverage was more than adequate

Growth Rate Projection Calculations for *Melaleuca argentea* Trees

- Only used a sample size of 54 monitoring trees over 1-4 years (generally only 1-1.5 years). A larger sample size would be better, with longer average monitoring period.
- Some natural tropical data sources from different habitats show reduced growth rates to that shown by the monitoring trees used for the projection. Despite this fact, the differing habitats (dry monsoon forest vs Perennial creek system) could easily explain such differences.

Interpretation of likely presence of present day OPV in the pre-discharge environment

- For the purpose of this study the influence of Climatic variability or changing trends in climate averages are unable to be considered in any detail in relation to the use of growth projections for predictions on the pre-discharge presence of OPV.

4 RESULTS

4.1 MAPPING REFINEMENT

In relation to the predicted outcomes of the vegetation mapping refinement process, the resultant mapping is considered to be well aligned with previously observed trends in vegetation distribution. Despite this fact, some relatively unexpected patches of mature OPV were identified as part of this process. Results such as this are considered important as they represent valuable features which otherwise might not have been identified. Furthermore, such features can now become part of a more accurate and spatially discrete framework for management of impacts to communities of significance.

Table 4-1 below presents the refined vegetation associations developed as part of the mapping refinement process. Table 4-2 presents multiple representative photos of all the "C" coded riparian vegetation units refined as part of this work. While more broadly presented in the following tables and figures, the mapping units from previous vegetation surveys are maintained despite the fact that they generally fall outside of the study area. The effort invested in accurately integrating the new riparian mapping with the broader vegetation model determined that it was worthwhile to present the complete vegetation model.

Vegetation Coding

Compared to previous mapping, the most significant degree of change has occurred to the previously mapped and coded C1 vegetation unit (Biota 2014a) and the communities which were substituted in its place. In addition these changes resulted in significant displacement of units such as Biota's previously mapped C3 and to a lesser degree C4 units (Biota 2014a). Prior to this study, the C1 unit essentially represented an amalgamation of the relatively common *Eucalyptus camaldulensis* and *E. victrix* woodlands of the area with the highly restricted OPV variant of this community, which possessed a significant *Melaleuca argentea* tree component. Consequently on separation, the spatially restricted *M. argentea* OPV variant maintained attribution to the C1 riparian class, and the FPV *E. camaldulensis/victrix* community was transferred to the C2 riparian class. The C1 riparian class was then split into 4 key groups depending on the physical "size class range" and inferred broad age structure of the community recorded. It is this separation into key "size class ranges" which is used further on to interpret and infer which of these OPV communities were likely to be naturally present in the pre-discharge environment. In addition to their likelihood of presence, it was also used to infer the likely physical size and age structure of such communities in the pre-discharge environment.

With the relatively common *Eucalyptus camaldulensis* and *E. victrix* woodlands of the area being transferred to the C2 riparian class, the C2 code structure also saw a significant degree of change. Within previous mapping the C2 and C3 classes were the domain of purely *E. victrix* overstorey dominated riparian communities, and so the inclusion of *E. camaldulensis* communities to the C2 class, while relevant, meant the coding was re-structured to incorporate this community and any closely affiliated communities recorded as part of the refinement process. As previously mentioned, vegetation description and spatial location changes were only made to riparian communities, and the communities which received changes at both these levels are delineated in Table 4-1 by bolding

of the new vegetation code. Beyond the communities which were refined in both their description and boundaries, a number of communities (those both part of the riparian zone and some fringing it) had purely their spatial boundaries altered, and in nearly all cases these changes were very minimal and generally a product of a scale changes. Table 4-3 below present's information which has been summarised about the "size class range" and physical structure/characters of populations of *Melaleuca argentea* within communities mapped as possessing or potentially possessing this species. In addition it also presents summaries of the inferred age structure, notes on presence/abundance, and average stem sizes for *Melaleuca argentea* populations present in those OPV communities which this species comprises a significant component of. Despite this table being created to present information about OPV (and to a lesser extent FPV) communities; for completeness, the table also includes the same information (where available) for all communities in which this species is either a known associated or potentially associated species.

Given the catchment sizes and at times quite topographically constrained creek profiles of Marillana and Weeli Wolli creeks a significant proportion of the incised creek bed is periodically represented by generally scoured alluvial beds with minimal vegetation. The significantly reduced biomass and typically increased surface water input frequency of these zones (based on the lack of groundcover and general understorey vegetation) determines that they are generally less sensitive to changes in groundwater availability when compared to their closely affiliated and more densely and structurally complex equivalents (C2A, and C3A). As a consequence these areas were delineated in the mapping refinement process to create the major creek bed communities; C2A, and C2Asb ("sb" denotes 'scoured bed'), representing *Eucalyptus camaldulensis and E. victrix* dominated creek bed communities, and the C3A and C3Asb communities representing the *E. victrix* dominated creek bed communities.

Vegetation Mapping

Figures 4-1 to 4-8 present the resultant vegetation map for the riparian study area, and include the surrounding broader project area mapping, which has been perpetuated from previous surveys. The vegetation maps presented constitute a modelled interpretation of the spatial distribution of described vegetation communities within the study area and, as with any model, are likely to contain some errors. Mapping errors have been minimised through extensive ground-truthing. The degree of ground-truthing effort conducted for the included groundwater dependent communities is such that the mapping is considered to be significantly more accurate than vegetation mapping typically undertaken within riparian areas. This fact can be attributed to the requirement to provide a very high degree of accuracy in relation to the spatial location and distribution of OPV communities.

Table 4-1: Summary of Vegetation Types Recorded in the Study Area. Includes old and new vegetation mapping codes to indicate which units have been refined (Bolded Veg codes in the new veg codes column are those which have had their description and boundraies refined)

Old code	New Veg code	Area (ha)	Main Vegetation Description	Distribution	Flora Sampling Sites	Vegetation Condition
Vegetation of Major Creeklines and Tributaries						
C1	**C1A**	15.7	**Small patches of *Melaleuca argentea* Woodland** Eucalyptus camaldulensis subsp. refulgens, *E. victrix* and *Melaleuca argentea* woodland (to open woodland) over Eucalyptus camaldulensis *Melaleuca argentea* and *Acacia coriacea subsp. pendens* low open woodland, over scattered to tall open shrubland of *Melaleuca glomerata*.	Fringing large pools of scoured creekbeds and channels in some of the wettest parts of Marillana Creek. No representations present in Weeli Wolli Creek.	1 quadrat: OXB06(Biota), Mapping Notes (JN).	Very Good to Good.
C1	**C1AA**	14.9	**Larger representations of Historical *Melaleuca argentea* Woodland** Eucalyptus camaldulensis subsp. refulgens, *E. victrix* and *Melaleuca argentea* woodland (M. argentea generally represented by scattered trees), over Eucalyptus victrix, *Melaleuca argentea*, and *Acacia coriacea subsp. pendens* low open woodland, over scattered to tall open shrubland of *Melaleuca glomerata* and *Acacia ampliceps*, over mixed low open shrubland and outcrops of *Cenchrus ciliaris* open tussock grassland.	Scoured creekbeds and channels in the wetter parts of the upper stretch of Marillana Creek located in the North West corner of the study area.	No Quadrats Occurs outside of tenure. Mapping Notes (JN).	Very Good to Good.
C1	**C1B** **- Marillana**	4.1	**Marillana - M. argentea Semi Mature low open woodland** Eucalyptus camaldulensis subsp. refulgens, and *E. victrix* woodland, over Eucalyptus camaldulensis, *Melaleuca argentea*, and *Acacia coriacea subsp. pendens* low open woodland, over tall open shrubland of *Melaleuca argentea*, *M. glomerata* and *Acacia ampliceps*, over mixed low open shrubland.	Marillana Creek: In the wetter parts of scoured creekbeds and channels of the primary low flow zone.	1 quadrat: YBI23(Biota), Mapping Notes (JN).	Very Good to Good.
C1	**C1B** **- Weeli Wolli**	8.9	**Weeli Wolli - M. argentea Semi Mature low open woodland** Eucalyptus camaldulensis subsp. refulgens, and *E. victrix* woodland, over Eucalyptus victrix, *Melaleuca argentea*, and *Acacia coriacea subsp. pendens* low open woodland, over tall open shrubland of *Melaleuca argentea*, *M. glomerata* and *Acacia coriacea subsp. pendens*, over mixed low open shrubland.	Weeli Wolli Creek: In the wetter parts of scoured creekbeds and channels, particularly on bends or low flow channel transitions at the end of creek straights.	1 quadrat: YBI23 (Biota), Mapping Notes (JN).	Very Good to Good.
C1	**C1/C2-A** **- Marillana**	19.89	**Marillana - M. argentea Young to Semi Mature low open woodland** Open woodland of Eucalyptus camaldulensis subsp. refulgens and *E. victrix,* over low woodland (generally dominated by saplings to young trees) of E. camaldulensis subsp. refulgens and *Melaleuca argentea*, over scattered tall-shrubs (to tall open shrubland) of *Melaleuca argentea*, *M. glomerata*, *Atalaya hemiglauca*, Stylobasium spathulatum and Sesbania cannabina, over very open sedgeland of Cyperus vaginatus and often accompanied by fringing strips of Typha domingensis	Marillana Creek: In the wetter parts of scoured creekbeds and channels, where it generally flanks the primary low flow channel.	1 quadrat: OS086 (Mattiske), Mapping Notes (JN).	Very Good to Good.

Vegetation of Stony Plains						
P1	P1	395.9	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia pruinocarpa* scattered tall shrubs over *A. bivenosa, A. ancistrocarpa, A. dictyophleba* shrubland over *Triodia wiseana, T. pungens*, *T.* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland	Undulating colluvial plains throughout the study area.	11 quadrats: BIL38^, BIL39, OXB03^, OXB09^, YEX05 (cleared), YSW07, YSW11, YSW12, YVI04 (cleared), YVI08, YVI10. 1 relevé: YSW-RBMA.	Excellent to Very Good.
P2	P2	1,065.3	*Corymbia hamersleyana, Acacia pruinocarpa* scattered low trees over *A. inaequilatera, A. sclerosperma* subsp. *sclerosperma, A. pachyacra* tall open shrubland over *Triodia pungens* hummock grassland	Occurred broadly over plains in the eastern half of the study area, fringing the floodplain on the southern side of Marillana Creek and on both sides of Weeli Wolli Creek.	14 quadrats: BIL07^, BIL08, BIL09, BIL10^, YAQ16^, YAQ24, YAQ29, YBI10^, YBI26, YEX14 (cleared), YEX19, YEX20, YEX23, YEX27. 2 relevés: YBI-RBMC, YBI-RBMD.	Good.
P3	P3	177.9	*Acacia pruinocarpa* low open woodland over *A. citrinoviridis, A. inaequilatera, A. sclerosperma* subsp. *sclerosperma* open shrubland over *Triodia longiceps* hummock grassland	Occurred along either side of Weeli Wolli Creek, fringing the floodplains along the central section of the creek.	3 quadrats: HDA14 (cleared), YBI11^, YBI17^. 1 relevé: YBI-RBMJ.	Very Good (some small areas Poor).
P4	P4	352.1	*Acacia pruinocarpa* low open woodland over *A. synchronicia, A. inaequilatera* scattered tall shrubs over *Triodia wiseana* open hummock grassland	Occurred in the southern half of the study area along Weeli Wolli Creek, where it fringed the floodplains on both sides of the creek.	6 quadrats: HDA07 (cleared), HDA15 (cleared), YBI19 (cleared), YEX03 (cleared), YEX04^, YEX32 (cleared). 1 relevé: YAQ-CSRB	Excellent to Good.
P5	P5	1547.2	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia bivenosa, A. ancistrocarpa* open shrubland over *Triodia basedowii* open hummock grassland	Occurred broadly over the stony plains of the Billiards area along either side of Weeli Wolli Creek, and also in small areas around the JSW and YJC mines.	18 quadrats: BIL18, BIL33^, HDA12 (cleared), YAQ23^, YBI06^, YBI07^, YBI09^, YBI14, YBI16, YBI21, YBI22, YBI27^, YBI28, YBI29, YBI34S^, YEX15, YEX33 (cleared), WW30. 4 relevés: YBI-RBMA, YBIRBMB, YBI-RROA, YEX-N.	Excellent to Good.
P6	P6	144.1	*Acacia aptaneura* low open forest over *Eremophila forrestii* subsp. *forrestii* open shrubland over *E. lanceolata* low open shrubland over mixed very open grassland	Occurred only in the Billiards area, mainly in narrow stands adjacent to the floodplains along Weeli Wolli Creek; several small patches of this vegetation also occurred on plains and hill crests.	8 quadrats: BIL32^, HDA08^, HDA13, YBI12^, YBI13, YBI15^, YEX09 (cleared), YEX12 (cleared). 2 relevés: BIL-RSPA, YBI-RBMI.	Good.

Old code	New Veg code	Area (ha)	Main Vegetation Description	Distribution	Flora Sampling Sites	Vegetation Condition
P7	P7	35.6	*Eremophila fraseri* subsp. *fraseri* open shrubland over mixed very open grassland	Occurred on three small areas of plain with a calcrete substrate near the proposed PBS development.	2 quadrats: BIL25^, BIL48. 1 relevé: YBI-RBMG.	Good.
P8	P8	32.4	*Eucalyptus gamophylla* scattered low mallees over *Acacia inaequilatera* scattered tall shrubs over *Triodia schinzii* hummock grassland	Gently sloping pediment slopes and colluvial plains at the base of a range of low hills north of the proposed PBS development.	2 quadrats: BIL22^, BIL42^.	Excellent.
P9	P9	380.1	*Corymbia hamersleyana* scattered low trees over *Eucalyptus gamophylla* scattered low mallees over *Acacia inaequilatera, A. ancistrocarpa, A. pruinocarpa* tall open shrubland over *Petalostylis cassioides* open shrubland over *Triodia basedowii* open hummock grassland	Occurred broadly over the plains on the western side of Weeli Wolli Creek, north of Marillana Creek.	6 quadrats: BIL12^, BIL13, BIL41^, BIL45^, YEX31 (cleared), YEX33 (cleared).	Very Good.
Disturbed	Disturbed		N/A	Clustered around infrastructure and mining, scattered elsewhere	N/A	Heavily Disturbed

Table 4-3: Summary of the *Melaleuca argentea* size class, size/age structure, and vegetation structure data attributed to the various communities which possessed or potentially possessed M. argentea in the study area

New Veg code (M=Marillana, W=Weeli Wolli)	Condensed Vegetation Description	Generalised *M. argentea* Age Class/Range	Notes on *Melaleuca argentea* presence	Average stem sizes - *Melaleuca argentea*
C1AA	*Eucalyptus camaldulensis subsp. refulgens, E. victrix and Melaleuca argentea woodland, over Eucalyptus victrix, Melaleuca argentea, and Acacia coriacea subsp. pendens low open woodland, over tall open shrubland of Melaleuca glomerata and Acacia ampliceps.*	**M-SM(+)** Generally M (to SM+) aged trees present.	Strong evidence (large trunks in situ) indicates the historical presence of Regular Mature to at least Semi-Mature/Mature individuals in the creek bed	Average Stem diameters of 40-100cm for the older age classes present, while young individuals were not present in normal numbers (some areas possessed young, but overall they were generally absent)
C1A	*Eucalyptus camaldulensis subsp. refulgens, E. victrix and Melaleuca argentea woodland over Eucalyptus camaldulensis Melaleuca argentea and Acacia coriacea subsp. pendens low open woodland.*	**M-SM** Generally M to SM classed trees present, but including the full range of age classes.	Presence of regular/scattered mature to at least Semi-Mature/Mature individuals in a section of the creek bed vegetation.	Average Stem diameters of 40-90cm for the older age classes present, while young individuals are still present and common ranging from 20-40cm
C1B - M	*Eucalyptus camaldulensis subsp. refulgens, and E. victrix woodland, over Melaleuca argentea, and Acacia coriacea subsp. pendens low open woodland, over tall open shrubland of Melaleuca argentea, M. glomerata and Acacia ampliceps.*	**Y-SM Plus*** Y-SM to Y-SM(+) classed; often some individual “Mature” trees present (*), but generally not ‘M’ class (mature) and if ‘M’ class then only 1 to 2 max.	Presence of either: Populations generally classed in the Y-SM and Y-SM(+) age ranges as well as Multiple (3 or more recorded) individual "Mature" trees of SM **to** SM(+) age class (and rarely above – 1 to 2 individuals maximum) OR; at least some populations classified as SM(+) as well as the presence of at last one "Mature" tree (SM to SM(+)) and a spatial correlation or proximity to a patch(s) of Dense historical vegetation (desktop mapping from 1994 aerial photo)	Average Stem diameters of the older age classes present ranging from 25-40cm (young individuals in the 10-25cm range are still present in significant numbers) with some older outlier individuals present in the range of 40-50cm

New Veg code (M=Marillana, W=Weeli Wolli)	Condensed Vegetation Description	Generalised *M. argentea* Age Class/Range	Notes on *Melaleuca argentea* presence	Average stem sizes - *Melaleuca argentea*
C1B - W	*Eucalyptus camaldulensis subsp. refulgens, and E. victrix woodland, over Melaleuca argentea, and Acacia coriacea subsp. pendens low open woodland, over tall open shrubland of Melaleuca argentea, M. glomerata and Acacia coriacea subsp. pendens.*	**Y-SM plus*** Y-SM to Y-SM(+) classed; often some individual "Mature" trees present (*), but generally not 'M' class and if 'M' class then only 1 to 2 max.	Presence of either: Populations generally classed in the Y-SM age range often including Multiple (2 or more recorded) individual "Mature" trees of SM **to** SM(+) age class OR; at least some populations classified as Y-SM combined with populations no younger than Y-SM(-) as well as the presence of at least one "Mature" tree (SM to SM(+)) and a spatial correlation with a patch(s) of Dense historical vegetation (desktop mapping from 1994 aerial photo), or on a typical creek profile which tends to enhance water availability (i.e. bend at the end of a straight in a confined creek profile).	Average Stem diameters of the older age classes present ranging from 15-35cm (young individuals in the 5-15cm range are still present in significant numbers) with multiple older outlier individuals present in the range of 30-45cm (other age class structures also apply - see adjacent cell)
C1/C2-A - M	*Open woodland of Eucalyptus camaldulensis subsp. refulgens and E. victrix, over low woodland of E. camaldulensis subsp. refulgens, Melaleuca argentea saplings, over scattered tall-shrubs of Melaleuca argentea, M. glomerata, Atalaya hemiglauca.*	**Y-SM(-)*** Generally Y-SM(-) classed; occasionally up to Y-SM(*), with occasional 'SM' individual "Mature" trees present.	Presence of : Populations generally classed in the Y-SM(-) age range (occasionally with infrequent Y-SM age class recordings) as well as Multiple (2 or more recorded) individual "Mature" trees of SM **to** SM(+) age class (and above) OR; at least some populations classified as SM as well as the presence of at last one "Mature" tree (SM to SM(+)) and a spatial correlation or proximity to a patch(s) of Dense historical vegetation (desktop mapping from 1994 aerial photo)	Average Stem diameters of the older age classes present ranging from 10-25cm, while young individuals in the <10cm range are present and generally dominant. Generally requires the presence of multiple recorded "Mature" tree individuals present in the range of 30-45cm (other age class structures also apply - see adjacent cell)
C1/C2-A - W	*Low woodland of Eucalyptus camaldulensis subsp. refulgens and Melaleuca argentea (and to a lesser extent E. victrix) saplings to young trees (With scattered trees), over scattered tall-shrubs (to tall open shrubland) of Melaleuca glomerata, Atalaya hemiglauca, Acacia coriacea subsp. pendens.*	**Y-SM(-)*** Y-SM(-) classed, occasionally up to Y-SM (*), with occasional 'SM' "Mature" trees present	Presence of : Creek sections possessing populations with a relatively variable age class and generally classed in the young and Y-SM(-) age range and often including thin strips of vegetation fringing the Low flow channel and dominated by young individuals. These areas are also often correlated with typical creek profiles which tend to enhance water availability (i.e. bend at the end of a straight in a confined creek profile) but with reduced numbers of individuals representative of the upper end of the Y-SM(-) age class .	Average Stem diameters of the older age classes present ranging from 10-20cm, while young individuals in the <10cm range are present and generally dominant. Generally requires the presence of multiple recorded "Mature" tree individuals present in the range of 30-45cm (other age class structures also apply - see adjacent cell)

New Veg code (M=Marillana, W=Weeli Wolli)	Condensed Vegetation Description	Generalised *M. argentea* Age Class/Range	Notes on *Melaleuca argentea* presence	Average stem sizes - *Melaleuca argentea*
C2/C1-M	***Strips of vegetation lining the low flow channel of:*** *Scattered Eucalyptus camaldulensis trees, over low open forest of Eucalyptus camaldulensis and Melaleuca argentea saplings/young-trees, over tall open shrubland of Acacia ampliceps, Melaleuca argentea, Melaleuca glomerata, and Atalaya hemiglauca generally accompanied by fringing strips of dense Typha domingensis.*	**Y*** YOUNG classed individuals present; with some slightly older individuals occasionally present (*)	Presence of: Creek sections possessing populations with a somewhat variable age class and generally classed in the young age range but including strips with ages generally restricted to a age classes no higher than Y-SM(-), and often including extensive linear strips of vegetation fringing the Low flow channel and dominated by dense recruitment consisting mainly of young individuals of Both *Melaleuca argentea* and *Eucalyptus camaldulensis*.	Average stem diameters of the main population considered young, and ranging from 5-10cm, with scattered individuals with stem diameters of 10-15cm present. Individuals recorded with a stem diameter above 20cm are generally absent.
C2/C1-W	***Strips of vegetation generally lining the low flow channel of:*** *Low woodland of Eucalyptus camaldulensis subsp. refulgens and Melaleuca argentea saplings/young-trees, over scattered tall-shrubs of Melaleuca glomerata, Atalaya hemiglauca, and Stylobasium spathulatum.*	**Y*** YOUNG classed individuals present; with some slightly older individuals occasionally present (*)	Presence of : Creek sections possessing populations with a relatively consistent age class and generally classed in the young age range. In some areas small outcrops of generally young populations with low numbers of sm(-) individuals present were attributed to this vegetation unit. This unit is often represented by very thin strips of Melaleuca co-dominated vegetation fringing the Low flow channel and dominated by young individuals. These areas are also often correlated with the fringes of longer creek pools and sections of fast flowing water.	Average stem diameters of the main population considered young, and ranging from 5-10cm, with scattered individuals with stem diameters of 10-15cm present. Individuals recorded with a stem diameter above 20cm are generally absent.
C2A	*Eucalyptus camaldulensis subsp. refulgens, E. victrix open woodland, over Acacia coriacea subsp. pendens, Atalaya hemiglauca and Acacia citrinoviridis low open woodland, over Melaleuca glomerata and Acacia citrinoviridis tall open shrubland, over low shrubland typically dominated by Corchorus crozophorifolius and Tephrosia sp.* Fortescue creeks.	No Data beyond their general absence from the community (but may be present in some areas as young individuals)	Only Present as an associated species	N/A

VEGETATION LEGEND

Rio Tinto

Part 2 - Riparian Vegetation of Marillana and Weeli Wolli Creeks

Mapping Refinement and Assessment of Values and Significance

4.2 HISTORICAL SURVEY AND QUADRAT BASED EVIDENCE FOR THE DISTRIBUTION OF MELALEUCA ARGENTEA IN THE PRE AND POST DISCHARGE ENVIRONMENT

For the purpose of assessing the significance of riparian vegetation within the study area, it was determined that part of this process involved building a picture of the pre-discharge riparian environment. This involved a comparison of the presence of obligate phreatophytes and facultative phreatophytes as well as OPV within data and outputs from recent survey work conducted in the study area by Biota (multiple surveys summarised in; Biota 2014a), and historical surveys conducted in the study area by Mattiske (1995a, 199b, 1995c) pre-discharge. Figures 3-1 to 3-5 presented earlier in the document display the location of the most relevant riparian quadrats sampled as part of these flora and vegetation surveys conducted in the study area. Figure 2-2 presents a map illustrating the boundaries of the Key pre and post-discharge flora and vegetation surveys conducted within the vicinity of the study area. This map helps to interpret the spatial location of data patterns presented in this section. The quadrat locations depicted in Figures 3-6 are represented by two separate sets of symbols for the surveys conducted by Mattiske (1995a, 1995b, and 1995c) in the pre-discharge environment, and Biota (2003-2014) in the post-discharge environment. Labelling within each set of symbols indicates the presence/absence of *Melaleuca argentea* and *Eucalyptus camaldulensis* at the time of survey. More specifically they combine to depict which quadrats:

- did not possess *Melaleuca argentea*;
- possessed *M. argentea* only as an associated species within the sampled area;
- were described to possess *M. argentea* as a co-dominant species within the recorded vegetation description; and
- were either described to possess *Eucalyptus camaldulensis* as a co-dominant species within the recorded vegetation description, or only as an associated species within the sampled area.

Given that a number of the sampled quadrats presented are located outside of the current study area, and that water availability in these areas may be different (especially upstream of the study area within Weeli Wolli Creek) to that discussed in this report, their location within or outside of the study area has been differentiated so as to avoid confusion about the trends displayed by the data. Of these quadrats, Mattiske sampled 11 within and 11 outside of the study area (1995a, 1995b, 1995c). Biota (2004-2014 summarised in; Biota 2014a) sampled 15 quadrats within and 2 outside of the study area over various survey periods. Of the Mattiske quadrats sampled pre-discharge 0/11 of the quadrats within the study area and 3/11 outside of the study area described *M. argentea* as a co-dominant species within the sampled vegetation. Furthermore, of the Mattiske quadrats; 0/11 within the study area, and 2/11 outside the study area, only recorded *M. argentea* as an associated species in the sampled vegetation. *Eucalyptus camaldulensis* was recorded to be either a co-dominant or an associated species within a total of 7/11 quadrats within and 7/11 quadrats outside of the study area.

The broad trends shown by the Mattiske data indicates that within the pre-discharge vegetation of the study area, *Melaleuca argentea* appears highly restricted in its distribution such that sampled quadrats failed to detect it. Also, as expected; quadrats further south, and out of the study area on Weeli Wolli Creek (closer to Weeli Wolli Springs and sampled by Mattiske pre-discharge; Mattiske 1995c), were the only pre-discharge sampled quadrats to record *M. argentea* as a co-dominant

species. Furthermore, as expected, the Mattiske quadrats indicated that *Eucalyptus camaldulensis* was relatively widespread in its distribution throughout the study area.

In the post-discharge environment, some significant differences in the quadrat data, when compared to the pre-discharge data, were apparent (note that there are also some survey area spatial differences relating to this comparison). Of Biotas quadrats sampled pre-discharge (Biota 2014a), 5/15 of the quadrats within the study area and 0/2 outside of the study area described *M. argentea* as a co-dominant species within the sampled vegetation. Furthermore, of the Biota quadrats; 5/15 within the study area, and 0/2 outside the study area, only recorded *M. argentea* as an associated species in the sampled vegetation. *Eucalyptus camaldulensis* was recorded to be either a co-dominant or an associated species within a total of 9/15 quadrats within and 0/2 quadrats outside of the study area. The broad trends shown by the Biota quadrat data indicates that within the post-discharge vegetation of the study area, *Melaleuca argentea* appears to be significantly less restricted in its distribution, when compared to pre-discharge quadrats, such that sampled quadrats recorded this species 2/3 of the time (only 1/3 of the quadrats recording this species as a co-dominant component of the vegetation). As expected *E. camaldulensis* was relatively widespread in its distribution within the study area. While the proportion of sampling sites possessing *E. camaldulensis* are approximately the same in the pre and post-discharge study area, it's expected that discharge related vegetation augmentation is likely to have increased the distribution of sub-mature to mature populations of this species.

Some of the patterns displayed by this quadrat data, and relating to the distribution of OPV in the pre and post-discharge environment, are also be demonstrated by the conclusions, observations and vegetation mapping produced as part of this previous survey work. Vegetation mapping conducted by Mattiske (1995) for three separate Flora and Vegetation surveys within the Yandicoogina Project area, covered a significant proportion of the riparian environments of the current study area (Yandi Junction Central (1995a), Northern transport corridor (1995b) and Southern Transport corridor (1995c)). Within the current study area, the relevant vegetation mapping created as part of these surveys, did not identify a riparian vegetation unit which contained *Melaleuca argentea* as a co-dominant species. Instead Mattiske (1995) identified that this species (previously identified as *Melaleuca leucadendra*) was only present in small patches within certain zones of the large creek systems in the area. The relevant vegetation unit which was instead mapped in these areas was the "2d" coded community of *Eucalyptus camaldulensis* woodland. This is the same community which was missing from the Biota vegetation mapping in similar areas. The following plate is an excerpt from the Junction Central Report (Mattiske, 1995a), and mentions the very restricted distribution of *Melaleuca leucadendra* (Now *M. argentea*) within the relevant stretch of Marillana creek.

Community 2d (Recording Sites - OS030, OS033, OS085, OS086, OS092, TS103)

Woodland of *Eucalyptus camaldulensis*, lying in the major flow-lines which occur within the Yandicoogina Junction area. The occasional *Melaleuca leucadendra* occurs in minor scattered pockets within this community near the junction of the Marillana Creek with the side main creek (west of the exploration camp, 748300mN - 726000mE) and near the crossing on the eastern side of the survey area (7478800mN - 731900mE).

The understorey species are very diverse, with species ranging from grasses through to dense shrubs. Associated species included *Eucalyptus victrix, Cyperus* spp., *Cleome viscosa, Acacia citrinoviridis, Acacia coriacea, Atalaya hemiglauca, Melaleuca glomerata, Indigofera monophylla, Corchorus walcottii, Ptilotus obovatus, Cymbopogon ambiguus* and *Triodia pungens*. Opportunistic Site OS030 occurs slightly west of the boundary on the vegetation map on Figure 3.

This community is relatively habitat restricted to major creek beds which flood in cyclonic events, but it does occur regularly throughout the Pilbara Region.

Plate 5: Excerpt describing the 2d vegetation unit from the vegetation section of the report: 'Flora and Vegetation: Yandicoogina Junction Area' (Mattiske, 1995a)

Community 2d (Recording Sites - TS139, OS141, OS145, OS146, OS160, OS175)

Woodland of *Eucalyptus camaldulensis*, lying in the major flow-lines which occur within the Southern Transport Corridor. Pockets of *Melaleuca leucadendra, Melaleuca argentea* spp. *argentea* and *Melaleuca glomerata* occurs in minor scattered pockets within this community.

The understorey species are very diverse, with species ranging from grasses through to dense shrubs. Associated species included *Eucalyptus victrix, Cyperus* spp., *Cleome viscosa, Acacia citrinoviridis, Acacia coriacea, Atalaya hemiglauca, Melaleuca glomerata, Indigofera monophylla, Corchorus walcottii, Ptilotus obovatus, Petalostylis labicheoides, Abutilon fraseri, Dicladanthera forrestii, Eulalia aurea, Cymbopogon ambiguus* and *Triodia pungens*.

This plant community is relatively habitat restricted to major creek beds which flood in cyclonic events, but it does occur regularly throughout the Pilbara Region.

Plate 6: Excerpt describing the 2d vegetation unit from the vegetation section of the report: 'Flora and Vegetation: Southern Transport corridor, Yandicoogina Junction Project' (Mattiske, 1995c)

It should be noted that the Southern Transport corridor vegetation mapping does recognise a *Melaleuca leucadendra* (*M. argentea*) woodland community (unit 2f), but the last occurrence of this community is mapped as ending at the upstream boundary of the current study area. The following excerpt from this report describes the 2f community.

Community 2f (Recording Sites - TS143, OS148, OS150, OS154, OS167)

Woodland of *Melaleuca leucadendra* occurs on Weeli Wolli Creek; including very large trees and pockets of denser cover (which at times approximates a forest in structure). This denser stand is very atypical and is not replicated within the Pilbara Region and therefore is significant both locally and regionally.

Associated species include *Melaleuca glomerata, Melaleuca argentea* ssp. *argentea, Acacia coriacea, Acacia citrinoviridis, Cleome viscosa, Eucalyptus camaldulensis, Eucalyptus victrix, Stemodia grossa, Tephrosia* spp., *Flaveria australasica, Gossypium robinsonii, Sesbania cannabina, Cyperus* spp., *Stylobasium spathulatum, Rhynchosia* cf. *minima* and *Senna* spp.

These woodlands occur as pockets along Weeli Wolli Creek, however the main occurrence near the main crossing of Weeli Wolli Creek is distinctive due to its structural features which are not replicated in other areas of the Pilbara.

Plate 7: Excerpt describing the 2f vegetation unit from the vegetation section of the report: 'Flora and Vegetation: Southern Transport corridor, Yandicoogina Junction Project' (Mattiske, 1995c)

Despite the conclusions which the Mattiske pre-discharge surveys seem to present, it should be noted, these surveys only cover a 4km section of Weeli Wolli Creek at the upstream end of the study area (The Southern Transport Corridor survey 1995c). As a result, despite it being likely, there is no guarantee that the vegetation patterns mapped in this section continued north throughout Weeli Wolli in the pre-discharge environment.

The 1981 survey by integrated Environmental services titled "Ecological Appraisal of the Yandicoogina Project Area (1981)", also covered a significant proportion (the greatest; at approximately 90%) of riparian communities within the current study area. After describing the vegetation mapped within the study area and determining that no *M. argentea* dominated communities were identified, the vegetation section of this report provides some concluding statements, the following one of which relates to *Melaleuca* distribution within the study area.

Some vegetation types known to be present are too limited in extent, or are not sufficiently developed, to be classified as plant communities of the area. Elements of gorge vegetation do occur in rocky microhabitats and along drainage features but these do not form the assemblages known from elsewhere in the Hamersley Ranges. The species in the area include native fig *Ficus platypoda*, ant bush *Capparis spinosa* and the iron-ore palm *Astrotricha hamptonii*. The cadjeput *Melaleuca leucodendron* forms a forest at Weeli-Wolli Springs but only scattered clumps of this tree occur along the major creeks within the study area.

Plate 8: Excerpt about vegetation scales within the Yandicoogina project area from the Vegetation section of the report: 'Ecological appraisal of the Yandicoogina Project area (Integrated Environmental Services, 1981)'

The pre and post-discharge quadrat based sampling sites, and comparisons between pre and post-discharge vegetation mapping, seem to present relatively clear patterns in the distribution of obligate phreatophytic species and associated vegetation within the study area. The pattern which

has emerged is that riparian vegetation in the study area appears to have transitioned somewhat. OPV, while still considerably restricted, is transitioning to become less restricted in its distribution within the study area. Furthermore the conclusions and observations presented in pre-discharge surveys and provided above represent additional support for these conclusions.

4.3 DETERMING THE LIKELIHOOD OF PRESENCE FOR OPV COMMUNITIES IN THE PRE-DISCHARGE RIPARIAN HABITATS OF THE STUDY AREA

4.3.1 Application of the Deductive Process

The data acquired within the field component, and which created the refined vegetation mapping; supported the production of four general "size class ranges" (i.e. Inferred age) and physical-structure units for OPV communities within the study area. The spread of the field data acquired meant that 4 levels of inferred age structure became apparent, and as a consequence of the respective position of the growth projection figures, two sat either side of the cut-off points (the "reasonable maximum trunk diameter") for growth projected under two temporal discharge regimes. Having communities representing key intermediate age/physical structures sitting either side of the cut-off figures enabled the interpretations to incorporate some conservative conclusions in relation to the pre-discharge environment. The mapped OPV community directly below the cut-off figure (The C1/C2A community) was interpreted to represent areas pre-discharge that possessed a young transient and at times potentially co-dominant *M. argentea* component which comprised a minimal structural contribution within the broader community. The mapped OPV community immediately above the cut-off figure (The C1B community), was interpreted to represent areas pre-discharge that possessed a young (to semi-mature; at best) but consistently co-dominant *M. argentea* component most likely to be a significant part of the low open woodland strata of the community. What this dissection of the community groups also enabled, was a buffer of size class range between the cut-off mark and the communities clearly interpreted to be absent (the C2/C1 community) or present (the C1A community) in the pre-discharge environment.

4.3.2 Growth Rate Projections under Two Key Discharge Regimes – Seedlings Onwards

The projection of growth rates for *Melaleuca argentea* within Pilbara perennial creek habitats is an important piece of work which feeds into one of the key aims of the study: to interpret the likely presence and distribution of OPV in the pre-discharge environment. The monitoring data used to project these growth figures utilised *M. argentea* trees from a range of sizes, and while monitoring trees scored to be in healthy condition were favoured, in general the trees used represented a spread of condition ratings from healthy to severely stressed.

From this data the graph in figure 4-9 presents the calculated trends in predicted growth rate for the respective DBH ranges of the monitoring trees used. From this graph, a relevant range of projected growth for both time scales (9 and 15 years) was chosen as the rate to be used for drawing conclusions about the pre-discharge environment. Given that the growth rates used are based on changes in 2-dimensional trunk biomass, in this study, the cut-off growth rate chosen is influenced by the fact that different aged/sized trees generally produce different growth rates. This relationship can be seen in figure 4-9, as the trending growth rates projected from monitoring trees of varying DBH indicate a positive relationship between size (inferring age) and projected growth rates, suggesting that older/larger trees generally grow faster (in a two-dimensional biomass measure). This relationship is most likely to be a result of the increased canopy and root resource

which a larger tree (when compared to a smaller/younger tree) can utilise to add biomass per unit of time. According to a study by Stephenson et al., (2014) a global analysis of 403 tropical and temperate tree species, showed that for most species mass growth rate increases continuously with tree size. Therefore, based on the projected growth rate graph, and the plateau in growth rate projections between the 7-11 cm & 11-18 cm DBH ranges it was determined that from a seedling, 9 and 15 years of cumulative growth suggest that realised DBH would be in the vicinity of 30 cm. Consequently, it was assumed that the majority of trees in that population would be able to realise a projected growth rate of no greater than that which a 30cm tree could realise. From the graph in figure 4.9, the projected growth rate for a 30 cm tree (i.e. a tree falling within the 18-45 cm DBH range) would be approximately 35 cm for 9 years and 45 cm for 15 years. Consequently, in an effort to provide a conservative size boundary (cut-off figure), it was decided to round this figure to 30 cm for the 9 year growth period (Weeli Wolli Creek Discharge scenario) and 40 cm for the 15 year period (the Marillana discharge scenario). As discussed in the methods, to allow for degrees of potential error or bias in the projection data, and therefore add an additional degree of conservancy, calculated grow projections were reduced by 20%.

Final growth prediction cut-off figures (incorporating an additional 20% reduction) for obligate phreatophytic species populations (*M. argentea*) under the two discharge timelines are:

1. Weeli Wolli Creek communities (9 years of perennial stream flow) = 24cm DBH

2. Marillana Creek communities (15 years of perennial stream flow) = 32cm DBH

For the purpose of this study these figures are proposed to represent: The average maximum DBH (an average of the upper diameter size class present in a population) within a population which can be confidently attributed to growth in the relevant time period. The monitoring tree data used and the calculations made from this data to create the above presented growth projections are presented in Appendix 2.

4.4 INTERPRETATIONS OF THE PRE-DISCHARGE PRESENCE OF MAPPED VEGETATION COMMUNITIES, AND RESULTANT CONCLUSIONS ON THE DISTRIBUTION OF OPV COMMUNITIES IN THE STUDY AREA

Based on the deductive process presented, and the growth projections and associated which supported this process, an interpretation of the likelihood of communities being present in the pre-discharge environment (in at least a functionally similar form) was conducted on all of the Riparian communities of the study area. Based on the techniques, assumptions and growth projections used, as well as the ecological limitations constraining the interpretations, it is anticipated that the process was approached in as conservative a manner as was practicable (while still being able to make relatively straightforward conclusions).

Table 4-4 below presents the resulting interpretations of the likelihood that each mapped vegetation sub-association occurred in the pre-discharge environment in its current or similar form. Brief notes about the pre-discharge form of vegetation units are also provided in this table where appropriate. It should be noted that as previously explained; the results are purely an interpretation of likelihood, and as such are a best estimate based on field data, monitoring based growth projections, historical quadrat data, and knowledge of vegetation ecology, hydrogeology and broad fluvial processes.

Based on the presented interpretations, a number of conclusions about the distribution of OPV within the study area can be made. Firstly, in general; OPV with a high likelihood of being present in the natural pre-discharge environment (i.e. without the effects of discharge augmentation) is highly restricted within the study area. Representing approximately 2% of the study area, these communities are represented by the C1A, and C1B vegetation units. Within the study area these communities are generally restricted to small patches of vegetation fringing the main low flow channel on bends or at the end of long pools/straights within Weeli Wolli Creek, and similar positions within the more variable and often multiple low flow channels of Marillana creek.

4.5 RESULTANT SIGNIFICANCE ATTRIBUTED TO THE RIPARIAN COMMUNITIES IN THE STUDY AREA

The results of the included mapping refinement along with the above interpretations of likely presence in the pre-discharge environment were used to contribute to an assessment of significance for each of the riparian vegetation community (sub-associations) mapped as part of this study. The significance value attributed to each community is based on the significance framework presented in section 2.8. This Framework incorporates an assessment of the ecological values provided, the distribution or degree to which it is represented in the environment (local, sub-regional, regional), the condition, and the sensitivity to impact of each community mapped within the study area.

The resultant significance attributed to each riparian vegetation unit is initially assigned to one of the following significance ratings.

(1) Low, (2) Minor, (3) Minor-Moderate, (4) Moderate, (5) Moderate-High, (6) High, (7) Very-High

An additional “development significance” is also provided for each riparian unit mapped as part of this study.

The results of the significance assessment are presented in Table 4-5 below. It should be noted that Table 4-5 does not provide an indication of conservation significance as this is an additional level of subjectivity which is not considered valuable in the context of this study.

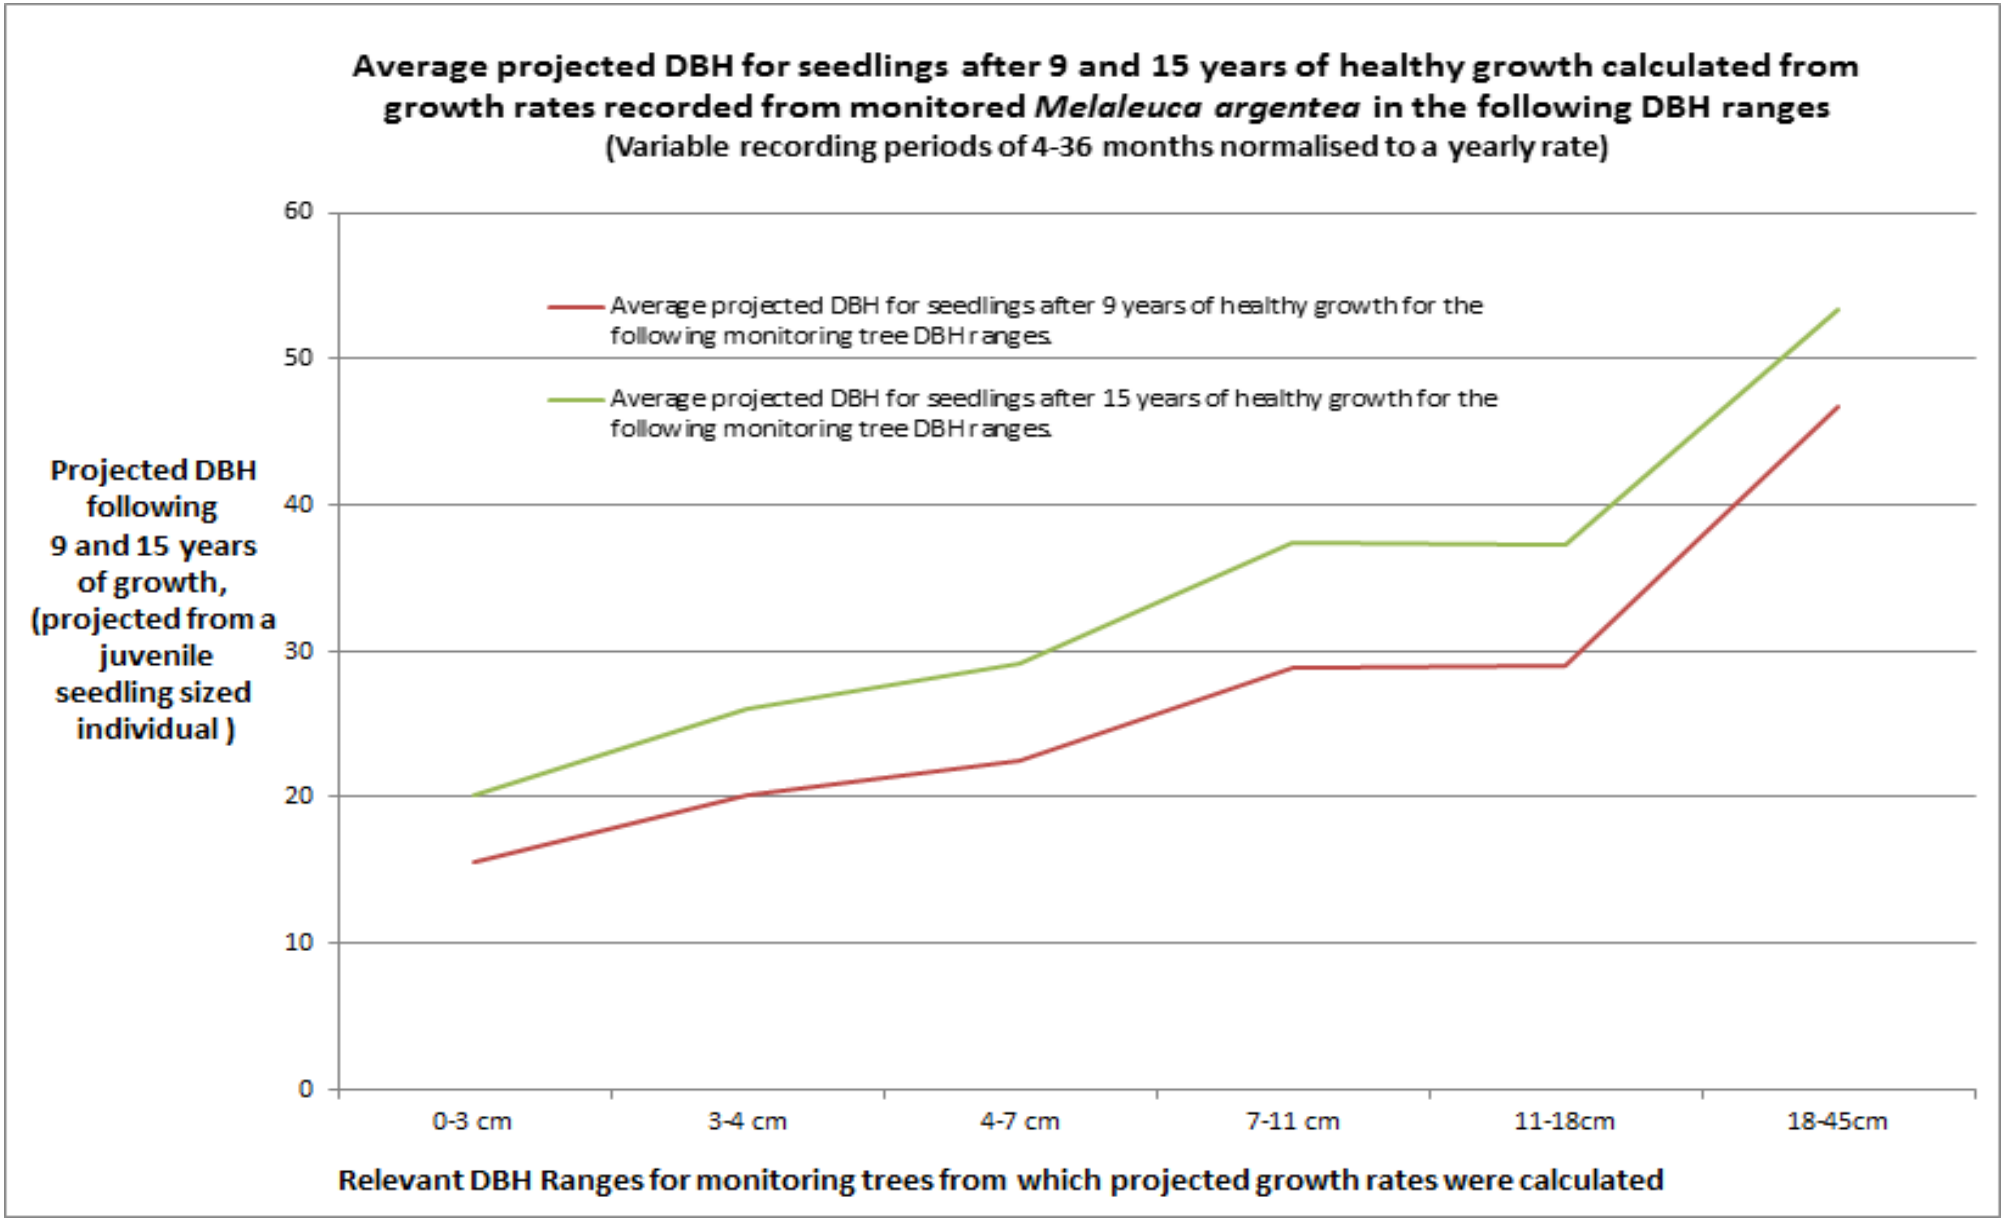

Figure 4-9: Graph showing the growth rate projections calculated from monitoring tree data (and two other minor data sources). The two blue arrows delineate the monitoring tree DBH zone from which an average projected growth rate was taken for the purpose of deducting conclusions about the pre-discharge riparian environment in Marillana and Weeli Wolli Creeks

Table 4-4: Interpretations of the likely presence of mapped and refined vegetation communities of the current study area within the pre-discharge environment

New Veg code (M=Marillana, W=Weeli Wolli)	Vegetation Type	Interpreted presence in the Pre-Discharge Environment	Notes about the Pre-discharge presence
C1AA	**Larger representations of Historical *Melaleuca argentea* and *Eucalyptus camaldulensis* Woodland**	**Clearly present in the Pre-discharge environment**	**Present in the same or a very similar form to the present day community, in both Structure and composition.**
C1A	**Small patches of *Melaleuca argentea* and *Eucalyptus camaldulensis* Woodland**	**Clearly present in the Pre-discharge environment**	**Present in the same or a very similar form to the present day community, in both Structure and composition.**
C1B - M	**Marillana – *E. camaldulensis* and *E. victrix* woodland over *M. argentea* Semi Mature low open woodland**	**Potentially present in the Pre-discharge environment in this form.**	**Likely present with a younger in a younger more transient form of *M. argentea* population but still comprising a significant component of the broader community.**
C1B - W	**Weeli Wolli - *E. camaldulensis* and *E. victrix* woodland over *M. argentea* Semi Mature low open woodland**	**Likely to be present in the Pre-discharge. Environment.**	**Likely present in a very similar form to the present day community.**
C1/C2-A - M	**Marillana - *E. camaldulensis* and *E. victrix* open woodland over *M. argentea* and *E. camaldulensis* Young to Semi Mature low open woodland**	**Unlikely to have been Present in the Pre-discharge Environment in this form.**	**Instead Likely to have been represented by a lower value community, most likely either the C2/C1 or C2A community.** **Potentially represented by a community with transient (coming and going over time with climatic phases and successive floods) young populations of *Melaleuca argentea* in these areas. Likely that *M. argentea* may not have formed a co-dominant component of the vegetation.**
C1/C2-A - W	**Weeli Wolli – *E. camaldulensis* and *M. argentea* Young to Semi Mature low open woodland**	**Unlikely to have been Present in the Pre-discharge environment in this form.**	**Instead Likely to have been represented by a lower value community, most likely either the C2/C1 or C2A community.** **Potentially represented by a community with transient (establishing and de-establishing over time with climatic phases and successive floods) young populations of *Melaleuca argentea* in these areas. Likely that *M. argentea* did not have form a co-dominant component of the vegetation.**
C2/C1 - M	**Marillana - *M. argentea* and *E. camaldulensis* Young low open forest,** ***(Generally represented by thin Strips of vegetation lining the low flow channel)***	**Not Present in the Pre-discharge environment in this form.**	**Instead most likely represented by the C2A or C3A community**

New Veg code (M=Marillana, W=Weeli Wolli)	Vegetation Type	Interpreted presence in the Pre-Discharge Environment	Notes about the Pre-discharge presence
C2/C1 - W	**Weeli Wolli - *M. argentea* and *E. camaldulensis* Young low open forest,** ***(Generally represented by thin Strips of vegetation lining the low flow channel)***	**Not Present in the Pre-discharge environment in this form**	**Instead most likely represented by the C2A or C3A community**
C2A	***E. camaldulensis* and *E. victrix* woodland bank/bed community**	**Present in the Pre-discharge environment.**	**The representations present in the present day study area are generally discharge "altered"; therefore the pre-discharge form of this community may be slightly different.**
C2Asb	***E. camaldulensis* and *E. victrix* woodland Scoured bed community**	**Present in the Pre-discharge environment.**	**The representations present in the present day study area are generally discharge "altered"; therefore the pre-discharge form of this community may be slightly different.**
C2B	***E. camaldulensis* and *E. victrix* Floodplain community**	**Present in the Pre-discharge environment.**	Current and Pre-discharge representations of this community are highly likely to be very similar if not virtually identical.
C2C	***Eucalyptus victrix* low woodland/ Acacia shrublands of the upper and outer creekbeds and tributaries**	**Present in the Pre-discharge environment.**	Current and Pre-discharge representations of this community are highly likely to be very similar if not virtually identical.
C3A	***E. victrix* Bank/bed community**	**Present in the Pre-discharge environment.**	**The representations existent in the present day study area are generally discharge "altered"; therefore the pre-discharge form of this community may be slightly different.**
C3Asb	***E. victrix* scoured beds community**	**Present in the Pre-discharge environment.**	**The representations present in the present day study area are generally discharge "altered"; therefore the pre-discharge form of this community may be slightly different.**

Table 4-5: Assessment of resultant Riparian significance for the riparian vegetation units mapped within the study area

New Veg code	Condensed Vegetation Description	Generalised *M. argentea* "Size Class Range"	Associated Ecological Values	Distribution/Representation/Rarity & Presence in the Pre-Discharge Environment	Significance	Condition	Sensitivity to relevant impacts	Development significance
C1AA	*Eucalyptus camaldulensis subsp. refulgens, E. victrix and Melaleuca argentea woodland, over Eucalyptus victrix, Melaleuca argentea, and Acacia coriacea subsp. pendens low open woodland, over tall open shrubland of Melaleuca glomerata and Acacia ampliceps.*	**M-SM(+)**	• Mature mesic woodland habitat. • Perennial water availability (at present and Pre/post-discharge). • High mesic flora species diversity. • Cryptic and Conservation significant fauna habitat (likely to include the Pilbara olive python, Northern Quoll, and potentially the Ghost Bat and PLNB). • Cryptic and conservation significant flora species habitat (for Stylidium Weeli Wolli). • High subsurface aquatic invertebrate diversity. • High local avifauna and bat species diversity (potentially including the Chocolate bat). • Some reduced value from cumulative impact. • Above average representation of the Major Creeklines of the Pilbara Ecosystem at Risk. • Good Potential for elevated sedge diversity, and possibly including cryptic species such as Fuirena ciliaris and Eleocharis geniculata, as well as a suite of habitat specific sedges, grasses and herbs. (Note: allot of these values are known from the similar well studied community associated with Weeli Wolli springs – while not proven in all other representations of an equivalent/similar community these values are likely to be present in substantial sized representations of this community – smaller representations are likely to contain only some of these values (info regarding the values associated with Weeli Wolli springs is provided in Appendix 3; DEC 2009b).	**Sub-regionally restricted and significant** The rocky rangeland creek variant of this community is uncommon and relatively restricted within the Hamersley sub-region. Larger areal extent representations of this community are substantially restricted in the Hamersley sub-region. The unique substrates and adjacent rocky habitats make it relatively unique when compared to riverine representations occurring in the wider Pilbara Bioregion. **The representation present in the study area is relatively large, extends outside of the study area, off tenement, and has suffered impact from adjacent mining operations (not Rio Tinto operations).** **Clearly present in the Pre-discharge environment, potential re-establishment post impact.**	**High**	**Good to Poor** (significant anthropogenic structural impacts from enhancement)	**High** (moderate to low at present; historically high)	**High**

New Veg code	Condensed Vegetation Description	Generalised *M. argentea* "Size Class Range"	Associated Ecological Values	Distribution/Representation/Rarity & Presence in the Pre-Discharge Environment	Significance	Condition	Sensitivity to relevant impacts	Development significance
C1A - Marillana	*Eucalyptus camaldulensis subsp. refulgens, E. victrix and Melaleuca argentea woodland over Eucalyptus camaldulensis Melaleuca argentea and Acacia coriacea subsp. pendens low open woodland.*	**M-SM**	• Relatively mature mesic woodland habitat • Perennial water availability (at present and Pre/post-discharge). • Above average to High mesic flora species diversity. • Cryptic and Conservation significant fauna habitat (likely to include the Pilbara olive python, Northern Quoll, and potentially the Ghost Bat, and Chocolate Wattle Bat). • Cryptic and conservation significant flora species habitat (for Stylidium Weeli Wolli). • High subsurface aquatic invertebrate diversity. • High local avifauna diversity. • Some reduced value from direct impacts. • Some increased value from discharge enhancement. • Above average representation of the Major Creeklines of the Pilbara Ecosystem at Risk. • Some potential for elevated sedge diversity, and possibly including cryptic species such as Fuirena ciliaris and Eleocharis geniculata, as well as a suite of habitat specific sedges, grasses and herbs. (Fuirena ciliaris has not been detected in previous flora and vegetation surveys in the study area, but Eleocharis geniculata has been found once in 2004).	**Sub-regionally restricted** The rocky rangeland creek variant of this community is uncommon and relatively restricted within the Hamersley sub-region. Larger areal extent representations of this community are substantially restricted in the Hamersley sub-region. The unique substrates and adjacent rocky habitats make it relatively unique when compared to riverine representations occurring in the wider Pilbara Bioregion. **The representations present in the study area are all quite small and disjunct, with the patch immediately downstream of the BHPBIO discharge point representing the largest and most significant.** **Clearly present in the Pre-discharge environment.**	**Moderate-high** (Smaller representations – Moderate)	**Very Good to Good** (some anthropogenic structural impacts from enhancement)	**High**	**High**
C1B - Marillana	*Eucalyptus camaldulensis subsp. refulgens, and E. victrix woodland, over Melaleuca argentea, and Acacia coriacea subsp. pendens low open woodland, over tall open shrubland of Melaleuca argentea, M. glomerata and Acacia ampliceps.*	**Y-SM Plus**	• Discharge augmented Semi-mature mesic woodland/low-woodland habitat. • Perennial water availability (at present and potentially Pre/post-discharge). • Above average mesic flora species diversity. • Cryptic and Conservation significant fauna habitat (likely to include the Pilbara olive python, and potentially the Northern Quoll. Also some potential for the Ghost Bat, and Chocolate Wattle Bat to forage here). • Cryptic and conservation significant flora species habitat (potentially for Stylidium Weeli Wolli). • Above average subsurface aquatic invertebrate diversity. • High local avifauna diversity.	**Locally to Sub-regionally restricted** The rocky rangeland creek variant of this community is uncommon and relatively restricted within the Hamersley sub-region. Larger areal extent representations of this community are substantially restricted in the Hamersley sub-region. The unique substrates and adjacent rocky habitats make it relatively unique when compared to riverine representations occurring in the wider Pilbara Bioregion. **The representations present in the study area are all quite small thin and**	**Moderate** (small areas) **Moderate-High** (larger patches)	**Good** (moderate anthropogenic structural impacts from enhancement)	**Moderate to high**	**Moderate** (Small patches) **Moderate-High** (larger patches, or small patches fringing the C1A unit)

New Veg code	Condensed Vegetation Description	Generalised *M. argentea* "Size Class Range"	Associated Ecological Values	Distribution/Representation/Rarity & Presence in the Pre-Discharge Environment	Significance	Condition	Sensitivity to relevant impacts	Development significance
			• Some reduced value from direct impacts. • Some increased value from discharge enhancement. • Above average representation of the Major Creeklines of the Pilbara Ecosystem at Risk.	**disjunct patches scattered among the broader riparian communities.** **Potentially present in the Pre-discharge environment in this form. Likely present in a younger more transient form. Potentially represented by a lower value community.**				
C1B – Weeli Wolli	*Eucalyptus camaldulensis subsp. refulgens, and E. victrix woodland, over Melaleuca argentea, and Acacia coriacea subsp. pendens low open woodland, over tall open shrubland of Melaleuca argentea, M. glomerata and Acacia coriacea subsp. pendens.*	**Y-SM Plus**	• Semi-mature mesic woodland/low-woodland habitat. • Perennial water availability (at present and potentially Pre/post-discharge). • Above average mesic flora species diversity. • Cryptic and Conservation significant fauna habitat (likely to include the Pilbara olive python, and potentially the Northern Quoll. Also some potential for the Ghost Bat, and Chocolate Wattle Bat to forage here). • Cryptic and conservation significant flora species habitat (potentially for Stylidium Weeli Wolli). • Above average subsurface aquatic invertebrate diversity. • Above average local avifauna diversity. • Some reduced value from direct impacts. • Some increased value from discharge enhancement. • Above average representation of the Major Creeklines of the Pilbara Ecosystem at Risk.	**Locally to Sub-regionally restricted** The rocky rangeland creek variant of this community is uncommon and relatively restricted within the Hamersley sub-region. Larger areal extent representations of this community are substantially restricted in the Hamersley sub-region. 4.6 HISTORICAL DMSI CHANGE DETECTION IMAGERY ASSESSMENT FOR USE IN THE INTERPRETATION OF THE PRE-DISCHARGE ENVIRONMENT

Figures 4-10 to 4-13 Present maps of the change detection Imagery for the period 2006-2014, created from yearly-acquired DMSI imagery of the study area. Using DMSI, a comparative analysis of embedded visible and infra-red electromagnetic radiation intensities produces a measure (index) of vegetation cover for each year. The change in this index of vegetation cover from year to year is measured and spatially amalgamated to provide an image of cumulative change over this period. The resultant change detection image is represented by a thematic colour map, which depicts positive and negative change in vegetation cover as different colour palates. Plate 9 provides a legend for the thematic colour mapping presented in the change detection imagery, the summary of which is that red equates to a clear loss of vegetation cover, white is no change and Blue equates to a clear increase in vegetation cover.

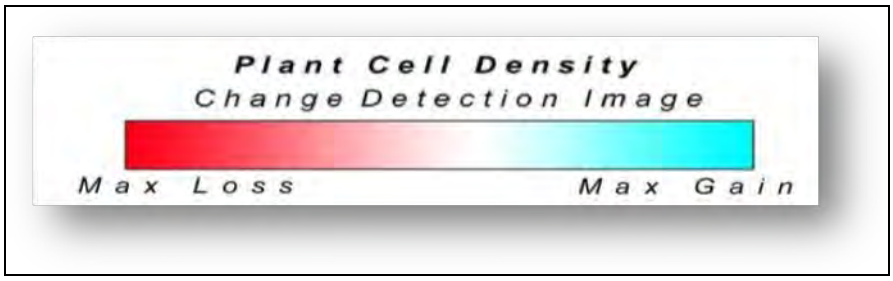

Plate 9: Legend for the thematic colour mapping presented in DMSI Change detection imagery

Key vegetation cover trends evident within Marillana Creek include, positive cover changes in low flow channel zones within areas downstream of discharge points, with negative cover changes in some of the areas positioned laterally away from discharge, or where additional discharge points have been removed. It should be noted that in the case of Marillana Creek a large proportion of vegetation augmentation likely to have occurred following discharge commencement, would have most likely occurred in the period prior to the acquisition timing of the DMSI image used (1995-2005). Despite this fact issues presented in section 3.3 outline the reasons behind the decision to rely on the 2006-2014 change detection imagery for presenting trends in vegetation cover within the study area.

Along Weeli Wolli Creek, the vegetation cover trends are generally more clearly and consistently positive within the main incised bed and bank zones. Despite this fact some clear vegetation cover loss anomalies are present in the vicinity of the confluence with Marillana Creek and in the scoured beds downstream of the confluence. Because all discharge related vegetation augmentation is likely to have taken place in the 2006-2014 period, the 2006-2014 DMSI change imagery is the best imagery for showing both positive and negative vegetation change within the Weeli Wolli Creek stretch of the study area. While similar trends to those shown in Weeli Wolli Creek are shown by change detection imagery for Marillana Creek, the trends are less consistently distributed, and appear harder to correlate with the distribution of various community boundaries mapped as part of this study. For this and other reasons the pre and post discharge aerial photography comparisons may present the best visual evidence for vegetation augmentation within the Marillana creek stretch of the study area.

Figures 4-10 to 4-21 are provided to present finer scale (spatially) examples of vegetation cover change detected by DMSI (2006-2014) of the study area. The presented examples are indicative of vegetation change trends noticed throughout the study area. Overlain on top of the change

detection imagery of these examples are two separate layers of vegetation mapping of most relevance to the study area. The "Vegetation Mapping units C1A and C1B combined" mapping polygons represent OPV mapped as part of this study and interpreted as highly likely to have been present in the pre-discharge environment. With both of these OPV units being interpreted to be part of the pre-discharge environment, and possessing somewhat similar structure and significance, they were combined for this mapping exercise to help provide visual simplicity when being analysed for correlation with patterns in the change detection imagery. The "Vegetation Mapping units C1/C2A and C2/C1 combined" mapping polygons represent present day OPV which is considered highly unlikely to have been present in the pre-discharge environment, and therefore is considered an augmented or artificial form of the pre-discharge community. These mapping polygons have been overlain to highlight the regular and often substantial degree of correlation between the boundaries and distribution of mapped OPV, and the boundaries and spatial distribution of positive vegetation change anomalies (potential vegetation augmentation).

The correlation evident between OPV mapping and positive vegetation change anomalies demonstrate that the spatial distribution of recent vegetation changes aligns with the distribution of communities interpreted as likely to be artificial and therefore not likely present in the pre-discharge environment in the same form. This spatial alignment lends weight to the accuracy of the interpretations made (section 4.4) about the historical presence of certain present day OPV communities. The provision of alternative evidence for the validity of interpretations made about the pre-discharge environment from present day field data is important for the process of firming up these interpretations and ultimately providing confident conclusions about the value and significance of riparian communities present in the study area.

4.7 PRE AND POST-DISCHARGE AERIAL PHOTOGRAPHY COMPARISON PROVIDING EVIDENCE OF DISCHARGE BASED VEGETATION AUGMENTATION AND INFLUENCE ON THE DISTRIBUTION OF OBLIGATE PHREATOPHYTIC VEGETATION (OPV)

The above presented DMSI change detection imagery helps to establish that present day OPV mapping shows a reasonable degree of spatial correlation with vegetation cover change anomalies existent in the post discharge environment. However, comparing the visual density and extent of vegetation present within pre-discharge aerial photography with the spatial position of presently mapped OPV appears to represent another piece of supportive evidence to these observations. Based on the below presented temporal comparisons of aerial photography, it can be seen in many cases that present day vegetation signatures occurring within the mapped boundaries of OPV communities, don't appear to be present in same spatial boundaries on the respective pre-discharge aerial photo. In such cases, these and similar spatial observations clearly appear to support interpretations that certain representations of OPV (particularly the C1/C2A and C2/C1 communities) are unlikely to have been present prior to surplus-water discharge commencing.

In the case of Marillana creek; strong disparities between aerial photo signatures from 1994 and 2014 are evident. These differences appear to suggest that a substantial amount of discharge sourced vegetation augmentation has occurred. However, reduced aerial photography quality along with reduced confidence in DMSI change detection imagery in the late 1990's diminish the confidence attributed to supporting trends apparent in these data sources. Weeli Wolli creek on the other hand, has generally only been subject to significant surplus-water discharge, and potential augmentation since 2006, and consequently confidence attributed to supporting trends apparent in these data sources is high. Furthermore; new development proposals present within this area are increasing the need for accurate information about the value, significance and sensitivity of riparian communities within the Weeli Wolli Creek stretch of the study area. As a consequence, the following comparative examples of pre and post discharge aerial photography for Weeli Wolli creek (and Marillana Creek) present promising aerial signature trends which appear to support previous conclusions made about the distribution of OPV in the study area.

Figures 4-22 to 4-32 present relatively small-scale examples of vegetation cover change via side-by-side comparison of available aerial photography from 1994 and 2014 for Marillana Creek, and from 2006 and 2014 for Weeli Wolli Creek. By presenting aerial photography side by side and at a small scale the figures are able to provide enough detail that the various zones of the creek profile (and their associate vegetation) are clearly able to be identified. Consequently the viewer is often able to clearly establish the changes to vegetation which have occurred between the two snapshots in time. In most cases, the presented examples aren't unusual anomalies, but rather good and easily presentable examples, and as such similar trends are to be noticed throughout the study area. Overlain on top of the comparative aerial photos are two separate layers of OPV mapping for the study area. The "Vegetation Mapping units C1A and C1B combined" mapping polygons represent OPV mapped as part of this study and which has been interpreted to possess a high likelihood of being present within the pre-discharge environment in a similar form. The "Vegetation Mapping units C1/C2A and C2/C1 combined" mapping polygons represent present day OPV which has been interpreted to possess a high likelihood of not being present within the pre-discharge environment. These mapping polygons have firstly been overlain show that the vegetation signature present in the post-discharge environment within (and often around and adjacent to) the bounds of the relevant phreatophytic vegetation polygons, is often clearly absent within the same polygon boundaries of

the pre-discharge aerial photography. Secondly this mapping has been overlain to help the viewer to establish identical spatial position within comparative aerial photos.

Beyond the clear differences between different temporal aerial photo signatures (vegetation) occurring within overlain mapping polygons, the comparative approach helps to illustrate the amount of vegetation augmentation which is apparent in both creek systems since discharge has commenced. Combined with the DMSI change detection imagery, the aerial photo comparisons (and the relevant time periods they cover) help to establish the following things about riparian vegetation within various parts of the study area:

(1) The distribution of apparent vegetation augmentation within the study area (Source: DMSI).

(2) Whether said augmentation patterns show positive correlations with mapping boundaries for significant vegetation (Source: DMSI, and to a lesser extent aerial photography).

(3) The timeline and spatial location of said augmentation (Source: DMSI and aerial photo).

(4) Whether areas of augmentation (evident in 2014) were represented by very minimal vegetation or vegetation of a significantly different aerial signature in the pre-discharge environment (Source: Aerial Photography).

(5) In situations where present day vegetation augmentation patterns correlate spatially with the C1/C2A and C2/C1 vegetation mapping units, and relevant aerial photo signatures instead suggest very minimal or significantly different vegetation was present in the pre-discharge environment, the combination of data supports the previous conclusion in that situation that the significant community is a result of augmentation, and was not present in the Pre-discharge environment.

Put simply, one of the key distinctions here is that using a combination of aerial imagery has the potential to first, using DMSI change detection imagery, attribute vegetation change to a specific spatial boundary over a particular time frame, and then using aerial photo comparison determine the likelihood that the vegetation currently present (in the same spatial bounds), was not present at the beginning of the relevant time period. So through combination, being able to confidently make such conclusions may play an important part in the process of establishing the likely source of change.

Based on the combination of DMSI change detection imagery and aerial photo comparison in the pre and post-discharge environment, the patterns evident within both seem to in many cases, clearly support conclusions made so far about the distribution and extent of OPV. Furthermore, the patterns evident within both data sources also appear, in most situations to support the interpretations made about which OPV communities are likely a product of discharge based vegetation augmentation and were not likely to be present in the pre-discharge environment.

4.8 PERCEIVED "SENSITIVITY" TO HYDROLOGICAL IMPACTS ATTRIBUTED TO LOCAL RIPARIAN VEGETATION BASED ON A COMBINATION OF HYDROLOGICAL SENSITIVITY, PROXIMITY TO POTENTIAL HYDROLOGICAL IMPACTS, AND ATTRIBUTED SIGNIFICANCE

The above sections have made available a set of resultant significance ratings to context the value present within the local riparian environment and associated communities in light of historical changes. Rather than purely map out these significance ratings to present the distribution and magnitude of significance within local riparian communities, it was deemed to be more useful to produce a summary map which presents a measure of the "sensitivity" to hydrological impacts which is perceived to be attributed to riparian communities mapped within the study area. The resultant "sensitivity" scale represents a combination of multiple factors:

(1) Dependency of each riparian community on past/present/future surface and groundwater sources (moisture dependency).

(2) Potential for significant (in the context of each community) changes to surface and groundwater availability throughout their mapped distribution under current and proposed development scenarios.

(3) The significance (perceived value) of each riparian community in the pre-mining environment (which is a combination of values, degree of restriction, and condition), and therefore the importance of maintaining similar forms of each community in the present day environment.

This "sensitivity" rating is in no way a prediction for impact, but rather a more holistic scale of importance for directing management effort to the most worthy and potentially susceptible/at-risk biological features present. The key learnings made about which OPV communities are most likely to have been present pre-discharge and their associated sensitivities form a significant component of the sensitivities attributed to communities depicted in illustrated sensitivity scale.

The "moisture dependency" factor used for the "sensitivity" rating is applied through a combination of broad knowledge of the requirements of key species associated with each community (as presented in section 2.4), the influence of biomass (associated with each community) on water requirements, and the influence of a communities spatial position within riparian habitats on general water availability under various scenarios. The second factor (listed above) relating to potential for changes to water availability is applied through broad local knowledge of current and proposed changes to natural and artificial water sources (some of which are a product of altered catchments and associated changes to hydrological regimes), as well as awareness of broad potential trends in natural water availability based on the best current information sources. The majority if information relating to potential changes to water availability in the study area is sourced from the URS report titled "Riparian Zones Environmental Risk Assessment" (URS 2015).

Figures 4-33 to 4-37 present the resultant spatial distribution and scale of "sensitivity" attributed to the most relevant Riparian communities of the study area (the C coded riparian units presented in this study).

4.9 SUMMARY OF KEY RESULTS

Beyond the refined vegetation model presented as part of this study, the following key conclusions have been interpreted from the results:

From the above results and it has been determined that at present there are approximately 1.01 km2 of riparian vegetation within the study area which can be considered to represent OPV communities. Of this 1.01 km; the results and interpreted conclusions of this study suggest that only 0.44 km2 (the C1AA, C1A, and C1B riparian vegetation units of this study) can be confidently considered to represent OPV communities likely to have been present in the pre-discharge environment (i.e. Pre-mining), and in a similar form. What this essentially determines is that 0.57 km^2 of mapped riparian communities (the C1/C2A and C2/C1 communities) were deemed to possess a present day *Melaleuca argentea* "size class range" below the projected "cut off figure" for a *Melaleuca argentea* population capable of comprising a significant component of pre-discharge vegetation.

Of the 0.44 km^2 of OPV mapped to occur in the study area, only 0.29 km^2 (29 ha) is represented by OPV within Rio Tinto tenure, as the C1AA unit is located off tenure. Of this 0.29km^2 (the C1A and C1B vegetation units) only 0.16 km^2 (16ha or approximately 0.8% of the study area riparian vegetation) represents the C1A community. Based on the findings of this study, the C1A vegetation unit is the community most accurately defined as being equivalent to the community described in the Yandicoogina "High Level Values statement (Rio Tinto 2011b). Based on the systematic qualitative assessment of significance conducted as part of this study, the C1A community is the only vegetation unit presented as part of the mapping refinement to be attributed the "development significance" rating of High. The remaining community determined likely to be representative of OPV within the pre and post-discharge environment, and which was attributed a Moderate-High "development significance", is the C1B vegetation unit. This unit, while still highly confined and restricted to fine scale riparian habitats, is more widely scattered through the study area, and represents 0.13 km^2 (13 ha or approximately 0.65% of the study area riparian vegetation). The two remaining present day OPV units (C1/C2A & C2/C1 vegetation units), have been interpreted as unlikely to represent OPV in the pre-discharge environment, and as a result of multiple factors have been attributed a "development significance" of Minor-Moderate. This significance rating essentially places them on "par" with the C2A community. Based on the results of this study, the C2A community; represents the community interpreted as most likely to be existing in the place of the C1/C2A and C2/C1 vegetation units pre-discharge (i.e. these communities now possess a significance equivalent to the C2A community).

Given the number of topics covered and the many components presented as part of the results, a recap of what has been explored and conducted so far is included at this point to aid the following discussion through the provision of enhanced awareness of the work conducted in this study.

As part of this study the following topics have been explored:

- The study area, large creek systems of the Hamersley Ranges, Marillana and Weeli Wolli Creeks and how they compare.
- Previous flora and vegetation surveys conducted in and around the study area and associated vegetation mapping.

- The definition of phreatophytic species, OPV, FPV and Groundwater Dependant Ecosystems.
- Factors contributing to biological significance.
- Relevant high-value/significant riparian vegetation communities within the Pilbara and their associated distribution.
- The inherent sensitivity of local Riparian communities, and more specifically GDE/OPV, to Hydrological impacts.
- The history of anthropogenic surface water discharge in the study area.
- The influence of surplus-water discharge on riparian vegetation and phreatophytic vegetation distribution.
- *M. argentea* Growth rate projections under artificial irrigation.
- Remotely sensed imagery and its role in illustrating the potential augmentation of riparian vegetation by surplus-water discharge.
- Establishing a Framework for significance to use in a qualitative assessment process for attribution biological significance.

As a result of field work conducted in this study we have:

- Presented the results of the mapping refinement exercise.
- The mapping refinement has resulted in the production of a riparian vegetation map which determines the fine scale distribution of OPV and FPV communities present throughout the study area.
- Presented the results and general trends relating to phreatophytic vegetation of pre and post discharge historical vegetation surveys conducted in the study area.
- Produced average *Melaleuca argentea* growth projections for 9 and 15 year time periods and applied a deductive theory to determine the likelihood for this species' pre/post discharge presence in riparian habitats of the study area.
- From growth projections and deductive theories, made conclusions about the potential distribution of OPV communities in the pre-discharge Riparian habitats of the study area.
- Conducted a systematic qualitative assessment of the significance of riparian communities of the study area based on associated ecological values, local and regional distribution/restriction, condition, and likelihood of presence pre-discharge.
- Presented remote sensing based evidence to support the conclusions made about the distribution of OPV in the pre and post discharge environment of the study area.
- Interpreted anomalies within DMSI change detection imagery based on learnings about the distribution of pre-discharge OPV and discharge augmented vegetation.
- Created a "sensitivity" to impact map for the study area, which presents a combination of significance, hydrological sensitivity, and proximity to potential hydrological impacts for all riparian communities mapped within the study area.

5 DISCUSSION

5.1 COMPARISON OF HISTORICAL FLORA AND VEGETATION SURVEY DATA

Comparisons of the pre-discharge surveys of Mattiske (1995a, 1995b, 1995c) and Integrated Environmental Services (1981), with the multiple post-discharge surveys of Biota (2004-2014, summarised in; Biota 2014a) were conducted as part of this study.

The clear conclusion which these surveys present, with relation to the distribution of OPV in the current study area, is that; beyond small isolated pockets of vegetation where this species was observed to be associated with or a co-dominant of resident *E. camaldulensis* woodlands, this species was not typically present in the pre-discharge riparian environment. Conversely its distribution in the post-discharge environment as either a co-dominant component of OPV or merely an associated species within *Eucalyptus* spp. woodlands/open-woodlands distribution appears to be significantly increased, but in general still quite restricted. While some comments have been made about the relatively broad scale of the vegetation mapping conducted as part of the pre-discharge surveys (Mattiske 1995a; 1995b; 1995c), the sampling effort conducted in both pre and post-discharge surveys appear relatively equivalent, and so it would be expected that the quality and representativeness of both vegetation models would be relatively similar.

The absence of pre-discharge quadrat data and associated vegetation mapping (sourced from Mattiske 1995c), in the stretch of Weeli Wolli Creek most relevant to the proposed Pocket-Billiards study area (**PBS**) does raise some questions. Namely; what might comparative patterns pre to post-discharge in this area show if pre-discharge surveys had covered this creek stretch? The important distinction in this case is that the Southern Corridor survey of Mattiske (1995c) did survey the 4 km upstream stretch of Weeli Wolli just south of the PBS project where Weeli Wolli Creek emerges from the Packsaddle Range. This stretch of Weeli Wollli Creek does represent the tail end of the zone immediately downstream of the springs, and which could be easily interpreted as the creek stretch in the vicinity of the PBS project most likely to have possessed near perennial water availability pre-discharge (see Figure 2-2 for illustration of this creek stretch; represented by the overlap between the current study area and Mattiske's "Southern Transport Corridor" survey area, (Mattiske 1995c)). Essentially; the broad perceived pre-discharge trend in surface/sub-surface water availability through this area, is that it was reducing when moving downstream (away from the spring) and out of the packsaddle range to the confluence with Marillana Creek.

Mattiske quadrats located in the stretch of Weeli Wolli Creek immediately upstream of the study area boundary (see figure 3-1), show *M. argentea* co-dominance within the vegetation of some quadrats. However, moving downstream from this stretch, further away from the spring, and essentially out of the Packsaddle Range (through the 4 km stretch of overlapping study area boundaries), *M. argentea* is no longer recorded in the pre-discharge quadrats. In light of the above described broad water availability trend and its likely influence on OPV, it is important to note that patterns in pre-discharge *M. argentea* distribution through the same area (shown by pre-discharge quadrat sampling data), tend to support the trend and support its observed influence on OPV distribution. Furthermore, despite surplus-water discharge providing perennial water availability, more subtle present day patterns in *M. argentea* distribution and structure also tends to support the broad trends in pre-discharge water availability. Consequently it is postulated that downstream of the last available pre-discharge quadrats (within the PBS project area), broad trends in pre-discharge

M. argentea and associated OPV distribution were likely to follow the patterns shown in the Mattiske (1995c) sampled zone immediately upstream. This pattern suggests that; beyond minor populations present in very small and isolated occurrences of OPV (as shown by the C1B community distribution), *Melaleuca argentea* is most likely to have been relatively absent throughout the stretch of Weeli Wolli Creek which runs through the PBS project area.

5.2 THE MAPPING REFINEMENT EXERCISE

Previously; due to the broad scale nature of mapping in the area, and inherent OPV mapping inaccuracies resulting from community aggregation, mapping indicated that OPV communities in the study area (the previously coded C1 vegetation unit) represented a combined area in the order of 260ha or 2.6km^2. The new figures of 1.01km2 of post discharge OPV and 0.44km^2 of inferred pre-discharge OPV represent a significant change in the distribution and extent of this type of riparian community, and both pre and post discharge quadrat data tend to support this result along with the trends present in DMSI imagery, historical aerial photography, and historical observations. Consequently, based on the present day total of 19.5 km^2 of riparian vegetation associated with large creek habitats of the study area, only approximately 2.3% of this area is likely to represent OPV present in the pre and post-mining environment.

A key conclusion of the results is that the C1A and C1B communities, possessed a "size class range" above the "cut off figure", and were interpreted to represent those refined communities likely to be present in the Pre-discharge environment. Conversely the C1/C2A & C2/C1 vegetation units fell below the "cut off figure" and were interpreted as absent. It should firstly be noted that the C1/C2A and C1B communities are those communities which possess a maximum *M. argentea* size class which respectively falls immediately below and above the "cut off figure" for determining likely presence in the pre-discharge environment. This essentially means that the "size class range and inferred age structure for *M. argentea* populations in both these communities determines that, beyond the inferred pre-discharge presence/absence, they alternatively have a low potential of being present (in the case of C1/C2A) or absent (in the case of C1B) in the pre-discharge environment. Put simply;

- In many cases the **C1B** OPV community **may not** have been present pre-discharge; in which case it is likely that the C1/C2A & C2/C1 were correctly inferred to be absent as well;
- Alternatively, in many cases the **C1/C2A** OPV community **may** have been present pre-discharge; in which case it is likely that the C1A and C1B were correctly inferred to be present as well.

The key distinction here is that there is a low potential for these scenarios to be correct, but while low there is still potential, and as such a caveat is placed on pre-discharge interpretations attributed to these two communities (the C1B, and C1/C2A communities). This caveat essentially reminds the that; in some cases patches of present day OPV represented by the C1/C2A mapping unit may have represented OPV pre-discharge, and conversely some patches of the C1B mapping unit may not have represented OPV pre-discharge. While minimal, this potential variability in the accuracy of the inferences/interpretations about the presence of OPV pre-discharge, is purely a product of the maximum *M. argentea* population size class for each community falling above and below the "cut off figure". This relative position is illustrated in Plate 10, along with the relative confidence in the inferences/interpretations attributed to each present day OPV community. While this distinction is

an important one, an equally important distinction should be made for the opposing C1A and C2/C1 vegetation units. In both cases, the degree of size separation between the "cut off figure" and the estimated "size class range" of these units (see Plate 10 for an illustration), determined that the confidence in the attributed inference of likely pre-discharge presence as OPV, is high. Consequently it is concluded that the interpretations of pre-discharge OPV presence attributed to the C1A and C2/C1 units are considered most accurate, and that in some situations a degree of uncertainty remains about the interpretations attributed to the C1B, and C1/C2A vegetation units.

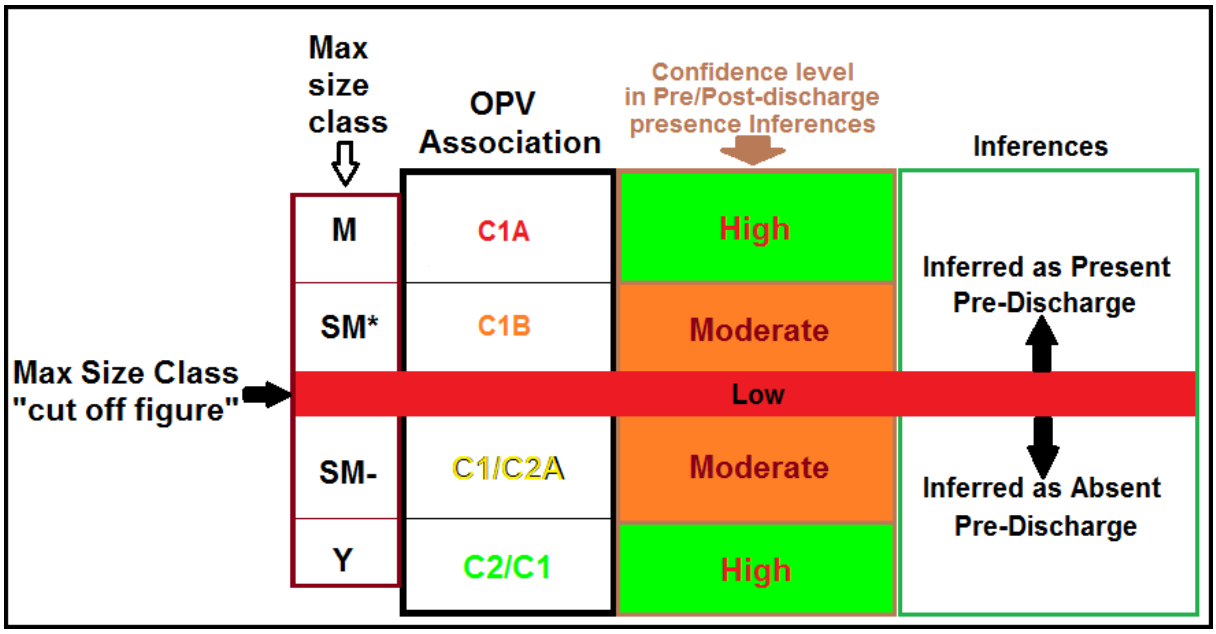

Plate 10: Presents an illustration of the relative position of mapped OPV communities in relation to the maximum size class "cut off figure" and the associated confidence levels for the relevant pre/post-discharge inferences/interpretations which have been attributed to each community.

5.3 LIMITATIONS AND ASSUMPTIONS INVOLVED IN INTERPRETING THE LIKELY PRESENCE OF OPV IN THE PRE-IMPACT ENVIRONMENT

The problem of how to determine the presence and distribution of a significant community in a pre-impact environment is not a typical one. Furthermore; to solve this problem, studies would typically rely on historical information collected about the about the pre-impact environment. In the case of the study area, the historical information did not cover the entire study area, and was generally not detailed enough to provide sufficient insight to fully resolve the problem. Therefore in lieu of adequate pre-impact information this study used present day field data combined with growth projection data and a deductive process of comparative interpretation to enable an understanding of the pre-mining environment. This technique has various inherent limitations and assumptions which have to be made to provide an interpretation of likely pre-impact presence. Consequently, the interpretive process used could easily be classed as atypical, however it provides the best available measure for interpretations and inferences in the absence of adequate historical information. With this in mind, some of the pertinent limitations, and potential issues with the technique used are important discussion points to be addressed.

The accuracy of the assumption that *Melaleuca argentea* is the primary indicator species for determining if a community represents OPV may be questioned. While *M. argentea* is considered to be an obligate phreatophyte and the tree species most sensitive to changes in water availability in

the Pilbara. *Eucalyptus camaldulensis* is considered to be a facultative phreatophyte which at times has been suggested to be an obligate phreatophyte in certain circumstances (Wen et al. 2009). The important distinction here is that in many cases *E. camaldulensis* can survive when the water table or availability of surface water fluctuates significantly. It is for this reason that the use of this species as an indicator for true (obligate) ground or surface water dependency is considered problematic. However, *M. argentea* is considered to be intolerant of similar changes in hydrology, and therefore a more consistent indicator of perennial water availability (Graham et al. 2003). Furthermore, in most if not all cases, the two species are associated, and so it is rare to find *M. argentea* without *E. camaldulensis* present. However the opposite is not true and it is quite common to find *E. camaldulensis* without *M. argentea*. Therefore the presence of *E. camaldulensis* without *M. argentea* indicates some degree of moisture dependency, but the addition of *M. argentea* in any situation generally indicates an increased degree of moisture dependency. It is for this reason *M. argentea* was used as the key indicator for the existence of OPV or true GDE.

Alternatively, a relevant question might be; does the presence of one obligate phreatophytic species determine that a community is considered to be OPV. Assuming the phreatophytic species represents a dominant/co-dominant species within the community, the answer must be yes, as the community description would change if its presence was removed or significantly reduced due to reducing water availability. In turn the reduction in water availability, combined with the dominant/co-dominant absence of the phreatophyte, would determine that the remaining community was not dependent on perennial water availability, and the OPV tag would no longer be applicable.

Influence of the physical environment

A second discussion point and potential point of contention is represented by the deductive process and assumptions used to interpret the likelihood of present day OPV communities occurring in the pre-discharge environment as OPV. This process essentially assumed that if the vast majority of the stems within a population were below a minimum DBH or “cut off figure” (that average DBH which a seedling is projected to grow to in the time available since discharge), then it was unlikely that the population in question represented a relatively mature population likely of being present in a similar form in the pre-discharge environment. While this assumption is logical, it may not be true in all situations. For example there may be situations within the creek profile where the morphology of the creek has changed significantly since discharge, such that it may no longer provide the same hydrological conditions, and therefore may not be able to support OPV without discharge inputs. There is some potential for this and other similar effects to influence the results of this study (potentially causing a false negative result). However, assuming they are the result of natural physical changes, most probably at fine scales within the creek system, then the resulting changes to the distribution of OPV is also a natural one, and the results remain correct. There are potential situations where these changes may be a result of anthropogenic changes to hydrology. In such cases, observations and evidence (both physical and biological) suggesting the changes are anthropogenic are relied upon to determine the true cause of vegetation changes. In the case of this study, there were no obvious biological changes detected which might be attributable to moderate scale changes in creek morphology. Furthermore, from a physical sense, regular visitors to the creek system have not reported any obvious and atypical physical changes to creek morphology.

Influence of the biological environment

Changes to the biological environment may also provide other potential sources of contention to the deductive assumptions used. One such source of contention might be surrounding the validity of inferences made from the size structure and inferred age structure of a community at any one time. For the purpose of this report the age structure (and conversely size structure) of a population is defined as the distribution and frequency of individuals among various potential age (or size) groups. In graphic form, age structure is portrayed as an age pyramid whose relatively broad base indicates the number of young individuals while the peak reflects the increasing likelihood of death as individual's age. A population whose age structure has a very broad base and a sharp narrow peak is said to be "young" (or un-stable), while a structure whose base is not much wider than the rest of the pyramid is considered "mature" (or stable) and possesses a relatively even frequency distribution (Barbour et al. 1987).

In the case of this study, the key size/age structure of value when trying to determine presence/absence pre-impact would be one with a broad base, and a sharp peak with a significant proportion of the potential pyramid height not represented by any individuals (i.e. no individuals which fall into the upper size/age classes are present). It could be perceived that a major impact event such as a 100 year flood could strip a creek of the majority of its resident *M. argentea* population, such that the population which established post flood-impact would be quite small/young and of a very consistent size/age structure.

It is this same average size, and size structure which would, in this study, generally be interpreted as a population likely to have established as a result of augmentation post-discharge. While there is no doubt that such an event would influence the data of this type of study, it is highly likely that the flood event and its impacts would be known about and taken into account when attempting to set up the study. In this case, there are no known events in recent history where flood waters have stripped significant proportions of tree populations resident in the study area. It is also considered that such an event may lead to larger more mature trees being one of the key groups of survivors, and consequently the results would be skewed in the opposite direction.

5.4 LIMITATIONS AND ASSUMPTIONS ASSOCIATED WITH THE GROWTH PROJECTIONS

Another potential source of contention may be the validity of the growth projections. For this study it was considered that the best way to determine the average amount of growth which *M. argentea* would likely realise in 9 and 15 years is to measure individuals of this species in the same or very similar environments for at least 9 years (preferably 15). However, this type of data has not been collected, and while a significant amount of monitoring has been conducted in Weeli Wolli and Marillana Creeks, no long term DBH data is easily accessible for individual trees. This is because trees are generally only recorded with a distance along and a distance out from the transect. Consequently, when the data is scrutinised, it quickly becomes clear that determining which trees are which for longer periods of time is quite problematic.

In nearly all cases, mostly due to tree number labels being lost in the field, the degree of confidence that DBH measurements were from the same tree decreased with successive monitoring rounds. It is for this reason that the monitoring data used in this study for growth projections, generally only used a one to a few years of monitoring data for each tree. So what of the validity of the growth projections? The first obvious question relates to the validity of the technique used. For this study it was deduced that the use of the change in horizontal two dimensional (cross-sectional) trunk area would be the most relevant and consistent figure to use for projections, especially when considering that the field data collected in both cases was essentially trunk diameters. Obviously the use of

diameters (in that form) to compare and project growth was not wise, as change in DBH for different sized trees represents significantly different increases in trunk biomass. Consequently, the decision to convert diameter changes to changes in two-dimensional trunk biomass was a clear choice of comparative measure given the base data was represented by changes in diameter.

From a mathematical sense the logic used seems sound, but the pertinent question remains, does the projections calculated actually represent average growth? It is obvious that the monitoring data used for the projections, does not take into account the number of trees which either died, or for many years suffered damage, disease or insect attack and so did not increase trunk diameter at normal rates (or at all). While this is a legitimate consideration, in some ways it is not considered relevant to the technique used. The technique used in this study assumed that regardless of how slow some individuals grew (due to a combination of environmental factors and chance), the important and most determining parameter was that growth exhibited by individuals which represents a relatively average to above average growth rate (sustained by similarly average/above-average conditions). By focusing on this figure the assumption was that in any population, a certain percentage in individuals would grow at relatively optimal rates, and therefore these individuals would often represent the larger of the individuals present in a population.

Therefore by assessing and classifying populations by the average size range present in a population, one would in turn get a reading for the average maximum size (i.e. the upper size class within the attributed “size class range”). Thus the individuals in a population whose size represents the average maximum size of the population should provide an indication of the size realised by average to above average growth rates relevant to the population. Finally, it is assumed that; by comparison of average growth rates per year of monitoring trees, to the trunk cross-sectional area (2-D biomass) realised by the larger trees of an in-situ population, a division calculation can provide an estimate for the number of years the larger trees took to grow.

The final assumption is that for this comparison to provide an indication of how long that population might have been present in relation to the time period of focus; the in-situ population must lack the presence of individuals of a size equivalent to at least a few of the typical/expected upper size classes. The typical/expected upper size classes are those sizes/ages which the species is typically known to realise, but which in such cases have not yet been realised due to the average age of the population. Plate 11 shows two basic examples of age structure (conversely size structure), with the left representing a relatively even and stable population. The age/size structure on the right is one broadly equivalent to that of a population which might be assumed to be relatively young and have established following a recent perturbation. This structure possesses an un-even frequency distribution, but more importantly lack individuals in the upper size/age classes typically known to be realised by the species in question. It is this pattern in age/size structure which is inferred by this study to indicate a lack of maturity within a population and therefore a potential for the population to have only established since surplus-water discharge commenced.

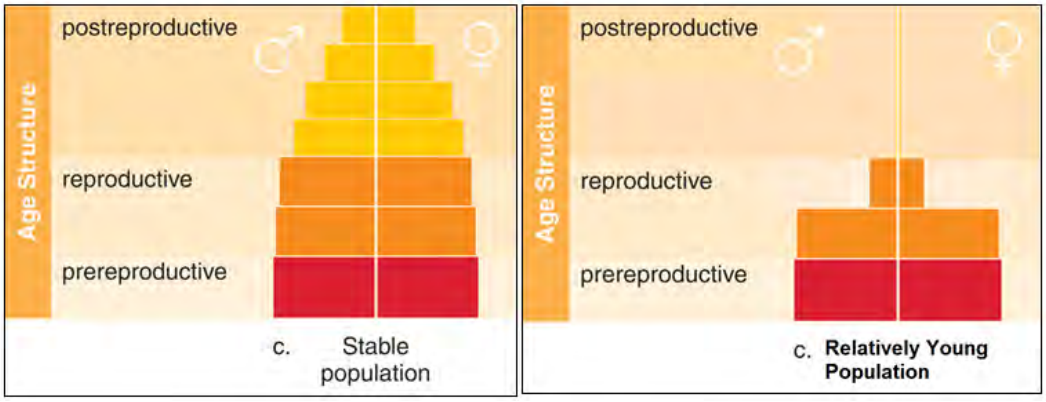

Plate 11: Presents a theoretical age structure for a relatively stable and mature population on the left, and for a relatively young, unstable and non-climax population on the right

It is an acknowledged limitation of this method that within this group of the largest individuals, a number may have taken a significantly longer time period to reach that size (possessing stunted growth: due to whatever reason) than the time period indicated by projected figures to be associated with their diameter. In some ways this effect was allowed for by factoring in a buffer to the growth projections; in this case the actual data was reduced by 20%.

To allow an additional degree of conservancy and therefore further allow for this effect; when deciding which side of the projected diameter cut off figure (for both temporal growth regimes) a population would be classified to fall, the upper limits of diameter observed for that population were required to be clearly below the cut off, and not falling too close to the "cut off figure" set. Given these allowances, it appears unlikely that the stunted growth effect would significantly influence the age of individuals in the upper size class (for a population), beyond the margins allowed for. Consequently For the purpose of this study it is considered that these allowances are sufficient to take this effect into account.

An additional allowance, and therefore degree of conservatism is represented by the USE of DBH for growth projections and "diameter at knee to waist height" for trunk size data estimated in the field. Given that diameter reduces from the knee/waist-height to breast-height, the figures used for the "size class ranges" are **larger** than their actual respective DBH, and so when this slightly inflated figure was compared to the "cut off figure", which is in DBH it allowed for an additional buffer of conservatism. For example if the biggest individual in a population has a diameter of 20 cm (at knee to waist height) and we compare it to a 24 cm "cut off figure" (in DBH), rather than comparing 20cm with 24 cm (tree to cut-off), it's likely that in fact we may be comparing 18 cm to 24 cm (tree to cut-off). The quantitative size of this effect is unclear, but when combined with other sources of conservatism the result is an increased confidence in the conclusions made for populations deemed to be under the "cut off figure" and therefore deemed unlikely to be present in the pre-discharge environment as OPV.

An additional degree of confidence in the deductive process used and the resultant conclusions is represented by the supporting inferences which can be made from the age structure of a community, regardless of the maximum upper age class observed. It is assumed that if the age structure is skewed towards the younger age classes, and therefore the majority of the population is represented by very similar aged individuals, then the population is more likely to have grown in response to a change in environmental conditions. Plate 12 below shows an example of a population of *M. argentea* with an equivalent age structure.

Generally it is the populations with these age structures which possess the lower maximum age class which are likely to determine that the population will fall below the projected "cut off figure" (DBH) and therefore potentially be classified as only occurring post impact. In situations where there appeared to be a greater range of age classes present and a more even spread of numbers of individuals across the age structure (such as that illustrated in the left side of plate 11), caution was taken when deciding which side of "cut off figures" these populations would be classified to fall within. In most cases populations with such an age structure would inevitably be decided to represent an "age class range" falling above the "cut off figure", and therefore present pre-discharge. However, in general, the use of caution involved the consideration of additional size class and size/age-structure characteristics and criteria when determining the broad "size class range" to which populations were attributed (see Table 4-3 for details).

Plate 12: Example of a population of minimal size variation, and therefore representing a very uneven age structure dominated by young individuals of a similar age

Assumptions of maintaining optimal growth

Further to the effect discussed above, it is important to consider the potential that; because of the general process of attrition and the changing sources and magnitudes of perturbations associated with the fluvial environment (most particularly, variably sized flood events), the likelihood of individuals reaching size classes considered semi-mature and mature (based on size definitions provided in this study) may be quite low. As a consequence, it is possible that the individuals of a similar size (i.e. approximately semi-mature to mature) which are present within a population, may in general be much older than that age predicted by growth projections for their DBH. Therefore, the conservative allowances discussed above may be insufficient to allow for the potential difference. The sources of delay to growth which might result in a potential failure to consistently reach demonstrated growth potential over a mature individual's life span, are likely to be many and variable in their effect and duration. While such an effect on long term growth is possible, a key observation which does not support this being likely is the existence of *M. argentea* populations dominated by relatively mature and large individuals. There are many examples of this age structure in the Pilbara, and their existence indicates that it is unlikely that most older large *M. argentea* individuals are unable to have achieved that size in an efficient time span. In most cases, the variability surrounding the distribution of these older individuals appears to be driven by a combination of fine scale spatial variability in the provision of suitable moisture and shelter (from flood damage) conditions and the chance that an individual's position coincides with these conditions.

Beyond the effect discussed above, it should also be considered that maybe the absence of older individuals within a population may not always be an indication of how long the population has been sustained in that area. If this line of argument is considered, it seems possible that in certain situations the environmental conditions of a site are not suitable enough to support older individuals, and instead a young age structure may have been sustained in that area for a long time. Such a situation is typically considered to be likely in areas where, for example, *M. argentea* are generally only present as an associated species. In these areas it appears as though the availability of moisture is a limiting factor such that individuals establish in small niches for short periods of time, but do not tend to last long enough to contribute to an increasing sized population. Despite this the important distinction is to be made in situations where; young individuals get to a significant density, such that they reach a cover/abundance sufficient enough to comprise a co-dominant component of the surrounding community (and are distributed more widely). In such situations it is assumed that the increased density of individuals (and inferred recruitment success rates) indicates that the resident population is not limited by environmental conditions such as moisture availability, and will consequently continue to grow towards maturity (assuming conditions do not change considerably).

In areas where *M. argentea* is a co-dominant member of a resident community; it is this latter described tendency for the environment to support growth to maturity (in at least a small portion of the communities areal extent), which is considered most likely to occur in the natural environment. Regardless of the reality, it is an important principle of this study that a large part of the significance of these riparian communities is attributed to the values associated with their structural and compositional diversity. In general, structural and compositional diversity tend to be greatest when a community reaches maturity, or possesses a population age structure representing a stable population; such as that depicted in Plate 11. This principle determines that in situations where the environment is not able to support a more mature community, then the values attributed to that community are reduced when compared to areas where mature communities are able to be supported. Therefore it is assumed that; if a *M. argentea* population is a co-dominant community member, but the population continues (somewhat indefinitely) to be represented by a consistently young age structure, then it's likely to be inconsequential that this study wrongly interprets its likelihood of presence in pre-discharge environment. Reason being, that its value/significance in reality and its value/significance attributed in this study are likely very similar, given that the values/significance attributed in this study are to a large degree, a product of characters associated with mature, and potentially climax communities.

5.5 SIGNIFICANCE OF RIPARIAN COMMUNITIES

Riparian maturity and significance

When it comes to values associated with a community, the above identified link with maturity or the degree to which an ecosystem represents a climax community is often a focus of consideration when attributing significance to riparian communities. The "High Values Statement" for the Yandi project area, attests to this focus. Within this Statement and under the heading of Flora and vegetation; one community is listed to possess high values in the area. Described as; "riparian woodland of *Eucalyptus victrix*, *Eucalyptus camaldulensis*, *Melaleuca argentea*, *M. glomerata"*, this riparian community essentially represents a mature and potentially climax community, whose *Melaleuca argentea* component exists in the woodland layer determining that it is made up of mature trees between 10-30m tall (Low-woodland = trees under 10m tall, Woodland = trees 10-30m tall) (Aplin

1979). If we look at the equivalent community in the refined mapping produced as part of this study, the very closely associated equivalents to the community described in the High values statement are the C1AA, and C1A vegetation units. The C1AA community is situated off tenure, and while it represents the largest representation of "high value" riparian vegetation in the study area (15 ha; potentially larger as it appears to extend beyond the study area boundary), its values are presently reduced due to mining related drawdown currently in effect as a result of BHPBIO mining activities. Within the study area, the C1A community is represented by a number of quite small representations all of which occur on Marillana creek. Totalling 16 ha in areal extent, the largest and most significant representation of this community in the study area covers 7 ha and occurs directly downstream of the BHPBIO discharge point. This patch appears to be associated with the large bend in the creek and the underlying CID deposit which intersects the subsurface of the creek in this area. The remainder of the representations of the C1A community are all relatively small, with the second largest covering approximately 2.7 ha, (50X500 m long). As a consequence of the generally smaller spatial extent of the remaining areas, in many cases they possess a reduced number of values or reduced quality of resident associated values, when compared to larger occurrences. This reduced number/quality of values is generally attributed to the influence areal extent can have on these factors, such as its effect on the likelihood of an area supporting conservation significant flora and fauna. One example of such a factor might be the population of chocolate bats known to occur at Weeli Wolli springs, and which is likely to occur there due to the size and subsequent appeal of the riparian community present.

Beyond the above two discussed communities which are essentially equivalent to that listed in the "Yandi High Values Statement" (Rio Tinto 2011b), the next closest (or similar) community is represented by the C1B community. This community is scattered throughout parts of both Marillana and Weeli Wolli creeks, and is considered to be fairly equivalent to Biota' previously mapped C1 community (Biota 2014a). In comparison with the C1A community, the C1B community is a eucalypt woodland which possess *M. argentea* as a co-dominant species in the low-woodland layer (trees under 10 m), and therefore represents a community with a less mature population of *M. argentea*. It is believed that this difference is likely to be associated with a reduced consistency in perennial water availability in these areas (more likely a product of differences in ground as opposed to surface water availability) when compared to other areas such as those mapped as the C1A or C1AA community. The C1B community covers a total area of approximately 13 ha, with the largest single representation also associated with the area directly downstream of the BHPBIO discharge point (3.5 ha). The remainder of the representations of this community are all quite small and are generally restricted to occurring within close proximity of the low flow channel. The second largest representation of this community covers 1.7ha, while the remainder of the larger patches cover between 0.4 and 0.8 ha.

This pattern of reducing areal extent as the estimated maturity of the associated *M. argentea* component reduces, appears consistent with the theory that the maturity of the resident community is a measure of the consistency of perennial water availability. The reasoning is assumed to be; that areas where the water table is broadly responsible for maintaining perennial water availability are often few, and their influence is often wider in its areal extent; hence the small number of larger areal extent representations of OPV. As a result the majority of perennial water sources which remain are often reliant on quite small scale topographical or geological features which enhance water availability through; mounding, small perched alluvial aquifers, consistent surface water pooling, or the provision of anomalously low points in the broader environment. These secondary sources of perennial water generally occur over small often disjunct spatial scales,

with these same physical/topographic characters often leading to slightly reduced consistency in perennial water availability, which in-turn influence the cover/structure of the resident obligate phreatophytes. Consequently the observation that, as the maturity of the OPV reduces, so too does the areal extent and distribution, aligns with the observation that; as you transition from zones of perennial water availability to zones of ephemeral water availability the areal extent of zones possessing perennial water also tend to reduce in size and distribution.

Riparian Significance and water availability

As discussed previously, with respect to the significance of riparian communities in the Pilbara, it appears generally true that the more consistently perennial the water availability is and the greater the areal extent of this water availability (with special mention to broad and long examples), the higher the number and quality of the ecological values associated with the vegetation supported by such areas. Furthermore, the distribution of large occurrences of consistently perennial water availability, and their associated vegetation, is quite restricted, very uncommon, and generally associated with small stretches/portions of the riparian habitats of large creek systems. Together these two key sets of inherent attributes combine to ensure that the larger good quality examples of OPV will generally remain the more significant of the riparian communities within the Hamersley ranges. Therefore the range of examples of reducing degrees of perennial water availability (perennial through to ephemeral) and associated reducing degrees of phreatophytic vegetation quality and maturity will essentially tend to represent the reducing degrees of significance attributed to riparian communities within the Hamersley Ranges.

With this in mind, it is noted that the fine scale of the phreatophytic vegetation mapping produced as a part of this study provides good examples of this range or scale in riparian community significance and their associated changes in distribution within the riparian zone. The significant survey-effort conducted to produce this mapping, and the resultant strict treatment of OPV, and to a lesser extent FPV units which resulted, provides a relatively complete set of communities with which to consider the value and significance of phreatophytic vegetation within the study area. Consequently it is believed that the quality of information which it provides creates an effective framework and associated spatial model for the management and mitigation of potential impacts to sensitive phreatophytic vegetation in the study area. While the initial focus of this study was on the most sensitive of the phreatophytic species (*Melaleuca argentea*), the study has also provided significant additional information on the distribution and structure of *Eucalyptus camaldulensis* and *Eucalyptus victrix* woodlands/low woodlands of the study area. In addition to this we have a relatively comprehensive set of location data for the "mature" *Melaleuca argentea* individuals of the study area which also help with the process of management and mitigation, and give good insight into the hydrological processes/anomalies which are operating in the sub-surface and surface zones of the relevant fluvial habitats.

5.6 CREEK MORPHOLOGY AND ASSOCIATED VEGETATION DISTRIBUTION

What was previously observed, and what this study has continued to highlight, is that the relevant stretches of these two creeks possess significantly different morphologies, and associated vegetation community distributions. Through much of the relevant stretch of Marillana Creek, the surrounding topography seems to prevent the formation of fringing floodplain landforms and associated communities. This restriction to floodplain morphology obviously has a significant influence on the morphology of the incised channel zone and the distribution and composition of communities within

it. From the field work conducted, it appears as though the resultant flow confinement creates a comparatively level surface within the incised channel zone, where the surface flow routes are less predictable. Consequently multiple low flow channels are observed to have formed, and the distribution of OPV tends to be spread more broadly/laterally within the incised channel profile.

The relevant stretch of Weeli Wolli creek on the other hand, tends for the most part to possess a clear and relatively broad floodplain landform, with a relatively narrow, and often comparatively V shaped incised channel morphology upstream of the confluence. Downstream of the confluence clear floodplains flank a much more broadly braided incised channel landform, overlying what appears to be deeper and therefore more transmissive layers of alluvium. These differences, existent within and between the respective individual creeks, highlight the complexity of the ongoing struggle to decipher how the inner workings of these fluvial systems influence water availability, and community distribution. Deciphering this puzzle seems hard enough. However, an additional degree of complexity is present when attempting to decipher what changes to water availability and community distribution might occur with the onset of hydrological influence from mining (and changing degrees of influence from mining).

Incised channel morphologies and *E. camaldulensis* distribution

The distinctions made above, about the differences between the morphologies of the stretch of Weeli Wolli creek south of the confluence and the Marillana Creek stretch highlights how differing morphologies can influence water availability and community distribution. Within the southern stretch of Weeli Wolli creek; the low flow channel remains singular and positioned in an often clearly lower (i.e. somewhat etched into a V shaped incision) incised low flow channel within the broader incised channel zone. What this appears to do is determine that the route of the low flow channel remains relatively constant, and predictable, and that OPV is clearly restricted to this feature. Knowing the requirements of OPV, it is clear that the restriction of such communities to the singular low flow channel of this creek stretch is a result of the increased consistency of perennial water availability which a relatively constant low flow route can provide. With relation to FPV such as *Eucalyptus camaldulensis* woodlands, the distribution of this community can be more variable, but what is known is that it would tend to establish around such features which seemingly provide comparatively more consistent water availability.

This observation is interesting when you consider that previous mapping (based on significantly reduced riparian survey effort) suggested that *E. camaldulensis* co-dominated communities were extensive along the relevant stretch of Marillana Creek, but were for the most part absent from the relevant stretches of Weeli Wolli creek (particularly that stretch upstream of the confluence). Recent mapping work indicated that while such communities were comparatively less laterally distributed within Weeli Wolli (as would potentially be expected), they were however present along the entire length of the stretch upstream of the confluence. For the author of the refined mapping, the apparently large difference between the two vegetation models was somewhat perplexing. Despite walking the most relevant parts of this entire stretch of the creek and the collection of a fairly extensive array of data points, the often minor visual differences between *E. camaldulensis* and *E. victrix* can tend to create doubt as to the actual extent of *E. camaldulensis* co-dominated communities. However, in relation to the relevant stretch of Weeli Wolli creek upstream of the confluence; observations made about stream morphology seemed to support the significant change to the mapped distribution of this community within the refined mapping produced. The above broad scale observations about stream morphology, in combination with small scale on ground

observations, indicate that the fine scale position/route of the incised channel zone had remained constant for substantial time periods. Such a consistency in the distribution pattern of surface water input within a creek system of this catchment size is considered likely to encourage the establishment of FVP. This fact would therefore tend to support the refined vegetation mapping and the distribution of an *E. camaldulensis* co-dominated community surrounding the bed and banks of the described low flow channel.

Incised Channel morphologies and augmentation

Another conclusion that the above described patterns to the stream morphology within Weeli Wolli creek tends to support, is that the creek section south of the confluence appears to feature a fairly consistent distribution and degree of augmentation to resident vegetation. The apparent consistency in the path of surface water flows, and therefore in the distribution of perennial water availability, is considered likely to initiate and sustain the process of vegetation augmentation. Given that this established flow path is known to have been consistent at least throughout the period which surplus-water discharge inputs are known to have occurred, it is likely that it is has played a significant role in the distribution and degree of vegetation augmentation apparent. Plate 133 shows an example of the vegetation which often tightly fringes the present day water line of the low flow channel within Weeli Wolli creek. Successive examples of this vegetation along the stretch of Weeli Wolli south of the confluence possess a vegetation structure, composition, size structure, and distribution which indicates it is most likely to be a product of recent perennial water availability and resultant augmentation. Plate 144 and Plate 155 below show two examples of apparent vegetation augmentation within Weeli Wolli Creek, with significant sized patches of the C2/C1 vegetation unit being present and absent at the different time sequences (pre and post-discharge).

Plate 13: Example of apparently augmented C2/C1 vegetation on Weeli Wolli Creek

Plate 14: Comparative aerial photo example (2014 left side; 2006 right side) of a patch of apparently augmented vegetation on Weeli Wolli Creek North. Yellow polygon represents the present day C2/C1 vegetation unit (Location; E: 737995, N: 7479291)

Plate 15: Comparative aerial photo example (2014 left side; 2006 right side) of a patch of apparently augmented vegetation on Weeli Wolli Creek South (yellow polygon represents the C2/C1 vegetation unit (Location; E: 733406, N: 7474109)

5.7 SYNTHESIS

A clear conclusion of this study has been that; within riparian habitats, the more consistently water is available the more significant the vegetation and associated habitats tend to become. Based on this conclusion and the results of the mapping refinement, in general the C1A and C1AA communities were determined to top the "development significance" scale for riparian communities mapped in the study area. With *M. argentea* forming a co-dominant member of the woodland layer, these two units were determined to be of high developmental significance, while the reduced phreatophytic species maturity of the C1B communities led to a "development significance" rating of

moderate. Communities of a different but similar composition, such as the C1/C2A, and C2/C1 coded vegetation mapping units, deemed in their current form to represent OPV, were also deemed to possess *M. argentea* populations of such age and physical structure that in the pre-discharge environment they were unlikely to have represented OPV. Consequently these units were attributed a present day significance and pre-discharge composition/structure essentially equivalent to that of the C2A *Eucalyptus camaldulensis*/*E. victrix* open woodland community (Minor-moderate development significance). It should be noted that despite the conclusion that communities such as the C1A, and C1B coded vegetation units were present in a similar form in the pre-discharge environment, all of the communities discussed in the above paragraph have experienced un-natural degrees of perennial water availability for between approximately 9 and 20 years. It therefore seems inevitable that like the C1/C2A, and C2/C1 vegetation units they too have experience significant augmentation, and their resultant significance is somewhat commensurately and un-naturally augmented.

Beyond the C2A *Eucalyptus camaldulensis*/*E. victrix* open woodland community (Minor-moderate development significance), the final riparian community of note on the scale of significance is represented by the C3 coded *Eucalyptus victrix* low open woodland community. This community was attributed a "Minor development significance" due to its widespread distribution, lower diversity, and generally ephemeral nature. As previously discussed; on the scale of significance these communities highlighted in the mapping refinement and assessment conducted as part of this study all fall below the significance attributed to the large areal extent representations of OPV. The well-known and most obvious example of such large areal extent OPV representations is that of Weeli Wolli Springs. While there are sure to be other similar quality examples present within the Hamersley Ranges, with somewhat similarly large areal extent representations known to occur in the vicinity of flat rocks, it is noted that the closest but still significantly reduced example in the study area is the C1AA community. Despite this fact the values of this community are already reduced by the effects of development associated with neighbouring stakeholders.

Conclusions

The final conclusions of this study are:
