This study investigated physiological and morphological response to flooding and recovery in Eucalyptus camaldulensis subsp. Refulgens, a riparian tree species from a dryland region prone to intense episodic flood events.

E. camaldulensis subsp. Refulgens underwent considerable morphological changes during flooding, including extensive adventitious root production, increased root porosity and stem hypertrophy. Physiologically, net photosynthesis and stomatal conductance were maintained for at least 2 weeks of flooding before declining gradually. Despite moderate flood-tolerance during flooding and presumably high environmental selection pressure, recovery of reduced root mass after flooding was poor.

Priority Species Project Progress Report 2013 **2014**

Internal reference: RTIO-HSE-0207486

The Priority Species Project, initiated in 2012, aims to improve knowledge of priority plant species and develop methods to successfully germinate and establish priority species, to enable priority plant species to be integrated into Rio Tinto rehabilitation programmes. This work is being undertaken in conjunction with the Department of Parks and Wildlife.

13 plant species were selected as being potentially suitable for establishment in rehabilitation: Eremophila magnifica subsp. magnifica, Indigofera sp. Bungaroo Creek, Indigofera sp. gilesii, Acacia bromilowiana, Sida sp. Barlee Range, Ptilotus subspinescens, Ptilotus mollis, Acacia subtiliformis, Isotropis parviflora, Grevillea sp. Turee, Hibiscus sp. Canga, Themeda sp. Hamersley Station, and Aluta quadrata. Indigofera sp. Bungaroo Creek and Ptilotus subspinescens were found to readily germinate in laboratory conditions, and a field trial was established at Brockman 4 late in 2013.

Regional Variation in Metal Concentrations of Pilbara Fish in Relation to Concentrations in Water and Sediments **2014**

Internal reference: RTIO-HSE-0216967

This study aimed to characterise and document natural, background metal concentrations in freshwater fishes from different locations across the Pilbara in order to understand how local geology may affect baseline metal levels in fish tissues and surface waters. Metal concentrations were analysed from water, sediment and muscle and liver tissues from fish collected from up to 13 sites as yet unimpacted by mining across the Pilbara during October (dry season) of 2012.

Levels of dissolved metals from water samples were generally low. However, some elevated concentrations of Boron, Copper and Zinc were recorded. Concentrations of heavy metals in sediments were variable across the Pilbara. Generally, sediment concentrations were well below the Interim Sediment Quality Guidelines (ISQG). However, metal concentrations in excess of ISQG TVs were recorded for Chromium and Copper at some sites. There was no relationship between metal concentrations in sediment and those in water. Metal concentrations in fish tissue (muscle and liver) varied between species with some significantly higher in some particular species. The study concluded that variation in metal concentrations in water, sediment and fish across pools in the Pilbara was likely to be mainly dictated by the local geological setting in which the pool occurs.

Marandoo Native Pivot. Scope 2 Monitoring. Final Monitoring Report **2014**

Internal reference:

The Native Pivot Project involves a series of scientific trials into the effect of fertigation on plant species native to the Pilbara region. This report details the results from the first year of monitoring.

Fertigation is resulting in measurable differences to soil properties. Soil moisture was higher in the '2x' and the '1x treatments than the '0.5x' and the '0x' treatments. Soil moisture was observed to converge in all treatments during the wet season in Jan/Feb 2014. The germination of target species was low in the seeded species trial component, the presense of non-target native species is thought to have affected germination. The fertigation treatments were determined to have had a significant effect on the abundance, cover and health scores of native vegetation in the Pivot trials.

Dampier Port Rehabilitation Trials **2014**

Internal reference: RTIO-HSE-0246218

This report presents the results of a final monitoring survey of two rehabilitation trials established at the Dampier Port. The aim of the trials was to evaluate the effect of a range of mulch and soil treatments on the success of rehabilitation.

The outcome of the trial in terms of informing rehabilitation methods for the dredge spoil areas, is that the soil properties in both locations support native vegetation growth without treatment or amelioration (the soil has no properties that are considered inhibitive or detrimental to the growth of Pilbara native species). In addition the treatments were shown to have no significant effect and therefore won't be incorporated into future rehabilitation. Salinity and sodicity of the dredge spoil decreased over time and it is likely it will continue to decrease with time, which is considered an improvement in soil properties to enable native vegetation growth

Progress Report 2014, Ecological responses of native fishes to dynamic water flows in northwest arid Australia **2014**

Internal reference: RTIO-HSE-0246021

This three year Australian Research Council linkage Project commenced in 2013 and aims to increase understanding of the effects of altered stream flows on the Pilbara freshwater aquatic environment. Project aims: 1. Quantifying fish biodiversity and population structure in relation to hydrological and environmental parameters to identify thresholds of ecological concern for water management; 2. Determine the fundamental physiological, morphological and behavioural adaptations of fishes to variations in water quality using experimental manipulations; and 3. Examine spatial scales of gene flow to determine if increased flows increase genetic connectivity relative to natural-flow sites.

To date work has focuses on characterisation of baseline physicochemical parameters across aquatic habitats within the Fortescue River catchment (Aim 1), analysis of variation in rainbow fish morphometrics and mechanosensory lateral line systems in response to geographic region and water management regime (Aim 2), and extraction of DNA samples from 17 populations across the Fortescue River catchment (Aim 3). The project will culminate in the development of a predictive model for stream restoration relevant to future closure scenarios for above and below-groundwater mines. Results from an honours thesis indicate that rainbow fish body shape varies according to geographic region but fish from a dewatered site (WW Ck) were more streamlined than other populations from the upper Fortescue catchment. This statement of results has been superseded by the results of the actual thesis report RTIO-HSE-0252169.

Yandi rehabilitation review **2015**

Internal reference:

This study reviewed the implementation success of Pilbara rehabilitation strategies for geologies and vegetation types similar to Yandicooogina. The review includes a discussion on the different rehabilitation methodologies and analogous success / failure rates for different types of ground disturbance.

Monitoring data from other Pilbara mining operations suggest that alluvial-style waste materials can be successfully rehabilitated to achieve a stable, self-sustaining native vegetation community using standard rehabilitation practice. Similar success has been achieved with the rehabilitation of short-term and long-term disturbance areas. However, due to the small number of waste fines rehabilitation projects and limited success to date, the ability to successfully rehabilitate waste fines cells (without capping) is yet to be proven. There is also a knowledge gap pertaining to the rehabilitation of created ecosystems, such as the wetlands proposed to be constructed within the mine voids at Yandicoogina. These gaps include factors such as surface water controls, topsoil application rates and seed mix.

Landform design

Results of flume investigations of the stability of rock mulches **1998**

Internal reference:
RTIO-HSE-0109221

This study assessed the potential for rock mulches to be stripped from the soil surface by overland flows.

Although 150-300mm diameter BIF was not removed by simulated overland flows, even for 100mm/hr simulated runoff on 55% gradients, considerable scour of the spoil between the rocks was observed, indicating potential for long-term development of rills or gullies if the level of rock cover was less than 100%. Large reductions in sediment concentrations were observed when finer rocks were mixed with BIF. The data indicate that it is crucial for any rock mulch to cover a wide range of particle diameters, including a component of finer rocks. The resulting mixed rock created a framework of large rocks that resist movement by flows, while the smaller rocks reduce erosion being anchored within the larger (framework) rock. For rock mulches with a mixture of rock diameters, 80% cover produced acceptable erosion rates. Sediment loads were slightly higher for 40% cover by rock of mixed diameters, and it was speculated that this may also achieve acceptable erosion rates with the addition of vegetation.

Yandicoogina Conceptual Study on Backfilling of Mine Voids **2009**

Internal reference:
RTIO-PDE-0068220

This study was undertaken to estimate backfill volumes to 5 m above the average original water level at Junction Central, Junction South East, Junction South West, Oxbow and Billiard South.

A total of 205 million loose cubic metres (LMm3) of material is required to backfill the pits to 5m above the water table: Junction Central requires 72LMm3, Junction South East 86LMm3, Junction South West 34LMm3, Oxbow 38LMm3 and Billiard South 178LMm3. Thus the deficit of 55LMm3 of material would need to be mined from surrounding hills to meet a total target of all pit voids backfilled to 5m above water table.

Final Landform Design Criteria for Use During Mine Planning **2012**

Internal reference:
RTIO-PDE-0159989

Rio Tinto Iron Ore WA have historically designed closure landforms for waste materials with berms ~10 m, lifts ~20 m and ad hoc alterations to batter gradients where erosion rates have been perceived to be unacceptably high. This report integrates recent advances in characterisation and modelling of materials, climate and erosion processes to provide appropriate final landform batter characteristics for key Pilbara mineral wastes and soils.

Material properties of mineral wastes were assessed and classified for the range of mineral wastes found across Rio Tinto Pilbara sites. Climate sequences were used to model and test potential erosion rates for a range of batter configurations (shapes (linear, concave), heights, gradients, berm capacity) and validated against existing slopes for which material and climate data were available. This information was used to develop a searchable waste dump batter database for all major mineral wastes and soils, intended for use during mine planning design.

Yandicoogina JSE pit landform water balance **2013**

Internal reference:
RTIO-HSE-0208317

JSE is predicted to form a saline sink unless the pit is backfilled to at least the pre-mining water table. This report presents the outcomes from a GoldSim model that simulates water conditions post-mining to calculate the minimum volume of backfill required to create stable and environmentally acceptable conditions in the long term.

To minimise the duration of ephemeral ponding, the modelling showed that a capping layer (above the waste fines cells 495m elevation) between 2.4m and 3.5m thick is required. However, these conditions were only achieved when ET rates of 1,200mm/yr were used on the capping layer. Lower ET rates could be used on the waste fines cell walls (500m elevation). In the event that the rehabilitation scheme failed and the vegetation reverted to typical Pilbara grass vegetation (300mm/yr), the reduced ET rates would result in ponding occurring typically 5 times longer than the base case.

Contamination

Impact of Nitrogen from Explosives on Mine Site Water Quality — 2008

Internal reference: RTIO-PDE-0054638

The likely issues associated with the use of nitrogen based explosives on mineral waste and any leachate water are explored in this report. The amounts of explosives used on site are described, along with nitrogen chemistry and toxicity. Nitrogen concentrations for various mine sites and specific lithologies are presented which includes concentration in rock assays and liquid extracts.

It was concluded that the largest risk of nitrogen contamination is likely to arise from the discharge of surface waters that have been in contact with blasted materials and are discharged off site into creeks or waterways. This becomes a more significant issue if the water is also acidic. Algae (ie cyanobacteria) plumes have been identified in acidic water at Tom Price

Control Measures for Potentially Acid Forming Pit Wall Rocks — 2010

Internal reference: RTIO-PDE-0079541

Desktop study of potential strategies to manage exposed sulfidic materials and find viable options for management was conducted with a focus on the Hope Downs 1 and Tom Price sites.

Chemical treatments have the potential to be effective only in the short-term and only for minor water quality issues. Grouting of the pit walls is expected to have limited applicability, although grout curtains behind the wall may have success (untested). Cover technologies have the greatest potential to be effective over the long term, but would need to be resistant to puncture by underlying rocks, resistant to weathering and UV damage ie shotcrete, geomembranes. For long term performance the exposed surface need to be as stable and free of loose material as possible. Treatment effectiveness will also depend on the site conditions, eg chemical less effective at Tom Price.

Yandicoogina Preliminary Site Investigation (PSI) & Sampling and Analysis Plan (SAP) 2010 — 2010

Internal reference: RTIO-HSE-0094696

A preliminary site investigation was carried out to establish potential sources of contamination resulting from the current and historical site activities. Additionally, assess the implications of potential impact to soil, groundwater, environmental and human receptors.

Based on the findings of the preliminary site investigation, the main sources of contamination from the mining operations include; hydrocarbon (mainly diesel) storage / handling facilities and fuel pumps. Other sources of contamination include vehicle wash-down and maintenance facilities, waste oil handling facilities, liquid waste storage facilities, ammonium nitrate and fuel oil, equipment laydown landfilling, wastewater treatment and land farm facilities. Risk ranking analysis identified four facilities as "potentially high risk". On the basis of the preliminary conceptual site model, it is recommended that a ground investigation is undertaken.

Workshop Summary and Desktop Review: Dewatering and Sulfate Accumulation — 2012

Internal reference: RTIO-PDE-0101903

This is a summary of a workshop held to determine the risks of dewatering sulphides within the pit wall. The outcomes from this workshop will be used to develop models to estimate the mass of sulfate produced as a consequence of dewatering activities.

There are many processes that contribute to poor pit water quality. Most of these processes are known and accounted for in existing models. However, the science of fluid flow in fractured rock is not well developed and this lack of knowledge restricts the outcomes of studies on pit water quality. There is a general lack of empirical data for estimating parameters used in models, creating a large degree of uncertainty in predictive models. Sensitivity analysis can be used to overcome some of these challenges.

Development of a conceptual model: Sulfate accumulation as a consequence of pit dewatering activities, memo — 2012

Internal reference: RTIO-PDE-0101903

Mine dewatering and the consequent lowering of the water table may result in desaturation of sulfide bearing lithologies. The objective of this work was to develop a conceptual model of the associated processes: where sulphide bearing rock intersects the pit walls, and where the sulphide bearing rock is located behind the pit walls but not directly exposed on the pit wall face.

The conceptual model developed estimates the mass of sulfate produced as a consequence of dewatering activities, considering processes during operations and after operations cease, and using sensitivity analysis where parameter inputs are uncertain. The model output provides the basis for an assessment of potential impacts on water quality for general risk assessment applications. Further work was identified to improve parameterisation of the model, including the collection of additional empirical data for pit wall fracturing, saturation of pit wall fractures and sulfide oxidation rates in talus and on pit walls.

Ethnographic or archaeological values

Water and Indigenous People in the Pilbara: A Preliminary Study, CSIRO: Water for a Healthy Country — 2011

Internal reference: RTIO-HSE-0218222

Water resources are vital to Indigenous identities, beliefs, environmental philosophies and livelihoods. This report provides a broad-scale scoping study of Indigenous relationships to water in the Pilbara and considers the potential impacts of Indigenous water values.

Indigenous belief systems perceive water as an elemental part of the broader cultural landscape, held and managed under customary systems of law. Water sources were derived during the Dreaming and are the most important features in the Pilbara cultural landscape. Interviews raised issues of long term drying, obstruction of water flow, over-extraction, inappropriate discharge from de-watering and access restrictions.

Context and Purpose

This document provides the information to address the following requirement of the Yandicoogina PER.

> *"Undertake a desktop study of successful and unsuccessful rehabilitation strategies and outcomes in similar geologies and vegetation types in the Pilbara, including a discussion of the different methodology and success rates for the various proposed disturbance types including:*
>
> - *created landforms (e.g. waste rock dump, tailings storage facility)*
> - *short-term disturbances (e.g. borrow pits and access tracks)*
> - *long-term disturbances (e.g. construction camp, permanent accommodation village and administration buildings); and*
> - *linear and/or fragmentation disturbances (e.g. roads, power lines, bore fields)"*

The Yandicoogina ore body is a specific type of paleochannel[1] known as a Channel Iron Deposit (CID). The CID mined at Yandicoogina consists of three main layers of overburden material (a mixture of lateritic pisolite, poorly sorted angular to sub-rounded BIF, chert and dolomite gravels in a sandy matrix), the iron deposit and the basement rocks and altered basement rocks.

The key waste types that will result from mining at Yandicoogina are referred to as Channel Iron Deposit (CID) waste and Alluvials. The erodibility potential of these waste types at Yandicoogina has been assessed with the majority of waste classified as high erodibility when utilised in final landform design at Yandicoogina.

Rio Tinto Iron Ore aims to create landforms that are safe and stable, considered aesthetically compatible with the surrounding landscape, supportive of native vegetation, and are non-polluting.

[1] Paleochannels are remnants of ancient streams cut into old rocks and filled with sediments from younger rocks; such that they reflect historical drainage lines. The contemporary equivalent is called an alluvial channel.

Assessment of Rehabilitation Strategies

To enable a discussion of the "success" or otherwise of past rehabilitation strategies and outcomes, a review of rehabilitation monitoring results that compares rehabilitation areas to "similar" reference or control sites has been undertaken. Reference sites can be described as an unmined site, usually representative of the 'natural' landscape surrounding the mine site or rehabilitated area. The reference site generally consists of the target vegetation community, soil type and terrain and provides an example of what the rehabilitated area should achieve. For example to determine the success of waste dump slope rehabilitation it has been compared to a reference site that has been established on an undisturbed slope in the surrounding environment. Similarly rehabilitation of flat areas has been compared to reference sites established in an area of flat undisturbed vegetation, with the vegetation being typical of the surrounding area. By comparing rehabilitated areas to undisturbed reference areas (with similar terrain and topography) effectively it is answering the question as to whether the rehabilitated areas have similar biodiversity to surrounding communities. This aligns with the overall closure and rehabilitation strategy outlined in the Yandicoogina Closure Plan, that is to establish ecosystems with similar biodiversity and cultural heritage values as surrounding reference sites.

This high level approach is suitable for gaining a general understanding of the success of a rehabilitation area (regardless of site specific completion criteria which might apply). As rehabilitation (and related closure strategies and outcomes might differ between sites depending on the site based risks and environmental values) comparing rehabilitation to similar reference sites also allows us to understand how the rehabilitation is performing against the general objective of creating a stable, non-polluting landform, that comprises local native vegetation that is self-sustaining and compatible with the surrounding environment.

It is acknowledged that Yandicoogina has specific objectives and completion criteria proposed in its Closure Plan including those listed relating to stability and biodiversity in ***Table 1***.

Table 1: Yandicoogina objectives and completion criteria relating to biodiversity and landform stability.

Function	Objective	Indicative Completion Criteria
Landform Stability	Rehabilitated landforms are stable and designed to manage floodwater appropriately.	Erosion does not threaten the long term stability of the landform.
Biodiversity	Final landforms are rehabilitated to be compatible with post-mining land use.	Vegetation on rehabilitated land is native and self-sustaining. Habitat for native fauna is provided in appropriate rehabilitated areas. The prevalence of invasive species (weeds, feral animals) is similar to that in nearby reference site.

By reviewing previously completed rehabilitation areas on similar geologies in Pilbara ecosystems (against adjacent similar reference/control sites), we can get an understanding of what rehabilitation methods might be transferable and utilised at Yandicoogina to help Yandicoogina achieve its objectives and completion criteria.

As the rehabilitated areas assessed in this discussion are located at numerous locations and terrains across the Pilbara, a range of vegetation types will be assessed (by default). It is acknowledged that some of the vegetation communities proposed to exist following rehabilitation and closure at Yandicoogina are considered new types of rehabilitation for RTIO such as wetland habitat within mine voids. As a result, examples of this disturbance type and proposed rehabilitation are not included in this discussion. Whilst general methodologies are likely to be transferable to implement this type of new rehabilitation (such as waste characterisation and resulting landform design and shaping, topsoil application, ripping and seeding) there is a recognised knowledge gap as to the details for the rehabilitation methods such as topsoil application rates, surface water controls required and vegetation species mix to utilise.

Created Landforms (Waste Rock Dumps, Tailings Storage Facilities)

The proposed final landform at Yandicoogina on closure will include some rehabilitated slopes external to the pit areas, such as where current infrastructure has been decommissioned and removed. In addition the edge of the backfilled waste within the pit areas that will slope down into what will eventually be pit lakes will also be rehabilitated. It is therefore important to review successful and unsuccessful rehabilitation strategies of slopes built of similar materials to what is predicted to be encountered at Yandicoogina. This rehabilitation type (built slopes) may be present in the rehabilitated land and wetland habitats that are likely to be introduced at Yandicoogina at closure.

At present, as there are no rehabilitated slopes at Yandicoogina with sufficient monitoring data to enable a review and discussion of rehabilitation success, rehabilitated slopes at Pannawonica Operations and Brockman Two Operations have been reviewed. The Pannawonica Operations in the Robe Valley are situated in a similar geology to Yandicoogina, with the mining of iron ore from a channel iron style deposit. In addition Brockman 2 Pit 2 deposit was mined in the late 1990's and involved the mining of ore and waste from a detrital iron ore deposit. The resultant single waste dump from the mining of ore from Brockman 2 Pit 2 deposit is comprised primarily of an erodible waste type considered similar (in terms of physical characteristics and erodibility) to the CID and alluvial wastes that are encountered as a result of mining ore at Yandicoogina from the Channel Iron Deposit.

This section will therefore focus on different strategies utilised for rehabilitated slopes at the Pannawonica Operations by reviewing rehabilitation success at Mesa J Waste Dump S and Mesa J Waste Dump T and Brockman 2 pit 2 Waste Dump 1. The strategy utilised to rehabilitate a tailings storage facility located at Pannawonica's Mesa J operation and early monitoring results will also be discussed.

Successful and Unsuccessful Rehabilitation Strategies

Mesa J Operations Waste Dump S

Waste Dump S at Mesa J Operations had rehabilitation of its slopes completed between 2002-2004 and these have a monitoring transect located on them. The same dump had further slopes rehabilitated in 2007 and has a monitoring transect located on it. Both areas were battered to 15 degrees slopes, comprise of a 12-15m lift height and had 150mm of topsoil applied and ripped into the surface and seed was applied. Approximately 90% of the single lift dump was rehabilitated as at 2007 (~40Ha). The monitoring transects on the slope of Waste Dump S are positioned where the lift height is approximately 8-10m.

The most recent monitoring of these areas, completed in 2013 showed both areas had good perennial species diversity with 13 species present (higher than the slope control sites that had seven species present). The 2002-2004 rehabilitation, lower storey vegetation was absent until 2013, and then only represented a very small proportion of the total cover. The lower storey vegetation at this site was primarily made up of a mixture of *Triodia* and small or juvenile shrubs and the upper storey dominated by *Acacia* shrubs. The 2007 rehabilitation dominant stratum was the upper storey of *Acacia* shrubs, including *Acacia bivenosa* and *Acacia ancistrocarpa.*

Landscape function indices for stability were 61% for the slope reference sites while the rehabilitate sites were 59% (in 2013). The nutrient cycling and infiltration values for the rehabilitation sites were also higher than the values measured in the slope reference site in 2013. All three indices compared favourably to the average scores achieved by the sloping reference sites. Due to the mature stage of ecosystem development these scores are not expected to change substantially in the future until *Acacia* senescence, or a disturbance event occurs, such as fire.

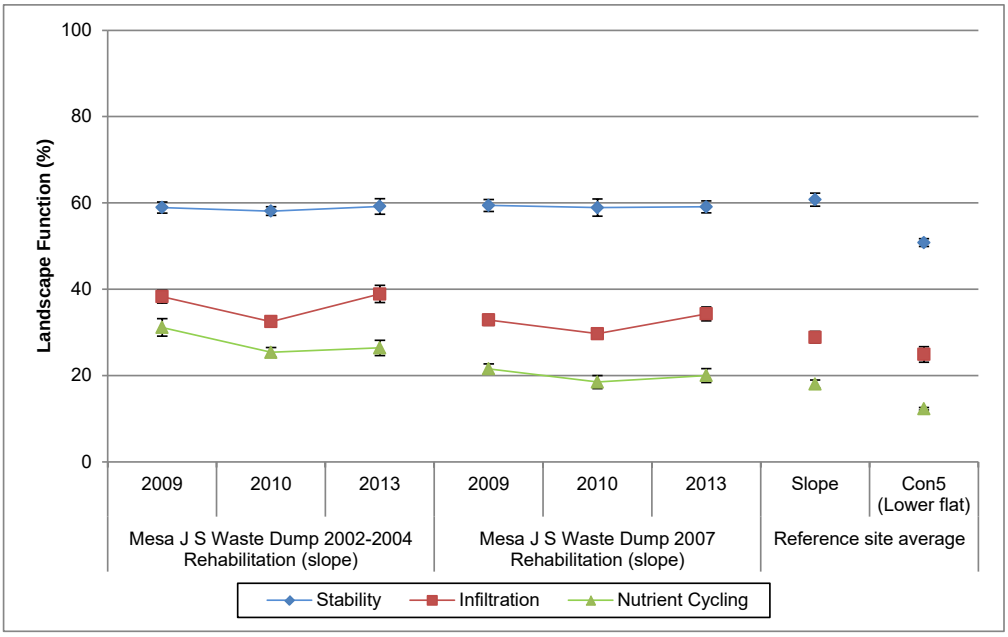

Figure 1: Changes in landscape function of the 2002-2004 and 2007 rehabilitation on the Mesa J S Waste dump (slope), in comparison with the sloping reference sites (Con7 and Con10) average, and Con5.

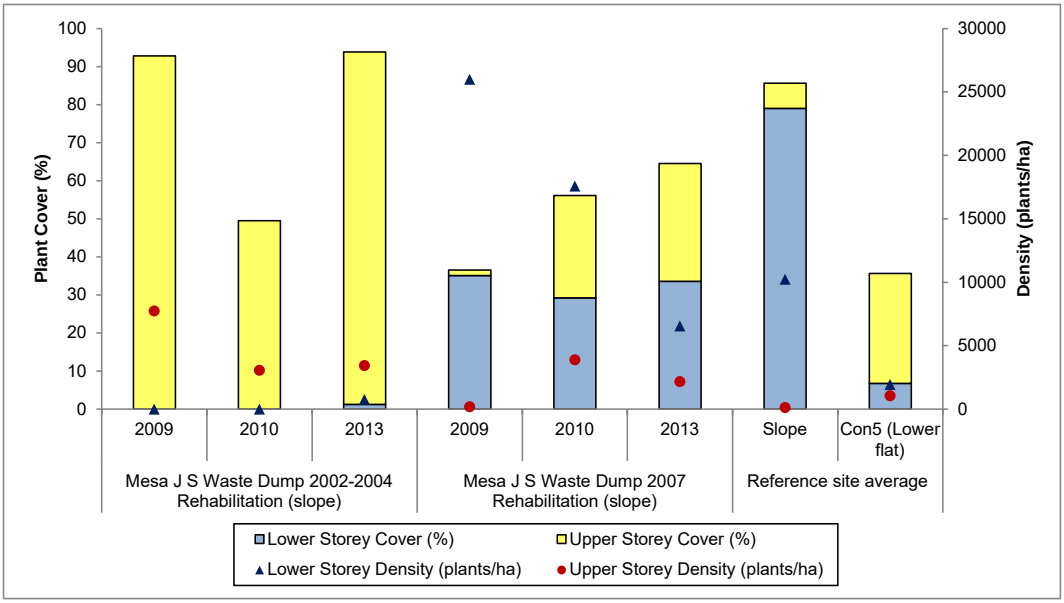

Figure 2: Changes in the plant cover index and density (lower and upper storey) of the 2002-2004 and 2007 rehabilitation on the Mesa J S Waste dump (slope), in comparison with the sloping reference sites (Con7 and Con10) average, and Con5.

The plant cover percentage was 63% and 93% for the two rehabilitation areas which was both higher and lower than the slope reference site which had 85% vegetation cover. The density

of the cover was dominated by upper storey plants in both rehabilitation sites whilst the slope reference site was dominated by a lower story (refer to ***Figure 1*** and ***Figure 2***).

In terms of habitat complexity (which is used as an indicator of suitability of habitat for fauna) of the Waste Dump S rehabilitation areas several faunal niches were available such as litter, logs and rocks. Kangaroo scats were observed at both transects providing evidence that native fauna were utilising the rehabilitation area.

Since this site was first monitored in 2009, the proportion of the slope eroded has decreased on the 2002-2004 rehabilitation area from 14% to less than 9% in 2013. On the 2007 rehabilitation area, erosion increased slightly but the overall proportion of slope eroded was low. The vast majority of the erosion that was present was on the lower slope of the transect; erosion present on the upper slopes of both transects was minor.

Rehabilitation monitoring data to date suggests that the rehabilitation on Waste Dump S at Mesa J Operations is on track to achieving a stable, self-sustaining native vegetation community similar to the control sites. Whilst total plant cover percentages and density values are within or above the range of the combined slope and flat reference sites the composition/breakdown of this cover is different to the reference sites at the older (2002-2004) Mesa J S Waste Dump rehabilitation. A large proportion of the vegetation on the rehabilitation comprises of upper story cover (*Acacia's*) as opposed to lower story cover (*Spinifex sp*.) which is the dominant strata in the reference sites. This aspect will require review over time to determine if any intervention (specific species reseeding) is required. Whilst erosion is present it appears to be either stabilising over time or only on a small proportion of the slope that was assessed.

Overall the indicators of rehabilitation monitoring discussed here suggest that the right species are present (albeit in different proportions to the reference sites), the cover is adequate, and a number of landscape function indices are within the range of (or above) the reference sites indicating that this rehabilitation is heading in the direction of being considered stable, native and self-sustaining with habitat for native fauna present.

Brockman 2 Pit 2 Waste Dump 1

Pit 2 Waste Dump 1 at Brockman 2 Operations is comprised of waste that came from the adjacent Pit 2 deposit (detrital iron ore deposit) and is considered a similar waste type (in terms of physical characteristics and erodibility) to the alluvial and CID wastes that are encountered as a result of mining ore at Yandicoogina from the Channel Iron Deposit. The Pit 2 Waste Dump 1 is built with a single lift with the total dump height ranging from 8-20m and 15-20 degree outer slopes and was rehabilitated in 1999. It is assumed the dump had topsoil applied and was ripped and seeded (no records have been found to confirm this although evidence of cross ripping can be seen on aerial photos). The last monitoring of this rehabilitation was completed in 2012 (via a transect established on the waste dump slope where the lift height is ~8m) and the results are discussed below.

The total species number recorded in the rehabilitation was six which was within the range of values recorded in the three reference sites (six to nine species). *Spinifex, Acacias* and several other native perennial species were identified in the rehabilitation as well as the reference sites. The density of the S*pinifex* and native perennial plants was lower in the rehabilitation at 2.7 plants per quadrant than the range of the reference sites which were 5.8 – 19.4 plants per quadrant. Despite this the percentage perennial cover of the rehabilitation (53%) was within the range of the reference sites (38-70%).

In terms of habitat complexity *Spinifex species*, grass, shrub and litter cover were all comparable to or higher than values recorded in the reference sites, and good numbers of logs and rocks were present. Overall, the fauna habitat could be considered good, with the range of vegetation strata present suggesting that the site is likely to support a diversity of small mammal, reptile, bird and invertebrate species. Erosion monitoring of Pit 2 Waste Dump 1 described the site as very stable, with minimal erosion and no measurements provided for gullies (suggesting they were too small for measurement or that no gullies were located along the monitoring transect). No landscape function measures were completed during this monitoring.

Overall monitoring in 2012 showed that relatively good rehabilitation has developed after 14 years with species diversity and cover similar to reference sites, fauna habitat considered good and the rehabilitated slope in a stable condition. It was noted that the density of the *Spinifex* was lower than in reference sites although this is likely to improve in time (given that the species are present in the rehabilitation area).

Mesa J Operations Waste Dump T

A different rehabilitation strategy was applied at Mesa J operations in 2007 that involved a single lift waste dump having subsoil applied (as opposed to topsoil). The T Waste Landform was reworked in 2007, the slopes were battered to 15 degrees and stockpiled subsoil (less than five years old) was applied, prior to the area being ripped and seeded. The total lift height of the waste dump is 22-25m whilst at the area of monitoring the lift height is 20m. Due to the sloping gradient of the rehabilitation, monitoring results for the rehabilitation slopes were compared to the average achieved by the sloping reference sites.

Rehabilitation monitoring of the T waste landform in 2013 found there were seven species recorded, the same number as both sloping reference sites. Despite the similar number of species present native perennial plants have established poorly and between 2010 and 2013, plant cover and density only slightly improved (***Figure 3***). The rehabilitation had minimal vegetation compared to the average of the sloping reference sites. The lower storey contributed two thirds of the cover with *Triodia pungens* the most frequently sampled species. The upper storey contributed less than 1% cover with only four *Acacia* individuals sampled.

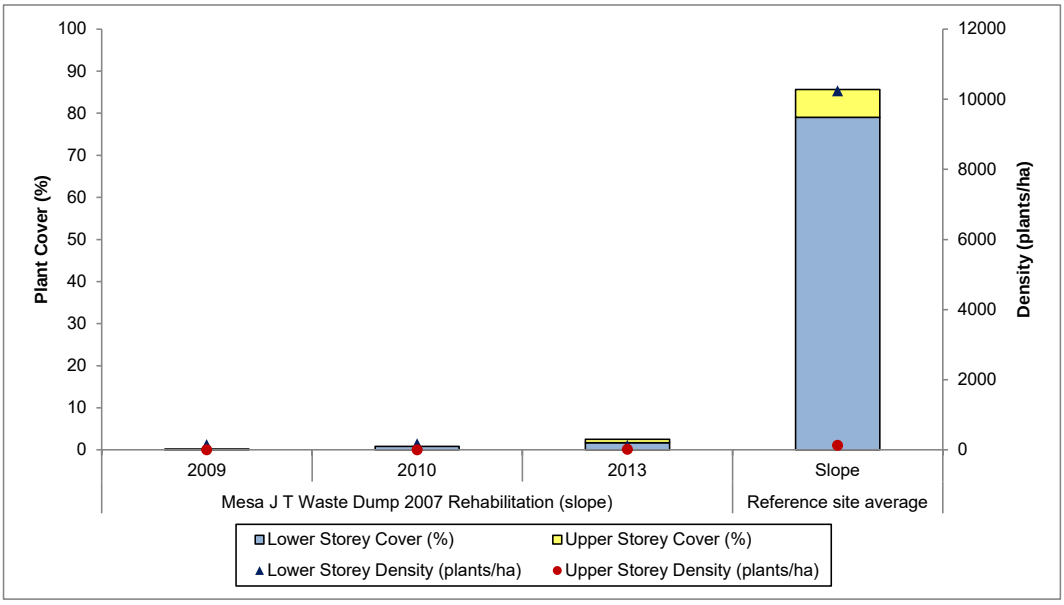

Figure 3: Changes in the plant cover index and density of the 2007 rehabilitation on the Mesa J T Waste Landform (slope), in comparison with sloping reference site (Con7 and Con10) average

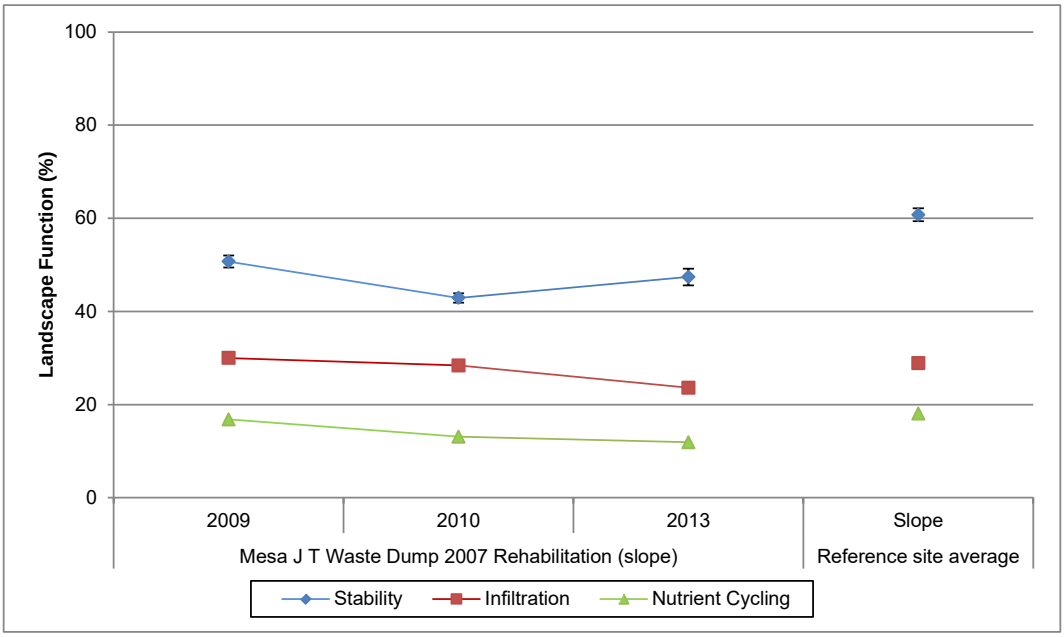

Figure 4: Changes in landscape function of the 2007 rehabilitation on the Mesa J T Waste Landform (slope), in comparison with sloping reference site (Con7 and Con10) average

In terms of landscape function all three indices achieved scores lower than the average scores achieved by the sloping reference sites (refer to ***Figure 4***). The low scores can be attributed to a lack of rocky material on the soil surface and poor vegetation establishment.

A moderate degree of habitat complexity was present with numerous vegetation strata present from grasses to a few shrubs taller than three metres. Faunal habitat was available in the form of grass litter and rocks.

Erosion was a significant issue affecting the performance of the rehabilitation on the T Waste Landform. Since 2009 monitoring, the proportion of the slope eroded doubled to 30%. Both the upper and lower slope display areas of substantial erosion, indicating loss of water resources and therefore reduced potential productivity of the ecosystem.

At the same time as the T waste landform slope rehabilitation was completed, a flat section (on the top of the dump) was also completed. The rehabilitation involved flattening the area, applying subsoil then ripping and seeding. The landscape function scores of this flat area of rehabilitation compare favourably with those achieved by similar flat reference sites. Despite this the vegetation has not established well on the flat rehabilitation with total native perennial cover and density substantially lower than that of the reference sites and the habitat complexity was considered moderate (similar to the slope rehabilitation). There was no erosion (as expected as the area was flat).

The monitoring results to date of the T waste landform slope rehabilitation suggest that while the utilisation of subsoil may assist rehabilitation in achieving some of the rehabilitation indices considered important, in this example it is unlikely to lead to successful rehabilitation. The utilisation of the subsoil on the flat area and slope and resultant low vegetation cover and density suggest the application of subsoil may have contributed to these low values (and not the values being a result of rehabilitation being on a slope versus on a flat area). The use of subsoil should be the subject of ongoing monitoring / trials.

The evidence of extensive erosion also suggests that the subsoil used (and underlying waste type) may not be suitable for use in lift heights of 20m even when battered to 15 degrees.

Mesa J Operations Tailings Storage Facility 1 (Mesa J TSF1)

RTIO has recently rehabilitated a tailings storage facility which was completed in 2014 at Mesa J Operations. The Mesa J TSF1 was originally a pit, however operated as a tailings storage facility between 1999 and 2004. It was decommissioned in 2004 and upon rehabilitation consisted of two low-lying areas that covered ~20% of the surface and an upper, dryer area that covered the remaining 80%. The tailings on the surface of TSF1 had been investigated in 2009 and it was determined suitable for plant growth with few potentially restrictive properties; in addition the TSF already supported areas of regrowth of native vegetation. As a result no topsoil was added during the rehabilitation process to trial whether successful rehabilitation could be achieved on the surface of tailings storage facilities without the utilisation of capping and topsoil.

The TSF rehabilitation commenced in December 2013 and was finished in February 2014 and involved the rehabilitation of the northern two thirds of the facility (~45Ha).

Rehabilitation involved ripping and seeding the surface of the TSF and trees that were present prior to rehabilitation works were retained (and worked around). Contour ripping was conducted to a depth of 600 to 800mm in all areas. Two seed mixes were utilised (with seed collected the year prior to rehabilitation) with one seed mix used for the lower lying potentially wet areas and a second seed mix for the remainder of the TSF. Species were selected specifically to be able to germinate and grow in “wet” inundated clays or water logged soils such as *Cyperus vaginatus.*

Monitoring of Mesa J TSF1 conducted mid 2014 showed that whilst the number of species present in the rehabilitation was within the range of the reference sites, the density of lower storey plants (which represents germination) in the rehabilitation was very low. There was less than 1% cover of lower storey perennial vegetation at the time of the 2014 assessment of the dryer areas, whilst the pre-existing upper story contributed up to 10% cover in some areas. Whilst it is expected the density and cover would be lower than reference sites given the young age of the rehabilitation these are particularly low numbers. The landscape function indices and habitat complexity measures were also lower than references sites, which was to be expected given the young age of the rehabilitation. There was a large amount of the weed species *Acetosa vesicaria* (Ruby Dock) and cattle present at the time of monitoring. Ruby Dock had been noted on the tailings dam prior to the rehabilitation commencing.

In regards to stability and erosion; while no rill or gully formations were present at the three low-lying monitoring transects, some low lying areas at TSF1 were showing signs of subsidence and erosion. A small but deep cavity and other smaller cavities were present adjacent to one of the monitoring transects and contoured rip-lines appeared to be deepening into gully-like flow lines in some areas. It is noted that all of the erosion products would remain internal to the tailings facility due to the shape of the landform.

Initial monitoring results of the rehabilitation suggest that the rehabilitation was showing signs of developing an ecosystem comprising of local native species although the rehabilitated area was threatened by the spread of ruby dock and disturbance by cattle. In addition early signs of erosion suggest that this needs to be monitored to determine if it will result in long term stability concerns.

It is too early to determine if tailings storage facilities similar to the Mesa J TSF1 can be successfully rehabilitated without the use of capping and topsoil. Continued monitoring of this rehabilitation will be undertaken to assess the ongoing development of the vegetation and rehabilitation success.

Early learnings from the rehabilitation methodology used for the TSF1 indicate that for future areas with Ruby Dock infestations it is worth considering completely eradicating Ruby Dock prior to commencing rehabilitation works. This could be achieved through an aggressive and long term spraying program. RTIO has examples of borrow pits along the Tom Price Rail Line located in a national park that are undergoing such a program and have almost eradicated the Ruby Dock.

The other critical learning from the TSF1 rehabilitation that is critical for rehabilitation success related to the post rehabilitation management of cattle (as opposed to rehabilitation methodology). Stray cattle accessed the rehabilitated TSF1 and during monitoring negative impacts on the vegetation and surface of the TSF1 from the cattle were evident. This highlights the need to exclude cattle and potentially other grazing animals as far as possible (such as goats) from rehabilitated areas to assist in the initial establishment of vegetation and long-term success of the areas. Grazing of historically rehabilitated areas can be seen across the Pilbara and anecdotally it appears the vegetation and ecosystems continue to survive. However areas of young rehabilitation (that have not yet become a self-sustaining ecosystem) appear to require protection from grazing animals during the early years of vegetation establishment. This is an important consideration for closure and particularly rehabilitation planning and implementation at Yandicoogina where areas of the operations co-exist with pastoral leases and areas of rehabilitation may be utilised post closure for grazing purposes.

Methodology and Success Rate

Based on the above examples at Mesa J and Brockman 2 of rehabilitation of created landforms comprising of erodible material, the success rates to date indicate the use of topsoil enhances rehabilitation success. Whilst the use of subsoil may assist in improving certain parameters of rehabilitation success (such as habitat complexity and functional indices and does enable some native species germination) it has proven less effective and in some places (such as on slopes) problematic for use in rehabilitation. Whilst this is a limited review of only a few rehabilitated slopes it confirms that topsoil management and the ultimate use of topsoil in rehabilitation greatly enhances rehabilitation success (when compared to subsoil). It also indicates that subsoil may assist in rehabilitation success but should be prioritized for use in flat areas and would require a review of the subsoil properties and seed mixes utilized (to improve germination success and ultimately vegetation establishment).

A review of the three sloped rehabilitation areas comprised of CID or similar waste types Waste Dump S, Pit 2 Waste Dump 1 and T waste landform has indicated that it is possible to achieve a stable, non-polluting landform, that comprises local native vegetation that is self-sustaining and compatible with the surrounding environment containing these waste types if appropriate landform design is utilised and topsoil and seed are applied.

The performance of the rehabilitation area that utilized subsoil suggests that when subsoil is proposed for utilization in rehabilitation it should undergo material testing (physical and chemical properties relevant to plant growth) to determine its applicability as a growth medium and that if subsoil is to be used it may be better placed on flat areas (as opposed to slopes). This testing may also look at potential techniques to improve the performance of the topsoil, such as ameliorants or fertilisers.

The fact that significant erosion was evident on the slopes utilised in a 20m lift, only minor erosion was noted on the lower slopes of the 8-10m lift and no erosion was noted on the 8m lift suggest that CID and alluvial waste if utilising a 15 degree slope should be built with a maximum 8-10m lift height.

The slope stability results seen in the three rehabilitation examples is further supported by testing on CID waste and alluvial materials completed in more recent years that indicate the appropriate maximum lift heights (when using a 15 to 20 degree slope) is from 0m to 10m (depending on the location of the site and associated climate). The "0m lift height" found in testing of some waste types and climate combinations suggest that some wastes will not be stable enough for use in final outer slopes.

The single review of a tailings storage facility highlights that whilst rehabilitation can be completed and germination can be achieved on a tailings storage facility surface without capping and topsoil application, the success of this is yet to be proven. The need for the exclusion of cattle in the immediate years post rehabilitation is also highlighted as a recommendation at Yandicoogina and the control and eradication of Ruby Dock prior to rehabilitation should be considered.

Short-term disturbances and Linear and/or fragmentation disturbances

In addition to created landforms such as built slopes the proposed final landform at Yandicoogina on closure will also have rehabilitation that was completed on short term disturbances and within a short time frame following disturbance. Examples of short term disturbances include; borrow pits, access tracks, clearing for power line and railway construction.

This disturbance can also regularly encompass disturbance described as linear and or fragmentation disturbances such as rehabilitation completed for the construction or removal of pipelines, roads, power lines, rail and bore fields. Whilst a majority of this disturbance is often narrow / long areas of disturbance adjacent to undisturbed vegetation with minor earthworks, it can also include significant earthworks and is likely to range from short term to longer term disturbance timeframes.

The short-term disturbance type often occurs on the surface of the landscape and often involves only minor earthworks that maintain the basic soil profile. Minor earthworks may include clearing topsoil for using an area as a laydown, or following topsoil removal excavating a shallow pit and utilising the material as borrow resulting in a borrow pit that requires rehabilitation. As a result of this disturbance type occurring (often at the surface of the landscape), the material types intersected are usually restricted to the first few metres from surface. This material (first few metres from surface) is generally comprised primarily of topsoil and subsoil (as opposed to alluvial and CID materials). Therefore in discussing rehabilitation methodologies and successful completion of this type of rehabilitation a range of examples from across the Pilbara of different ages have been reviewed and not just examples from Yandicoogina and Pannawonica Operations.

Rio Tinto regularly complete this type of rehabilitation and have refined methodologies over many years of learning and generally achieve good rehabilitation success for this type of rehabilitation. In addition the ability to utilise relatively fresh (young) topsoil, these disturbance areas are usually small or narrow and adjacent to undisturbed vegetation, which greatly enhances the ability to achieve successful rehabilitation.

Successful and Unsuccessful Rehabilitation Strategies

Yandicoogina Borrow Pits

Borrow pits associated with the railway at Yandicoogina were rehabilitated in the second half of 1998 and rehabilitation monitoring commenced in 1999. Monitoring of these borrow pits conducted in 2013 suggest that vegetation communities, in general, are similar to that of reference sites and differences appear to be a result of some reference sites being burnt during the monitoring period.

The rehabilitation methodology for these borrow pits is consistent with methodology used in current borrow pit rehabilitation and includes battering of all slopes, ensuring the borrow pits are free draining and pulling back salvaged vegetation and topsoil across the disturbed area at completion of the rehabilitation, no seed was applied. All borrow pits reviewed appear to have had topsoil replaced and were ripped. There is no evidence of erosion in any of the

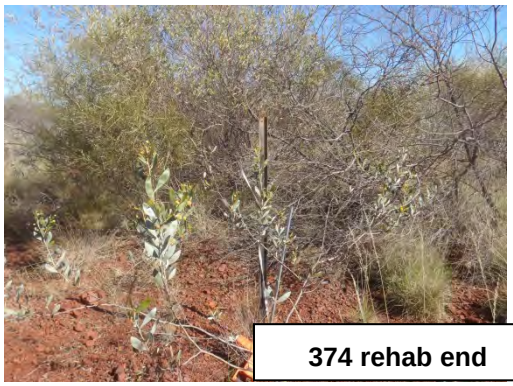
borrow pits. Monitoring results from three of the borrow pits are shown in ***Table 2*** below to give an indication of rehabilitation success as at 2013.

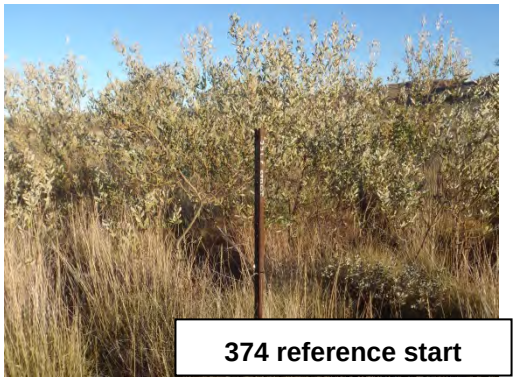
Table 2: Selected monitoring results of the Borrow Pit rehabilitation areas and reference site values (shown in brackets).

Borrow Pit	Age of Rehab (years)	No Species (Rehab)	Plants/ Quadrant	% Perennial Cover	Summary (sourced from the rehabilitation monitoring report)
BP363	14	7 (8)	4.3 (4.2)	45 (64)	The rehabilitated site continues to compare favorably with the reference site
BP374	14	7 (13)	5.6 (20.3)	55 (53)	The 2007 burn in the reference site significantly changed a number of key parameters, making comparison of the two sites difficult, overall, the rehabilitation appears to be developing well
BP417	14	7 (7)	3.3 (13.3)	49 (31)	Results in 2003 indicated that the vegetation communities of the reference and rehabilitated sites had become similar in most regards, a fire in 2010 has since altered this trend.

In addition to the above results all borrow pits were found to have an abundance of *Spinifex* species and *Acacia* species, which were the species dominant in the reference sites they were being compared to.

Figure 5 below shows as an example BP374 monitoring transect at the start and end of the transect and the reference site it is being compared to.





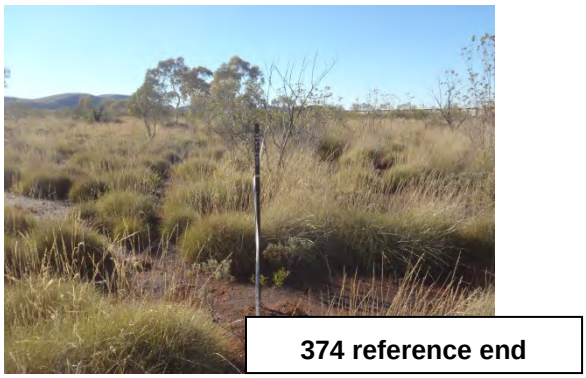


Figure 5: The start and end of the monitoring transect on borrow pit 374 at Yandicoogina and the start and end of the relative reference site transect (in undisturbed vegetation).

Hope Downs 4 Haul Roads, Borrow Pits, Power Line and Railway Rehabilitation

To further review rehabilitation strategies and success relating to short term disturbances the 2014 rehabilitation monitoring conducted across Hope Downs 4 is discussed. The monitoring completed at Hope Downs 4 involved assessing 35 locations across a range of rehabilitated disturbance types and associated reference sites. These included the mine access road (1 location), disturbance for power line construction (4 locations), borrow pits (11 locations), camps (4 locations), railway construction (15 locations) and mine disturbance (5 locations). All of this rehabilitation was completed during 2013 and resulted from disturbance to enable the establishment of the new Hope Downs 4 Mine. The rehabilitation methods utilised included reprofiling areas, replacing topsoil and salvaged vegetation and shallow or deep ripping of areas (dependent on compaction), no seed was applied.

A summary of the rehabilitation shows that vegetation in most of the Railway sites has established well, with good species establishment, species/quadrant and density comparable to that of the reference sites. Spinifex was present in all sites. All Railway and Powerline rehabilitated sites appeared to be stable. Weeds were only present in four of the 19 Railway and Powerline sites, with weed abundance (mostly Buffel Grass) low in all apart from one Powerline site where Spiked Malvastrum was abundant across the whole transect. Vegetation in many of the Mine Access Road, Camp and Mine rehabilitated sites has also established well, with total species numbers, species/quadrant and native plant density comparing favourably with the reference sites. Spinifex was establishing in most rehabilitated sites. Results are shown in ***Table 3*** and ***Table 4***.

Table 3: Rehabilitation monitoring results of the Railway line sites, with green shading indicating values within or above the reference site range which indicate rehabilitation heading in the right direction given its young age.

A fauna habitat assessment showed that fauna habitat is beginning to develop well in many sites, though more time is needed to assess this.

Methodology and Success Rate

The methodology utilised for rehabilitating short term disturbances in general appears to be working to achieve successful rehabilitation (stable, non-polluting landform, that comprises of local native vegetation that is self-sustaining and compatible with the surrounding environment) and is proposed for use to rehabilitate similar types of disturbance at Yandicoogina. This methodology involves salvaging and stockpiling vegetation and salvaging and stockpiling topsoil prior to disturbance, then reprofiling areas, returning the stockpiled topsoil and vegetation and deep or shallow ripping along the contour as appropriate. With regard to borrow pits the initial placement of them in the landscape and resultant excavation is critical to enabling the borrow pits to be free draining following rehabilitation.

Long-term disturbances (e.g. construction camp, permanent accommodation village and administration buildings)

In addition to created landforms and short term disturbances the proposed landform at Yandicoogina on closure will also have rehabilitation that was completed on long-term disturbances. Examples of long- term disturbances include construction camps, landfill sites and accommodation villages. They are considered in this discussion as any generally flat disturbance that is rehabilitated within a medium to longer time frame following disturbance. The discussion of rehabilitation strategies and success rates for long-term disturbance will involve a review of monitoring results for a rehabilitated landfill at Yandi and fixed plant rehabilitation completed at Mesa A.

Landfill Sites at Yandicoogina

Two landfill sites (adjacent to each other) that were rehabilitated in 2009 after being disturbed (active) at Yandicoogina for three and a half years and last monitored in 2014 are considered examples of longer term disturbance and discussed below.

The decommissioned landfill sites had clean fill imported to cover the pits, then it had topsoil applied, was ripped and seeded and monitored for the first time in 2013, then again in 2014.

Numbers of total species in the two landfill sites were nine and 11 which was similar to those in the two reference sites (11 and 12 species), with a range of *Acacia species* as well as *Spinifex species*, native grasses, and various other native shrub and herb species identified at the rehabilitated sites. Species per quadrant values showed no clear separation between the reference site and the Landfill sites. Native plant density in the two landfill sites had changed very little since 2013, and was comparable to or higher than those in the reference sites. Mean bare areas values (which provides an indication of cover values) in the two landfill sites and the reference sites were similar to each other, with no significant differences.

Results for the two landfill sites show that rehabilitation has established and developed well, with most measured and calculated parameters similar to values recorded in the two reference sites and in some cases higher. No weeds were recorded in either landfill site, and both sites are stable, with no erosion recorded. Field notes for both sites describe the rehabilitation as excellent. Fauna habitat of the two sites is likely to be good for any small reptiles, mammals, birds and invertebrates that utilise spinifex and shrubs, but less suitable for ground dwelling species that utilise litter and logs.

Mesa A Fixed Plant Rehabilitation

A nine hectare area previously utilised as a laydown area for approximately three years by the fixed plant personnel at Mesa A operations was rehabilitated in 2012. The area had topsoil applied, was ripped and seeded. Monitoring of the area in 2013 showed the total numbers of species in the two rehabilitated sites were comparable to or greater than those recorded in the reference sites, species present in the rehabilitation included a number of *Acacia species* and other shrub, herb and grass species as well as *Spinifex species*. The plant density values were lower in the two rehabilitated sites at 2.3 and 2.3 plants per quadrant as compared to the reference sites (5.3 and 6.4 plants per quadrant), which is expected given the young age of

the rehabilitation. The percentage of perennial cover was also very low in the rehabilitated sites (1% and 4%) as compared to the reference sites (43% and 51%).

There were no signs of erosion in the rehabilitated sites and it was too early to do an assessment of habitat diversity (to determine appropriate habitat for fauna). It is too early to determine if the rehabilitation is on track to be successful. The early indicators of the rehabilitation certainly show it is not doing as well as some other shorter term rehabilitated areas such as the areas reviewed at Hope Downs 4. This may be a result of differences in weather and rainfall received at the two sites or as a result of the disturbance being longer term (which may lead to reduced quality of topsoil). The other factor that may be contributing to the rehabilitation success at the Mesa A Fixed plant area is that it is surrounded by disturbed areas (and not immediately adjacent to undisturbed native vegetation).

Methodology and Success Rate

The two examples for longer term disturbance reviewed suggest that it may be more challenging to achieve rehabilitation success in areas of longer term disturbance (than short term disturbance areas). In both cases the rehabilitation methodology has shown that the areas are stable and have native species present, with the landfill indicating density and cover is similar to the reference sites whilst further monitoring of the Mesa A rehabilitation will determine if cover values will be achieved in time. Whilst only a review of two areas the rehabilitation methodology of landform shaping, topsoil application, ripping and seeding appears to support the development of successful rehabilitation in longer term disturbance. An important step of the rehabilitation of the longer term disturbance (as opposed to short term disturbance) is the addition of seed. The addition of seed in the rehabilitation process should be considered regardless of the disturbance type but based on the likely viability of the seed bank with the topsoil utilised in the rehabilitation. In addition the germination of seed in rehabilitation areas may also assist if the proposed rehabilitation habitat being established is different to the habitat from which the topsoil was sourced, which may be the case in Yandicoogina where some wetland habitats will be developed as a part of the closure of the site.

APPENDIX D

29. Appendix D Conceptual landform design closure options

This section summarises the discussion, considerations and anticipated outcomes of conceptual landform combinations have been developed and reviewed by Rio Tinto over recent years. Any of the scenarios presented below could be adopted at the current stage of mining, but could result in different economic, environmental and social impacts, opportunities and / or outcomes than presented in the Yandicoogina Closure Plan.

29.1 Considered options

The following closure scenarios present different landforms options have been developed by Rio Tinto, taking into consideration the location of CID beneath the existing creek systems and potential expansion activities. Each closure scenario presented below has the potential to influence the surface and ground water systems in different ways, and thereby has the potential to achieve different environmental and social closure outcomes.

As part of Rio Tinto's internal review, it was recognised that landform stability and the management of mineral waste, which can be moved and shaped to control water movement, comprise some of the larger closure cost aspects. While the cost implications of the closure scenarios have been reviewed by Rio Tinto, the cost implications are not discussed in this report.

29.1.1 Closure scenario 1 No backfill

Mining activities to date have maintained a minimum 200m standoff from the existing creeks[45], to preserve the creek ecosystem wherever possible. In the "no backfill" scenario, mineral waste would nominally be used to stabilize pit walls where a high risk of wall collapse is identified, to prevent flood water from entering the voids. Mineral waste not used would remain external to the pit. This would leave large voids exposing the groundwater table (Figure E1).

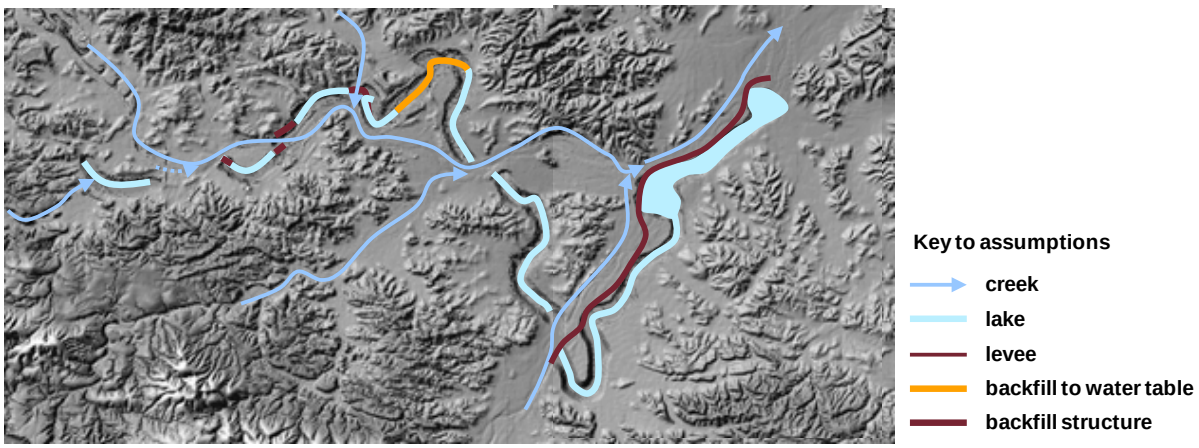

Figure E1: No backfill closure scenario.

Conceptual modelling[46] suggests that due to the strong creek recharge mechanisms, water levels in the voids upstream of JSE would recover in less than 5 years, creating a chain of lakes that are disconnected from the creek system. Water lost through evaporation would result in the water table recovering to a level that is less than 10m below the pre-mining water levels with water quality of less than 1000mg/l (although the cumulative impact of the upstream mining activities has not been accounted for and could result in a doubling of the water salinity[47]).

[45] With the exception of Phils Creek for which mining approval for the removal and realignment of the creek has been approved under Ministerial Statement 914.

[46] RPS Aquaterra (2012) Yandicoogina closure options: Preliminary water modelling results. Prepared for Rio Tinto Iron Ore, 22 December 2011. RTIO-PDE-0103618.

[47] RPS Aquaterra (2012) Yandicoogina closure options: Preliminary water modelling results. Prepared for Rio Tinto Iron Ore, 22 December 2011. RTIO-PDE-0103618.

At JSE, however, the water table would recover to 15m or more below the original water table. The 15m drop results from a combination of the decreasing water level from the upstream voids in Marillana Creek, limited connection to local creek systems and the large surface area subject to evaporation. The evaporation rates would keep the water table suppressed, even though the water table would be higher on both the northern (Marillana Creek) and southern (Weeli Wolli Creek) extents. The change in groundwater gradient draws water from under both the Marillana Creek and Weeli Wolli Creeks, creating a permanent cone of depression under both creeks. Salts[48] would continuously accumulate within the JSE pit, such that the water quality would eventually be classified as hypersaline. Salts trapped within the void would be permanently removed from the water systems.

Regional groundwater flows would be unaffected by the saline sink at JSE. Groundwater flow would be maintained down the alluvial systems associated with Marillana Creek and Weeli Wolli Creek[49]. However, because the groundwater table would not recover to the original levels, the riparian community structure would be permanently changed.

Development of the Billiard deposits, if following this same closure concept of no backfill with the separation of pit void and creek system, would result in similar conditions as JSE – a hypersaline lake with cone of depression permanently extending under Weeli Wolli Creek. However, the Billiard void would have a larger and longer connection to the remaining CID and alluvial aquifers. This would allow more water to be drawn from the regional groundwater system and could terminate groundwater flow from the Weeli Wolli Catchment to the Fortescue Marsh.

29.1.2 Closure scenario 2 Backfill to pre-mining water table

Backfilling mine voids to the pre-mining water table level aims to cover the groundwater table and thereby stop evaporation processes and preserve water quality. As there is insufficient mineral waste generated through the act of mining to cover the groundwater table, it is assumed that the hills adjacent to the voids would be mined to fill the voids (Figure E2). Filling the voids to groundwater level does not, however, reinstate the original topography or create a free draining surface. As such, the pit walls adjacent to the pit are not stabilised and the pit void continues to capture runoff.

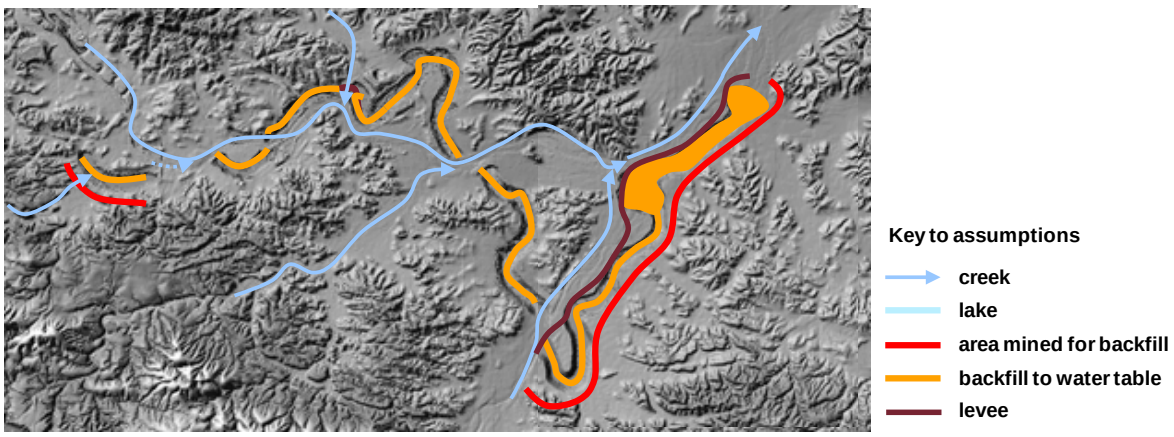

Figure E2: Backfill to pre-mining water table closure scenario. Locations illustrated as "area mined for backfill" (in red) do not represent an intention to mine these areas, and are supplied only to indicate the magnitude of the area required to be mined to achieve this outcome.

Conceptual modelling[50] suggests backfill to the original groundwater table level would facilitate the recovery of the water table to pre-mining levels. However, due to the strong creek recharge mechanisms, the water table would fluctuate significantly (up to 10m). When the water table fluctuates above the backfill level shallow pit lakes would be formed. (Backfill to 10m above the pre-mining was estimated to be required to completely suppress the groundwater table.)

[48] All salts accumulated within the voids in the closure scenarios are derived solely from groundwater constituents. Mineral waste characterisation shows there are no salts that will be leached from mineral wastes under neutral or acidic conditions.

[49] Additional groundwater modelling is required to verify this conclusion as it was not a factor assessed as part of previous modelling activities.

[50] RPS Aquaterra (2012) Yandicoogina closure options: Preliminary water modelling results. Prepared for Rio Tinto Iron Ore, 22 December 2011. RTIO-PDE-0103618.

The lakes would be subject to evapoconcentration processes, causing salts to build up in the void soils. The salts, combined with regular inundation and prolonged water logging, would generate conditions that would not be favourable to vegetation growth.

Groundwater salinity would remain relatively similar from Oxbow through JSW and JC, but would increase by around 60 percent at JSE. If this same scenario was continued through to Billiards, salinity within the Billiard void would increase seven-fold due to the large potential exposure area.

Backfilling above the pre-mining water, to ensure no ephemeral lakes form, would substantially reduce groundwater quality issues and improve the growing conditions within the voids.

Several studies have been undertaken to determine the potential source of material to achieve the necessary backfill. Colloquially referred to as “backfill hill”, the volume of material required to backfill the voids to the water table[51], in addition to the mineral waste generate through mining, is over 55 million m^3. This equates to excavation of an additional +400ha of undisturbed land and hills adjacent to the mine. Backfilling to the water table will still leave shallow (up to 20m deep) pits. Additional excavation would be required if backfill to above the water table was preferred.

Groundwater through flow to Fortescue Marsh would be maintained under this scenario, and no drawdown would be experienced in the alluvial aquifers under the creeks. However, the level of backfill would not stabilise the pit walls. Only a few centimetres of wall failure / erosion on the top of the pit wall could be sufficient to allow flood water to flow into the voids, and start the processes that lead to creek capture. If the voids capture the creek, the frequency of surface water low flow and flood events would change. This could have an impact on the creek flow regimes and ecosystems (as previously discussed).

29.1.3 Closure scenario 3 Maintaining creek flows

The “maintaining creek flows” scenario prioritises the use of available mineral waste to stabilise the pit walls, strengthen flood bunds and thereby preserves the creek systems as far as practicable. No attempt to suppress the groundwater table is made. Instead deep lakes are encouraged to form, and excess mineral waste not required to support the creek system is placed to reduce the surface area of the lakes, rather than reduce the depth of the lake (Figure E3).

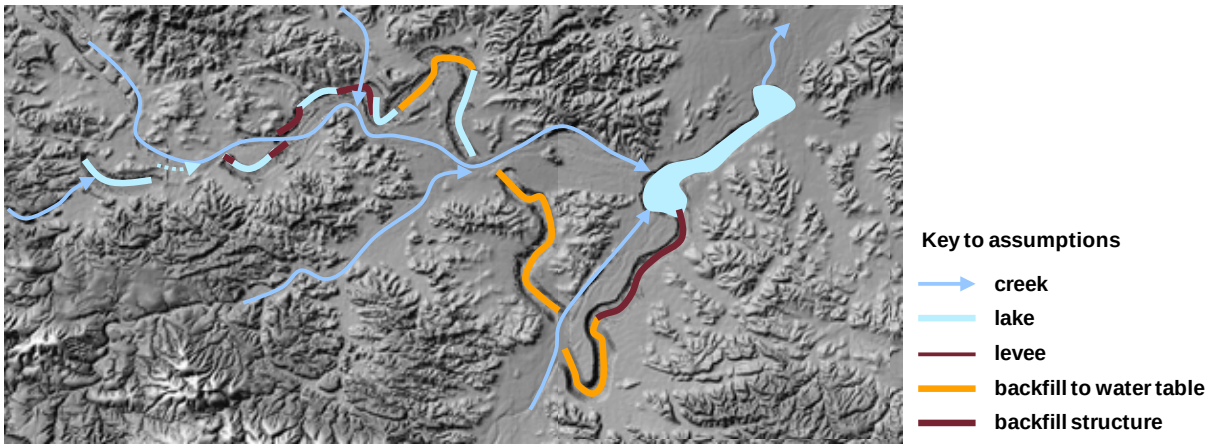

Figure E3: Maintaining creek flows closure scenario.

Mineral waste priority locations were identified (from high to low) to minimise the potential for pit walls to collapse and to increase resilience to large flood events:

- Phils Creek reconstruction. Phils Creek is removed as part of the JSW pit development. Additional mineral waste would be used to strengthen the land bridge (constructed during operations) by increasing the buttressing either side of the land bridge. This configuration would minimise the potential for pit walls to collapse and increase resilience to large flood events.
- Marillana Creek between the JSW A and C areas. The area where Marillana Creek divides the JSW –A (southern) deposit from the JSW-C (northern) deposit restricts surface water flows between two flood bunds. Once the ore is removed, the bridge of CID ore and alluvium that remains under Marillana Creek has the potential to collapse into the void. Mineral waste would be used here to strengthen the pit walls and, leaving the flood bund in place, strengthen the flood bund. This configuration would increase resilience to large flood events.

[51] Rio Tinto (2009) Yandi Conceptual Study on Magnitude of works to Backfill Voids, June 2009, RTIO-PDE-0068220.

- JSW area A adjacent to Marillana Creek. This pit wall is also located in the floodplain. Mineral waste would be used here to strengthen the pit walls and again, leaving the flood bund in place, strengthen the flood bund. This configuration would increase resilience to large flood events.
- JSE waste fines cover. Mineral waste is placed over the JSE waste fines cells to prevent the creation of a lake. This would prevent the permanent drawdown of the groundwater table under Marillana and Weeli Wolli Creek adjacent to the JSE deposit.
- Billiard southern expansion. The Billiard expansion intersects the Weeli Wolli Creek floodplain and could potentially mine through Weeli Wolli Creek. The long pit wall parallel to the creek has a high potential to fail. The mineral waste estimated to be generated from mining the northern portion of the Billiard deposit would allow the entire southern portion of void to be backfilled to surface to reinstate a floodplain.

In this scenario lakes will form in the Oxbow, JSW, JC and Billiard areas.

Modelling suggests the groundwater table would recover to approximately pre-mining levels in spite of the creation of several lakes. This situation evolves due to several different water interactions.

At Oxbow, the lake would behave as sink and water quality would deteriorate over time as a consequence. However, recharge from local runoff (terminating in the lake) would sustain the water levels around the pre-mining level. By behaving as a sink, salts would be prevented from interacting with the downstream alluvial and lake systems.

The JSW lakes would have a strong connection to the alluvial aquifers beneath Marillana Creek and would be rapidly recharged with the fresh alluvial waters. The surface area of the lakes would be relatively small in relation to the through flow rates, enabling the water to stay relatively fresh.

The JC lake would behave as a sink. However, because the lake is fed via water travelling through the CID from the JSW area, the salt content would be relatively low and the lake would take longer to become saline than Oxbow. The water level at JC would not recover to pre-mining level and a cone of depression would extend from JC under Marillana Creek into the JSE area.

The cone of depression at JC would cause the water flow direction to reverse through the JSE area, when compared to the pre-mining flow direction. This would pull the fresh groundwater in the Weeli Wolli aquifers through the JSE area, achieving approximately the pre-mining water levels.

Downstream of the JC cone of depression in Marillana Creek, the alluvial aquifer would be rapidly recharged from the surface water flows. This would sustain the pre-mining water table, in this sensitive riparian area, at the pre-mining water quality.

In the southern backfilled portion of the Billiard expansion area water levels and water quality would be returned to pre-mining conditions. Around the Billiard lake a small cone of depression may form during periods of prolonged dry weather. However, because this lake would receive all flows from Weeli Wolli Creek, the water levels would fluctuate with rainfall and overtop following large flood events (possibly every two to three years or so).

29.1.4 Closure scenario 4 Multiple small, deep lakes

This scenario is the same as scenario 3, with the exception of the Billiard expansion area. In this scenario multiple small, deep lakes are encouraged to develop through the Billiard void by placing the waste back into the void at staggered intervals as well as diverting Weeli Wolli Creek through the void (Figure E4).

This configuration would create a chain of lakes down Weeli Wolli Creek. During dry periods the lake water levels would drop, creating a groundwater cone of depression in the adjacent remnant alluvials aquifer. Because surface water flows are diverted into the voids, filling each void in sequence before overtopping the backfill then filling the next void, the alluvial aquifers would no longer be regularly recharged and the low flow channel and flood plain outside of the mined area could cease to function. As a result the composition of the riparian vegetation adjacent to the Billiard deposit could be significantly altered.

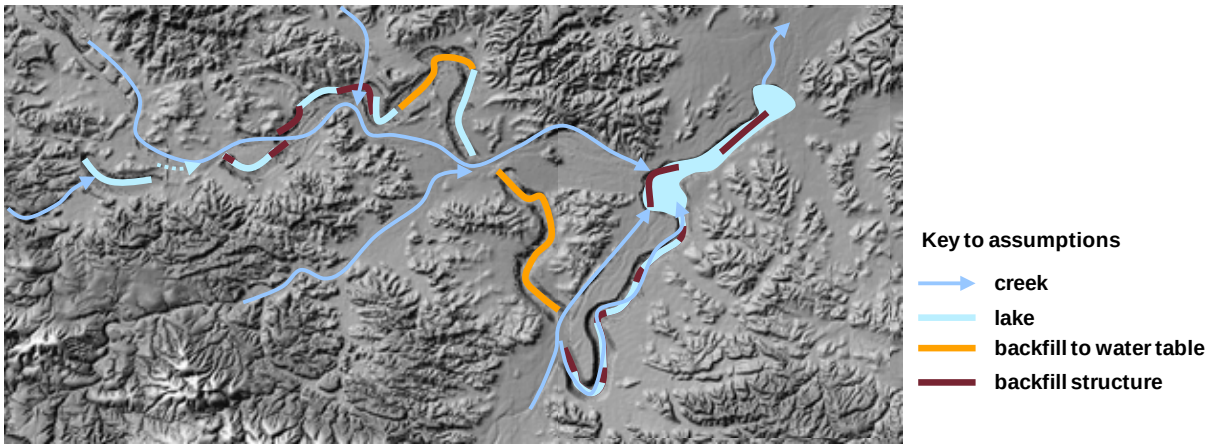

Figure E4: Multiple small, deep lakes closure scenario.

The mineral waste between each lake would be vegetated to create artificial wetlands with waterways to allow the flood water to pass between voids.

As with scenario 3, the water quality would remain relatively fresh as the accumulated surface water area is roughly the same. Similarly, the flood frequency through to Fortescue Marsh would be akin to scenario 3 (overtopping every two to three years).

29.1.5 Closure scenario 5 One permanent lake

This scenario is the same as scenario 3, with the exception that an additional CID deposit located between the existing JSE area and the Billiard expansion area, under Weeli Wolli Creek, is mined. Little to no backfill occurs within the Billiard area, such that waste dumps are left external to the mine area. Weeli Wolli Creek is diverted into the void, creating one long, continuous lake.

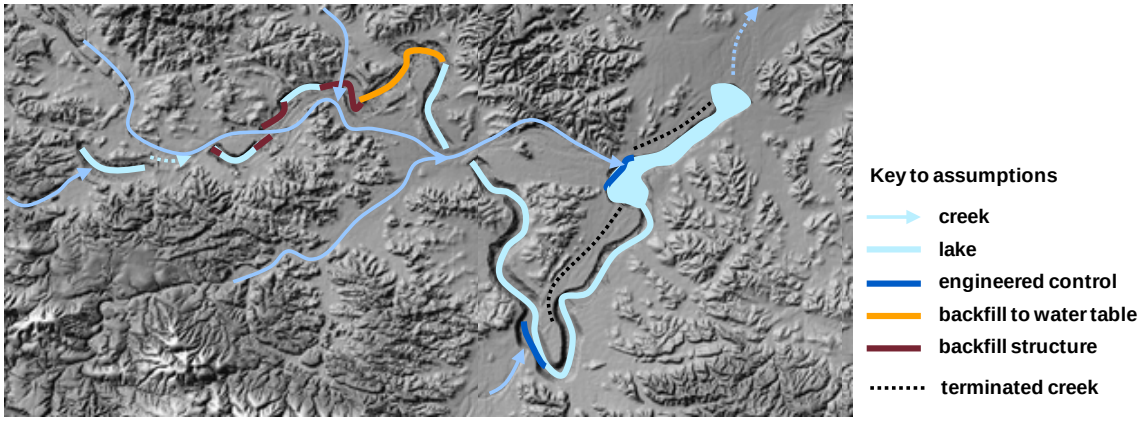

Figure E5: One permanent lake closure scenario.

As with scenario 4, the lake would capture all flows along Weeli Wolli Creek, and the riparian community adjacent to the mined area would experience similar impacts (changes to the vegetation community). The contribution of fresh surface water flows would maintain fresh water quality within the lake for most of the time. During periods of sustained drought, however, the water quality would be expected to diminish.

Due to the magnitude of the surface water volumes during flood events, the flood frequency through to Fortescue Marsh would be akin to scenario 3 (overtopping every two to three years).

29.1.6 Closure scenario 6 Continuous channel

Unlike all of the other scenarios consider, the “continuous channel” scenario does not seek to preserve the existing ecosystem. This scenario was designed to answer the question “can we create a stable alternative ecosystem if we mine the entire CID”. The scenario assumes mining activities remove all of the economic ore within the mapped CID (from Oxbow to Billiards) to create a singular, continuous pit. In this scenario Marillana and Weeli Wolli Creeks and their tributaries are diverted into the mined void and mineral waste is use at strategic locations to control the water movement into the void (Figure E6).

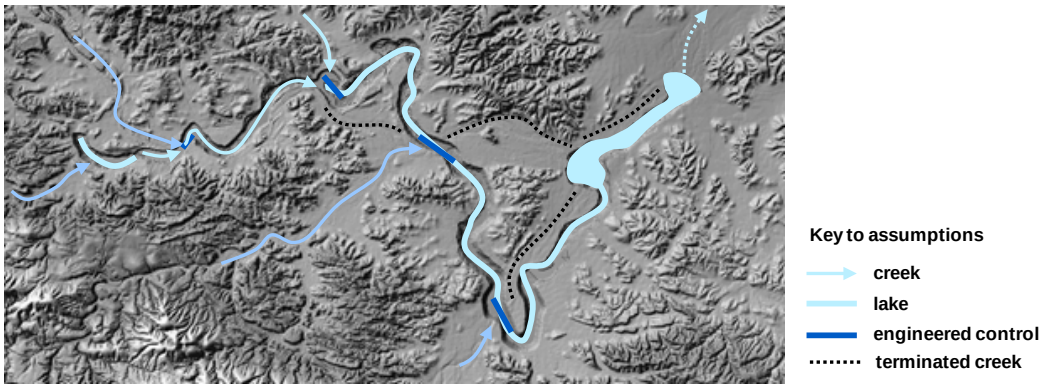

Figure E6: Continuous channel closure scenario.

In Weeli Wolli, surface water would cascade 30m over the edge of the void directly into the lake. In Marillana, surface water would be conveyed over the edge of the pit, and continue to flow along the clay base of the void before merging with the lake. In both creeks, the increase in flow velocities as water enters the voids could cause considerable erosion of the in situ alluvial soils up stream of the void and some degradation or change in the creek bed, banks and riparian community could occur.

Diverting all surface water flows into the void would enable the pit lake water quality to remain permanently fresh (at around 100mg/l to 200mg/l). The lake would extend from the middle of the JC area to Billiards. Groundwater would sustain the freshwater lake throughout the dry season. When the creeks flow, the lake level would rise (up to 6m) and fall, occasionally overtopping to send water through to Fortescue Marsh. A cone of groundwater depression would extend out around the void, such that riparian communities up gradient of the void would also be impacted.

The lake would include a large shallow area of water. The shallow water would encourage a littoral zone to form, which would help regulate the health of the lake by providing habitat for aquatic flora and fauna.

Diversion of the surface water flows into the void would deprive the remnant creek sections, downstream on Oxbow on Marillana Creek and areas adjacent to the Billiard deposit, of flood water. The vegetation community would be substantially altered, which would result in significant habitat loss. However, the creation of permanent freshwater lake could create a new fauna refuge.

Due to the magnitude of the surface water volumes during flood events, the flood frequency through to Fortescue Marsh would be akin to scenario 3 (overtopping every two to three years). However, the total volume of water that would report to Fortescue Marsh is expected to be substantially reduced in comparison to scenario 3.

APPENDIX E

30. Appendix E Yandicoogina closure risk assessment

Yandicoogina 2015 closure risk assessment					Risk Evaluation								
Threat Title	Potential causes (Triggers / Indicators)	Existing Controls and Commitments	Site specific overview	Evaluation Rationale (Maximum reasonable consequence)	Likelihood	Health	Safety	Environment On-site Off-site	Environment Community	Compliance	Risk Management	Detailed Action Descriptions
Planning and knowledge												
Contaminated sites												
Under-estimated general contaminant clean up requirements	• Use of chemicals and hydrocarbons during operations • Housekeeping practice and maintenance of work areas and equipment	• Regular maintenance / inspection / audit of work place procedures • Spill management kits readily available • Contaminated sites register maintained across life of operation	• Some hydrocarbon spills at hydrocarbon (mainly diesel) storage / handling facilities and fuel pumps facilities identified, managed through site processes • Experience with removal of infrastructure suggests some minor additional clean up may be required during decommissioning • Phase 1 inspection to be undertaken on decommissioning	A large, previously unidentified oil spill is found after beneath a concrete slab during the decommissioning activities and requires decontamination.	R			L			I	YA-XX. Complete Phase 1 and Phase 2 (where required) contaminated sites investigations and required actions to remediate contamination.
Under-estimated acid and / or metalliferous drainage management requirements during operations (pre-closure) & decommissioning phase	• Potential for acid / alkaline / metalliferous / neutral / saline drainage generation during operation of mine • Water management, storage and monitoring practices • Water quality prior to return to environment e.g. via infiltration or discharge	• Geochemical characterisation of waste material show material is 'inert', no elevated sulfur, no potential for acid drainage generation • Discharge water quality monitored. Includes sampling and trigger / response requirements • Wet season management plans used to control run off. • Groundwater operating management plan to monitor groundwater quality	• No evidence of alkaline / neutral / saline drainage during operation of mine • Leakage of water through waste fines cell is recognised, however leakage is regularly intercepted by dewatering bores (re-circulation) and monitoring of that water quality has shown no potential issues.	Leakage of water from the waste fines cell(s) compromises the quality of groundwater beneath the waste fines storage facility. Groundwater treatment is required prior to relinquishment.	R			L			I	No further action required at this time.
Acid and / or metalliferous drainage generation (after closure) creates a contaminated site	• Interaction of water and mineral waste could generate acid / alkaline levels that leach metals / salts from the mineral waste or local environment • Presence of temporary or permanent open water bodies, enabling evapoconcentration to occur with creation of alkaline / hypersaline water quality • Ability of metals / salts to move through environment to impact a sensitive receptor, to meet definitions in Contaminated Sites Act 2003	• Geochemical characterisation of waste material show material is 'inert', no elevated sulfur, no potential for acid drainage generation • Geochemical test work completed on mineral waste and natural groundwater shows potential for alkaline water generation and associated metal leaching under specific, extreme evapoconcentration conditions	• Preliminary pit lake water quality modelling completed. Some modelling scenario showed that Oxbow West (and possibly Oxbow East which has yet to be modelled) could generate hypersaline lake water. Model results are highly dependent on climate forecasts and water quality exiting the upstream BHPBIO mine via groundwater. If hypersaline water quality conditions are produced, pit lake will be a groundwater sink, such that saline water and any associated potential metals / metalloids in solution would be confined to the Oxbow West lake. • No modelling undertaken for Oxbow East. Lake is likely to be through flow because Oxbow West as a sink is likely to have a lower head pressure, resulting in water moving from alluvial aquifer through Oxbow East to terminate in Oxbow West. • Preliminary modelling suggested JC would not be hypersaline due to groundwater leakage, i.e. not absolute sink. Further validation of leakage is required. • Geochemical test work suggests hypersaline water quality could create alkaline water conditions, leading to the leaching of metals if pH exceeds ~9. • Geochemical modelling shows that metals are re-sorbed / removed from solution with fresh water addition which reduces pH to <9, e.g. significant rainfall / surface water flows. Further modelling is required to conclude if anticipated regular surface water flow contributions to Oxbow West will prevent / limit pH 9 conditions. • Closure plan for Oxbow West and East pit lakes include minimising potential for biotic activity (i.e. no rehabilitation in pit), to further minimise pathways for metals to move into the environment.	Evapoconcentration processes in Lake Oxbow create highly saline, alkaline water which results in the release of metal contaminates into the lake water at levels that exceed agreed completion criteria. The metals are trapped in the lake water, and are resorbed when the pH is lowered due to fresh water flows from the Oxbow creek into the pit lake.	P				L		II	YA-29. Undertake alkaline leach tests on Yandicoogina waste materials. YA-XX. Update groundwater recovery (level) model to include latest data, Oxbow East and PBS lake scenarios. YA-XX. Develop local scale groundwater model and associated water quality model for JC. Confirm that JC has no hypersaline (as an indicator of potential contamination) water quality risk. YA-XX. Develop local scale (joint) groundwater model and associated water quality model forOxbow East and Oxbow West. Investigate if surface water flow will reduce / eliminate pH 9 conditions or control aqueous metal / metalliod conditions
Human health impacts from in situ fibrous material exposures	• Hazardous fibres exposed in situ by mining, mined and moved to encapsulated areas or naturally present in soils disturbed by mining / rehabilitation activities • Erosion of materials containing hazardous fibres post-closure	• Physical materials characterisation, some fibres present in mineral waste materials, surface alluvials and associated with infrastructure installation (cuts through non-mined geology) • Fibrous materials management plan enacted	• Actinolite in Dolerite intersected during construction of the rail loop, in rail cuttings, F5 canyon and other areas near loop. Exposures around rail loop covered. • Riebeckite/Crocidolite - Weeli Wolli Banded Iron Formation in Central pit. Crocidolite in colluvium Hairpin and Waterstand areas. All intersected potentially fibrous material has been encapsulated. • Fibres (not defined as hazardous, only potential) identified in colluvium / alluvium outside of pit. This material could be disturbed if extensive groundworks undertaken or if erosion management fails. • During pre-closure, progressive rehabilitation and decommissioning, management procedures in accordance with Fibrous Materials Management Plan will need to occur.	Pit wall in junction central area collapses and exposes hazardous fibrous materials after closure.	R	M					II	YA-XX. Before ground disturbance, review potentially hazardous fibrous materials status to resolve areas of hazardous materials. YA-XX. Implement Fibrous Materials Management Plan in designated hazardous fibrous areas

Void management													
Lake and / or lake fringe habitat has undesirable impacts on general ecosystem function.	• Open water bodies in Pilbara naturally attract fauna (feral and native species) for food/ water/ refuge, safe access to water required • Concentration of natural groundwater or mineral waste derived salts through evapoconcentration in open water bodies • Release of metals from natural geology or mineral waste into water (infiltration or groundwater flow) • Water provides opportunity for plant /weed growth, good and bad (toxic algal blooms, noxious weeds) • Certain plant / animal species bio-accumulate / magnify toxic metals • Instability associated with saturated, unconsolidated ground, can be increased by high trafficability	• Void closure management guidance • Geochemical waste characterisation, good understanding of water chemistry / reaction chemistry • Physical waste characterisation • Rehabilitation handbook • Landform design guidance • Safe access to lake edges established via adjacent waste dumps (except Oxbow) • Wetland rehabilitation trial established to review performance of common riparian species and waste dumps when near water table / pit lake • Aquatic fauna research underway to understand natural levels of toxic metal accumulation / impact on native species	• Water models show salinity to be highly variable between lakes. Water quality including high salinities observed to occur naturally in pools, thus some natural tolerance to salinity and associated water quality conditions expected of flora / fauna; although regular flushing of pools means solutes don't build up over long time periods as expected in some lakes. • Integrated water quality modelling across pit lakes is challenging due to computation limits in current models; will need to continue to update models as technology advances to facilitate integrated modelling of water levels and quality at resolutions suitable for local scale impact resolution. • Only Oxbow has potential for undesirably high salinity. Closure plan aims to discourage plant growth in Oxbow, to minimise potential for environmental interactions. • Only flow from PBS lake expected to have interactions with riparian areas outside pit lake and only during large flood events when dilution will reduce saline water. Further study required to understand surface water flood mixing effects. • Full suite of water quality parameter predictions, including nutrients, still to be developed. May require some physical test areas, early development of pit lake, to better understand behaviours / calibrate models. • Fortescue Marsh wetland bird habitat near by. Expect pit lakes to attract avifauna usually attracted to Fortescue. • Predatory fauna species and weeds noted to increase where discharge is occurring. Plan to manage for similar increase on lake fringe compared to undisturbed riparian areas, e.g. in invasive species management plans. • Novel ecosystem needs to be developed to ensure self-sustaining lake fringe vegetation / healthy littoral zone, no identical lake system exists in Pilbara • Specific vegetation requirements to create sustainable lake fringe ecosystem under investigation. Need to understand performance with respect to water availability, sustainable complex, tolerance for metals, biomagnification potential. • Potential to create habitats for high priority species i.e. Northern Quoll, Pilbara Olive Python due to presence of permanent water supply requires investigation. • Aquatic fauna baseline research underway. Tolerance to heavy /toxic metals under investigation. • Investigation required to understand if / how biotic elements need to be introduced to lakes to achieve acceptable ecosystem health. • Egress to lakes via adjacent, rehabilitated waste dump, but stability of waste dumps could be compromised by heavy traffic i.e. cattle	Heavy cattle incursions to access lake water denudes vegetation, destroys habitat and destabilises pit fringe. Due to high water availability and lack of competition, weedy plants take over and vegetate lake fringe. (Possible - Low - Class II) Toxic blue-green algal bloom occurs in pit lake creating anoxic water conditions. Aquatic species in pit lake suffer including fish mortalities. Impact confined to individual lake. (Unlikely - M)	U				M			II	YA-34. Review the available water balance model technology to enable improved prediction of pit lake water levels. YA-31. Confirm groundwater and pit lake quality, and how the water quality will change over time. YA-19. Assess the impacts of flood water flushing of PBS lake on downstream vegetation and fauna (towards Fortescue Marsh) YA-30. Undertake geochemical modelling with groundwater chemistry to understand additional salt loads and other pit lake water chemistry. YA-XX. Consider early development of pit lake at Yandi to study chemical / geochemical / biogeochem water quality evolution / behaviour and use to calibrate models for other lakes YA-13. Undertake research to improve knowledge of rehabilitation of new landforms / habitats, including the best methods for restoration of Pilbara creek habitats / establishment of novel lake fringe ecosystems. YA-38. Undertake rehabilitation trials for different landform and substrate types to inform restoration / rehabilitation plans YA-XX. Integrate results from aquatic fauna heavy metal studies into closure plan YA-17. Assess the ability of pit lake water to sustain aquatic flora and fauna, and support other species. YA-XX. Investigate means to deter feral / unwanted predator species from lake areas

Yandicoogina 2015 closure risk assessment					Risk Evaluation								
Threat Title	Potential causes (Triggers / Indicators)	Existing Controls and Commitments	Site specific overview	Evaluation Rationale (Maximum reasonable consequence)	Likelihood	Health	Safety	Environment On-site	Environment Off-site	Community	Compliance	Risk Management C	Detailed Action Descriptions
Lake poses public liability and / or health risk	• Lake(s) in a location that is easily accessible by the general public e.g. near or visible from a public road • Lake(s) is near an existing attraction e.g. area of cultural significance or tourist attraction • Access to the lake edge is not via a dedicated, safe path • Contaminants well above recreational guidelines • Strongly acidic or alkaline lake water, or releases noxious gases • Toxic algal blooms and / or noxious weeds • Waterborne pests and disease e.g. mosquitos	• Void closure management guidance • Geochemical waste characterisation, mineral waste does not contain toxic minerals • Water quality modelling ongoing, preliminary results identify areas of potential high salinity e.g. Oxbow and JC only • PBS lake designed to encourage flood flushing, to prevent high salinities/ problematic water quality from developing • Mineral waste buttress designed to merge with natural surface to create safe access areas	• Lakes areas are near tourist attractions (Fortescue Marsh, Weeli Wolli Springs) and cultural sites. Camping adjacent to Weeli Wolli Creek occurs in area. Further work required to establish if water will be acceptable for swimming, fishing etc. to inform post-mining land-use. Discussions with stakeholders on post-mining land-use still in progress. • Geochem tests suggest problematic water, i.e. desorption of metals into water, only likely to occur in very high salinities. Water modelling suggests only Oxbow could experience these conditions. • Access to Oxbow area to be discouraged by: making other areas more inviting, vegetation not encouraged to establish in void, safe egress via haul road ramp only, removing access roads through area. Noting that BHPBIO rail access road adjacent to Oxbow is under BHPBIO control. • Rehabilitated waste dumps adjacent to lakes will provide safe access to lake areas, except in Oxbow where safe egress only via haul road ramp. • Healthy lake littoral zones believed to assist in managing public liability health issues. Rehabilitated waste dumps adjacent to lakes provide opportunity to develop lake littoral zones, to encourage development of ecosystem e.g. fish to eat mosquito larvae. Further investigation required to develop site specific public health risks triggers and cross reference with ecosystem health management plans. Further study is required to identify the timeframe to stabilise the lake ecosystems. • Open faces around pits will be bunded, except where surface water flows are required to enter the pits.	Salinity in JC lake reaches hypersaline / alkaline conditions during an extreme drought period and metal levels increase in the water. The resulting water quality causes some skin irritation to public users.	R	L				L	L	II	YA-XX. Understand which characteristics of lake ecosystem health also address / minimise public health risks YA-XX. Predict how the lake ecosystem will evolve, consider timeframe and biodiversity over time
Degradation of regional groundwater quality or levels	• Concentration of natural groundwater or mineral waste derived salts through evapoconcentration in open water bodies • Groundwater flow through pit lake or mineral waste with connection to regional aquifer • Density driven saline groundwater flow from groundwater sink-style pit lakes • Downstream groundwater users (people, plants or animals)	• Void closure management guidance • Environmental surveys include regional groundwater dependent ecosystem • Geochemical waste characterisation and column leach tests • Preliminary integrated ground-surface water modelling (with recovery) completed • Management of mineral waste to minimise surface water area exposed to evapotranspiration, to minimise salinity • Management of closure landforms to influence groundwater flow direction, to trap potential salts in areas with least potential to influence environment i.e. Oxbow West and JC	• Bores downstream of PBS used for pastoral & mining applications. Further downstream water enters Fortescue Marsh which has naturally saline water. • Preliminary integrated groundwater and surface water modelling complete; however, new information of groundwater systems expected to become available to improve model calibration as more boreholes are drilled in Oxbow and PBS areas and dewatering of mine progresses. • Modelling suggests groundwater interaction from former mine area to regional groundwater system will be limited post-closure because most water moving through mine areas will terminate (groundwater sink) at either Oxbow or JC lakes; only PBS groundwater flow expected to leave area. Climate is a strong influencing factor on water balance. • Basic salinity movement accounted for in models. Oxbow expected to have high salinity but with negligible potential for flow to regional aquifer. JC also may have high salinities but there is higher uncertainty as to potential leakage volume to regional aquifer. Further drilling and local water balance modelling are required to confirm leakage to regional aquifer. • Modelling shows leakage from alluvial aquifer to (former) CID aquifer / pit lakes is a major component of water balance. Water levels in alluvial system will recover to approximately pre-disturbance levels with some depressed (lower level) areas surrounding the JC pit. • Integrated water quality modelling across pit lakes is challenging due to computation limits in current models; will need to continue to update models as technology advances to facilitate integrated modelling of water levels and quality at resolutions suitable for local scale impact resolution. • Water quality changes over time could have an impact on stygofauna habitat. Further investigation is required to quantify the long term implications to stygofauna populations as a consequence of the groundwater changes.	Water quality within the PBS pit deteriorates to significantly more than 4000mg/l salt, such that when the salts are carried via groundwater through flow to the downstream bores the water quality within the aquifer exceeds the completion criteria of 4000mg/l and the water can no longer be used for stock drinking water purposes.	R				M	L	M	II	YA-32. Undertake drilling to develop an improved hydrogeological conceptual model that covers areas relevant to the closure plan YA-33. Undertake program (i.e. drilling) to develop a better understanding of surface water and groundwater interactions. YA-37. Review the behaviour of Phil's Creek during mining to understand the amount of leakage, to inform the water modelling YA-34. REPEAT Review the available water balance model technology to enable improved prediction of pit lake water levels. YA-XX. Investigate the long term implications of groundwater quality changes on stygofauna populations

Yandicoogina 2015 closure risk assessment

Threat Title	Potential causes (Triggers / Indicators)	Existing Controls and Commitments	Site specific overview	Evaluation Rationale (Maximum reasonable consequence)	Risk Evaluation: Likelihood	Health	Safety	Environment On-site	Environment Off-site	Environment Community	Compliance	Risk Management	Detailed Action Descriptions
Geotechnical zone of instability compromises closure outcomes	• Influence of erosion, subsidence, seismicity, wall slip • Influence of groundwater recovery and surface water flow on stability. • Creek system neighbouring or within zone of instability, potential stream capture • Ecosystem downstream of void dependent on surface water flows • Poor communication of zone of instability to facilitate identification of important features	• Geotechnical assessments for wall stability and zone of collapse as part of mine design reviews, as required • Pit walls design factor of safety 1.3, geotechnical assessment show zone of collapse for high risk locations (near creeks, infrastructure etc.) • Pit wall in JSW-A, JSW-C (parts of), JSE and PBS pits to be buttressed to manage risk of pit walls adjacent to creek collapsing. • Commitment to rock armour chute / spillway for floodwater expected to flow into PBS pit lake(s) • Conceptual location for abandonment bunds established	• No material available to buttress JC pit lake next to Marillana Creek, but historically wall has performed well. Buttress gap in JSW-C pit wall could be weak point for wall collapse. Further geotechnical assessment is required. • Oxbow pit walls 30m stand-off from tenure boundary. BHPBIO deposit next to Oxbow pits, could complicate stability management. No material available to buttress Oxbow walls. Stand off from BHPBIO rail expected to be sufficient to prevent rail impacts post-mining. Surface water flow over Oxbow pit walls expected, no management proposed currently. Identification of an appropriate location for water flow to enter Oxbow pits is required. • Flood water expected to flow into PBS pit down dedicated 'chute' ramp protected against erosion using rip-rap. Levee can be robbed for stone, but will still need additional stone on closure. Further design work required to confirm location of 'chute' and design after upper benches of pit are established. Location selection to consider natural flow paths for flood water (geomorphology). • Pit areas are compartmentalised to ensure if pit wall collapses and if flooding of pit occurs, only a known, small volume of flow could be captured such that impact to the creek flood regime would be minimal. • Flood levees along the edge of the JSW-A, JSW-C, JC and part of the PBS area will be left in place and integrated into the closure landform e.g. as abandonment bunds and/or flood protection features.	Geotechnical zone of instability expands beyond predicted areas (e.g. JSW-C) and during a flood the creek flows enter the pit. (Flow to Fortescue would not be impacted as maximum volume captured is very small.) Repair of the collapsed wall is required.	U				M		L	II	YA-39. Review the geotechnical stability of pit walls and design requirements for creek supporting structures YA-41. Assess the stability of pit walls adjacent to the BHPB rail and identify a management strategy to ensure continuity of the rail post-closure. YA-XX Identify and manage location for flow of surface water flow into the Oxbow pits. YA-XX Identify and manage location for flow of surface water flow into the PBS pit.
Closure landforms													
Built landforms (excluding mine void areas) erode and / or collapse	• Physical material properties considered in design • Drainage and erosion management • Construction of landforms / waste dumps to design requirements • Sensitive receptors identified downstream	• Physical materials characterisation completed • Waste dumps proposed to be returned to the pit areas • Multi-disciplinary pit and waste dump design sign-off processes, considers landform design guidelines and provides rehabilitation designs where appropriate • Rehabilitation design developed for Phil's Creek landbridge, to reinstate diverted creek flow • RTIO Rehabilitation handbook used for general rehabilitation activities • Rehabilitation designed to be stable without vegetation • Permanent diversion drains identified, prevents flow over reconstructed landforms • Invasive species management plan will be developed as part of decommissioning activities	• All waste dumps are expected to be returned to pit areas. Mineral waste is dominantly alluvium / colluvium and is erodible. • Areas of pits backfilled with mineral waste to near surface are considered closure landforms rather than mine voids i.e. waste fines / tails storage areas, JC initial mining area, JSE, as all above the water table and away from lake fringe. Pit wall edges will still be present, and bunded to prevent inadvertent access over wall but walls are relatively stable and expected to be subject only to minor erosion. • Large landforms associated with ore crushing / processing infrastructure. Rehabilitation designs for these large landforms, constructed from mineral waste but already integrated into landscape, will be required. • Phils Creek to be reconstructed on original alignment before closure (to complete mining in JSW-C pit), and the structure will be modified on closure to ensure long term stability. Conceptual closure design is complete, based on proposed re-instated structure. Longer term geotechnical stability of landbridge still to be proven, this is the first structure of its kind to be built in the Pilbara. Structure likely to be functioning as a creek for ~20 years before closure, providing time to study and correct any issues or modify closure design to accommodate requirements to ensure structure is stable. • Conceptual drainage requirements included in closure plan, including local drainage controls features, retained diversion structure, retention basin etc. Some run-on from local hills may occur in some backfilled areas. Detailed drainage designs to be produced prior to closure. • Capping of waste fines storage facilities proposed. However, review of local surface conditions will be undertaken to determine if a suitable ecosystem can be established without capping and what the drainage management requirement might be. e.g. high soil moisture storage of fines / clays may encourage development of grassland community habitat rather than plains habitat. • Capping of landfill sites included in closure plan. • Monitoring and remediation activities are undertaken after initial construction of areas. • Feral / cattle management required until vegetation is self-sustaining • A re-work factor to remediate erosion that occurs early after landform constructed is included in the closure cost estimate for the site, to ensure adequate resources are available to address issues.	Phils Creek landbridge seepage causes tunnelling, landform slumps and erodes, results in re-work to stabilise and re-instate landbridge. Downstream flows from Phils Creek to Marillana Creek flow into a neighbouring pit lake. Flow down Marillana Creek is continued, but without contribution (small) from Phils Creek.	U			L	L	VL		II	YA-05. Undertake detailed hydrological and engineering assessment to determine the extent of structures required to control erosion. YA-35. Identify sources of backfill material and capping material to achieve closure landform. YA-XX. Undertake regular reviews of the Phils Creek landbridge performance to understand any potential implications to closure, and modify / complete detailed closure design as appropriate. YA-XX. Complete rehabilitation designs for large process / crusher facilities.

Yandicoogina 2015 closure risk assessment					Risk Evaluation								
Threat Title	**Potential causes (Triggers / Indicators)**	**Existing Controls and Commitments**	**Site specific overview**	**Evaluation Rationale (Maximum reasonable consequence)**	**Likelihood**	**Health**	**Safety**	**Environment On-site**	**Environment Off-site**	**Environment Community**	**Compliance**	**Risk Management**	**Detailed Action Descriptions**
Surface treatment on landforms limits vegetation growth	• Availability of top soil stockpile soil / poor stockpile management e.g. soil washed away • Low moisture retention i.e. hydrophobic soils development, very rocky materials • Chemical properties of materials on waste dump / rehab surface e.g. salt circulation, alkalinity	• Physical and geochemical materials characterisation complete. Material is inert and general expected to be acceptable growth media. • Rehabilitation handbook provides direction on surface treatment options • Annual stockpile reconciliation of top soil and sub soil stockpiles, return of 200mm to create quality surface growth media • Wetland rehabilitation trial established, will provide feedback on general waste erosion performance, will look at value of adding mulch	• Waste material is mainly alluvium or colluvium and is good growth material. • Wetland rehab trial has been established to provide some guidance. Opportunity to undertake further rehabilitation after mining ceases in Junction Central pit. • Sufficient soil stockpiled for application of 200mm across disturbed area is predicted. • A re-work factor to improve the surface conditions is included in the closure cost estimate for the site, to ensure adequate resources are available to address issues. • Site has surplus water, which may be used to improve surface conditions and encourage plant growth. A trial would be required to determine if watering re-vegetation (increasing water availability) improves plant growth.	Soil chemical properties inhibit plant development, such that some plants grow but the completion criteria for revegetation are not achieved. Additional surface treatments, i.e. mulch, fertilisers, gypsum etc. are required to support plant growth.	U				L	VL	M	II	YA-XX. Investigate and implement opportunities for rehabilitation trials YA-09. REPEAT Develop (and maintain) a progressive rehabilitation schedule.
Vegetation is not self-sustaining	• Vegetation established, but does not re-seed in same abundance • Weed competition • Species selection / insufficient species diversity • Animal interference i.e. feral animals eating new growth • Changes to soil water conditions e.g. salinity, water logging etc	• Rehabilitation handbook provides guidance on seed selection for appropriate diversity • Top soil stockpiles provide seed bank • Wetland rehabilitation trial established to assist in appropriate species selection for post-closure soil water conditions • Invasive species management plan will be developed as part of decommissioning activities	• Limited revegetation activities have occurred on site as most of the mine area is being actively mined. Most re-vegetation activities will occur at closure. • Wetland rehabilitation trial established at Phils Creek will provide guidance on some species germination and growth performance. • Top soil seed bank may be degraded by the time rehabilitation occur. Expected that additional seed will be sourced from local area to augment seed bank and ensure key species are present. • Seeds tested for germination prior to revegetation. Seeds sourced from reliable suppliers. Seed mix selected by rehabilitation specialists to provide adequate diversity, based on available species at time of rehabilitation. • Most creek disturbance is immediately rehabilitated i.e. rail disturbance, rehab is successful because of fresh topsoil. Creek areas disturbed for roads, drainage etc., can not be immediately revegetated. • A re-work factor to improve vegetation performance is included in the closure cost estimate for the site, to ensure adequate resources are available to address issues.	Species diversity is not sufficient to demonstrate self-sustaining characteristics and re-work is required post-closure to increase diversity to ensure the system is self-sustaining.	U				VL	VL	M	II	YA-14. Investigate creek rehabilitation requirements, considering landform pre-preparation, top soil application and if tube stock is necessary to achieve required outcomes. YA-09. Develop (and maintain) a progressive rehabilitation schedule.
Access through area post-closure poses public liability risk	• Post-closure access / land-use requirements, e.g. for stock, people, heritage, environmental monitoring, adjacent mining activities etc. • Potential for general public to create their own access if appropriate access not provided.	• Regular review and integration of stakeholder feedback into closure plan updates.	• Access roads will be required for long term monitoring. • Access road from Fortescue Marsh to Weeli Wolli Springs is planned to be kept post-closure. It is recognised this road is used by TO's, pastoral station, tourists. The existing road is planned to be moved to facilitate mining at PBS. • Expect general public interest closed mine area is expected to be high, such that tourist 'exploration' through old mine area is likely to occur. Common for tourist information and internet sites to include old mine areas in brochures. • Other mining companies in area that have historically (recent) travelled through the Yandicoogina mine area to connect their mines to port / distribution areas. • Post-mining land use has yet to be resolved. Key stakeholder access needs are still being investigated. • Cultural sites are located all around mine area. TO's likely to create their own tracks if not provided. • Opportunity to investigate methods to control access, where required e.g. discourage cattle access to lake edges, limit general public access to areas where vegetation still establishing.	An access road provided through the area performs badly without regular maintenance e.g. scours, results in a minor car accident. Minor erosion has minimal environmental impact.	U		M		VL	M		II	YA-XX. Engage with key stakeholders to define post-closure land use YA-XX. Identify what mine features key stakeholders want to be retained, including access roads. YA-XX. Review liability of retention of mine features and agree where ownership of liability for retained features will be transferred. YA-36. Consider the landscape design requirements for the repatriation of cultural artefacts back into the closure landform. YA-XX. Review the design of retained featured, i.e. roads, to ensure they are fit for purpose. YA-XX. Investigate and implement infrastructure options to prevent / discourage access use of retained access routes, i.e. for monitoring, where appropriate.

Yandicoogina 2015 closure risk assessment					Risk Evaluation								
Threat Title	Potential causes (Triggers / Indicators)	Existing Controls and Commitments	Site specific overview	Evaluation Rationale (Maximum reasonable consequence)	Likelihood	Health	Safety	Environment On-site	Environment Off-site	Community	Compliance	Risk Management	Detailed Action Descriptions
Other regional considerations													
Environmental outcomes outside of disturbance areas do not align with approved environmental impacts	• New (previously unidentified) environmental sites, not considered in existing environmental impact assessment • Changes to environmental conditions due to cessation of artificial support / mitigation activities, e.g. water supplementation • Change to drainage patterns on closure e.g. removal of temporary diversions, drains etc.	• Internal ground disturbance approval request system to prevent inadvertent disturbance • Baseline biological / ecosystem health surveys and existing monitoring to define post-mining status • GIS system includes results from all flora, fauna, vegetation surveys • Operational management plan for discharge includes actions relating to water quality and discharge extent targets (proximity to Fortescue Marsh), to ensure environmental issues are managed during operations • Significant species management plan implemented during operation to minimise impact to select species • Vegetation management plan implemented during operations to monitor and manage impacts to vegetation (riparian, understorey and weeds)	• Pools artificially sustained by discharge will dissipate and return to natural conditions post-mining. It is recognised that some species may be displaced (localised environmental 'impact') as these changes occur, i.e. change of current diversity and abundance as the system returns to pre-disturbance environmental conditions. This change will occur early in the pre-closure phase. • Environmental conditions and land use are expected to be very different from the pre-mining conditions, including the introduction of permanent water bodies and altered groundwater levels (lower than pre-mining) closer to pre-disturbance conditions. Pre-disturbance, pre-mining and current environmental conditions provide some guidance as to potential environmental outcomes in the region. However, there are no similar systems present in the Pilbara. As such the measures that define a healthy ecosystem will need to evolve overtime. • Salts from the PBS lakes will be flushed into the Weeli Wolli Creek during very large (100 year) flood events. These salts will be deposited in Fortescue Marsh. Impacts to the ecosystem are expected to be minimal due to flood dilution. Deposition of the salts in the already saline salt Marsh is not expected to have an impact.	The cessation of discharge along Weeli Wolli Creek results in some plant death as vegetation assemblage adapts to reduced water availability. The plant death makes the banks for susceptible to erosion during large flood events and parts of the current creek bank are washed away during a large flood event.	P			VL	L			II	No further action required at this time.
Adverse impact to flora or fauna with conservation status or wider regional impact to high value environment	• Scheduled, listed or declared rare and / or threatened species of flora or fauna present in/adjacent to site - Pilbara Olive Python, Northern Quoll, Lepidium, • Downstream regional area of high value - Fortescue Marsh • Environmental conditions post-closure differ significantly from pre-mining conditions • Post-mining land use differs from pre-mining land use	• Internal ground disturbance approval request system to prevent inadvertent disturbance • Baseline biological / ecosystem health surveys and existing monitoring to define post-mining status • GIS system includes results from all flora, fauna, vegetation surveys • Operational management plan for discharge includes actions relating to water quality and discharge extent targets (proximity to Fortescue Marsh), to ensure environmental issues are managed during operations • Significant species management plan implemented during operation to minimise impact to select species • Vegetation management plan implemented during operations to monitor and manage impacts to vegetation (riparian, understorey and weeds)	• Pools artificially sustained by discharge may currently be utilised by Pilbara Olive Python, although no increases in Python numbers in the area have been observed as a result of increased pool habitat. Pools expected to return to natural size, frequency and duration. No impact to Python is anticipated. • The long term impacts of the changed post-mining ecosystem and post-mining land use on species of significant and conservation significance is yet to be quantified. Basic understanding of impacts to stygofauna understood, but final conclusions based on detailed water outcomes required. Monitoring and management plans will need to be updated during the decommissioning study to address species of conservation significance, to demonstrate closure outcomes are as predicted. • Downstream impacts to Fortescue Marsh have been quantified and negligible impact is expected. Flood water regime will be preserved. Monitoring will be required to demonstrate the closure outcomes are as predicted.	The post-closure ecosystem attracts increased numbers of feral predators which decrease the number of conservation significant fauna species through predation. Direct action / management to reduce predator numbers would be required to assist species recovery.	U				H	M	M	III	YA-18. Assess the impacts of closure implementation on groundwater dependent vegetation. YA-12. Assess impacts of closure implementation on stygofauna populations. YA-XX Assess impacts of closure implementation on species of conservation significance.

Yandicoogina 2015 closure risk assessment					Risk Evaluation								
Threat Title	**Potential causes (Triggers / Indicators)**	**Existing Controls and Commitments**	**Site specific overview**	**Evaluation Rationale (Maximum reasonable consequence)**	**Likelihood**	**Health**	**Safety**	**Environment On-site**	**Off-site**	**Environment Community**	**Compliance**	**Risk Management**	**Detailed Action Descriptions**
Heritage site condition / cultural value is degraded as a result of implementing the closure plan	• New (previously unidentified) heritage sites, not considered in existing assessment, discussions, agreements or with authority to disturb • Changes to landforms on closure have potential to alter conditions at downstream sites, e.g. consider drainage, landform footprint, erosion implications • Cessation of maintenance of / to heritage site	• Internal ground disturbance approval request system • GIS system includes results from heritage surveys • Heritage sites within mine area, S18 application etc. prior to disturbance • Ongoing consultation with Traditional Owners	• Many heritage sites identified throughout area, concentrated along creeks and noted high significance area near confluence of Marillana and Weeli Wolli Creeks. The environmental quality of the creek systems is closely linked to Traditional Owner cultural values. • Creek functions have been preserved as part of closure strategy. This is expected to preserve the cultural value associated with the creeks. • Change in groundwater levels at confluence of Marillana and Weeli Wolli Creek could led to change in vegetation complex during mining or after mining. It is unclear if the change would alter cultural values.	Change in vegetation complex near ethnographic site is viewed unfavourably by Traditional Owners	P					L		II	YA-21. Finalise the Yandicoogina Cultural Heritage Management Plan (to include closure strategies) and implement it as a working document. YA-23. Undertake a gap analysis to identify areas requiring heritage survey and areas of significance which should be avoided and managed. YA-24. Undertake heritage surveys as required (ethnographic and archaeological) with the traditional owners. YA-27. Consult with the traditional owner group regarding specific water values.
Stakeholders Consultation													
Consultation fails to identify stakeholder concerns	• Large number of stakeholders in the project • Clarity of explanation / prediction of closure outcomes, communication styles, long term engagement of agreed outcomes through generational change. • Stakeholder expectations change over time, due to changing global benchmarks for mine rehabilitation success, intergenerational change, regulatory changes etc. • Stakeholders do not endorse site closure as their issues / concerns were not addressed	• RTIO stakeholder engagement practice with key stakeholders i.e. Traditional Owner M&L, etc. • Ad hoc consultation with key stakeholders • Detailed engagement planned during decommissioning study • Stakeholder engagement register	• Key regulators already engaged in discussions. There is a lack of clarity surrounding regulator expectations for pit lakes, and a new guidance note is expected to be released from EPA. Review of the new EPA pit lake guidance with respect to Yandicoogina is required. • DoW have acknowledged the difficulties of water modelling and are willing to work with Rio Tinto to resolve water outcomes in greater detail. Future updates to the groundwater recovery models and water balance salinity models will need to be discussed with DoW. • Gumala TO's already engaged in discussions, have expressed some concerns with regards to water quality. Completion criteria for water quality have been established and discussed with TOs. It is recognised that due to the length of time between opening and closing the mine, TOs will need to be engaged on a regular basis to ensure opinions of current Elders are acknowledged and new opinions of the next generation of TOs are integrated into the closure planning process. • Local Government aware of development, but have not been engaged in closure outcomes or long term public liability / management that could evolve if mining tourism to area becomes fashionable. It is likely that Local Goverment will need to be engaged in discussions regarding post-mining land-use.	Stakeholder perceptions change over time and the predicted outcomes based on the current closure plan are no longer accepted, such that substantial changes to the closure strategy are required.	R					M	L	II	YA-XX Review regulatory advice regarding pit lakes, identify any gaps in plan and update accordingly YA-25 Maintain regular comunication with Gumala and wider TO stakeholders through directed, closure specific enagement sessions. YA-XX Engage Local Government to understand their requirements for mine closure.
Key stakeholder expectations													
Closure outcomes do not meet stakeholder(s) / community expectations	• Absence of rehabilitation trial or data to support predicted outcomes, closure activties fail to achieve completion criteria • Communication of anticipated closure outcomes and post-closure land use needs i.e. wrong plant species established • Unrealistic expectations for economic potential opportunities / post-closure land use capability i.e. aquiculture in pit lakes	• RTIO stakeholder engagement practice with key stakeholders • Monitoring established for water, rehabilitation trials started • Numerical completion criteria established for some aspects	• Limited data available to define numerical targets and / or confirm criteria can be achieved. Opportunity to modify completion criteria over time, following stakeholder consultation • Significant water modelling complexity makes it difficult to provide accurate predictions, technology not yet advanced to provide integrated predictions. • Communication with stakeholders is ongoing and evolving i.e. development of 3D visual aids, maps, cross-sections • Post-closure land use proposes to return to natural ecosystem as land use capability for post-mining land will be limited. It is recognised that underlying tenure is Pastoral land-use, which is not compatible with post-mining landforms. Risks associated with cattle considered as part of landform design, but resolution and agreement of post-closure land-use still pending • Traditional Owners suggest they will use created lakes post-closure.	Completion criteria is still not achieved 15 years after decomissioning activities were finished. Remediation and additional environmental management is required to achieve acceptable standard for relinquishment.	U					M	M	M	II	YA-01. Confirm that the mine plan and schedule can deliver a closure landform that aligns with closure objectives. YA-42. Conduct & communicate visual amenity assessment of final landform options

Yandicoogina 2015 closure risk assessment

Threat Title	Potential causes (Triggers / Indicators)	Existing Controls and Commitments	Site specific overview	Evaluation Rationale (Maximum reasonable consequence)	Risk Evaluation: Likelihood	Health	Safety	Environment On-site	Environment Off-site	Community	Compliance	Risk Management Category	Detailed Action Descriptions
A stakeholder's expectations conflict with that of another stakeholder, causing delays to plan approval and / or closure	• Conflicting stakeholder expectations or areas of authority e.g. different regulators for environment, heritage, health, economic, tourism • Conflicting legal obligations e.g. State Agreement and EPA • Interactions between catchment land uses, including mining developments, at different points in time	• RTIO stakeholder engagement practice with key stakeholders	• Uncertainty associated with BHPBIO Yandi mine upstream of Oxbow. Activities will have direct impact on options / success of closure at Oxbow. Need to seek clarity regarding BHPBIO activities. • Pastoral Station requirements are unknown, but conflict with post-mining land-use capability at Yandicoogina. It is unclear if Yandicoogina is legally obliged to return land to conditions compatible with pastoral land-use. Need to better understand how State regulators, especially Dept State Development, envisage post-mining land development.	A mining tourism campaign centred on Weeli Wolli Creek is undertaken by a third party and increases tourist traffic to the Yandicoogina area. Rubbish left behind by tourists encourages and increases feral animals numbers, placing environmental values (i.e. priority species) at risk.	U				M	L	M	II	YA-07. Consult with BHPBIO to ascertain compatibility of closure strategies with the BHPBIO Yandi mine. YA-07. Consult with BHPBIO to ascertain compatibility of closure strategies with the Marillana Station (owned by BHPB). YA-XX. Consult with DSD with regards to wider development expectations for post-mining land-use.
Closure strategy prevents or limits future exploitation of resources	• Backfill sterilises ore reserves • Lakes or habitat restoration prevent / limit future access to adjacent resources	• RTIO stakeholder engagement practice with key stakeholders • Integration of potential Billiards North expansion deposits into current closure plan options	• Backfill is part of closure strategy and will cover some resources. Future exploitation of the resource will be possible but will require excavation of mineral waste, dewatering and creek diversions (high cost). • An alternate closure strategy to facilitate access to Billiards North and Braid deposits has been considered as part of the closure planning.	Closure strategy prevents access to future mineralisation and expansion, requires closure strategy to be re-negotiated with stakeholders.	U					L		I	YA-XX. Refine closure strategy to include Billiards North and other deposits during Billiards North mining studies
Other expectations													
Mine closure has a significant, long-term detrimental impact on local communities	• Local communities receive direct support from operation for basic community services e.g. doctor • Significant proportion of community are directly or indirectly employed by operation		• Work force is dominantly Fly In- Fly Out and has little interaction with local communities, includes employees and services. No long term detrimental economic impacts to communities from mine closure are anticipated. • TOs receive some financial support associated with mine development.	Local community develops a dependence on revenue / support from Yandicoogina between now and mine closure, some transitional support is required.	R					VL		I	YA-XX. Review impact of closure on local communities (part of decommissioning scope)
Obligations Agreements and commitments													
Closure is not implemented in accordance with the approved closure plan	• Mine development changes prevent closure plan from being implemented as planned • Closure plan proves to be overly challenging to implement or implementation results in a different outcome than anticpated	• Integration of closure plan with LoM report	• Closure plan requires 3 yearly updates, will ensure closure plan remains current with respect to mine developments • The closure requirements have been embedded into the Life of Mine report and are communicated to the Business every 18 months. • Regulator inspection are expected to occur throughout the remaining mine life, potential for regulators to also raise concerns if they identify an aspect that may be in conflict with the intent of the closure plan.	Regulator identifies an inconsistency in closure implementation. Site/stakeholder engagement, updates to the closure plan and potentially re-work is required to ensure an acceptable closure outcome.	R					L	M	II	YA-XX. Review closure aspects with each Life of Mine plan update, to ensure implementation aligns with agreed strategy. YA-XX. Update the closure plan and seek approval for an alternative or modified closure strategy when signficant changes are anticipated to occur on site YA-XX. Send closure plan to regulators for review every three years.

APPENDIX F

31. Appendix F Closure issues identification tracker

The following closure tasks have been completed and the results integrated into the closure plan OR have been retired as the task is no longer relevant to the current strategies or the task is now adequately managed through a standard work practice.

Ref	Issue	Action	Status	Comment
YA-3	Closure landform	Undertake drilling to determine ore quality in currently un-mined areas.	Complete	-
YA-4	Water	Develop a closure water model to predict impacts of the channel configuration.	Complete	2011 Hydrogeology modelling
YA-6	Cultural heritage	Undertake heritage surveys across the length of the Yandicoogina mining operation, including currently undisturbed and un-surveyed areas along creek lines, to identify cultural heritage implications of the channel configuration and closure plan	Retired	Channel configuration no longer strategy Closure plan reviewed through task YA-24
YA-8	Other	Confirm the channel configuration as the preferred closure option, or develop an alternative option if required.	Complete	Alternative developed
YA-20	Cultural heritage	Finalise site salvages audit and register, and implement a method to maintain and update data.	Retired	Action is part of a standard work practice
YA-22	Cultural heritage	Undertake an annual review of Heritage approval consents and ensure statutory obligations and conditions have been met.	Retired	Action is part of a standard work practice
YA-26	Cultural heritage	Regularly update RTIO and DAA heritage site and report registers with new information on sites (recording, salvage etc) in the Yandicoogina mine area.	Retired	Action is part of a standard work practice
YA-30	Contaminants	Undertake geochemical modelling with groundwater chemistry to understand additional salt loads and other pit lake water chemistry	Retired	Action has been split into multiple stages
YA-31	Water	Confirm groundwater and pit lake quality, and how the water quality will change over time.	Retired	Action has been split into individual lakes
YA-15	Biodiversity	Establish faunal reference sites, and commence monitoring faunal assemblages	Retired	Operational control. Part of Monitoring program (not current action)

1 INTRODUCTION

1.1 Background

The Rio Tinto Iron Ore (RTIO) mine at Yandicoogina (Yandi) is located in the East Pilbara region of Western Australia. A number of temporary creeklines traverse the mine area, including Marillana, Yandicoogina, Phil's and Weeli Wolli creeks. The mine has been operating since 1996, and as part of mine operations dewatering of the Yandi Junction South East (JSE) and Central pits has been necessary since 1998, with excess water discharged directly into Marillana Creek (via discharge outlets D02, D03, D05 & D08), and more recently into Weeli Wolli Creek near JSE (via discharge outlet D06). Discharge varies between months and years, but volumes of 12.23, 11.62 and 14.00 GL/year were discharged into Marillana Creek in 2012, 2013 and 2014, respectively (see Table 1).

Rio Tinto is developing three new deposits at Yandi Junction South West (JSW-A & JSW-C) and Yandi Oxbow. Rio Tinto is also proposing to develop the Pocket and Billiard South deposit. Additional dewatering and discharge operations are necessary as part of these developments as around 95% of the ore occurs below the water table. As part of these current developments, discharge at Yandi has been rationalised and, since April 2013, now occurs primarily via a new discharge outlet (D09), located on Marillana Creek approximately 3 km upstream of the Weeli Wolli Creek confluence, and at the existing D06, directly into Weeli Wolli Creek, from JSE. Some discharge still occurs through D02, D03, D05 and D08 adjacent to the operations plant on Marillana Creek, in order to support riparian vegetation and stygofauna communities in this area (see Figure 1 for discharge outlet locations).

Rio Tinto baseline hydrological modelling indicates that under maximum potential discharge, approximately 37 - 43 GL/annum will be discharged. This equates to 99 - 115 ML/day, but will ultimately depend on dewatering discharge rates by BHPBIO's Yandi operations located further upstream on Marillana Creek. Under this maximum discharge scenario, surface flow is modelled to extend from discharge point D09 on Marillana Creek, into Weeli Wolli Creek and up to 17 km downstream of the Weeli Wolli-Marillana Creek confluence (Figure 1).

Additional discharge into Marillana Creek occurs upstream of Rio Tinto's Yandicoogina mine, at BHP Billiton Iron Ore's (BHPBIO) Yandi mine. This mine has been in operation since 1994, and also dewaters their developing pit, with excess dewatering water discharged into the upstream section of Marillana Creek. Downstream of these mining operations, Marillana Creek flows into Weeli Wolli Creek (see Figure 1). Rio Tinto's Hope Downs 1 (HD1) operation is located on Weeli Wolli Creek approximately 20 km upstream of the confluence with Marillana Creek, and HD1 also discharges surplus dewatering water into Weeli Wolli Creek. In 2014, Hope Downs 1 discharged a combined total (via spurs and gabion) of 38 GL into Weeli Wolli Creek. Since late 2007, excess water from Rio Tinto's Yandicoogina operations has also been discharged into Weeli Wolli Creek (from discharge outlet D06; see Figure 1 for discharge location). In 2014, a total of 14.94 GL was discharged from Rio Tinto's Yandicoogina operations directly into Weeli Wolli Creek, upstream of the Marillana confluence and adjacent to the JSE pit (Table 1). Including discharge from all outlets into both creeklines, a combined total of 28.94 GL was discharged to the environment (Marillana and lower Weeli Wolli creeks) by Rio Tinto Yandicoogina operations in 2014 (Table 1). This is up from 25.16 GL in 2013 and 19.61 GL in 2012 (Table 1).

This cumulative dewatering discharge has the potential to affect the health of aquatic ecosystems in the downstream receiving environments of Marillana Creek and lower Weeli Wolli Creek. Potential effects include changes to water quality and to duration and magnitude of flow, as well as changes in macroinvertebrate assemblages with flow-on effects to higher trophic levels, including fish. The JSW development also requires realignment of Phil's Creek (a tributary of Marillana Creek), as well as the construction of flood protection levees within the margins of the creek which will reduce the width

of the creekline. These activities also have the potential for downstream impacts, including increased erosion and turbidity.

Table 1. Volume (GL) discharged from Rio Tinto's Yandicoogina into Marillana Creek and Weeli Wolli Creek between 2010 and 2014.

	Discharge outlet into Marillana Creek						Discharge into Weeli Wolli	Total discharged into Marillana & lower WW creeks
Year	DO2	DO3	DO8	DO5a+b	DO9	Total	DO6	
2010	1.20	0.95	2.93	4.11		9.19	7.41	16.60
2011	2.29	2.61	3.38	4.52		12.80	7.41	20.21
2012	1.10	2.56	2.94	5.63		12.23	7.38	19.61
2013	1.09	1.92	3.10	0.42	5.09	11.62	13.54	25.16
2014	1.05	0.92	2.81	2.12	7.10	14.00	14.94	28.94

The specific and cumulative effects of these operations on Marillana and Weeli Wolli creeks need to be assessed. Therefore, Rio Tinto commissioned *Wetland Research and Management* to undertake a study of the aquatic biota of Marillana Creek and lower Weeli Wolli Creek. The purpose of this was to a.) assess specific effects of Rio Tinto's (and BHPBIO's) Yandi current operations on Marillana Creek, and b.) provide data that supports the HD1 Living Water Survey, to assess Cumulative Impacts on the Weeli Wolli system. To this end, the study area was broken into three reaches of differing discharge regimes to document current ecological condition. The three study reaches were;

1.) Reach One – Marillana Creek downstream of BHPBIO's discharge but upstream of Rio Tinto's Yandi discharge. This covers zones 1, 2 and partially covers zone 5 from Ministerial Statement 914

2.) Reach Two – Marillana Creek downstream of Rio Tinto's Yandi discharge to the extent of surface flows (now approx. 0.25 km upstream of the confluence with Weeli Wolli). This covers zones 2a, 3, 4 and 5 from Ministerial Statement 914.

3.) WW-Five – Weeli Wolli Creek downstream of the previous extent of surface flows (WW-Four) and downstream of the Weeli Wolli-Marillana confluence. Monitoring this reach commenced during the wet season of 2012, to capture the impacts of the extended surface flows along Weeli Wolli Creek as a result of discharge from the JSW orebody. This covers zone 3a from Ministerial Statement 914.

This report presents the findings from two rounds of sampling at both Marillana and Weeli Wolli creeks during October 2013 (late dry) and April 2014 (late wet). Comparisons are made to earlier datasets collected bi-annually since October 2008. Data from the dry-13 and wet-14 sampling rounds reflect the effect of changes in discharge volumes and locations associated with the development of JSW and Oxbow.

1.2 Study objectives

The aim of this study was to:

- document current ecological condition of Marillana Creek and lower Weeli Wolli Creek with respect to water quality and aquatic biota assemblages (microinvertebrates, macroinvertebrates, hyporheic fauna[1] and fish),
- assess the current effects of Rio Tinto's Yandicoogina mine and any change over time, and
- provide data to feed into a Cumulative Impacts study of the Weeli Wolli system.

[1] Aquatic invertebrate fauna which reside in the alluvium below the streambed where water percolates through spaces between the rocks and cobbles.

2 SURVEY METHODS

2.1 Compliance

There are no specific guidance statements for undertaking aquatic fauna surveys. However, field surveys employed sampling design, methods and general approaches consistent with the following:

- Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC/ARMCANZ 2000);
- Environment Protection Authority (EPA) Guidance No. 20, Sampling of Short Range Endemic Invertebrate Fauna for Environmental Impact Assessment in Western Australia (EPA 2009);
- EPA Position Statement No. 3, Terrestrial Biological Surveys as an Element of Biodiversity Protection (EPA 2002);
- EPA Guidance No. 56, Terrestrial Fauna Surveys for Environmental Impact Assessment in Western Australia (EPA 2004).

Aquatic fauna sampling by WRM is consistent with methodology used by government and Universities for similar surveys, including the Pilbara Biological Survey (i.e. Pinder *et al.* 2010) and National Monitoring River Health Initiative (Department of Environment Sport and Territories *et al*. 1994).

This study was conducted under Fisheries Licence EXEM 2314 (Instruments of Exemption to the Fish Resources Management Act 1994 for Scientific Research Purposes) and DPaW Licences SF009111 and SF009720 (Reg. 17; Licence to Take Fauna for Scientific Purposes). As a condition of these licences, taxa lists and reports are required to be submitted to the respective authorities.

Surveys were undertaken in the late dry (29th October - 3rd November) of 2013 and late wet season of 2014 (8th - 13th April). Sampling during the wet and dry seasons allows seasonal changes in fauna composition to be characterised, and provides a more comprehensive record of species present than sampling in a single season.

2.2 Sites and sampling design

Marillana Creek was stratified into two reaches, reflecting differences in mining operations and discharge:

- Reach One - downstream of BHPBIO's Yandi discharge and upstream of Rio Tinto's Yandi discharge,
- Reach Two - downstream of Rio Tinto's Yandi discharge as far as perennial surface flows reach (just upstream of the confluence with Weeli Wolli) (Figure 1).

Weeli Wolli Creek was also stratified into separate reaches of differing historic flow regime. Five reaches along Weeli Wolli Creek have been sampled, including:

- Reach One - in the area of Weeli Wolli Spring where permanent pools historically were located,
- Reach Two - within the reach of historic permanent flow downstream of the spring,
- Reach Three - downstream of this point to the junction with Marillana Creek, where the creek historically was highly ephemeral and dry for much of the year, and
- Reach Four - the now permanent reach below the Marillana Creek confluence towards the Fortescue Marsh (WRM 2013a)

- Reach Five – ephemeral pools located downstream of Reach Four. This reach was added to the sampling program prior to the May 2012 survey in order to collect baseline data for the development of the JSW and Oxbow deposits at Rio Tinto's Yandi (see Figure 1). The additional discharge from these developments is expected to increase the current extent of surface flows along Weeli Wolli Creek by approximately 4 km, depending on volumes discharged and response of the system. The cumulative increase to the surface water footprint will be a further 5 to 9 km from the current extent if BHPBIO's Yandi, Rio Tinto's Yandi and HD1 all discharge at their maximum licensed rates. As such, it was necessary to collect baseline data from pools further downstream than Reach Four.

The sampling design aimed to take six replicate samples within each reach (depending on water availability) to characterise the fauna and conditions along each reach, and to provide adequate statistical power to allow statistical testing of differences between reaches and at a reach over time. Replicates were located to provide a geographical spread within each reach, but positions were also influenced by access (Figure 1). A number of sites on Marillana Creek were dry and unable to be sampled during previous sampling events (i.e. wet-10). This was due to a break in discharge from BHPBIO's Yandi and lack of wet season rainfall at this time. In addition, MAR1-4, MAR1-5 and MAR1-6 were all dry during the dry-13. Sites located in the upper reach of Marillana Creek Reach Two (MAR2-1 through to MAR2-3) were not sampled during the current study due to changes in the dewatering discharge regime at Rio Tinto's Yandi. Sites in this reach have been moved progressively downstream, and now number MAR2-4 through to MAR2-9 (see section 3.1 for a more detailed explanation of changes to sampling sites).

Site photographs are provided in Appendix 1.

2.3 Field sampling

Sampling in the dry-13 and wet-14 was conducted using the same methods as those used in previous years along Marillana and Weeli Wolli creeks. Details and rationale are provided in previous reports (i.e. see WRM 2014a). In summary, methods used were as follows:

- *In situ* measurement of dissolved oxygen (DO), water temperature (^{o}C) and pH was made using hand-held WTW and TPS field meters (Plate 1).

- Water samples were collected for laboratory analyses of major ions, alkalinity, dissolved metals and nutrients. Samples for nutrients and dissolved metals were filtered in the field through 0.45 µm Millipore nitrocellulose filters. All sample bottles and filtering gear were acid-washed (0.1% nitric acid) prior to use, double-wrapped in polyethylene bags after collection, with samplers wearing nitrile gloves at all times. All water samples were kept cool in an esky while in the field, and either refrigerated (ions & metals), or frozen (nutrients) as soon as possible for subsequent transport to the laboratory. All laboratory analyses were conducted by the ChemCentre, Bentley, WA (a NATA accredited laboratory). All water quality variables measured are summarised in Table 2.

- Qualitative visual observations of habitat characteristics were made at each site to assist in explaining any patterns in faunal assemblages in relation to possible discharge effects. WRM have standard worksheets for this task so that recordings between sites remain as comparable as possible. Habitat characteristics recorded included proportional (%) cover by inorganic sediment, submerged macrophyte, floating macrophyte, emergent macrophyte, algae, large woody debris, detritus, roots and trailing vegetation. Details of substrate composition were also recorded and included percent cover by bedrock, boulders, cobbles, pebbles, gravel, sand, silt and clay.

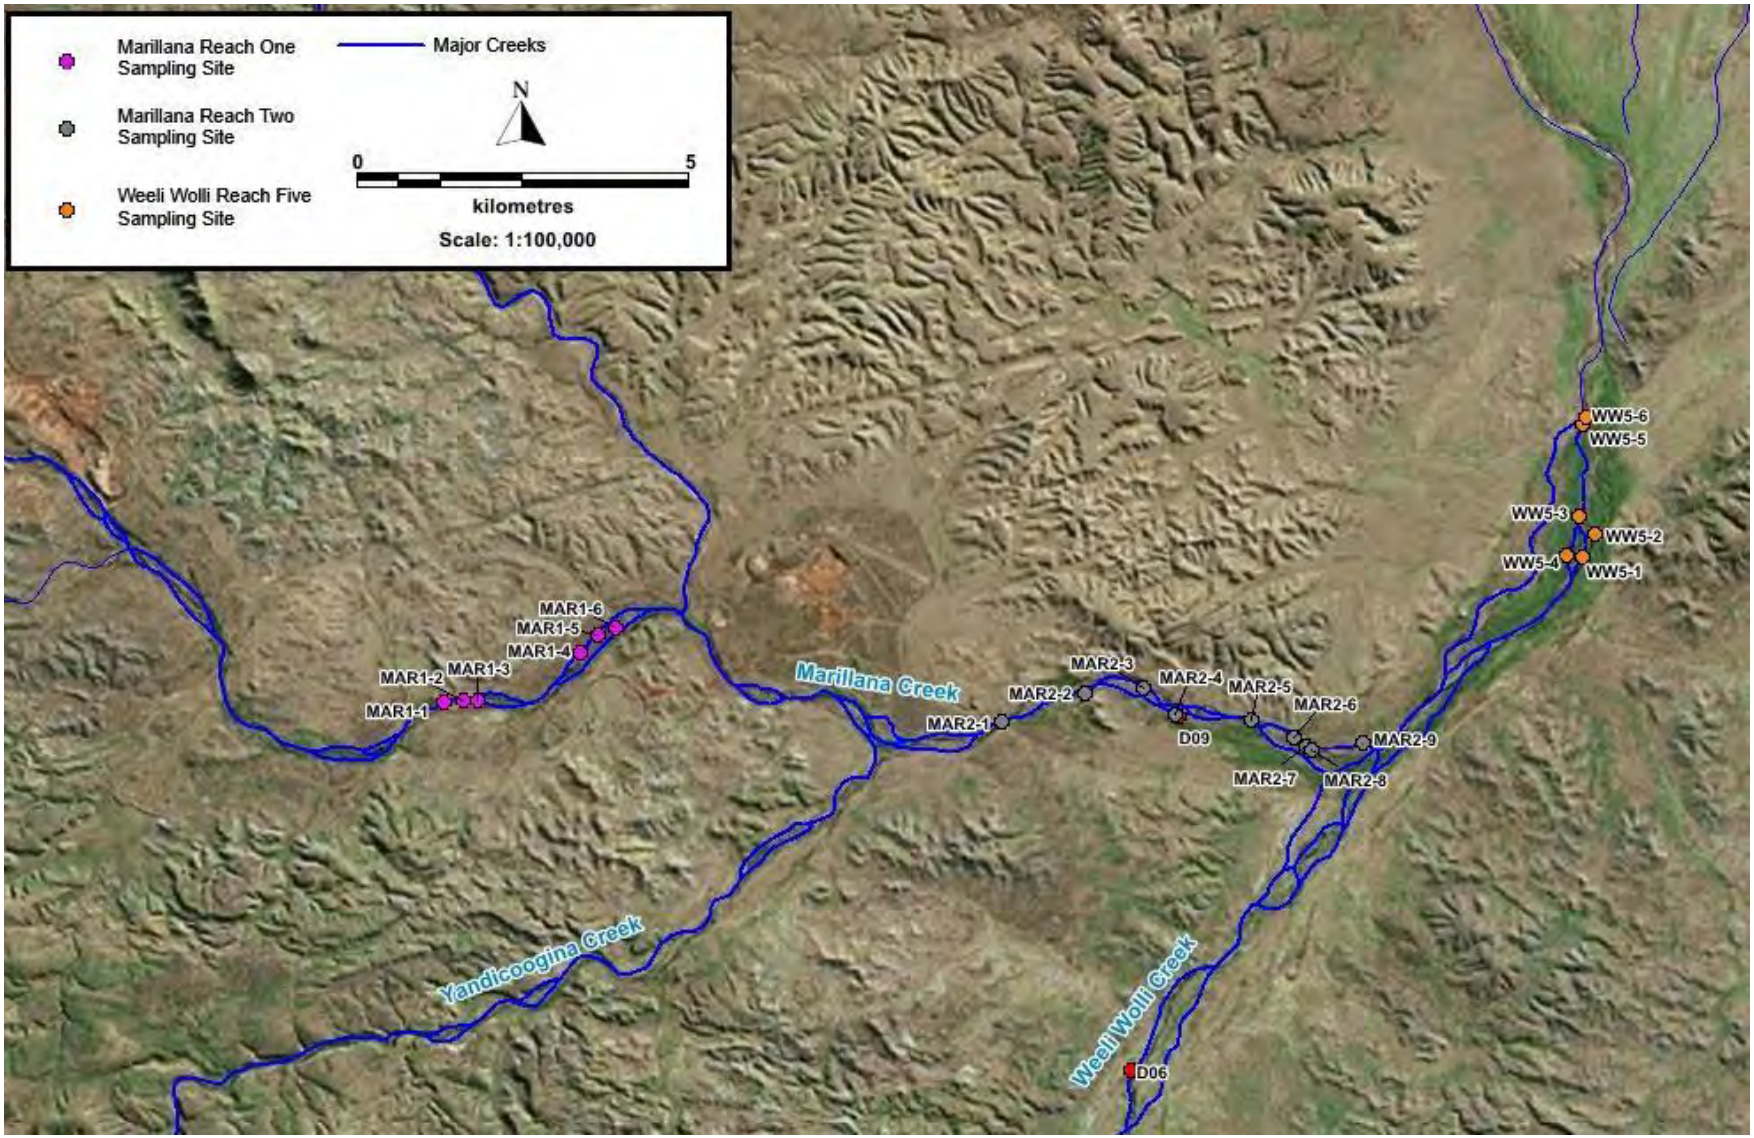

Figure 1. Location of all reaches and sampling sites along Marillana Creek and Weeli Wolli Creek.

Table 2. All water quality parameters measured.

Parameter	*Units*	*Parameter*	*Units*
In situ		***Dissolved metals***

Total Phosphorus (total P)	mg/L	Turbidity	NTU

- Microinvertebrates (i.e. zooplankton) were collected from the water column using a 53 µm mesh pond net to sweep over a standard 15 m distance at each site. Samples were preserved in 70% ethanol for laboratory enumeration and identification. Samples were processed by identifying the first 200-300 individuals encountered in an agitated sample decanted into a 125 mm^2 gridded plastic tray, with the tray then scanned for additional missed taxa also taken to species, and recorded as 'present'. Specimens were identified to the lowest taxon possible, *i.e.* species or morphotypes.

- Hyporheic fauna were collected using the Karaman-Chappuis method (Delamare Deboutteville 1960). This involved digging a hole (30 cm deep x 40 cm diameter) in alluvial gravels adjacent to the water's edge (see Plate 1). The hole was allowed to fill with water percolating through the gravel and swept with a small 110 µm mesh hand-net.

Plate 1. Using the portable TPS pH meter at MAR2-5 (left), and hyporheic sampling at WW5-5 using the Karaman-Chappuis method (right). Photos by WRM ©.

- Benthic macroinvertebrates were collected using a 250 µm mesh pond net. In order to allow comparisons to be made between sites, a standardised sampling approach was adopted, whereby 10 m of riffle habitat was selectively sampled at each site. This standardised for habitat and avoided issues with greater fauna diversity due to greater habitat diversity on any reach. Each sample was washed through a 250 µm sieve to remove fine sediment, while leaf litter and other debris were carefully washed into the sieve and then discarded. Samples were preserved in 70% ethanol for laboratory enumeration and identification. Collected specimens were then identified to the lowest possible level (genus or species level) and enumerated to log10 scale abundance scale (*i.e.* 1 = 1 individual, 2 = 2 - 10 individuals, 3 = 11 – 100 individuals, 4 = 101-1,000 individuals, *etc.*).

- Fish were sampled using a number of methods, including seine netting, gill nets, dip nets and electrofishing. Electrofishing was conducted with a Smith-Root Model LR24 battery powered backpack electrofisher. Light-weight fine mesh gill nets (10 m net, with a 2 m drop, using 10 mm, 13 mm, 19 mm and 25 mm stretched mesh) were used at each site and were set in deeper water for the duration of sampling at that site. Smaller species and juveniles were sampled by beach seine (10 m net, with a 2 m drop and 6 mm mesh) deployed in shallow areas where there was little vegetation or large woody debris. Generally, two hauls of the seine were conducted at each site to maximise the number of individuals caught. Fish were identified in the field, with standard length[2] (SL) measurements taken, and then released alive.

2.4 Data analysis

All data collected were entered into Excel 2010 spreadsheets.

In order to undertake analyses on faunal data (hyporheic fauna and macroinvertebrate fauna), previous data were amalgamated, and taxonomy was aligned to enable temporal comparisons of taxa richness. This meant that some recent species-level identifications were reverted to genus

[2] Standard length (SL) - measured from the tip of the snout to the posterior end of the last vertebra or to the posterior end of the midlateral portion of the hypural plate (i.e. this measurement excludes the length of the caudal fin).

level, due to updates in taxonomic knowledge and development of new dichotomous keys for some groups (e.g. species of Oligochaeta, Baetidae mayfly and Lepidoptera moth larvae).

2.4.1 Assessment of conservation significance of fauna

The conservation significance of all aquatic fauna recorded was assessed using established lists of conservation fauna. For invertebrates, reference was made to the IUCN Redlist of Threatened Species (IUCN 2014) and DPaW Threatened and Priority Fauna List (DPaW 2013b). Fish species were compared against the IUCN Redlist of Threatened Species (IUCN 2014), DPaW Threatened and Priority Fauna List (DPaW 2013b), and Australian Society for Fish Biology Conservation List (ASFB 2001). Reference was also made to other Pilbara studies, as well as databases such as The Australian Faunal Directory, The Australian National Insect Collection Database and in-house WRM database for distribution and occurrence information for all aquatic species.

2.4.2 Hyporheic fauna classifications

All taxa recorded from hyporheic samples were classified using Boulton's (2001) categories;

- stygobite – obligate groundwater species, with special adaptations to survive such conditions,
- permanent hyporheos stygophiles - epigean[3] species which can occur in both surface- and groundwaters, but is a permanent inhabitant of the hyporheos,
- occasional hyporheos stygophiles – use the hyporheic zone seasonally or during early life history stages, and
- stygoxene (species that appear rarely and apparently at random in groundwater habitats, there by accident or seeking refuge during spates or drought; not specialised for groundwater habitat).

2.4.3 Univariate analysis

Univariate statistics were performed using SPSS software (Version 19.0 for Windows). Independent samples were used as replicates and two-way analysis of variance (ANOVA) was applied to test for significant differences in species richness of microinvertebrates, macroinvertebrates and hyporheos fauna, and abundance of fish between reaches and years, for each season separately. Two-way ANOVA was also undertaken on environmental data (water quality and habitat characteristics). Any data recorded in percentages were arcsin transformed (proportions) prior to analysis.

A Levene's test was used in the first instance to test for equality of variances (Levene 1960). Data were log transformed where necessary. Tukey's post-hoc tests were utilised in the case of significant differences to locate reach and/or year differences.

To examine change over time in water quality and taxa richness (all faunal groups), regression analysis was undertaken in Excel 2010 for each season separately. Trendlines were fitted for each reach, and r-values and statistical significance determined to assess whether there was a significant linear trend over time. In addition, Spearman Rank Correlation was also undertaken to assess the strength of association between ranked variables (time vs water quality or biotic variables) in the case where relationships over time may not have been exactly linear.

3 Epigean – living or occurring on or near the surface of the ground.

2.4.4 Multivariate analysis

Multivariate analyses were performed using the PRIMER package v 6 (**P**lymouth **R**outines in **M**ultivariate **E**cological **R**esearch; Clarke and Gorley 2006) to investigate differences in water quality and aquatic fauna assemblages (macroinvertebrates, microinvertebrates and fish age-classes) across reaches and years, for each season separately. Relationships between faunal assemblages and physico-chemical characteristics were also examined. The PRIMER package, developed for multivariate analysis of marine fauna samples, has been applied extensively to analysis of freshwater invertebrate data. Multivariate analyses were conducted on all data collected since 2008. Analyses applied to the data included some or all of the following:

1. Describing pattern amongst the fauna assemblage data (macroinvertebrates and microinvertebrates) using ordination techniques based on Bray-Curtis similarity matrices (Bray and Curtis 1957). The clustering technique uses a hierarchical agglomerative method where samples of similar assemblages are grouped and the groups themselves form clusters at lower levels of similarity. A group average linkage was used to derive the resultant dendrogram. Similarity matrices for environmental data were based on the Euclidean Distance Measure, and environmental data were log transformed, where necessary, and standardised prior to analyses.
2. To examine whether there were any spatial differences in environmental and/or biotic data between reaches, canonical analysis of principal coordinates (CAP) was undertaken within the PERMANOVA add-on in PRIMER. This test finds axes through the multivariate cloud of points that either (i) are the best at discriminating among *a priori* groups (discriminant analysis) or (ii) have the strongest correlation with some other set of variables (canonical analysis) (Anderson and Robinson 2003, Anderson *et al.* 2008). The CAP analysis produced an ordination and vectors corresponding to Spearman Rank Correlations >0.5 (i.e. of water quality variables or individual species) were superimposed on this ordination.
3. Permutational multivariate analysis of variance (PERMANOVA) was undertaken (two-factor crossed design) to determine whether there was any significant difference in environmental or biotic data (i.e. microinvertebrate, macroinvertebrate fauna assemblages and fish age-class structures) between reach and year (Anderson 2001a, b, McArdle and Anderson 2001, Anderson and ter Braak 2003, Anderson *et al.* 2008).
4. The relationship between the environmental (water quality and habitat) and biotic data was assessed using the BVSTEP routine. This was used to calculate the minimum suite of parameters that explain the greatest percent of variation (i.e. the parameters which most strongly influence the species ordination).
5. Change in water quality and species assemblages over time were further assessed graphically by plotting distance to “baseline” centroid (being the initial sampling event). This created a plot showing change in similarity with “baseline” data over time. Values for water quality were based on Euclidean distances, and values for species assemblages based on Bray-Curtis percent similarity. Plots were prepared for each season separately.

In order to analyse the fish data using these multivariate techniques, each species was first split into ‘pseudo-species’ based on age-classes. Total abundances of each ‘pseudo-species’ were then analysed in PRIMER. Age-classes used in these analyses were estimated from the literature (see section 3.7.4 and Table 14).

3 RESULTS AND DISCUSSION

3.1 Sites affected by current construction and development

A number of Marillana Creek aquatic monitoring sites had undergone considerable change in channel morphology and characteristics between the wet-13 and dry-13 sampling events due to construction associated with developments at Yandicoogina. These changes are detailed below:

New locations for MAR1-2 and MAR1-3

Dewatering associated with the JSW development, along with the construction of a haul road across MAR1-2, meant that the site is now dry and can no longer be used as a sampling point. MAR1-3 was similarly impacted by dewatering, with the site being dry during the dry-13 sampling round and signs of senescence of emergent vegetation apparent. As such, two new sites were established upstream of the old MAR1-2 site to ensure a total of six monitoring sites remain available for sampling now and in the future: MAR1-2, located 0.3 km downstream of MAR1-1, and MAR1-3, located 0.5 km upstream of the haul road at the old MAR1-2 site.

Changes in Marillana Reach Two

Due to changes associated with Yandicoogina's dewatering and discharge operations, pools at MAR2-1, MAR2-2 and MAR2-3 have all dried and no longer contain water associated with discharge (they may still hold water at various times due to intense rainfall associated with cyclonic activity). Since the development of JSW commenced, the majority of discharge now occurs via the D09 outlet located further downstream, with discharge outlets upstream of MAR2-1 being no longer in use. Discharge from the new D09 outlet was clearly affecting the creek in the vicinity of MAR2-4, immediately downstream, creating a broader area of water within the channel (Plate 2). In order to replace impacted sites upstream of the D09 discharge, three new sites downstream of MAR2-6 were established: MAR2-7, MAR2-8 and MAR2-9 (Plate 3).

Plate 2. Images showing the influence of the D09 discharge at MAR2-4 (left) and the new MAR2-7 site established downstream of MAR2-6.

Plate 3. The new MAR2-8 (left) and MAR2-9 (right) sites established downstream of MAR2-6.

3.2 Water quality

Water quality data were compared against ANZECC/ARMCANZ (2000) water quality guidelines, using default trigger values (TVs) for physical and chemical stressors applicable to tropical northern Australia. Water quality data was also compared against site-specific TVs (SSTVs) (WRM 2013b). SSTVs were developed by WRM for Marillana Creek Reaches One and Two, with different SSTVs developed for Weeli Wolli Creek Reach Five. This was necessary because Weeli Wolli Creek in this reach has slightly different water chemistry to Marillana Creek upstream (WRM 2013b).

3.2.1 Dry-13 and Wet-14

Dissolved oxygen (DO)

Daytime dissolved oxygen ranged from 20.6% (at WW5-1) to 129.4% (Mar2-7) during dry-13, and 22.1% (MAR1-1) to 150.6% (MAR2-9) during wet-14 (Figure 2). DO values were outside ANZECC/ARMCANZ (2000) guidelines at a number of sites in both seasons (i.e. below 85% or above 120%; Figure 2). DO values at MAR1-1, MAR2-6 and MAR2-8 during the dry season, and MAR1-1 and MAR1-4 during the wet season were below lower SSTVs for Marillana Creek (62%). DO values at WW5-1, WW5-2 and WW5-4 during the dry season, and WW5-4 during the wet season were below lower SSTVs for Weeli Wolli Creek Reach Five (85%). Low DO concentrations can be caused by high biological oxygen demand (BOD) and the decomposition of algae, which consumes oxygen in the process. Many sites which exhibited low daytime DO were either standing pools, or had sluggish flow passing between pools (e.g. MAR2-8, MAR1-4 and WW-Five sites during the dry season). MAR1-1 also had a large amount of decomposing algae in dry-13, so low oxygen levels would not be unexpected.

Conversely, DO levels recorded from MAR2-7 and MAR2-9 in dry-13, and MAR1-3, MAR2-5, MAR2-9 and WW5-2 in wet-14 were considered super-saturated, i.e. < 120% (Figure 2). Super-saturation occurs when net photosynthesis exceeds total oxygen consumption, and is common in areas of high algal and macrophyte growth, and/or areas of high turbulence (e.g. riffle zones). Sites from which super-saturated DO was recorded are likely to experience oxygen stress overnight, when respiration by plants, algae and fauna depletes oxygen levels. Super-saturation is also known to cause gas bubble disease in fish (Bouck 1980). However, the oxygen needs of aquatic biota differ between species and between life history stages.

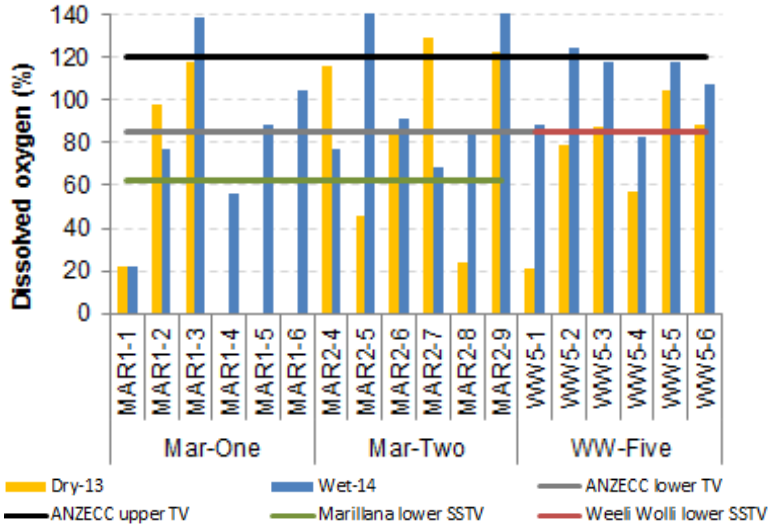

Figure 2. Dissolved oxygen (%) recorded from Marillana and lower Weeli Wolli Creeks in the dry-13 and wet-14, in comparison to ANZECC/ARMCANZ (2000) TVs and SSTVs. NB: Upper SSTVs were equivalent to the ANZECC upper TVs.

pH

pH was circum-neutral to basic, ranging from 7.2 (MAR2-4) to 7.9 (MAR1-3) in the dry-13, and 7.2 (MAR2-4) to 8.7 (WW5-3) in the wet-14. Although a number of pH values were recorded in excess of ANZECC/ARMCANZ (2000) upper TVs (> 8), Weeli Wolli Creek SSTVs were only exceeded at WW5-3 during the wet-14 (8.74).

Electrical conductivity (EC)

All sites were classified as "fresh" as defined by the DoE (2003)[4]. In the dry-13, EC ranged from 847 µS/cm (MAR2-4) to 1040 µS/cm (MAR1-1 & WW5-2; Figure 3). During the wet-14, EC ranged from 825 µS/cm (MAR2-9) to 941 µS/cm (MAR1-2 & MAR1-5). In both seasons, EC at all Marillana Creek sites was in excess of ANZECC/ARMCANZ (2000) guidelines. However, only at MAR1-1 and MAR1-2 were Marillana Creek SSTVs exceeded, both in the dry-13. EC at all WW-Five sites exceeded ANZECC/ARMCANZ (2000) TVs and SSTVs in both seasons. Naturally, surface waters in arid/semi-arid zones exhibit more concentrated electrical conductivity in the dry season, as a consequence of high evaporation levels and low rainfall. Although some dilution occurs following wet season rains, salinity can often remain high due to the variability of flows and flushing of stored salts (Jolly *et al.* 2008).

Alkalinity

Dry season alkalinity ranged from 202 mg/L (MAR2-4) to 337 mg/L (WW5-2), while in the wet-14 it varied between 217 mg/L (MAR2-9) and 281 mg/L (WW5-1). SSTVs were exceeded at MAR1-1 (306 mg/L), WW5-2 (337 mg/L) and WW5-3 (317 mg/L) in the dry season. No alkalinity value from either Marillana Creek or Weeli Wolli Creek Reach Five exceeded SSTVs in the wet season. Alkalinity of less than 20 mg/L is considered low; under these conditions, water is poorly buffered, and the removal of carbon dioxide during photosynthesis can result in rapidly rising pH (Sawyer and McCarty 1978,

[4] Fresh defined as < 1500 µS/cm, Brackish = 1500 – 4500 µS/cm, Saline = 4500 – 50,000 µS/cm, Hypersaline > 50,000 µS/cm (DoE 2003). Classifications were presented as TDS (mg/L) in DoE (2003) so a conversion factor of 0.68 was used to convert to conductivity µS/cm as recommended by ANZECC/ARMCANZ (2000).

Romaire 1985, Lawson 2002). As such, current results indicate the buffering capacities of Marillana Creek and Weeli Wolli Reach Five are good.

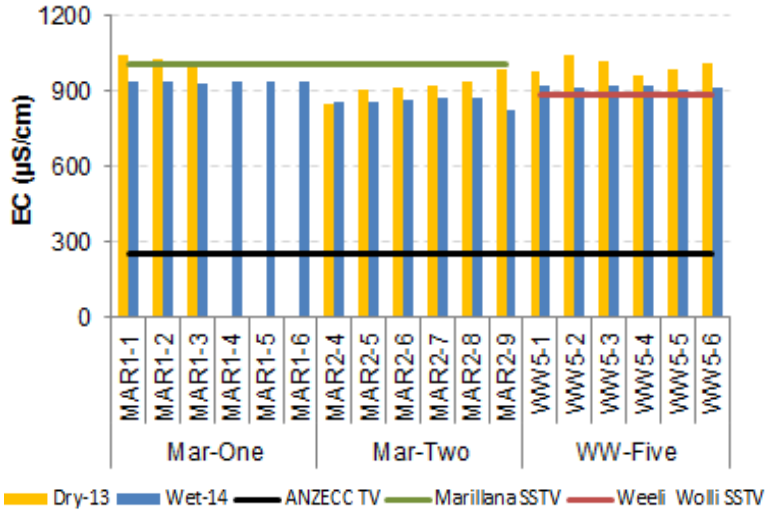

Figure 3. Electrical conductivity (µS/cm) recorded from Marillana and lower Weeli Wolli Creeks in the dry-13 and wet-14, in comparison to ANZECC/ARMCANZ (2000) TVs and SSTVs.

Ionic composition

The ionic composition of Marillana Creek was dominated by sodium cations and bicarbonate anions (generally in the order $Na^+ > Ca^{2+} > Mg^{2+} > K^+ : HCO_3^- > Cl^- > SO_4^{2-} > CO_3^-$). This was consistent between seasons and there was no difference between reaches (Appendix 3). There was some difference in the sub-dominance of cations, with some sites having higher concentrations of calcium and others magnesium. The sub-dominance of cations at a site varied between seasons. In contrast, the composition of major ions at Weeli Wolli Creek was generally dominated by calcium and bicarbonate, with some differences in the sub-dominance of cations along the length of the creek, i.e. $Ca^{2+} > Mg^{2+} > Na^+ > K^+ : HCO_3^- > Cl^- > SO_4^{2-}$ in the upper reaches, and $Ca^{2+} > Na^+ > Mg^{2+} > K^+ : HCO_3^- > Cl^- > SO_4^{2-}$ at the downstream Reach Four. There were some differences in the composition of ions between sites within WW-Five, with some sites being similar to WW-Four and being dominated by $Ca^{2+} > Na^+ > Mg^{2+} > K^+ : HCO_3^- > Cl^- > SO_4^{2-}$ (i.e. WW5-5 and WW5-6), and others being in the order $Na^+ > Ca^{2+} > Mg^{2+} > K^+ : HCO_3^- > Cl^- > SO_4^{2-}$ (i.e. WW5-1; Appendix 3).

Nutrients

Nutrient levels varied greatly between reach and season, however concentrations were consistently high at the site located at the D09 discharge outlet (MAR2-4) and generally decreased in concentration in a longitudinal gradient from this point downstream (Figure 4).

During the dry-13, nitrogen oxides (N_NOx) ranged from concentrations less than detection limits (< 0.01 mg/L at WW5-5) to 0.4 mg/L (MAR2-4). Wet season N_NOx ranged from less than detection (WW5-5) to 1.8 mg/L (MAR1-3 & MAR2-4). N_NOx concentrations were above ANZECC/ARMCANZ TVs at the majority of sites in both seasons, and Marillana Creek SSTVs for protection against eutrophication (1.16 mg/L[5]) were exceeded at MAR1-1, MAR1-2, MAR1-3 and MAR2-4 during the

[5] The Marillana Creek SSTV for N_NOx of 1.16 mg/L (WRM 2013b), acknowledges that background levels are already elevated compared to the ANZECC/ARMCANZ (2000) default TV for N_NOx of 0.01 mg/L for lowland rivers, and 0.03 mg/L for upland rivers. As minimal historic data exist, data used to derive SSTVs were collected from Marillana and Weeli Wolli creeks after commencement of dewatering discharge from BHPIO Yandi (in

wet season. Weeli Wolli Creek SSTVs (0.16 mg/L) were exceeded at WW5-2 and WW5-6 in the dry-13, and WW5-1 and WW5-3 in the wet-14 (Figure 4).

Since the development of the SSTVs, it is now understood that the ANZECC/ARMCANZ (2000) default 95% TV for NO_3 (as a toxicant) of 0.7 mg/L (= 0.16 mg/L N_NO_3) is too conservative (R. van Dam, ***eriss***, pers. com.). The new ANZECC/ARMCANZ nitrate TV (95% species protection) will be around 2 - 2.5 mg/L N_NO_3 (R. van Dam, ***eriss***, pers. com.). As such, the nitrate toxicity SSTVs for Marillana Creek and lower Weeli Wolli Creek were revised in the recent Hazard Analysis to 2.5 mg/L N_NO_3 (WRM 2015a). Given that nitrate is generally the largest component of N_NOx, the values recorded during the current study would not exceed the new revised nitrate toxicity SSTV.

Total nitrogen (total N) ranged from 0.1 mg/L (MAR2-9) to 0.4 mg/L (MAR2-4) in the dry-13, and 0.02 mg/L (WW5-5) to 1.8 mg/L (MAR2-4) in the wet-14 (Figure 4). ANZECC/ARMCANZ (2000) TVs (0.3 mg/L) were exceeded at most sites in each season, while Marillana Creek SSTVs (1.2 mg/L) were exceeded at MAR1-1, MAR1-2, MAR1-3 and MAR2-4 in the wet season (Figure 4). Total N concentrations were above Weeli Wolli Creek SSTVs (0.3 mg/L) at a number of WW-Five sites in both seasons (Figure 4).

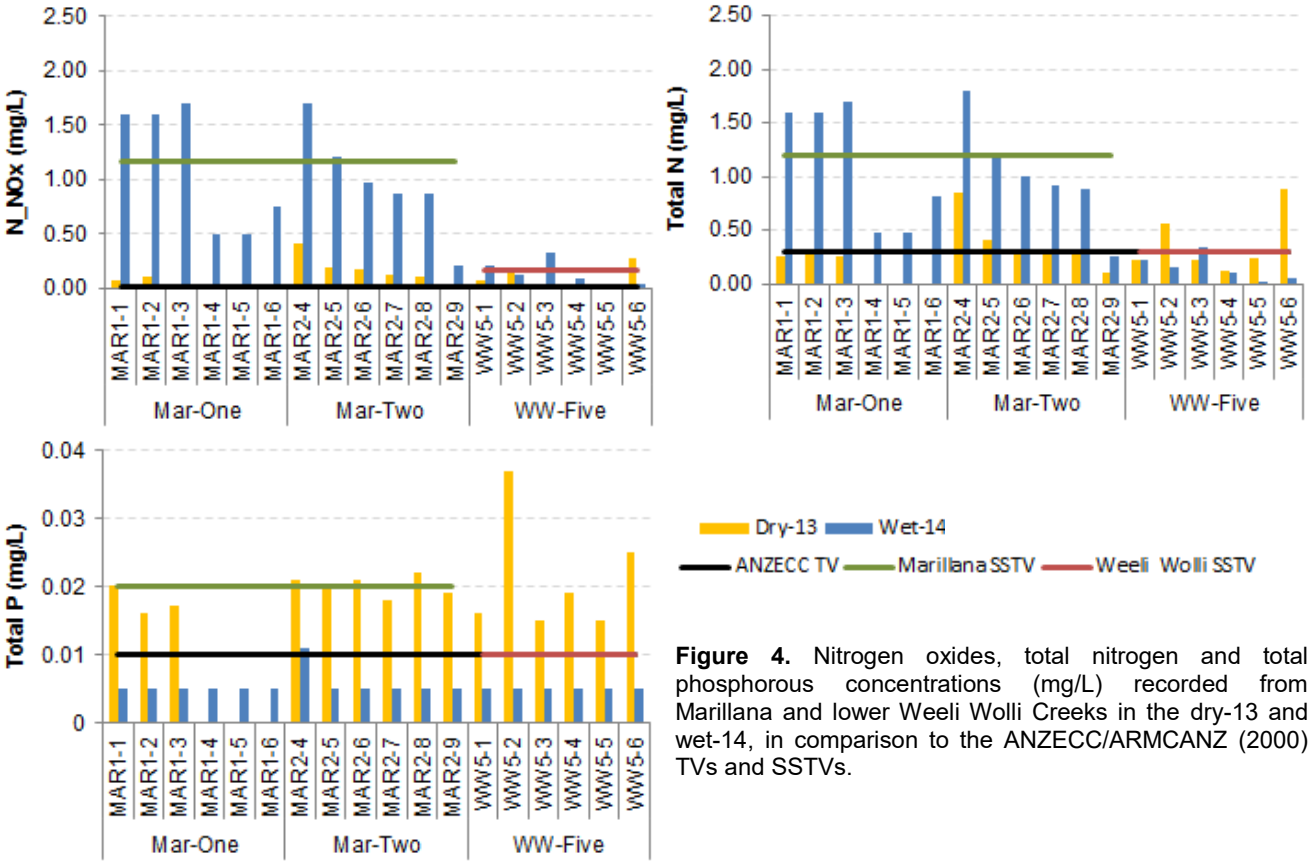

Figure 4. Nitrogen oxides, total nitrogen and total phosphorous concentrations (mg/L) recorded from Marillana and lower Weeli Wolli Creeks in the dry-13 and wet-14, in comparison to the ANZECC/ARMCANZ (2000) TVs and SSTVs.

Wet season total phosphorous (total P) concentrations were below detection limits at all sites (> 0.01 mg/L), with the exception of MAR2-4 (0.011 mg/L), where they exceeded ANZECC/ARMCANZ (2000) guidelines but not Marillana Creek SSTVs (Figure 4). In the dry-13, total P concentrations were in excess of ANZECC/ARMCANZ (2000) TVs at all sites, and Marillana Creek SSTVs at MAR2-4 (0.021

1994), Junction Central (in 1998), JSE (in 2006) and HD1 (in 2007). While not necessarily indicative of pre-development condition, the SSTVs are indicative of current background levels in the creeks.

mg/L), MAR2-6 (0.021 mg/L) and MAR2-8 (0.022 mg/L). Concentrations of total P were greater than Weeli Wolli Creek SSTVs at all WW-Five sites in the dry season (Figure 4).

Elevated concentrations of N_NOx, total N and total P downstream of MAR2-4 in both seasons was likely due to groundwater discharge from the D09 outlet. Historically, a longitudinal gradient in nutrient levels was observed along Marillana Creek Reach One, with concentrations of N_NOx, total N and total P declining with distance downstream from MAR1-1 (WRM 2012). The cause of this was linked to discharge from the BHPBIO Yandi mine upstream of MAR1-1, with a reduction of nutrient levels downstream due to assimilation by emergent macrophytes and algae. It appears that discharge of groundwater from JC, JSE and JSW via D09 may be having a similar influence on surface waters of Marillana Creek Reach Two, with Figure 4 presenting a longitudinal gradient of nutrient concentrations downstream of MAR2-4. Analysis of data from bores in the JSW and Oxbow deposits did indicate some nutrient enrichment of groundwater of this region (WRM 2013b). Elevated nutrient levels at some lower Weeli Wolli Creek sites were likely due to the large numbers of cattle which often congregate in this reach.

Metals

Concentrations of dissolved metals were generally low, however, dissolved boron (dB) and dissolved zinc (dZn) were elevated above 99% ANZECC/ARMCANZ (2000) guidelines at a number of sites (Figures 5 & 6). dB concentrations greatly exceeded the 99% ANZECC/ARMCANZ (2000) TVs (0.09 mg/L) at all sites both the dry and wet seasons (Figure 5). At MAR1-1, MAR1-2 and MAR1-3, dry season dB concentrations were also above 95% ANZECC/ARMCANZ (2000) TVs and SSTVs (0.37 mg/L[6]). Elevated concentrations of dB have been widely recorded from surface waters across the Pilbara, including the Fortescue River, Kalgan Creek, Marillana Creek, Mindy Mindy Creek, Coondiner Creek, Caves Creek and Duck Creek (WRM, unpub. data).

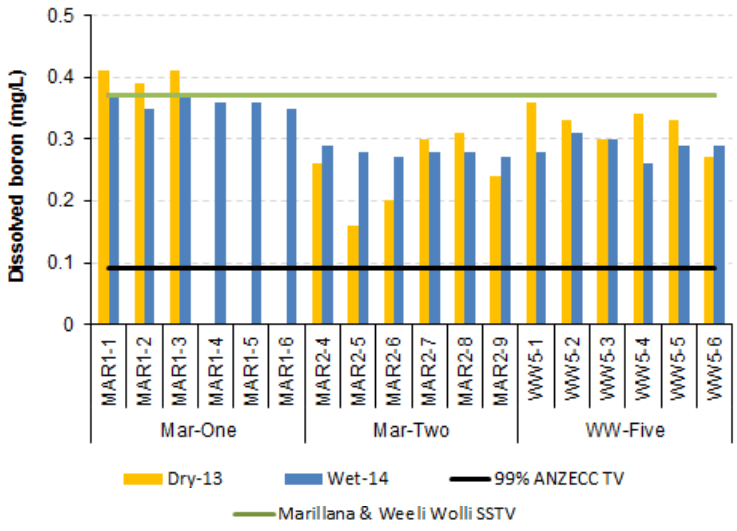

Figure 5. Dissolved boron concentrations (mg/L) recorded from Marillana and lower Weeli Wolli Creeks in the dry-13 and wet-14, in comparison to the ANZECC/ARMCANZ (2000) TVs and SSTVs.

Concentrations of dZn were in exceedance of 99% ANZECC/ARMCANZ (2000) guidelines at all Marillana Creek sites, and at Weeli Wolli Creek sites WW5-1 and WW5-6 during the dry-13 (Figure 6). In the wet-14, dZn concentrations from five sites along Marillana Creek (MAR1-1, 1-3, 2-4, 2-5 & 2-9)

[6] The SSTVs for dB and dZn were the same for both Marillana Creek and lower Weeli Wolli Creek, and equivalent to the 95% ANZECC/ARMCANZ (2000) TV (WRM 2013).

and four sites along Weeli Wolli Creek Reach Five (WW5-1, 5-2, 5-4 & 5-6) were above the 99% ANZECC/ARMCANZ (2000) TV (Figure 6). Water hardness is known to affect the toxicity of some dissolved metals, including zinc, where greater 'softness' places biota at increased risk, whilst greater water hardness may ameliorate toxicity (Markich *et al.* 2001, Charles *et al*. 2002). ANZECC/ARMCANZ (2000) provide algorithms to calculate trigger values for such metals which take hardness into account. As such, given the high water hardness at Marillana and lower Weeli Wolli Creek, the hardness modified trigger values (HMTVs) were considerably higher than default ANZECC/ARMCANZ guidelines[7] and SSTVs (Figure 6). Taking into account baseline conditions, as well as water hardness, dZn concentrations did not exceed the hardness modified site-specific TVs at any site in either season.

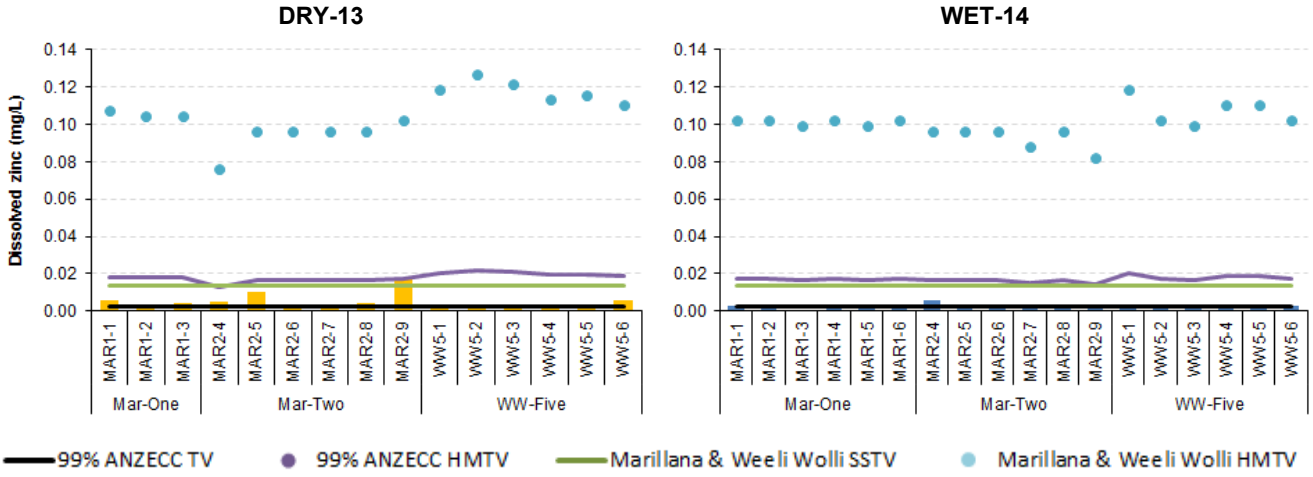

Figure 6. Dissolved zinc concentrations (mg/L) recorded from Marillana and lower Weeli Wolli Creeks in the dry-13 (left) and wet-14 (right), in comparison to the ANZECC/ARMCANZ (2000) trigger values, SSTVs, and HMTVs. NB: the SSTV was the same for both Marillana and lower Weeli Wolli creeks (0.014 mg/L).

3.2.2 Temporal changes in water quality

Temporal changes in water quality can be summarised as follows:

- There was no significant difference in pH between reach in either season. Dry season pH was significantly higher in 2011, compared to all other years, while wet season pH was also highest in 2011. There was a significant decline in Mar-Two pH between the wet seasons of 2009 and 2014 (p = 0.01, r = 0.93, Spearman p = 0.01; Figure 7).
- Dry season water temperature was highest in 2013, though this was statistically similar to that recorded in 2008. Wet season water temperature was highest in 2014, though statistically similar to 2010. Mar-One recorded significantly lower dry season water temperature than either downstream reach (Mar-Two or WW-Five). There was no significant linear relationship between temperature and time at either Marillana reach in either season (Figure 7).
- Significantly higher dry season EC was recorded in 2010, compared to all other years. EC was also significantly higher in the wet season of 2010 (though this was statistically similar to 2009 & 2013). In both seasons, EC was significantly higher from Mar-One compared to Mar-Two and WW-Five. There was no change in dry or wet season EC over time at either Mar-One or Mar-Two (Figure 7).

[7] Hardness modified trigger value considers the effect of hardness ($CaCO_3$) in freshwater on toxicity when deriving a trigger value using the appropriate algorithm. Algorithms for dissolved zinc HMTV = zinc 99% TV*(hardness / 30) $^{0.85}$, or SSTV HMTV = zinc SSTV*(hardness / 30) $^{0.85}$.

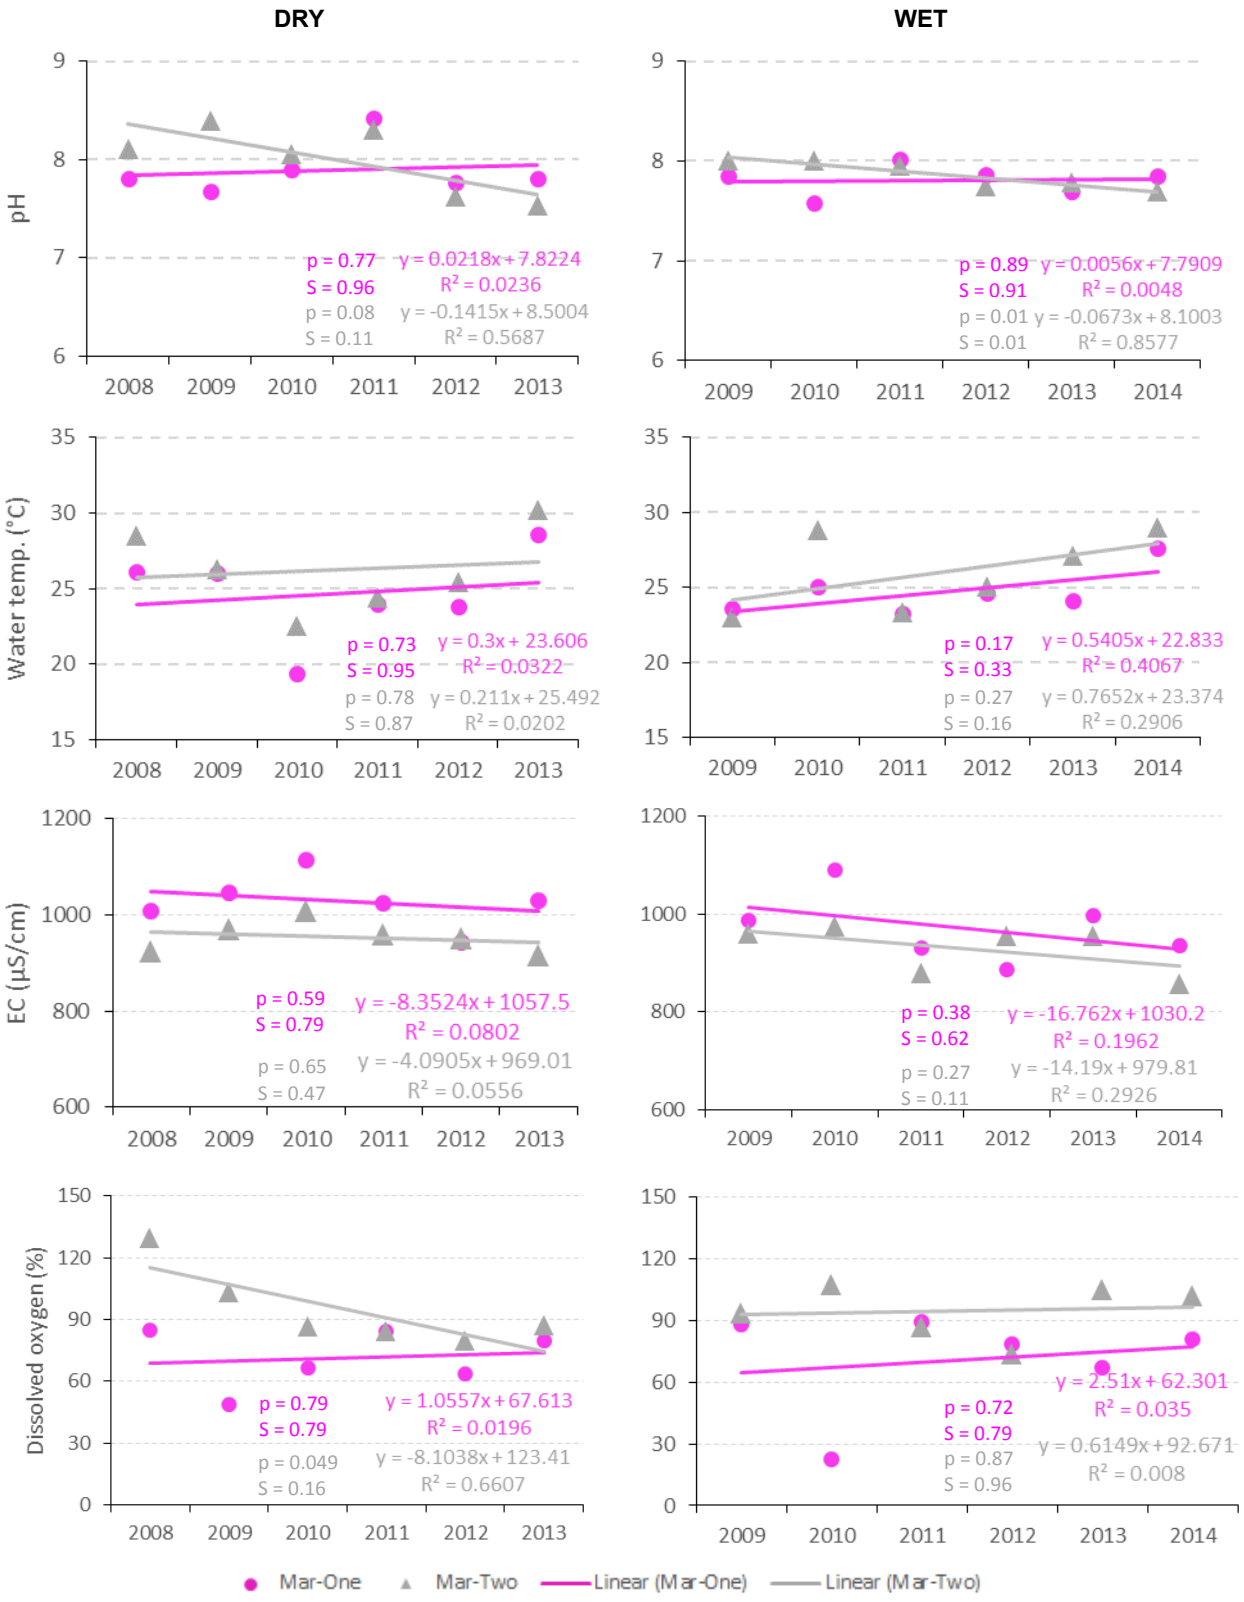

Figure 7. Linear regression plots of mean dry (left) and wet season (right) *in situ* water quality parameters against time for Marillana Reaches One and Two. Equations, *p*, Spearman correlation co-efficient (S) and r^2 values are displayed.

- In the dry season, DO was significantly greater from Mar-Two compared to Mar-One, however it was statistically similar to that of WW-Five. DO did not change significantly over time in either season in either Marillana reach (Figure 7).

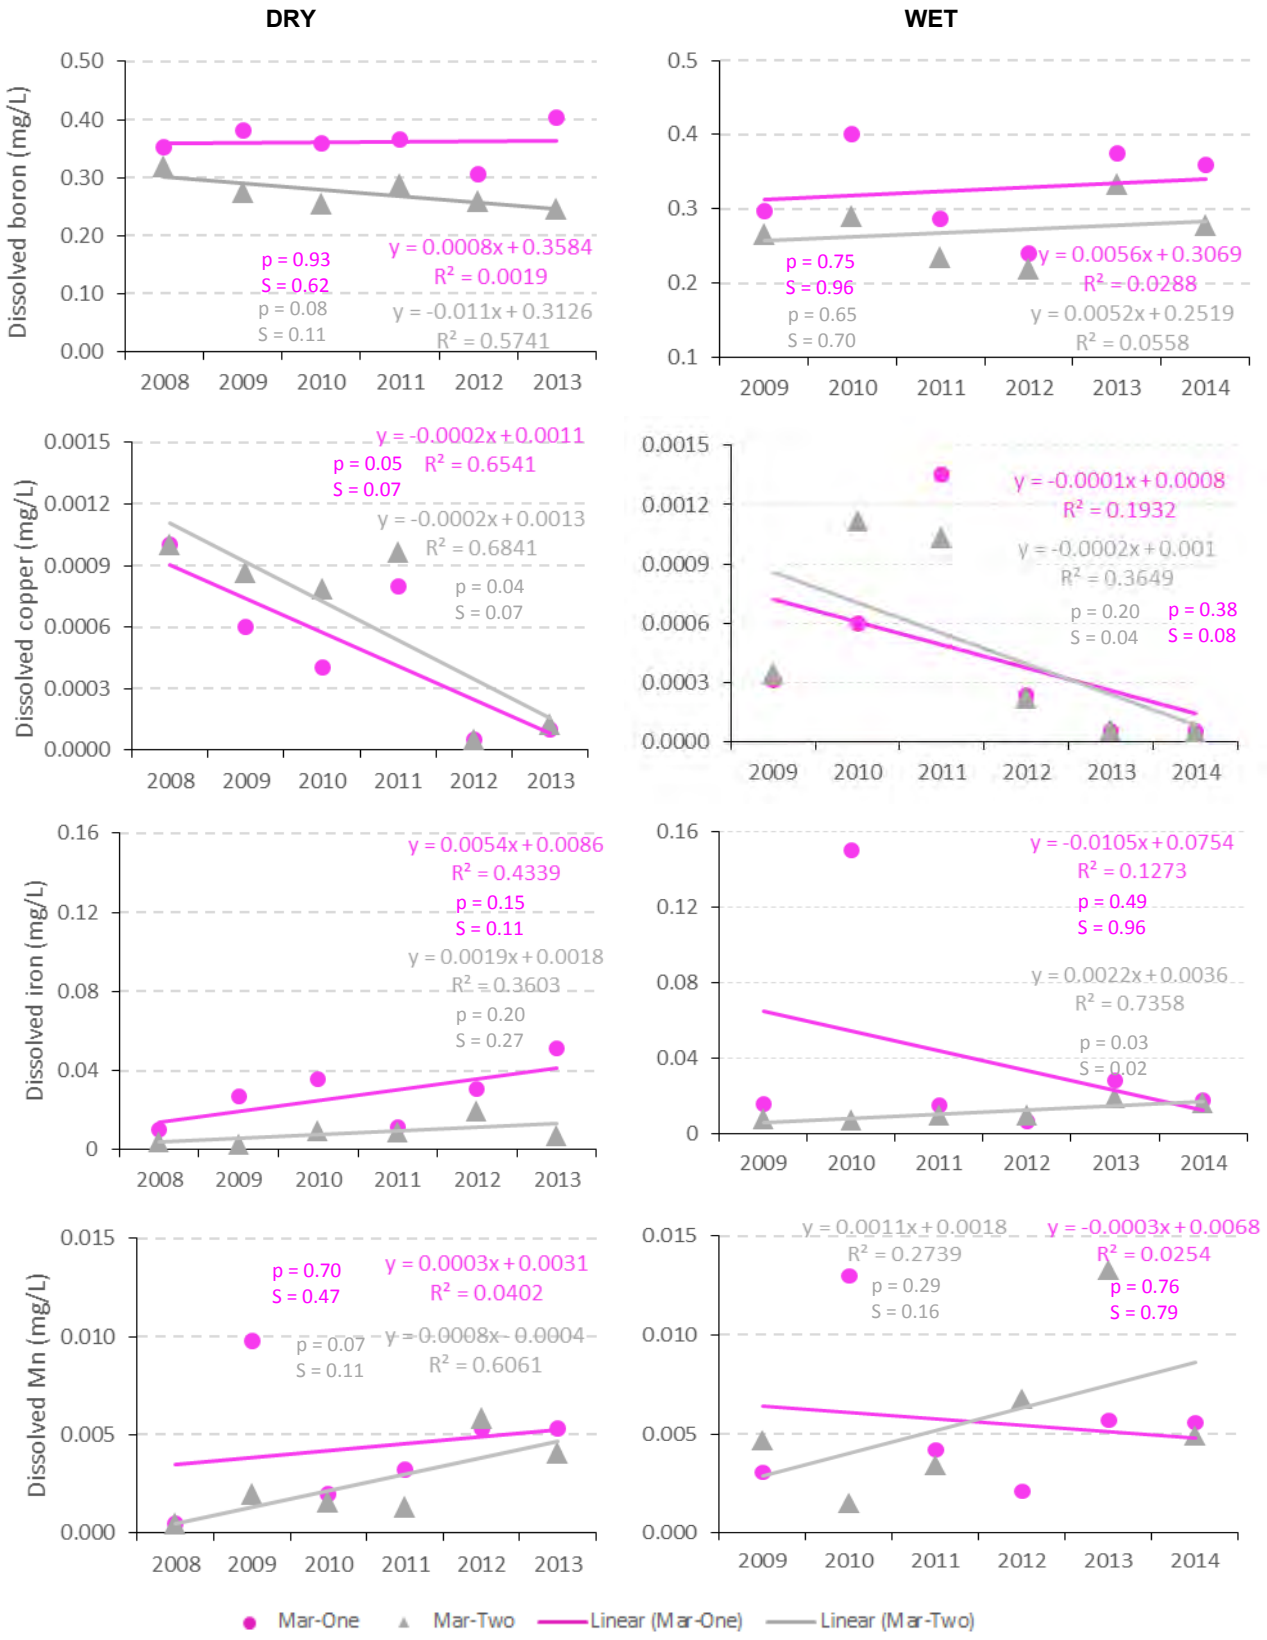

Figure 8. Linear regression plots of mean dry (left) and wet season (right) dissolved metal concentrations against time for Marillana Reaches One and Two. Equations, *p*, Spearman correlation co-efficient (S) and r^2 values are displayed.

- Dry season dB was significantly lower in 2012, compared to all other years, while dB was significantly greater from Mar-One, compared to Mar-Two and WW-Five. During the wet season, dB was significantly higher from Mar-One, while also being significantly greater in

2013 in comparison to other years. There was no significant linear relationship for dry or wet season dB over time at either reach (Figure 8).

- dCu was significantly lower in 2012 and 2013 during the dry season, while dCu was also significantly lower from WW-Five compared to other reaches. In the wet season, highest dCu was recorded in 2011 and 2010. There was no significant difference in wet season dCu between reaches. Regression analysis indicated a significant decline in dry season dCu between 2008 and 2013 at Mar-Two (p = 0.04, r = 0.82), while Spearman correlation co-efficient indicated a significant decline in Mar-Two dCu over time during the wet season (Spearman p = 0.04; Figure 8).
- There was a significant difference in dissolved iron (dFe) between reach (but not year) during the dry season, with highest dFe recorded from Mar-One. Wet season dFe was significantly different between year and reach, where highest dFe was again recorded at Mar-One. There was a significant increase in wet season dFe over time at Marillana Reach Two (p = 0.03, r = 0.86, Spearman p = 0.02; Figure 8).
- Dry season dissolved manganese (dMn) was lowest in 2008, however this was statistically similar that of 2010 and 2011. In the wet season, dMn was significantly lower from Mar-Two compared to Mar-One and WW-Five. There was no significant change in dMn over time from Mar-One or Mar-Two in either season (Figure 8).
- Calcium (Ca) was significantly higher from WW-Five, compared to at Mar-One and Two in the dry season. Similarly, wet season Ca from WW-Five was significantly higher than from other reaches. There was no significant dry or wet season linear relationship between dCa and time for either Marillana Creek reach (Figure 9).
- Dry season chloride (Cl) was significantly greater from Mar-One in comparison to other reaches, and between years, it was highest in 2008 and 2010. During the wet season, Cl was greatest from Mar-One, followed by Mar-Two, and was lowest at WW-Five. Cl did not significantly change over time at either Mar-One or Mar-Two in either season (Figure 9).
- Hydrogen carbonate (HCO_3) during the dry season was greatest in 2011, though this was statistically similar to 2010, 2009 and 2012. Wet season HCO_3 was significantly highest in 2010, and lowest in 2014. Regression analysis indicated a significant decline in dry season HCO_3 from Mar-Two between 2008 and 2013 (p = 0.046, r = 0.82, Spearman p = 0.02; Figure 9).
- Sulfate (SO_4) was highest from WW-Five, and significantly greater in 2010 compared to other years in the dry season. During the wet season, SO_4 was significantly higher from WW-Five compared to other reaches, and was greatest in 2010, though statistically similar to 2013 and 2011. Spearman correlation co-efficient suggested a significant decrease in SO_4 over time at Mar-One during the dry season (Spearman p = 0.04), however ANOVA testing did not concur with this significance (p = 0.16, r = 0.65; Figure 9).
- Total nitrogen (total N) was highest from Mar-One and Mar-Two during the dry season, and was greatest in 2011. In the wet season, total N from WW-Five was significantly greater than all other reaches. Total N concentrations did not change significantly over time at either Marillana reach in either season (Figure 10).
- Dry season total phosphorous (total P) was significantly greatest in 2013, but was statistically similar to 2011 and 2009. During the wet season, total P was significantly different between years, being the greatest in 2009, though statistically similar to 2011 and 2012. There was no significant difference in total P between reaches in either season. ANOVA testing detected a significant decline in wet season total P from Mar-Two between 2009 and 2014 (p = 0.045, r = 0.82; Figure 10).

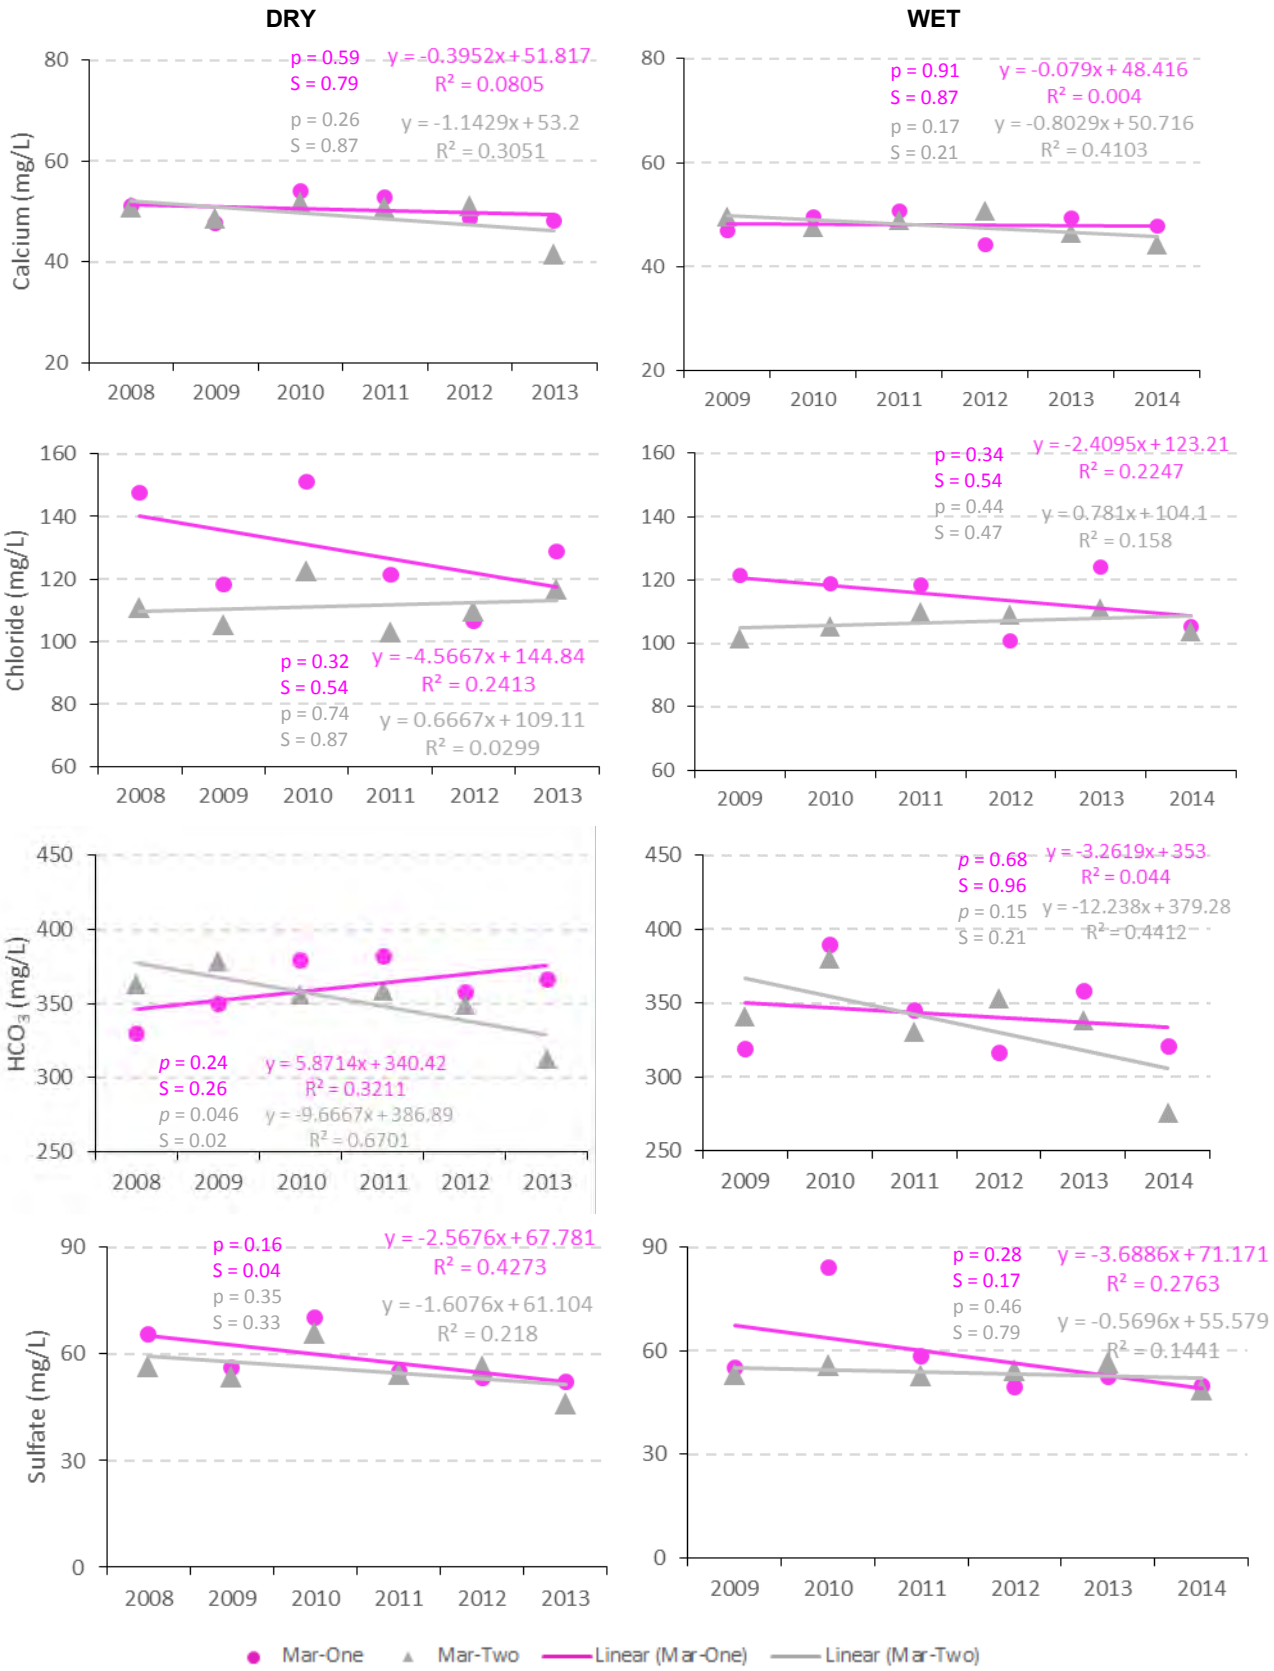

Figure 9. Linear regression plots of mean dry (left) and wet season (right) dissolved ion concentrations against time for Marillana Reaches One and Two. Equations, *p*, Spearman correlation co-efficient (S) and r^2 values are displayed.

Figure 10. Linear regression plots of mean dry (left) and wet season (right) nutrient concentrations against time for Marillana Reaches One and Two. Equations, *p*, Spearman correlation co-efficient (S) and r^2 values are displayed.

3.2.3 Multivariate analysis, including comparisons with Weeli Wolli Creek

All water quality data from Weeli Wolli Creek (four reaches: WW-One, Two, Three and Four, sampled between dry 2008 and wet 2014) were incorporated into the current dataset, and PERMANOVA and constrained CAP analyses performed in order to examine differences among reaches and years in ordination space. During the dry season, significant patterns were evident in the constrained CAP plot examining differences among reach (p = 0.001). The strength of the association between the data cloud and hypothesis of differences in reach was high, with a correlation of 0.98 along CAP axis 1, and 0.91 along CAP axis 2. Water quality samples from Marillana Creek separated from those of Weeli Wolli Creek along CAP1 due to higher concentrations of EC, Total N, chloride, sodium and dissolved vanadium (Figure 11). There was also a longitudinal separation of Weeli Wolli Creek reaches along CAP2 (Figure 11). The separation of upper Weeli Wolli reaches (i.e. WW-One, Two & Three) from downstream reaches (WW-Four & WW-Five) was primarily influenced by higher concentrations of hydrogen carbonate and alkalinity. Greater concentrations of potassium affected the separation of WW-Four and WW-Five sites from upstream sites (Figure 11). Similarly significant patterns were evident in the wet season (p = 0.0001; see Figure 11).

PERMANOVA testing indicated that there was a significant difference between reach (df = 6, *p* = 0.001) and year (df = 5, *p* = 0.001) in the dry season, and a significant difference between reach (df = 6, *p* = 0.001) and year (df = 5, *p* = 0.001) in the wet season (Table 3).

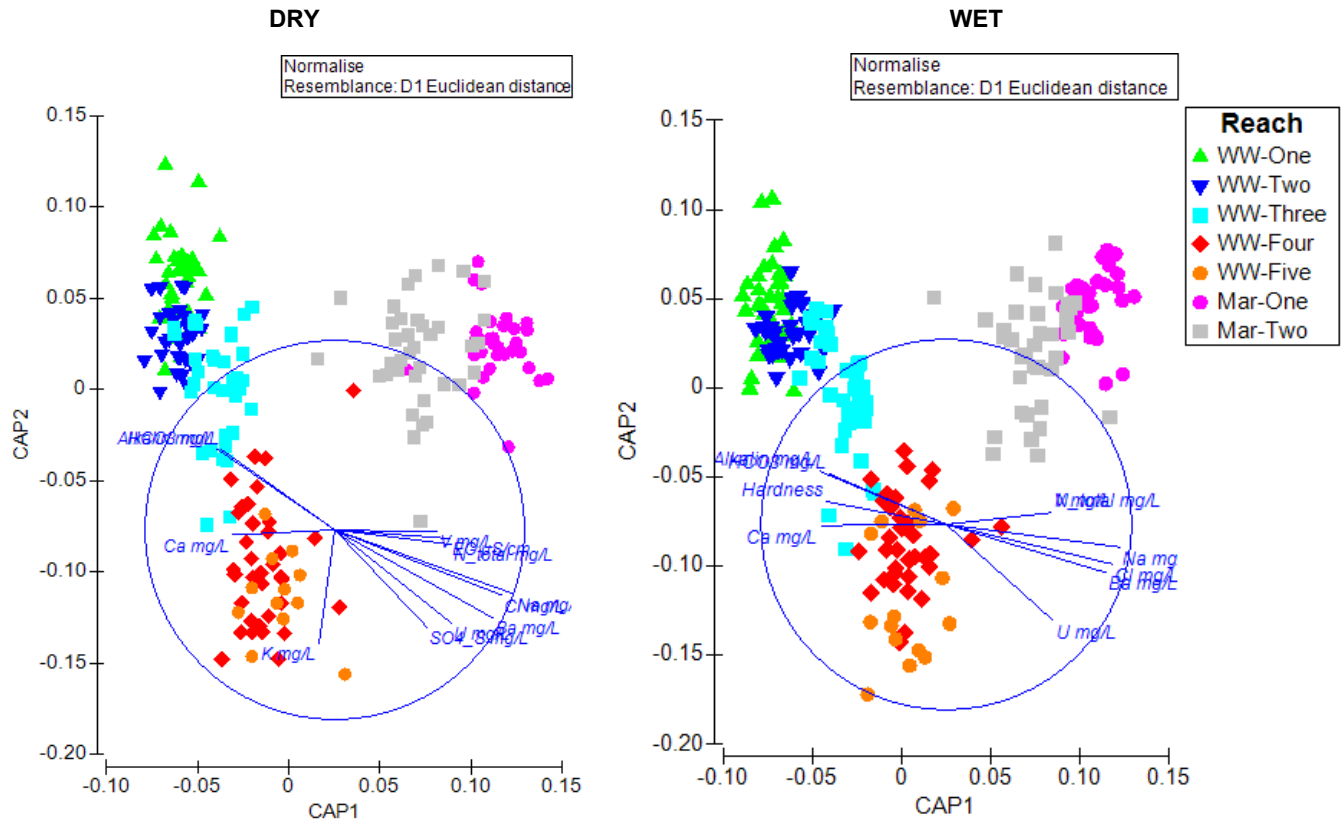

Figure 11. Constrained CAP plots of water quality data between reach in the dry (left) and wet season (right), with vectors of Spearman rank correlations overlain (correlation >0.5).

Table 3. Two-factor PERMANOVA results for dry and wet season data, comparing water quality between reach and year.

Dry Season	df	MS	Pseudo-F	p
Reach	6	301.84	21.862	0.001
Year	5	123.87	8.9716	0.001
Reach*Year	26	38.171	2.7647	0.001
Residual	186	13.807		
Total	223			
Wet Season	**df**	**MS**	**Pseudo-F**	**p**
Reach	6	301.83	26.182	0.001
Year	5	181.94	15.782	0.001
Reach*Year	27	30.67	2.6605	0.001
Residual	185	11.528		
Total	223			

Distance to centroid plots[8] showed varying similarity in water quality data to initial "baseline" monitoring (2008) in Mar-Two during the dry season (Figure 12). Between 2011 and 2013, similarity to "baseline" condition has decreased (increasing Euclidean Distance). In Mar-One dry season water quality has remained fairly consistent over time. In the wet season, there was a considerable change in water quality in Mar-One between the initial "baseline" sampling and the subsequent year (2010;

[8] Distance to centroid = location among groups in multivariate space (PERMANOVA); spatial median in the ordination space of the resemblance measure (in this case, Euclidean distance). An increasing Euclidean Distance indicates a decreasing similarity.

high Euclidean Distance), but after this time there was a decrease in Euclidean Distance, suggesting water quality was becoming more similar to "baseline" (Figure 12). In Mar-Two, wet season water quality remained relatively consistent, but with a decrease in similarity between 2012 and 2014 (Figure 12). This recent difference in water quality of Mar-Two was likely due to the change in dewatering discharge operations, with discharge primarily occurring from D09 and resulting in increased total nitrogen, manganese, dissolved boron and reductions in dissolved copper in this reach.

Figure 12. Temporal consistency in similarity (distance to centroid, PERMANOVA) between water quality data from initial sampling (2008 in the dry season, 2009 in the wet season) and subsequent sampling events. Distance values are based on Euclidean distance.

3.3 Habitat and substrate characteristics

3.3.1 Dry-13 and Wet-14

Substrate characteristics

The substrates of Marillana and lower Weeli Wolli creeks were comprised mainly of coarser rock types, such as cobbles, pebbles and gravel. Pebbles were the dominant substrate character among all three reaches, particularly in the dry-13 (Figure 13). Although still highly represented during the wet season, the cover by pebbles was supplemented by increased sand, silt and clay at some sites (Figure 13). At WW-Five, this may be related to the use of Gray's Crossing as a haul road by another mining company prior to wet season sampling, and also to the flushing of finer substrates into the system following wet season rains. At Marillana Creek, mining and development at Yandicoogina may have influenced substrate composition, with increased sand, silt and clay cover recorded at Mar-One sites located near haul road and mine pit activity (Figure 13).

Habitat characteristics

In both seasons, mineral substrate was the main in-stream habitat type recorded from all three reaches (Figure 14). Submerged macrophyte was more prominent in the dry-13, particularly at MAR1-3, MAR2-5, MAR2-9 and WW5-3, which were all highly receded pools at the time. Pools such as these allow for high light penetration and subsequent macrophyte growth. Algal cover was generally higher during the wet-14 at MAR1-3, MAR2-9, and particularly at WW5-4, where algae accounted for up to 75% of in-stream habitat (Figure 14).

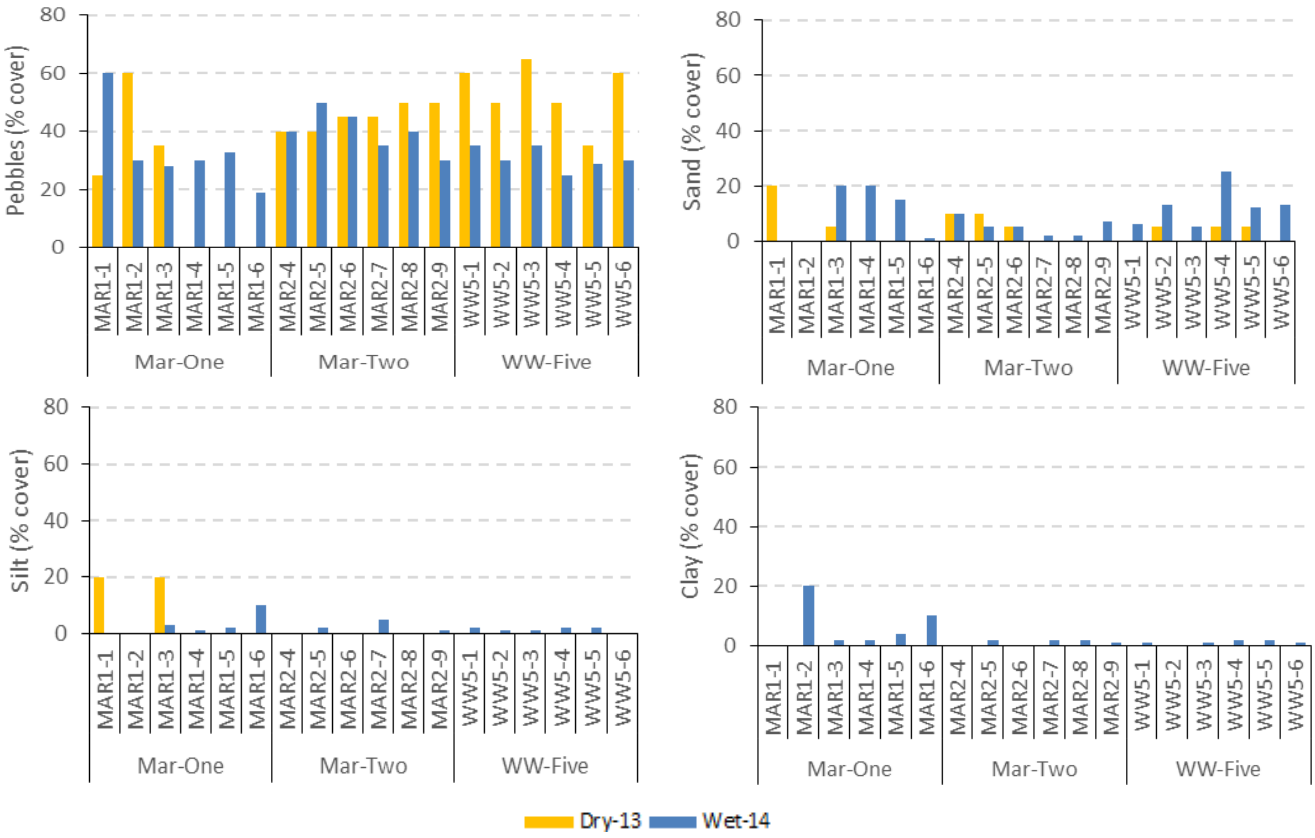

Figure 13. Percent (%) cover of pebbles, sand, silt and clay from Marillana and lower Weeli Wolli Creeks.

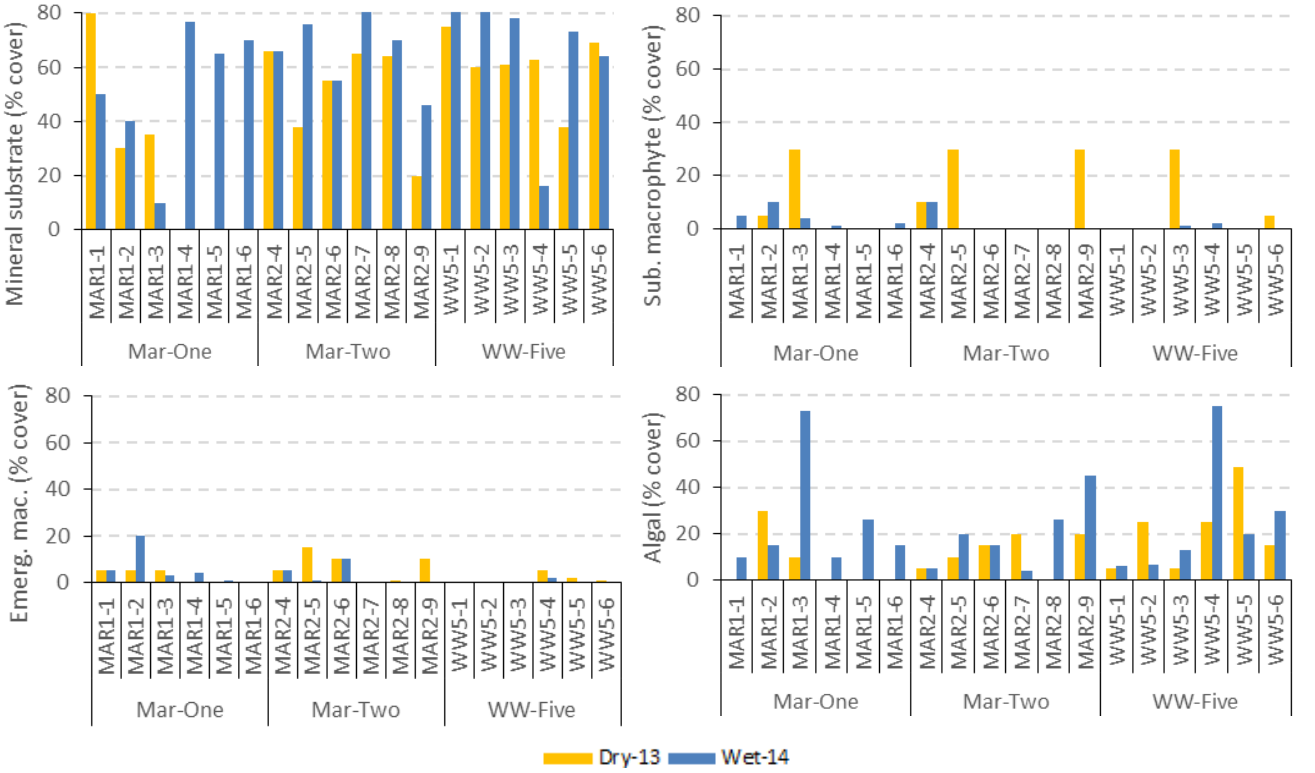

Figure 14. Percent (%) cover of various habitat characteristics of Marillana and lower Weeli Wolli Creeks.

Habitat diversity (number of different habitat types) was generally higher during the wet season, particularly at WW-Five sites, due to a greater area of creek being inundated. Within Mar-Two, there appeared to be a longitudinal gradient of habitat diversity downstream of MAR2-4, with diversity generally decreasing with distance downstream of the D09 discharge outlet (Figure 15). This is likely a reflection of the additional water inundating a greater areal extent of creekline, thus increasing habitat availability and heterogeneity.

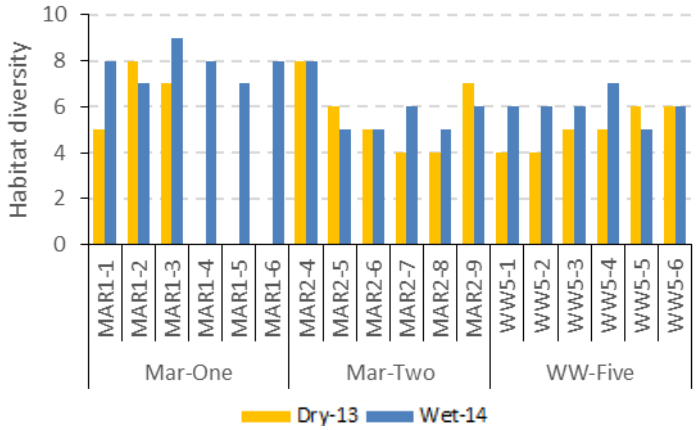

Figure 15. Overall habitat diversity (number of habitat types) of Marillana and lower Weeli Wolli Creeks in the dry-13 and wet-14.

3.3.2 Change over time and comparisons with Weeli Wolli Creek

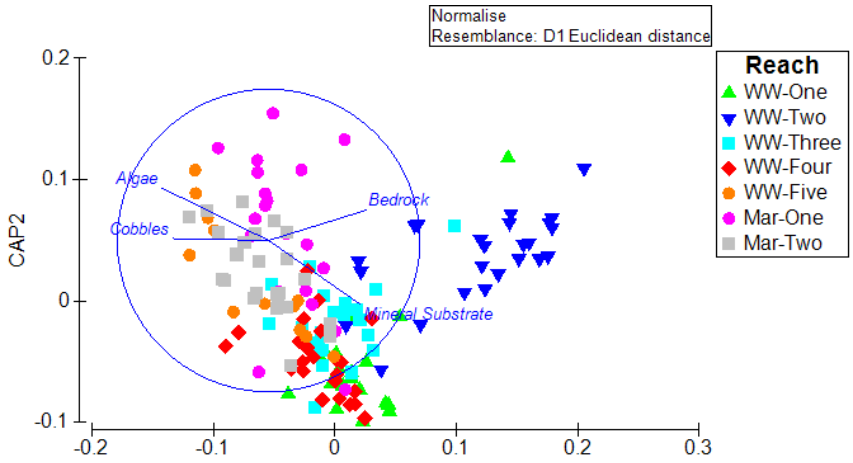
Significant patterns were evident in the CAP ordination examining differences in substrate and habitat composition between reach in the dry season (p = 0.001). The strength of correlations was reasonably high: 0.85 along CAP axis 1, and 0.70 along CAP axis 2. The majority of sites from WW-Two, as well as one site from WW-One (WW1-6) and one site from WW-Three (WW3-1) separated from all others, based on a higher percentage cover of bedrock, as well as greater cover by mineral substrates (Figure 16). The greater bedrock cover at these sites was due to the formation of a calcite precipitate in Weeli Wolli Creek, downstream of the HD1 gabion discharge point[9]. This was first observed during sampling in October 2009, and has since been progressing further downstream, well into WW-Three (WRM 2014b). There was some separation of Mar-One, Mar-Two, and WW-Five sites along CAP2, based on higher percentage cover of algae and cobbles, while mineral substrates influenced the separation of WW-One, Three and Four sites (Figure 16).

Significant patterns were also evident in the CAP ordination between reach in the wet season (p = 0.001), though correlations were not as strong as those of the dry season (0.84 along CAP 1, and 0.60 along CAP 2). The majority of WW-Two sites were again separated from other sites along CAP 1 due to coverage of bedrock (in the form of calcite precipitate), and also by a greater coverage of trailing vegetation (Figure 16). There was a high degree of overlap between Marillana Creek sites and remaining Weeli Wolli Creek sites, indicating increased similarities in habitat and substrate characteristics between these reaches during the wet season (Figure 16).

There was a significant difference in overall habitat and substrate characteristics between reach (df = 6, p = 0.001) and year (df = 3, p = 0.001) in the dry season. There was also a significant difference in habitat and substrate characteristics between reach (df = 6, *p* = 0.001) and year (df = 4, *p* = 0.001) during the wet (Table 4).

[9] For the purposes of making spatial and temporal comparisons the calcite armour was classified as 'bedrock' substrate, given that the armouring of the creek bed creates similar in-stream habitat to bedrock in terms of heterogeneity and diversity.

DRY



WET

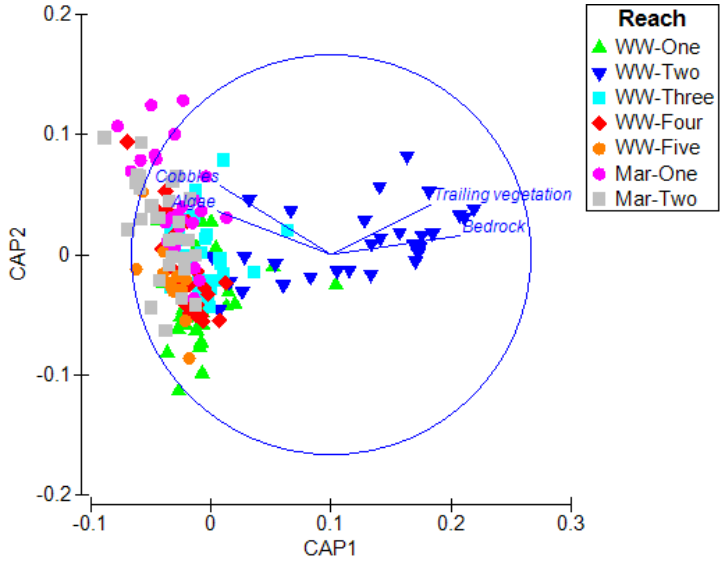


Figure 16. Constrained CAP plots of substrate and habitat data between reach in the dry (top) and wet seasons (bottom), with vectors of Spearman rank correlations overlain (correlation >0.5).

Total	187			

Figure 17 provides a graphic summary of dry and wet season temporal similarity in habitat and sediment characteristics between 2010 (initial "baseline" year) and subsequent sampling events. The dry season plot indicates a decreasing similarity (increased Euclidean Distance) in sediment and habitat characteristics over time in both reaches (Figure 17). Comparatively, the similarity of habitat characteristics in the wet season (compared to 2010) remained relatively consistent over time in Mar-One, after the initial change between 2010 and 2011 which was quite considerable (Figure 17). In Mar-Two, there was a decrease in similarity in wet season habitat (increasing Euclidean Distance) between 2011 and 2012, and again between 2013 and 2014 (Figure 17). The change in habitat in Mar-Two following the commencement of discharge from the JSW operations (i.e. between 2013 and 2014) was less than the change which occurred previously (between 2011 and 2012), prior to the commissioning of JSW.

Figure 17. Temporal consistency in similarity (distance to centroid, PERMANOVA) between habitat characteristics in 2010 and subsequent sampling events. Distance values are based on Euclidean distance.

3.4 Microinvertebrates

3.4.1 Taxonomic composition and species richness

A total of 110 microinvertebrate taxa were recorded from Marillana Creek and 83 taxa from lower Weeli Wolli Creek (WW-Five) during the current study. The microinvertebrate fauna comprised Protista, Rotifera, Copepoda, Cladocera (water fleas) and Ostracoda (seed shrimp).

The greatest number of microinvertebrate taxa was recorded from the Mar-Two in the wet-14, and the least recorded from Mar-One in the dry-13 (Table 5). However, the number of sites sampled from each was not the same between seasons, as three sites were dry in Mar-One during the dry-13. As such, the lower microinvertebrate taxa richness recorded from this reach may have been due to the lower number of sites successfully sampled at the time. The high number of microinvertebrate taxa recorded from Mar-Two during the wet-14 was almost entirely due to the high diversity recorded from MAR2-6 (45 taxa) as MAR2-5 recorded only one taxa at this time (Figure 18).

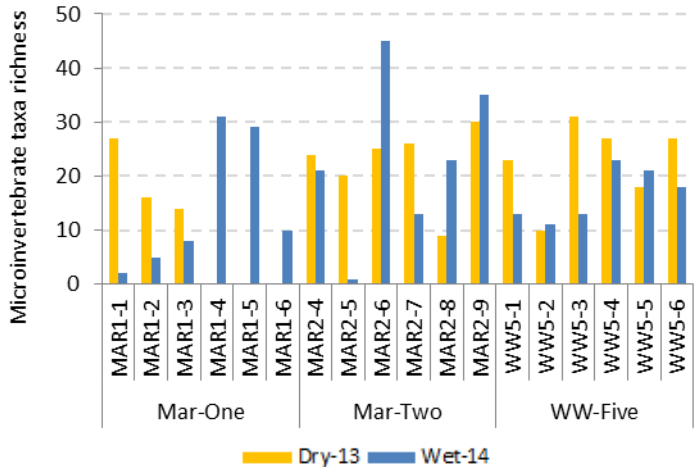

Figure 18. Number of microinvertebrate taxa recorded from each site in the dry-13 and wet-14.

Table 5. Total number of microinvertebrate taxa recorded from each reach during the dry-13 and wet-14.

	Total no. micro taxa	
Reach	**Dry-13**	**Wet-14**
Mar-One	36	46
Mar-Two	54	75
WW-Five	57	48

3.4.2 Conservation significance of microinvertebrates

The majority of microinvertebrate taxa recorded during the current study were common ubiquitous species, with distributions extending throughout Australasia or the world (cosmopolitan species). Of interest within the microinvertebrate fauna was the collection of species endemic to the Pilbara, Western Australia and/or taxa known to be rare or uncommon throughout their range. Such taxa included the rotifers *Lecane noobijupi*, *Lindia torulosa* and *Heterolepadella heterostyla*, and the Copepoda *Australoeucyclops karaytugi.*

The rotifer *Lecane noobijupi* is known only from Western Australia, and appears to have a disjunct distribution. It was described from specimens collected from a wetland in the Muir-Unicup catchment in the south-west of the state (Noobijup Swamp) and it had been thought to be restricted to that catchment (Segers and Shiel 2003). However, the authors have since recorded *Lecane noobijupi* from a number of systems in the Pilbara region, including Weeli Wolli Creek, Marillana Creek, Coondiner Creek, Mindy Mindy Creek, Kalgan Creek, Un-named Creek, Hardey River, Beasley River, Caves Creek, Duck Creek and Boolgeeda Creek (WRM, unpub, data), as well as the DeGrey River by DPaW (Pinder *et al.* 2010). It would now appear that the Pilbara may be the normal locality of this species, and the Muir location in the south-west was an isolated occurrence. During the current study, *Lecane noobijupi* was recorded from MAR1-4, MAR1-5, MAR2-8, WW5-4 and WW5-6.

Two rotifers recorded during the current study are species known to be rarely encountered/collected in Australia; *Lindia torulosa* and *Heterolepadella heterostyla*. *Lindia torulosa* has a cosmopolitan distribution but is uncommon in Australia. It has been recorded previously by the authors from Weeli Wolli Creek, Fortescue Falls, Bamboo Spring and the Coondiner Pool claypan (WRM unpub. data). It was not recorded during the PBS (Pinder *et al*. 2010). During the current study *L. torulosa* was recorded from MAR1-3, MAR1-4, MAR2-5, MAR2-6 and WW5-4. *Heterolepadella heterostyla* is thought to have a cosmopolitan distribution, but is uncommon/rarely collected. It is a littoral species and is usually recorded in stagnant waters. During the current study it was recorded from MAR2-9.

As well as Marillana and Weeli Wolli creeks, *H. heterostyla* is also known from Mindy Mindy Creek in the Pilbara (WRM unpub. data).

The Australian endemic cyclopoid copepod *Mesocyclops notius*, was recorded from MAR1-1, MAR1-4 and MAR2-9 during the current study. This species is previously known from the Lake Eyre Basin (Shiel *et al.* 2006), Lake Merrimajeel in the Murray-Darling (Cromel and Carpenter 1988), Mount Isa in Queensland (Hołyńska and Brown 2002), Lake Gregory in the Kimberley, W.A. (Hołyńska and Brown 2002), and the Fortescue Marsh in the Pilbara (Hołyńska and Brown 2002). It has also been previously collected by the authors from a reference site on Weeli Wolli Creek immediately upstream of HD1 (WRM unpub. data).

The copepod *Australoeucyclops karaytugi* is endemic to the Pilbara. Within the region, it is known from Weeli Wolli Spring, as well as other spring systems including Palm Springs (Caves Creek), Bamboo Springs (DeGrey) and Skull Springs (DeGrey), and the permanent pools Coppin Gap (DeGrey), Glen Herring Pool (DeGrey), Wannagunna Pool (Ashburton), Horrigan's Pool (Ashburton), and Pool on Billan Ballan (Yule). It was recorded from MAR1-5 during the current study.

These taxa have been consistently recorded from Marillana Creek since aquatic fauna surveys began in 2008. Other microinvertebrate taxa of significance which have been recorded from Marillana Creek previously, but were not recorded during the current study included *Lecane battilifer*, *Lecane latissima*, *Lecane rhenana*, *Proales micropus* and *Lepadella ptyerygoida*. Of these, the three Lecane rotifers are rare or uncommon throughout their range. The collection of the rotifer *Proales micropus* from MAR1-3 during the dry-10 constituted the first record of this species from Western Australia and perhaps only the second record within Australia. The collection of the rotifer *Lepadella ptyerygoida* from MAR2-1 during the wet-10 constituted the first record of the species in Australia. *Lepadella ptyerygoida* is very rare and previously known from North and South America and the Oriental region (Dr Russ Shiel, University of Adelaide, pers. comm.). The collection of new records and/or species of Rotifer is not unheard of in the Pilbara, as historically, aquatic microfauna have been less sampled across this region than either macroinvertebrates or fish. It is likely all these rotifer species are still present within Marillana Creek, but have simply not been collected in more recent sampling events. Microfauna are cued to natural cycles, with emergence from resting stages dependent on the cues to which they are 'tuned', such as day-length, chemistry, temperature, algal exudates or prey hormones. The speed of these species replacements can be in hours or days (cf. Tan and Shiel 1993, for billabong microfauna in eastern Australia), and as such, may not be timed with our sampling events within the creek. In addition, microfauna tend to be highly spatially patchy.

3.4.3 Spatial and temporal change in microinvertebrates

Taxa richness

During the dry season, there was a significant difference in microinvertebrate richness between year ($df = 5$, $p = 0.013$), but not between reach ($df = 2$, $p = 0.808$; Table 6). Microinvertebrate richness was highest in 2013 (21.80), though this was statistically similar to that recorded in 2010 and 2012. There was no significant difference in microinvertebrate taxa richness between reach ($df = 2$, $p = 0.103$) or year ($df = 5$, $p = 0.093$) during the wet season (Table 6). Regression and Spearman Rank Correlation analyses indicated that there was no significant change in microinvertebrate taxa richness over time for either reach in either season, i.e. no consistent increase or decrease in taxa richness (Figure 19). This suggests that the discharge operations at Yandicoogina have not adversely impacted the microinvertebrate taxa richness of the downstream Marillana Creek environment over time.

Table 6. Two-way ANOVA results comparing microinvertebrate taxa richness between reach and year, for each season. Degrees of freedom, mean squares and p-values are shown. Tukey's *post-hoc* results are presented in ascending order of mean microinvertebrate taxa richness, with groups with no difference in means joined by a black line.

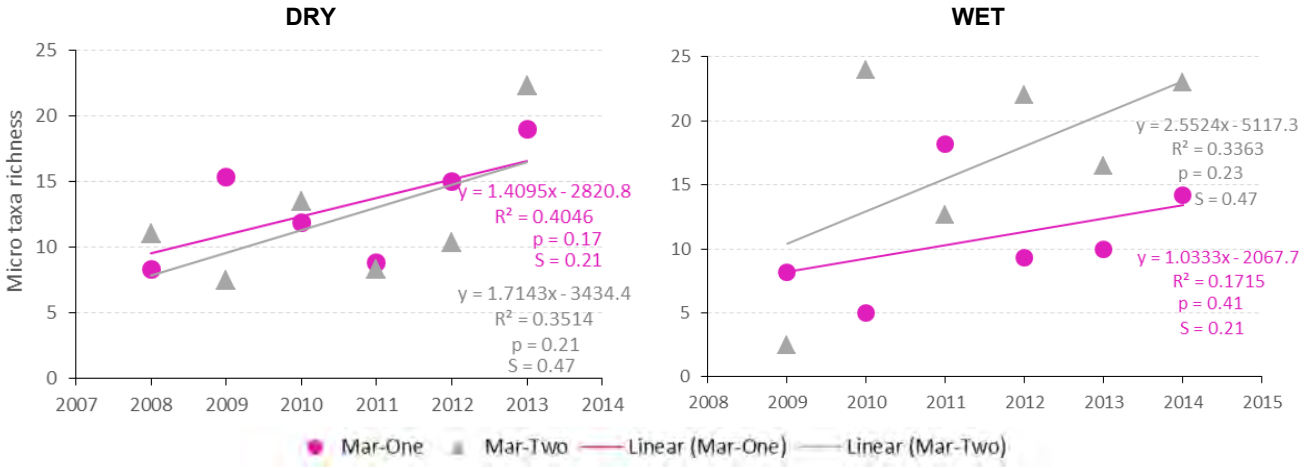

Figure 19. Linear regression plots of mean microinvertebrate taxa richness against time for Marillana Reaches One and Two in the dry season (left) and wet season (right). Equations, p-values, Spearman correlation co-efficient (S) and R^2 values are displayed.

Comparisons with Weeli Wolli Creek

Incorporating all Weeli Wolli Creek and Marillana Creek zooplankton abundance data into the analyses, some patterns were evident in the dry season constrained CAP plot examining differences between reach (Figure 20). The strength of the association between the data cloud and hypothesis of differences in reach was reasonably good, with a correlation of 0.74 along CAP axis 1, and 0.65 along CAP axis 2. Generally, there was some separation of samples amongst reaches, but with considerable overlap (Figure 20). Weeli Wolli Creek microinvertebrate samples from reaches One to Four tended to separate from the Marillana Creek and WW-Five samples along CAP1. This suggests

the microinvertebrate assemblages of WW-Five are more similar to Marillana Creek, than upper Weeli Wolli Creek. Spearman Correlation indicated that the separation of Marillana Creek and Weeli Wolli Creek was influenced by higher abundances of cyclopoid copepodites and nauplii, and small and medium sized indeterminate bdelloid rotifers from Marillana Creek.

Similar patterns were evident in the wet season, however, there was a greater separation of microinvertebrate samples by reach (Figure 20). WW-One separated from other Weeli Wolli Creek reaches along CAP1, and there was a greater separation of Mar-One from Mar-Two and WW-Five along CAP2 during the wet.

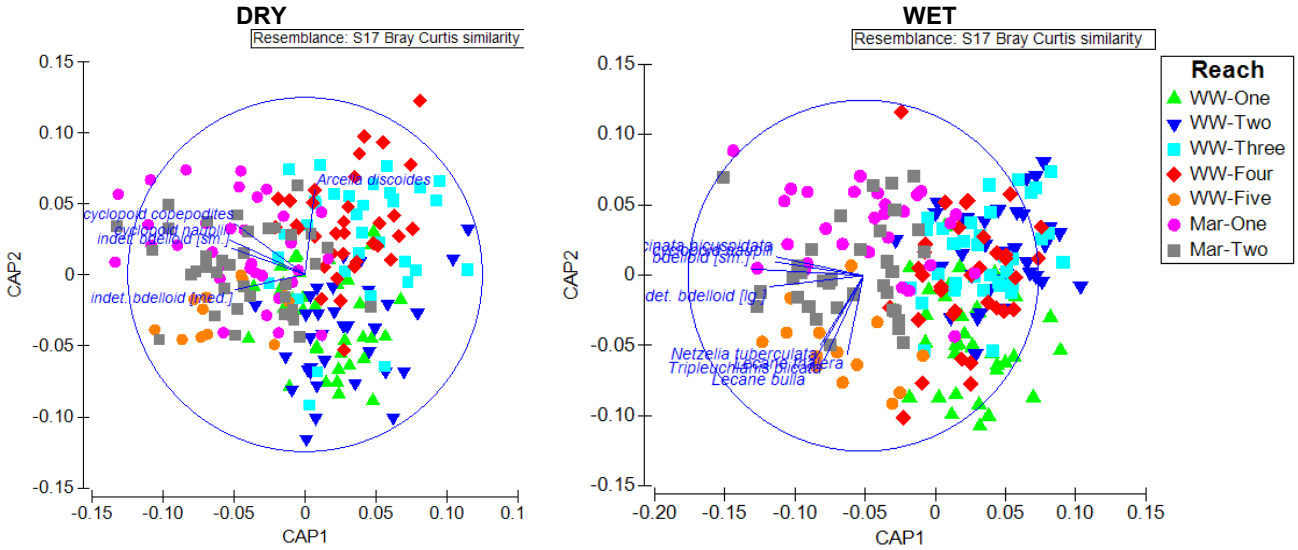

Figure 20. Constrained CAP plot of microinvertebrate abundance data between reaches in the dry season (left) and wet season (right), with vectors of Spearman rank correlations overlain (correlation >0.5).

PERMANOVA testing indicated that there was a significant difference in microinvertebrate assemblages between reach (df = 6, p < 0.001) and year (df = 5, p < 0.001) during the dry season. There was also a significant difference between reach (df = 6, p < 0.001) and year (df = 5, p < 0.001) during the wet season (Table 7). This indicates that the microinvertebrate assemblages of Marillana and lower Weeli Wolli Creek are different between reach irrespective of season, but do change temporally. Post-hoc analyses indicated that during the dry season, there was no significant difference in microinvertebrate assemblages between WW-Five and Mar-Two, nor between Mar-One and Mar-Two. However, during the wet season, the greater separation of samples meant that all Marillana Creek and lower Weeli Wolli Creek reaches were significantly different from one another.

Table 7. Two-factor PERMANOVA results for dry and wet season data, comparing microinvertebrate assemblages (log_{10} abundance data) between reach and year.

Dry Season	df	MS	Pseudo-F	p
Reach	6	9251.1	3.08	<0.001
Year	5	9588.0	3.20	<0.001
Reach*Year	26	4559.9	1.52	<0.001
Residual	181	3000.0		
Total	218			
Wet Season	**df**	**MS**	**Pseudo-F**	**p**
Reach	6	10445	3.52	<0.001
Year	5	12192.0	4.11	<0.001
Reach*Year	27	4547.6	1.53	<0.001
Residual	181	2965.7		
Total	219			

There was generally no correlation between microinvertebrate assemblages and water quality characteristics in either season (dry season BVSTEP; Rho = 0.20; wet season BVSTEP; Rho = 0.28). However, water quality variables which were found to have the greatest influence on the dry season microinvertebrate assemblages were water temperature, alkalinity, and concentrations of potassium, bicarbonate, barium, manganese and zinc. In the wet season, water quality variables showing the greatest influence on the microinvertebrate assemblages included alkalinity, hardness, and concentrations of calcium and sodium.

Change over time was examined using Bray-Curtis similarity between initial "baseline" sampling and each subsequent year. There was a slight increase in similarity of dry season microinvertebrate assemblages over time in both Marillana Creek reaches, suggesting that after a slight initial change, assemblages are becoming more similar to what they were during initial "baseline" sampling in 2008 (Figure 21). Overall, a ~16% increase in similarity occurred between 2009 and 2013 in both reaches. In contrast, there was a reduction in similarity of microinvertebrate assemblages during the dry season up until 2011 in both reaches. This constituted a ~44.4% and 46.6% change in microinvertebrate assemblages in Mar-One and Mar-Two, respectively, between 2009 and 2011 prior to JSW (and Oxbow) commissioning (Figure 21). Since this initial change, wet season microinvertebrate assemblages have remained relatively consistent over time in both reaches (Figure 21).

Figure 21. Temporal consistency in similarity (distance to centroid, PERMANOVA) between microinvertebrate assemblage data from initial sampling (2008 in the dry season, 2009 in the wet season) and subsequent sampling events. Values are based on percent similarity derived from Bray-Cutis similarity matrices.

3.5 Hyporheic fauna

3.5.1 Taxonomic composition and species richness

A total of 106 taxa were recorded from hyporheic samples collected along Marillana Creek and lower Weeli Wolli Creek during the dry-13, and 73 taxa in the wet-14 (Appendix 6). The vast majority of taxa recorded from the hyporheic zone in the dry season were classified as stygoxene (63%) and do not have specialised adaptations for groundwater habitats. However, 15% of the dry season taxa were classified as occasional hyporheos stygophiles, 9% were stygobites[10], and 10% were possible

[10] A stygobite is an aquatic animal that is restricted to groundwater and/or hyporheic environments (i.e. stygofauna). They have adaptations to survive such conditions, including elongated appendages and antennas, no eyes, and a lack of pigmentation.

hyporheic taxa. A taxa considered to be troglobite[11] (Myriapoda spp.) was also recorded from the hyporheic zone in the dry-13. Of the taxa recorded during the wet season, most were stygoxene taxa (56%), with 39% being considered hyporheos fauna[12] (16% occasional hyporheos stygophiles, 11% stygobites, and 12% possible hyporheic taxa). Stygobites were recorded from all sites during the dry-13, with the exception of MAR2-7 and WW5-6 (Figure 22). During the wet-14, stygobites were recorded from all sites except MAR1-5 (Figure 22). Generally, greater numbers of taxa hyporheos fauna were recorded from Mar-Two and lower Weeli Wolli Creek (WW-Five), however, less sites were successfully sampled in Mar-One. MAR1-5 did not support any taxa considered to be restricted to the hyporheic zone (Figure 22).

Classifications followed those of Boulton (2001), however, this type of analysis should be treated with some caution as results are likely affected by available information on life history, taxonomic resolution, and interpretation of classification categories.

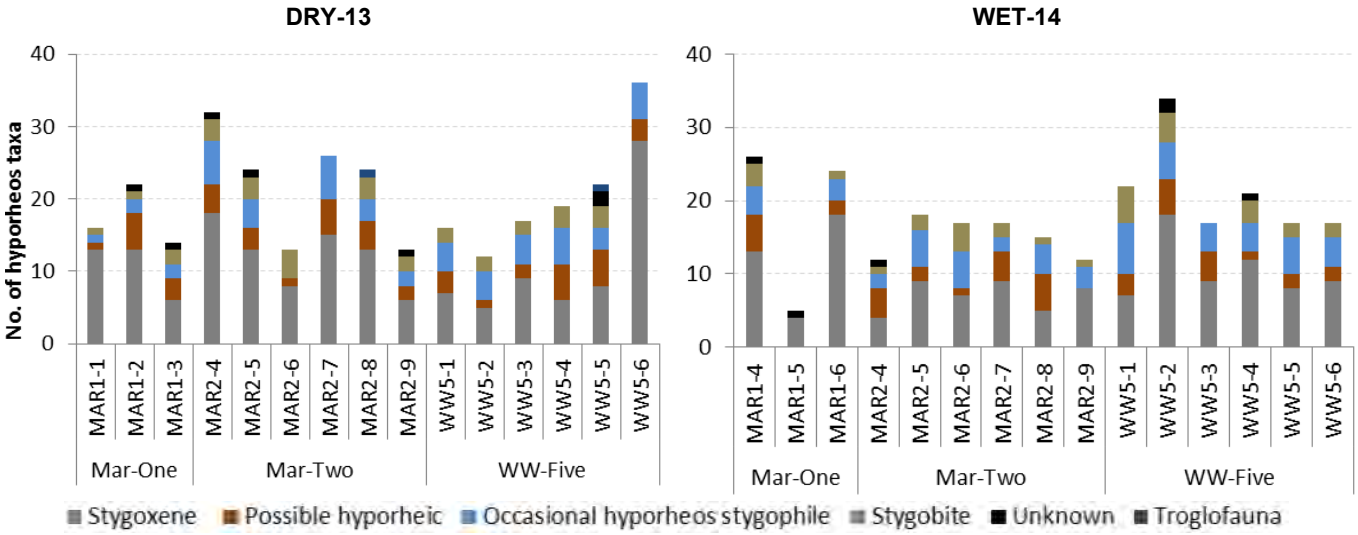

Figure 22. Proportion of taxa from each hyporheic classification category, showing data collected from each site in the dry season (left) and wet season (right).

3.5.2 Hyporheos taxa

Species considered to be restricted to the hyporheos included; the stygobitic amphipods *Chydaekata* sp., Paramelitidae sp. D, Paramelitidae sp. B, *Maarrka weeliwolli* and Paramelitidae spp. (damaged or immature; not possible to positively identify further than family); stygobitic copepod *Parastenocaris* sp.; stygobitic ostracods *Gomphodella* n. sp. (BOS334), juvenile *Vestalenula*, *Candonopsis* cf. *pilbarae* and juvenile *Pilbaracandona*; occasional hyporheos stygophiles including the oligochaetes *Allonais paraguayensis*, *Allonais pectinata*, *Nais communis*, *Pristina aequiseta*, *Pristina longiseta* and *Pristina* nr *sima*, copepods *Australoeucyclops karaytugi*, *Mesocyclops holynskae* and *Microcyclops varicans*, Collembolla Entomobryoidea spp., Poduroidea spp. and Symphypleona spp., Coleoptera *Limbodessus occidentalis*, *Austrolimnius* sp. (L), *Hydraena* sp., *Hydraena* sp. (L), *Limnebius* sp., *Ochthebius* sp., and Scirtidae spp. (L); and possible hyporheics including Nematoda spp., oligochaetes Oligochaeta spp. (imm./dam.), Naidinae spp. (imm.), *Pristina* sp. and Phreodrilidae spp. (imm.), cyclopoid copepodites and *Mesocyclops* sp., indeterminate cypridopsid ostracod, water mites Hydracarina spp. and Trombidioidea spp., immature and/or damaged baetid mayflies, and chironomid *?Pentanuera* sp.

[11] A troglobite is a terrestrial animal which lives entirely in the dark within cave systems or underground within fissures in bedrock. Similar to stygobites (stygofauna) they have adaptations to survive such conditions, including long antennas, no eyes, and a lack of pigmentation. The word 'troglo' means hole.

[12] Hyporheos fauna – animals restricted to hyporheic environments.

All stygobitic amphipods were identified by WRM using a morphological key designed by Helix (2011). However, a number of specimens were unable to be definitively identified to species-level using external morphology due to damage or immaturity. Such specimens have been referred to as Paramelitidae spp. (imm./dam.) here.

Paramelitidae sp. D (also referred to as Paramelitidae Genus 2 sp. B3 by a different environmental consultancy[13]) and Paramelitidae sp. B (also referred to as Paramelitidae Genus 2 sp. B2 by a different environmental consultancy[13]) are both currently undescribed species that appear to be restricted to Weeli Wolli Creek, Marillana Creek (WRM unpub. data; Helix 2010a, b, Helix 2011) and the Coondewanna Flats Catchment (Stuart Halse, Bennelongia, pers comm.). This suggests they are both short range endemics as defined by Harvey (2002)[14], and therefore of high conservation significance. During the current study, Paramelitidae sp. D was recorded from MAR2-6, MAR2-8 and WW5-2. Paramelitidae sp. B was more commonly recorded and widely distributed along lower Marillana Creek and Weeli Wolli Creeks being recorded from all WW-Five sites and all Mar-Two sites except MAR2-4 (Appendix 6). Neither species was recorded from the upper Marillana Creek reach (Mar-One) during the current study.

Chydaekata sp. is also an undescribed SRE. It is known from a small number of systems in close proximity; Weeli Wolli Creek, Marillana Creek, Coondiner Creek and Mindy Mindy Creek (Helix 2010a, Helix 2011, WRM unpub. data). During the current study it was recorded from MAR1-3, MAR2-6, WW5-1 and WW5-2.

The stygobitic amphipod *Maarrka weeliwolli* is also an SRE and has previously been recorded from multiple bores at Weeli Wolli and Marillana creeks (Finston *et al.* 2011). It appears to be restricted to these two creeklines. *Maarrka weeliwolli* appears to be less commonly recorded than the other three species of stygobitic SRE amphipods (WRM unpub. data). During the current study, *M. weeliwolli* was recorded from MAR2-5, WW5-1 and WW5-4.

Specimens of the harpacticoid genera *Parastenocaris* recorded from the hyporheic zone of MAR1-4 during the wet-14 were immature and not able to be accurately identify to species. As there is only one known described species of *Parastenocaris* known from the Pilbara, *Parastenocaris jane*, the specimens collected from Marillana Creek were named *Parastenocaris* cf. *jane* for the purposes of the current study. *Parastenocaris jane* is endemic to the Pilbara and known from bores at Paraburdoo, Turee Creek, Newman Airport, BHPBIO's OB25, BHPBIO's OB23, Homestead Creek and the Cane River (Karanovic 2006). However, morphologically distinct *Parastenocaris* specimens have been previously recorded from the Pilbara by the authors (from Skull Springs on the Davis River and Wanna Munna Up on Weeli Wolli Creek) which did not match the described *Parastenocaris jane* (WRM unpub. data). As such, it is not possible to determine whether the specimens recorded from MAR1-4 belong to the described species or a similar species likely new to science.

Four species of stygobitic ostracod were recorded from hyporheic zones; *Gomphodella* n. sp. (BOS334), *Vestalenula* sp., *Candonopsis* cf. *pilbarae* and *Pilbaracandona* sp. *Gomphodella* n. sp. (BOS334) is an undescribed species new to science. The species appears similar to described species such as *G. glomerosa* and *G. hirsuta*, but differs in that it has no ventral stria, is dorso-ventrally compressed and has a different shaped hemipenis (Dr Russ Shiel, University of Adelaide, pers. comm.). During the current study *Gomphodella* n. sp. (BOS334) was recorded from MAR1-4, MAR1-6, MAR2-6 and WW5-2. This is not the first record of the new species. It has previously been recorded from bores in the Yandi area (Dr Stuart Halse, Bennelongia, pers. comm.), as well as from

[13] Bennelongia morphotype name.
[14] Short range endemic as defined by Harvey (2002): a species occupying an area of less than 10, 000 km^2.

hyporheic zones on Marillana (MAR1-2, MAR1-3, MAR1-6, MAR2-4) and Weeli Wolli creeks (WW2-6, WW5-2 and WW5-5) (WRM unpub. data). *Gomphodella* n. sp. (BOS334) appears to be a short range endemic restricted to Marillana and Weeli Wolli creeks, and as such is a species of high conservation significance. Several *Gomphodella* species are known only from one locality and are commonly found in springs (Karanovic 2006, Reeves *et al.* 2007).

Candonopsis cf. *pilbarae* was recorded from the hyporheic sample of WW5-5 during the dry-13. The specimen was immature, and as such, the species-level identification could not be made with certainty. *Candonopsis pilbarae* is a stygobitic ostracod endemic to the Pilbara region. It is previously known from the DeGrey River and Ashburton River catchments. The collection from WW5-5 constitutes the first record of this species from the Weeli Wolli Creek catchment. Karanovic (2007) did suggest that *C. pilbarae* was likely more widely distributed than current records indicated (DeGrey and Ashburton catchments only) but that it is not a common species.

Juveniles of the stygobitic ostracod genera *Vestalenula* and *Pilbaracandona* were recorded from hyporheic zones during the current study. The *Vestalenula* sp. may be either *V. maltidae* or *V. marmonieri*, but it is not possible to identify juveniles and damaged specimens to species. *V. matildae* is endemic to the Pilbara and currently known only from the Ashburton and Weeli Wolli Creek catchments (Martens and Rossetti 2002, Halse *et al.* 2002). *Vestalenula marmonieri*, however, is also known from New Caledonia (Rossetti and Martens 1999). During the current study, stygobitic juvenile *Vestalenula* were recorded from hyporheic zone of MAR2-4. Six species of *Pilbaracandona* are currently known from the Pilbara, some of which appear to be widely distributed throughout the region and some of which are restricted to one locality, i.e. *Pilbaracandona rhabdote* is known only from the Fortescue Marsh (Karanovic 2007). Juvenile *Pilbaracandona* were recorded from MAR2-4 and WW5-1 hyporheic zones.

The oligochaetes *Allonais paraguayensis*, *Allonais pectinata*, *Nais communis*, *Pristina aequiseta*, *Pristina longiseta* and *Pristina* nr *sima* were all considered to be occasional hyporheos stygophiles. This is because they are known from Pilbara groundwaters, but are not exclusively restricted to the hyporheic zone. All species are widely distributed and have either an Australasian or cosmopolitan distribution, with the exception of *Pristina* nr *sima*. The specimens recorded from the hyporheic zones of MAR2-4 and WW5-4 did not match any currently described species but were closest to *P. sima*. The described species is known only from the south-west of Western Australia from Kalbarri in the north, southeast to Esperance. *Pristina* nr *sima* was also recorded by DPaW during the Pilbara Biological Survey from Chinaman Spring on the DeGrey River (Pinder *et al*. 2010). It is possible that this is a new species to science known only from the Pilbara. Most other oligochaetes collected from hyporheic zones were considered possible hyporheic taxa, except *Pristina leidyi* and *Pristina jenkinae* which are known surface water species (i.e. stygoxene). While most groundwater oligochaetes in Western Australia appear to have fairly widespread distributions, knowledge on the taxonomy and distribution of many groups is limited. Oligochaetes are considered likely to have greater subterranean dispersal capacities than other stygofaunal groups due to their vermiform shape and burrowing capabilities. Occasional hyporheos stygophile and possible hyporheic oligochaetes were recorded from the majority of sites sampled.

Three copepod species considered to be occasional hyporheos stygophiles were recorded from hyporheic samples during the current study. These were *Australoeucyclops karaytugi*, *Microcyclops varicans* and *Mesocyclops holynskae.* These species have all been recorded from Marillana and lower Weeli Wolli Creek hyporheic zones previously (WRM unpub. data). *Australoeucyclops karaytugi* is endemic to the Pilbara region, and is known from springs and surface water pools. During the current study it was recorded from the hyporheic zones of MAR1-2 and MAR1-6. *Microcyclops varicans* has been collected widely from surface waters, as well as groundwater environments including deep bores and hyporheic zone samples (Martens and Rossetti 2002, Halse *et al.* 2002, DEC

2009). It was recorded from all sites sampled during the current study, with the exception of MAR1-5. *Mesocyclops holynskae* is restricted to the Pilbara, but appears to have a disjunct distribution, being known from Weeli Wolli Creek, Mulga Downs Station and Pardoo (Karanovic 2006, Ecowise 2007). During the current study, it was recorded from lower Weeli Wolli Creek only (WW5-1 and WW5-4).

The dytiscid beetle *Limbodessus occidentalis*[15]was classified as an occasional hyporheos stygophile as this species is known from both epigean[16] and stygal habitats. This species is one of several diving beetle species recently found to inhabit groundwater calcrete formations across inland Western Australia (Watts and Humphreys 2006). Most individual calcrete aquifers contain an assemblage of diving beetle species, which also frequent surface waters and hyporheic zones connected to the aquifers (Leys *et al*. 2003, Watts and Humphreys 2006). Elsewhere in the Pilbara, *L. occidentalis* has been recorded from calcrete aquifers at Killara North (approximately 300 km south of Weeli Wolli Creek) and Moorarie (around 125 km west of Killara), and from surface waters and hyporheic habitats of the Fortescue River system (Weeli Wolli Spring, Gregory Gorge, Joffre Creek), the Ashburton River (Creek Pool near Mt Amy, Beasley River, Caves Creek, Duck Creek), the Robe River (Red Hill Creek pools) and the Harding River (Watts and Humphreys 2004, Pinder *et al.* 2010, WRM unpub. data). *Limbodessus occidentalis* specimens are most commonly collected from the edge of pools in sandy and gravelly riverbeds (Watts and Humphreys 2004). *L. occidentalis* was recorded from the hyporheic zone of MAR2-5, WW5-1, WW5-2, WW5-4 and WW5-6.

One of the chironomid species recorded from hyporheic samples was considered to be a possible hyporheic species, the Tanypodinae ?*Pentaneura* sp. This species is currently undescribed and appears to have a highly disjunct distribution in the Pilbara, being known from Weeli Wolli Creek, Marillana Creek, upper Fortescue River, Fortescue River South, Caves Creek (Palm Spring), as well as within the Robe River and DeGrey River catchments (WRM unpub. data). It was considered likely to be a hyporheic species due to its small size (they are at least half the size of other Tanyponids) and characteristic reduced eye (Dr Don Edward, The University of Western Australia, pers. comm.). During the current study, ?*Pentaneura* sp. was collected from the hyporheic sample of MAR2-9.

3.5.3 Temporal changes in hyporheos fauna

Taxa richness

The average number of hyporheos[17] taxa (using standardised, amalgamated taxonomy) collected from Marillana Creek during the dry season generally appeared to have increased over time in both reaches to 2012, with a considerable decrease in 2013, particularly in Mar-One (Figure 23). Two-way ANOVA supported the observation of a change in dry season taxa richness over time and found a significant difference in Marillana Creek hyporheos taxa between years (df = 5, p = 0.000; Table 8). The number of taxa considered to be restricted to the hyporheos was lowest in the 2008 and highest in 2012 (Table 8). This change was not reflected in a significant positive linear relationship between hyporheos taxa richness and time in either Mar-One (r = 0.55, p = 0.25, Spearman Rank Correlation p = 0.21) or Mar-Two (r = 0.71, p = 0.11, Spearman Rank Correlation p = 0.54; Figure 23). This was largely due to the considerable decrease in taxa richness between the dry of 2012 and 2013 in Mar-One, and decrease between the dry of 2010 and 2011 in Mar-Two.

[15] Previously known as *Boongurrus occidentalis* sp. nov. (Watts and Humphreys 2004). The genus *Boongurrus* has since been synomised with *Limbodessus* (Balke and Ribera 2004).
[16] Epigean habitats = on or close to the surface of the ground, i.e. surface water species.
[17] Hyporheos taxa – species adapted to hyporheic environments, including occasional hyporheos stygophiles, permanent hyporheos stygophiles, stygobites and possible hyporheic species.

There did not appear to be any change in hyporheos taxa richness over time during the wet season (Figure 23). In fact, there was no significant difference in hyporheos taxa richness between years (df = 5, p = 0.473), nor was there a significant relationship between taxa richness and time for either Mar-One (r = 0.14, p = 0.80, Spearman Rank Correlation p = 0.80) or Mar-Two (r = 0.29, p = 0.58, Spearman Rank Correlation p = 0.58; Figure 23).

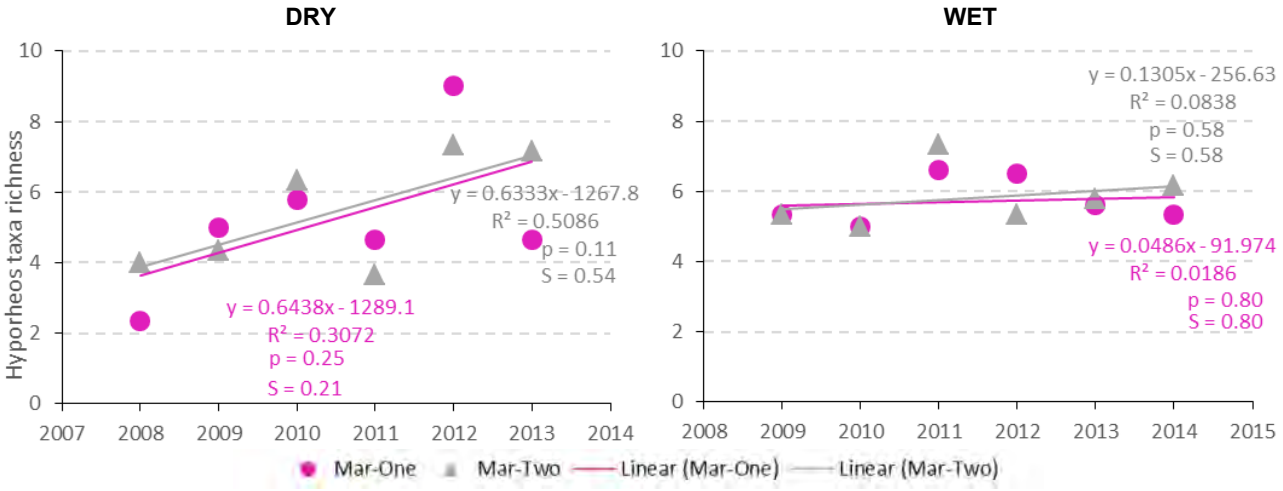

Figure 23. Linear regression plots of mean hyporheos fauna taxa richness against time for Marillana Reaches One and Two in the dry season (left) and wet season (right). Equations, p-value, Spearman correlation co-efficient (S) and R^2 values are displayed.

Table 8. Two-way ANOVA results comparing hyporheos fauna taxa richness between reach and year, for each season. Degrees of freedom, mean squares and p-values are shown. Tukey's *post-hoc* results are presented in ascending order of mean microinvertebrate taxa richness, with groups with no difference in means joined by a black line.

Dry season									
Source	***df***	***MS***	***p***	**Tukey's *post-hoc***					
Reach	2	1.41	0.722	**Mar-One**	**Mar-Two**	**WW-Five**			
Year	5	34.37	0.000	**2008**	**2011**	**2009**	**2010**	**2013**	**2012**
Reach*Year	6	6.58	0.184						
Corrected Total	79								
Wet season									
Source	***df***	***MS***	***p***	**Tukey's *post-hoc***					
Reach	2	7.42	0.308	**Mar-Two**	**Mar-One**	**WW-Five**			
Year	5	5.69	0.473	**2010**	**2009**	**2012**	**2013**	**2014**	**2011**
Reach*Year	7	4.50	0.648						
Corrected Total	75								

Additional hyporheos taxa recorded in more recent sampling events, but not present in the hyporheic zone in the dry-08, include the copepods *Australoeucyclops karaytugi* and *Mesocyclops holynskae*, *Vestalenula* and *Gomphodella* n. sp. (BOS334) ostracods, and the dytiscid *Limbodessus occidentalis*.

Although hyporheos taxa richness was slightly higher from lower Weeli Wolli Creek (WW-Five), this difference was not significant in either the dry (df = 2, p = 0.722) or wet seasons (df = 2, p = 0.308; Table 8).

3.6 Macroinvertebrates

3.6.1 Taxonomic composition and species richness

A total of 151 macroinvertebrate taxa were recorded from Marillana Creek in the dry-13, and 144 in the wet-14. Lower Weeli Wolli Creek (WW-Five) recorded 111 taxa in the dry-13, and 98 in the wet-14. The taxonomy of aquatic macroinvertebrates is constantly advancing, and there is now a greater level of resolution for a number of groups, particularly Oligochaeta, Baetidae and Crambidae. As such, the number of taxa recorded in this study may appear greater than reported for previous sampling events.

The greatest macroinvertebrate taxa richness was recorded at Mar-Two in the dry-13 (132 taxa; Table 9). The high richness at this reach was influenced by high numbers of taxa belonging to groups known to be tolerant to disturbance including Diptera (two-winged fly larvae), Coleoptera (beetles) and Hemiptera (true bugs), in both seasons (Table 9). There was a decline in taxa richness at WW-Five between the dry-13 (111 taxa) and wet-14 (98) sampling events. This was due, in part, to a decline in richness of disturbance-tolerant groups (Coleoptera and Hemiptera). Conversely, groups that favour riffle zones and enhanced water quality, i.e. Trichoptera (particularly Hydropsychids), Lepidoptera and Ephemeroptera increased in richness. This likely reflects the increase in flows across WW-Five sites during the wet season. There was no change in taxa richness at Mar-One between the dry-13 and wet-14 (95 taxa). In both seasons, Mar-One was characterised by high richness of Dipteran taxa (Table 9).

Macroinvertebrate taxa richness also varied between sites. MAR2-4 recorded the highest richness (70 taxa in the wet-14), followed by MAR2-5 (64 taxa in the dry-13; Figure 24). Macroinvertebrate richness was lowest at MAR2-8 (20 taxa), followed by WW5-1 (26 taxa) and WW5-2 (27 taxa), all during the dry season (Figure 24). Within Marillana Creek, taxa richness declined downstream of MAR2-4 and the D09 discharge outlet, in both seasons (Figure 24). Although this followed a similar trend to that of nutrients (see section 3.2.1), the longitudinal pattern in macroinvertebrate richness was more likely due to the greater areal extent of creekline inundated immediately downstream of the discharge point, and concomitant increase in habitat diversity and heterogeneity available for macroinvertebrates at MAR2-4 (see section 3.3.1).

Macroinvertebrate taxa richness is known to be related to hydrological performance; intermittent streams often harbour a lower taxa richness compared to permanent water bodies, with richness increasing with flow duration (Vinson and Hawkins 1998). Taxa richness is also known to increase with stream size, habitat heterogeneity, and macrophyte abundance (Heino *et al.* 2003). As seen in Figure 24, taxa richness is generally more consistent across sites in the wet-14. At this time, the creeklines were flowing consistently, and stream size was similar at each site.

Table 9. Macroinvertebrate taxa richness recorded from each reach during the dry-13 and wet-14.

Invertebrate group	No. of taxa					
	Dry 13			Wet 14		
	Mar-One	Mar-Two	WW-Five	Mar-One	Mar-Two	WW-Five

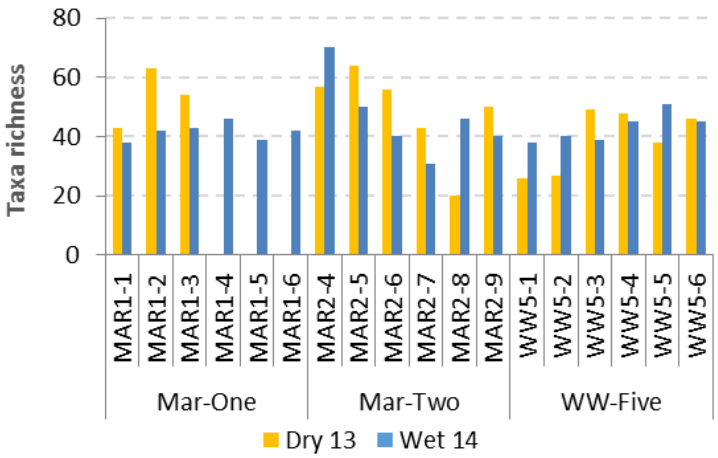

Figure 24. Macroinvertebrate taxa richness recorded from Marillana and lower Weeli Wolli Creeks in the dry-13 and wet-14.

3.6.2 Conservation significance of macroinvertebrates

Macroinvertebrates recorded during the current study were generally common, ubiquitous species, with distributions extending across Northern Australia, Australia or Australasia. However, a number were endemic to the Pilbara region, including the stygal amphipods *Maarrka weeliwolli, Chydaekata* sp., Paramelitidae sp. B, Paramelitidae sp. D, and immature or damaged Paramelitidae spp. Other endemics included the dragonflies *Nannophlebia injibandi* and *Ictinogomphus dobsoni,* and the aquatic beetles *Tiporus tambreyi and Laccobius billi*. The greatest number of Pilbara endemic taxa was recorded in the dry season; at MAR2-9 and WW5-4 (three taxa each; Figure 25).

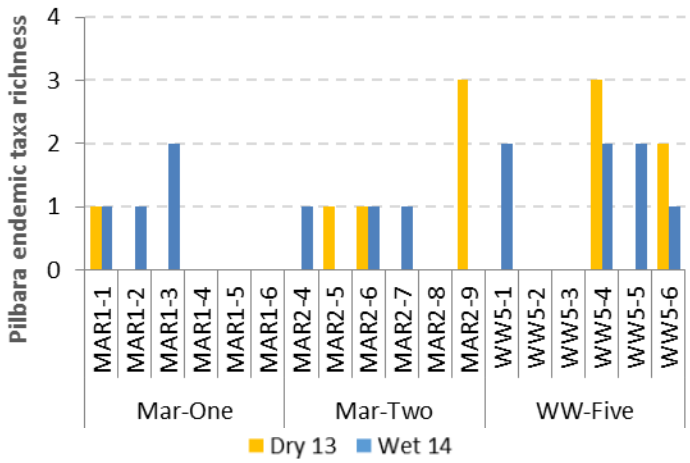

Figure 25. Richness of Pilbara endemic taxa recorded from Marillana and lower Weeli Wolli Creeks in the dry-13 and wet-14.

The Pilbara Archtail dragonfly, *Nannophlebia injibandi*, was recorded from a number of sites, including MAR1-1, MAR2-5, MAR2-6 during dry-13, and MAR1-1, MAR1-2, MAR1-3, MAR2-6, WW5-1 and WW5-5 in the wet-14. *N. injinbandi* was recorded infrequently during the Pilbara Biological Survey (Pinder *et al.* 2010), however it has been recorded from Weeli Wolli Creek, including sites upstream of the HD1 mine, Roy Hill on the Fortescue River, Fortescue Falls in Karijini National Park, and Skull Springs on the DeGrey River by WRM (WRM, unpub. data). There are also records of *N. injibandi* from Koodaideri Spring (Bennelongia 2011, WRM 2014). As such, this species appears to have a relatively broad, albeit disjunct, distribution throughout the Pilbara, but does not appear to be abundant or commonly recorded. It does appear to be distributed along the length of Marillana Creek, and is frequently recorded during WRM monitoring.

The Pilbara Tiger dragonfly, *Ictinogomphus dobsoni* (Plate 4), was recorded at MAR1-3 in the wet-14. *I. dobsoni* is known to frequent permanent still or sluggish waters (Watson 1991), and although endemic, appears to be reasonably common throughout the Pilbara. It has been recorded previously from Gregory Gorge (ANIC Database), Fortescue River on Millstream Station (ANIC Database), Fortescue Falls/Dales Gorge (DEC 2009) and from Hardey River (WRM, unpub. data). It was also recorded from sites across the Pilbara during the Pilbara Biological Survey, including Bobswim Pool (Ashburton), Robe River, Woggina Springs (Yule), Pelican Pool (DeGrey), Red Hill Creek, Horrigan's Pool (Ashburton) and Henry River (Pinder *et al.* 2010).

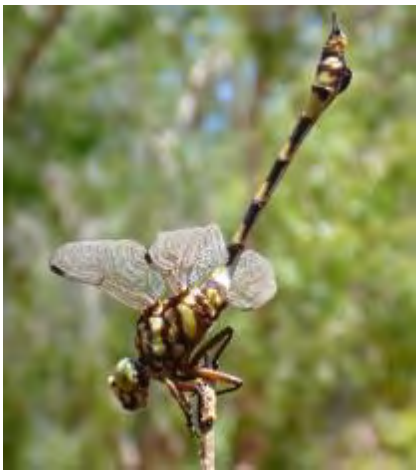

Plate 4. The Pilbara endemic dragonfly *Ictinogomphus dobsoni* (photo by Chris Hofmeester/WRM).

Interestingly, the Pilbara pin damselfly, *Eurysticta coolawanyah*, which has been recorded previously from MAR2-3, MAR2-4, MAR2-5, WW5-5 and WW5-6 downstream of Rio Tinto operations, was not recorded in the present study. This species is listed on the IUCN Redlist as **Near Threatened**, based on its distribution being restricted to an area of less than 500 km^2, and it being thought to occur at less than five locations (Millstream Station, Nanuturra Pools, Palm Pool and the Millstream area). However, the listing of the Pilbara Pin is considered to require revision, as it has since been recorded from over 40 locations throughout the Pilbara (Pinder *et al*. 2010). This increases its distribution above the 500 km^2 threshold defined by the IUCN. The absence of *E. coolawanyah* from Marillana Creek and lower Weeli Wolli Creek in the dry-13 and wet-14 is of interest but not of great concern.

As *E. coolawanyah* is known from areas outside the Marillana and Weeli Wolli Creek dewatering-discharge impact zones, populations are considered unlikely to be seriously affected at a regional level. Future monitoring will ascertain whether this species still occurs within the creek and was just not captured during the current study.

The four stygobitic amphipod species recorded in the hyporheic zone were also recorded in macroinvertebrate samples: *Maarrka weeliwolli, Chydaekata* sp., Paramelitidae sp. B and Paramelitidae sp. D, along with immature or damaged Paramelitidae specimens. No stygal amphipods were recorded from MAR-One in either season. Paramelitidae sp. B and Paramelitidae sp. D were both recorded at MAR2-9 during the dry-13, and Paramelitidae sp. B was recorded from MAR2-7 and MAR2-9 during the wet-14. Along lower Weeli Wolli Creek, Paramelitidae sp. D was present at WW5-6 during dry-13, and Paramelitidae sp. B at WW5-1 and WW5-4 during wet-14. *Chydaekata* sp. and *Maarrka weeliwolli* were both recorded at WW5-4 in dry season surface samples. All four stygobitic amphipod species are likely to be short range endemics, given their restricted distributions (see section 3.5.2).

The Pilbara endemic beetles *Tiporus tambreyi* (Dytiscidae) and *Laccobius billi* (Hydrophildae) were recorded at a number of Mar-Two and WW-Five sites, downstream of Rio Tinto. The dytiscid beetle *Tiporus tambreyi* appears to be common and ubiquitous across the Pilbara region (WRM unpub. data). However, the hydrophilid beetle *Laccobius billi* is a Pilbara endemic that appears to be rarely collected. It was only recorded from one site during the Pilbara Biological Survey; Cangan Pool on the Yule River (Pinder *et al.* 2010), approximately 100 km north-west of Marillana Creek. It has been recorded by the authors from Weeli Wolli Creek, Coondiner Creek and Mindy Mindy Creek (WRM, unpub. data).

3.6.3 Spatial and temporal change in macroinvertebrates

Taxa richness

Two-way ANOVAs were performed on amalgamated dry and wet season macroinvertebrate data, in order to test for differences between reaches and years (ANOVA and Tukey's *post-hoc* results are presented in Table 10). During the dry season, there was a significant difference in macroinvertebrate richness between year ($df = 5$, $p = 0.001$), but not between reach ($df = 2$, $p = 0.582$). Mean richness was highest in 2008 (40.75), though this was statistically similar to that recorded in 2013, 2011 and 2012.

Wet season macroinvertebrate richness was significantly different between year ($df = 5$, $p > 0.001$) and reach ($df = 2$, $p = 0.005$). Mean richness was highest in 2013 (41.43), though this was statistically similar to that recorded in 2014 and 2012 (Table 10). Lowest mean richness was recorded in 2010 (25.86), followed by that recorded in 2009 and 2011, respectively. This was due, at least in part, to the low mean taxa richness recorded from Mar-One in 2010 (11 taxa). At this time, only one site in this reach held water. This site appeared to have only recently filled, and therefore the macroinvertebrate re-colonisation and ecological succession of this pool were in their early stages, equating in low species richness. Macroinvertebrate richness was significantly higher at WW-Five, compared to the Marillana Creek reaches (Table 10). The high mean richness recorded at WW-Five in 2012 (48.17), plus the aforementioned low richness at Mar-One in 2010 primarily influenced this result.

Table 10. Two-way ANOVA results for dry and wet season macroinvertebrate taxa richness by reach and year, showing degrees of freedom, mean of squares, f-value and p-value. Tukey's *post-hoc* results are presented in ascending order of mean macroinvertebrate taxa richness, with groups with no difference in means joined by a black line.

Dry Season

Total	81										

During the dry season, there was no linear relationship between macroinvertebrate taxa richness and time for Mar-One (r = 0.45, p = 0.37, Spearman p = 0.54) or Mar-Two (r = 0.07, p = 0.90, Spearman p = 0.96; Figure 26). That is, there was no overall increase or decrease in taxa richness over time during the dry. However, during the wet season, there was a significant positive linear relationship between mean taxa richness and time for Mar-One (Spearman p = 0.02; Figure 26). Similarly, there was a significant increase in wet season taxa richness over time at Mar-Two (p = 0.02, r = 0.87; Spearman p = 0.02; Figure 26). Increasing wet season taxa richness at Mar-Two since 2008 is likely due to Rio Tinto's Yandi operations, with discharge providing increased habitat size and heterogeneity, increased flows and an increase in taxa known to be tolerant of environmental change.

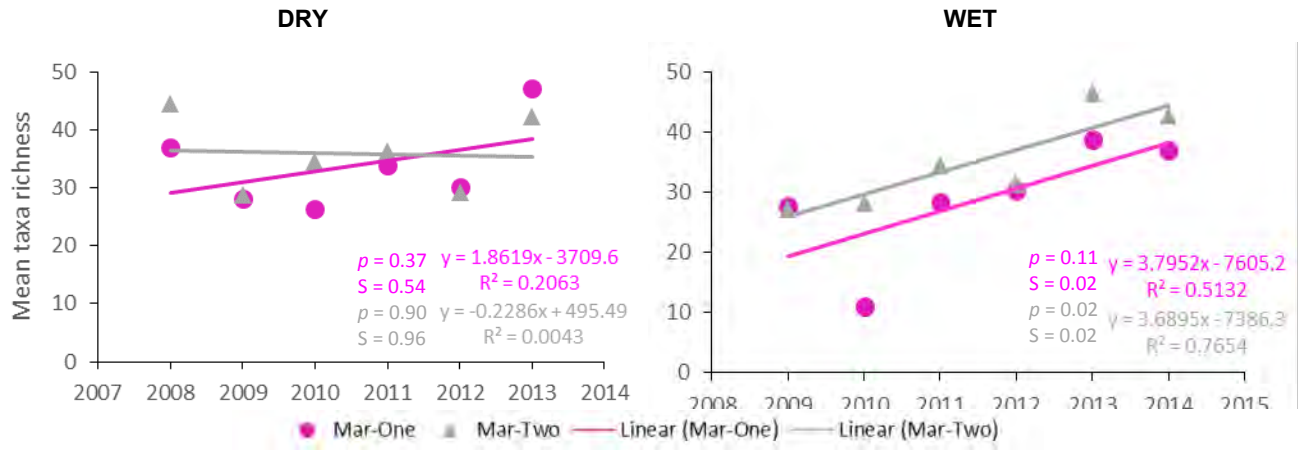

Figure 26. Linear regression plots of mean macroinvertebrate taxa richness against time for Marillana Reaches One and Two in the dry season (left) and wet season (right). Equations, p-value, Spearman correlation co-efficient (S) and R^2 values are displayed.

Comparisons with Weeli Wolli Creek

Incorporating all Weeli Wolli and Marillana Creek macroinvertebrate log_{10} abundance data into the analyses, patterns were evident in the dry season constrained CAP plot examining differences between reach (Figure 27). The correlation along both canonical axes was fairly high: CAP1 was 0.84 and CAP2 was 0.78. Macroinvertebrate assemblages from WW-Five separated from all other reaches along CAP1 based on higher abundances of taxa which prefer slow-flowing waters, such as the freshwater snail *Bullastra vinosa* and non-biting midge larvae *Chironomus* sp. (Figure 27). This reflects the intermittent nature of this reach, where sites are often reduced to small pools during the dry season. There was some overlap of Marillana Creek (Mar-One & Mar-Two) macroinvertebrate samples with those of WW-Four (the Weeli Wolli Creek reach immediately downstream of the confluence with Marillana Creek), suggesting macroinvertebrate assemblages in these areas were similar. There also appeared to be a longitudinal pattern in macroinvertebrate assemblages along Weeli Wolli Creek, with WW-One, WW-Two and WW-Three samples separating along CAP2 (Figure 27). The separation of WW-One from other reaches was influenced by higher abundances of stygal amphipods (Paramelitidae spp.).

Similar patterns were evident during the wet season (Figure 27). The correlation along both canonical axes was again fairly high: 0.84 along CAP1 and 0.72 along CAP2. While there was a longitudinal pattern along Weeli Wolli Creek, it was less pronounced than in dry season, with some overlap of reaches Two and Three (Figure 27). Comparatively, there was considerable overlap of Mar-One and Mar-Two samples with those of WW-Five, with species associated with low flows no longer affecting the separation of these samples (Figure 27). This indicates that the macroinvertebrate assemblages of lower Weeli Wolli Creek are at times more similar to those of Marillana Creek, likely due to increased flow consistency and habitat heterogeneity of these reaches during the wet season.

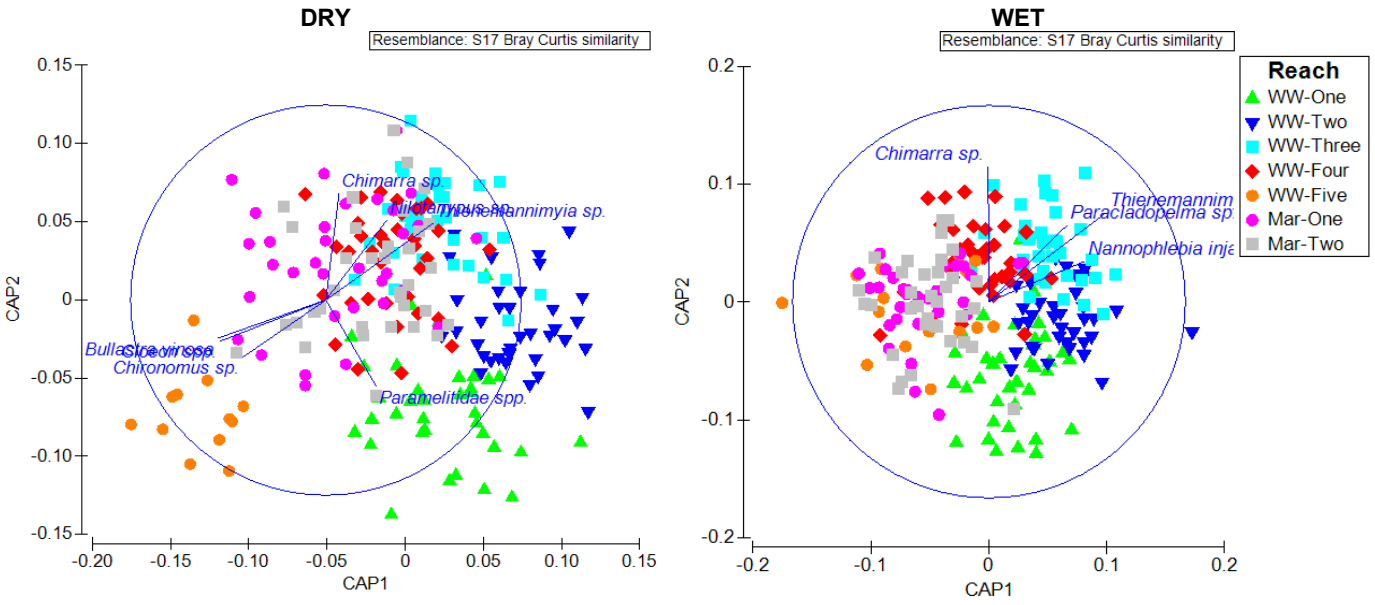

Figure 27. Constrained CAP plot comparing macroinvertebrate abundance data between reaches in the dry (left) and wet season (right), with vectors of Spearman rank correlations overlain (correlation >0.5).

PERMANOVA testing indicated that there was a significant difference between reach (df = 6, p = 0.001) and year (df = 5, p = 0.001) during the dry season. There was also a significant difference between reach (df = 6, p = 0.001) and year (df = 5, p = 0.001) during the wet season (Table 11).

Table 11. Two-factor PERMANOVA results for dry and wet season data, comparing macroinvertebrate assemblages (log_{10} abundance data) between reach and year.

Residual	186	962.86		
Total	224			

There was generally no correlation between macroinvertebrate assemblages and water quality characteristics in the dry (BVSTEP; Rho = 0.45) or wet (BVSTEP; Rho = 0.36). However, water quality variables which were found to have the greatest influence on the dry season macroinvertebrate assemblages were pH, DO%, and concentrations of chloride, bicarbonate, sulfate, ammonia and total phosphorus. pH, water temperature, DO, and concentrations of magnesium, sulfate, ammonia, and total phosphorus were found to have the greatest influence on the wet season macroinvertebrate assemblages.

Similarity of dry season macroinvertebrate assemblages remained relatively consistent over time in both Marillana Creek reaches, with a slight decrease in similarity occurring between 2009 and 2011, and a slight increase to 2013 (Figure 28). This concurs with regression analysis on macroinvertebrate taxa richness from Marillana Creek reaches, where no significant change over time was detected in the dry season (see Figure 28). During the wet season, however, there was a considerable difference in similarity over time between reaches (Figure 28). In Mar-One, macroinvertebrate assemblages did not show any change in similarity compared to "baseline" until 2011, after which little change was evident (Figure 28). The difference in similarity between the 2010 and the 2011 Mar-One wet season corresponded to a 55% change in assemblage similarity (Figure 28). In contrast, in Mar-Two, assemblages remained relatively consistent between 2010 and 2012, following the initial change. There was some increase in similarity (i.e. some return to "baseline" condition) after 2012 (Figure 28).

Figure 28. Temporal consistency in similarity (distance to centroid, PERMANOVA) between macroinvertebrate assemblage data from initial sampling (2008 in the dry season, 2009 in the wet season) and subsequent sampling events. Values are based on percent similarity derived from Bray-Cutis similarity matrices.

3.7 Fish

3.7.1 Species richness

Three of the twelve freshwater fish species known from the Fortescue River System were recorded from the Marillana and lower Weeli Wolli creeks during this survey: the spangled perch *Leiopotherapon unicolor*, Pilbara tandan (eel-tailed catfish) *Neosilurus* sp.[18], and western rainbowfish *Melanotaenia australis.* All three species were recorded from Mar-One and Mar-Two during the dry-13, however only western rainbowfish were recorded from WW-Five (Table 12). All three fish species were recorded all reaches in the wet-14. The lack of spangled perch and Pilbara tandan from lower Weeli Wolli Creek during the dry season was likely due to receding water levels at the time of sampling, with only small remnant pools remaining along the reach. It appears these species recolonised WW-Five in wet season, as rains increased water levels and reconnected this reach with Marillana Creek and the upper reaches of Weeli Wolli Creek (Table 12).

3.7.2 Abundance

A total of 2715 freshwater fish were collected during the current study; 761 in the dry-13, and 1954 in the wet-14 (Table 12). There was a general increase in fish abundance compared to the previous rounds of sampling, where 693 individuals were collected in the dry season, and 1609 in the wet season (WRM unpub. data). Western rainbowfish was the most abundant species collected in both seasons, making up 76% and 71% of all fish caught in the dry and wet seasons, respectively. During the dry-13, the greatest abundance of fish was recorded from Mar-Two (341), while in the wet-14, greatest fish abundance was recorded from WW-Five (709) (Table 12).

Table 12. Abundance of fish caught from Marillana Creek and lower Weeli Wolli Creek during the dry-13 and wet-14.

Dry-13				
	Western rainbowfish	Spangled perch	Hyrtl's tandan	Total
Mar-One	267	48	16	331
Mar-Two	221	38	82	341
WW-Five	89	0	0	89
Total	577	86	98	761
Wet-14				
	Western rainbowfish	Spangled perch	Hyrtl's tandan	Total
Mar-One	365	139	88	592
Mar-Two	438	187	28	653
WW-Five	586	84	39	709
Total	1389	410	155	1954

3.7.3 Comparisons with historic fish data

Abundance

In both seasons, higher mean abundances of all three fish species were recorded from the downstream reach, Mar-Two (although in most cases, these differences were not significant; see Table 13). The greater abundance of fish in Mar-Two may be due to the more predictable nature of flows in this reach. Discharge from BHPBIO operations upstream of Mar-One appears to be lower in volume and more sporadic than the discharge of Rio Tinto's Yandi operations further downstream, as Mar-One is often dry or appears recently flooded, whilst Mar-Two holds more water consistently.

[18] Previously referred to as *Neosilurus hyrtlii*. Recent genetic evidence indicates the Pilbara species is distinct from elsewhere in Australia.

Similarly, WW-Five is highly seasonal, often reduced to small receding pools for most of the year. The less predictable nature of flows/water availability in Mar-One and WW-Five would make conditions more difficult for fish to persist, particularly in the dry season.

On a temporal scale, the main significant findings of Two-way ANOVA and regression analysis performed on current and historical (dry 2008 – wet 2013) fish data were:

- There was a significant difference in dry season western rainbowfish abundance between years. The lowest abundance was recorded in 2013 and the highest in 2011. Lowest abundances were also recorded in 2013 during the wet season (Table 13). In both seasons, rainbowfish abundances have appeared to decrease in Mar-Two over time, but given the relatively lower numbers present in the initial "baseline" sampling event (2008 in the dry and 2009 in the wet), this reduction over time was not significant (Figure 29). Similarly, there was no significant relationship between rainbowfish abundance and time in Mar-One in either season (Figure 29).

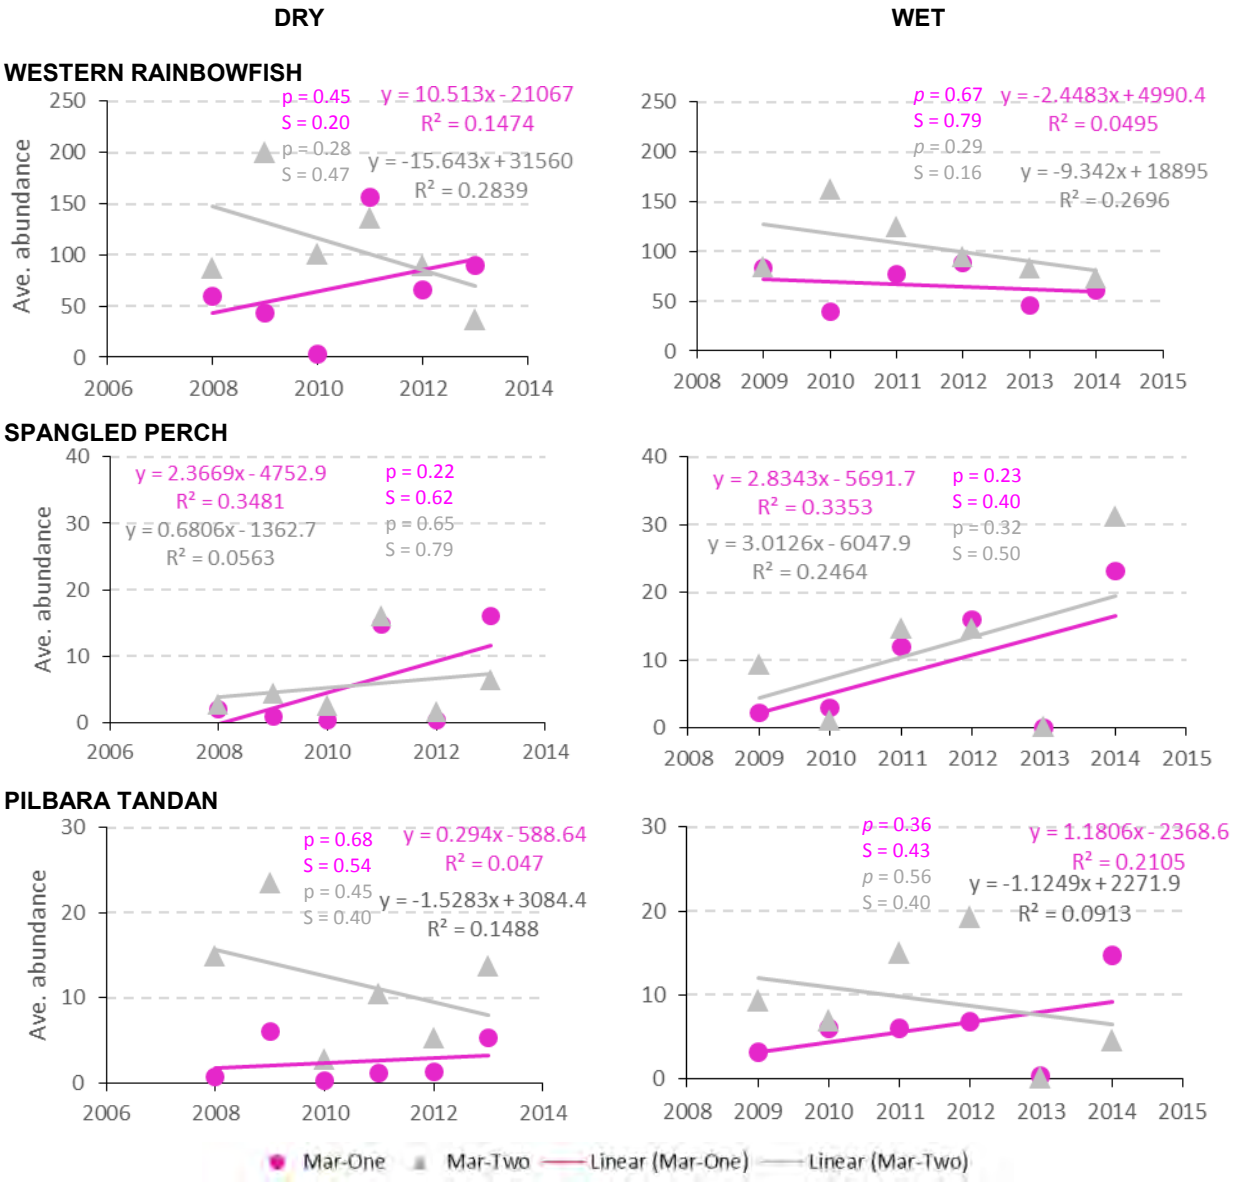

Figure 29. Linear regression plots of mean fish abundance against time for Marillana Reaches One and Two in the dry season (left) and wet season (right). Equations, p, Spearman correlation co-efficient (S) and R^2 values are displayed.

Table 13. Two-way ANOVA results for dry and wet season fish abundance data by reach and year, showing degrees of freedom, F-value and p-value. Tukey's *post-hoc* results are presented in ascending order of mean abundance, with groups with no difference in means joined by a black line.

	Reach* Year	7	2.59	0.020	

- In the dry season, there was a significant difference in spangled perch abundance between years, although Tukey's *post-hoc* testing could not locate these differences. Wet season spangled perch abundance was highest in 2014, however this was statistically similar to 2011 and 2012 (Table 13). There was no significant change in dry or wet season spangled perch abundance over time at either reach (Figure 29). In the wet season, abundances did appear to increase over time in both reaches, however, due to the apparent absence of spangled perch from Marillana Creek in the wet-13, this increase over time was not significant (Figure 29).

- Catfish abundances were significantly different between years during both seasons (Table 13). The highest dry season abundance of Pilbara tandan was recorded in 2009 and the lowest in 2010. During the wet season, catfish abundance was lowest in 2013 and highest in 2012 (Table 13). The abundance of Pilbara tandan did not significantly increase or decrease over time at the either Marillana Creek reach in either season (Figure 29).

3.7.4 Patterns in age class structures and comparisons with Weeli Wolli Creek

In order to examine patterns in the fish data further, each species was broken into four age classes based on body size (standard length), as measured in the field, with each age class treated as a pseudo-species in multivariate analyses. Age-classes were based on information garnered from published literature, and are provided in Table 14. Abundances within each age-class were totalled across the three reaches in each season. Mar-One from the wet-10, and WW-Five from the wet-13 were ultimately removed from multivariate analyses, due to low site replication (Mar-One) and low fish numbers (WW-Five).

Table 14. Sizes used for each of the age-classes for each fish species.

Species	Age-class	Size mm SL
Western rainbowfish	New recruit	< 30
	Juvenile	31-40
	Sub-adult	41-50
	Adult	>51
Spangled perch	New recruit	< 30
	Juvenile	31-50
	Sub-adult	51-70
	Adult	>71
Pilbara tandan catfish	New recruit	< 30
	Juvenile	31-70
	Sub-adult	71-90
	Adult	>91

Good recruitment of western rainbow fish was observed at Marillana Creek during both seasons. New recruits made up 38% of all rainbowfish recorded from Mar-One, and 32% of rainbowfish recorded at Mar-Two during the dry-13, while also accounting for 28% of all rainbowfish at Mar-One, and 40% of rainbowfish at Mar-Two in the wet-14. In comparison, rainbowfish recruitment was lower at WW-Five (21% of rainbowfish were new recruits in the dry-13, and 19% were new recruits in the wet-14). No spangled perch new recruits were recorded at any reach in either season, and only one Pilbara tandan new recruit was recorded in the current study; at Mar-Two in the dry-13. Similar trends have been recorded in previous surveys of Marillana Creek and Weeli Wolli Creek (WRM unpub. data), however the cause of the seemingly limited recruitment capacities of these species in Marillana Creek are currently unknown. Other age-classes of spangled perch and Pilbara tandan were well represented at both Marillana Creek reaches in each season, and at WW-Five during the wet-14. This suggests that although recruitment does not appear to be occurring within the creek itself, populations are being maintained by migration from downstream environments and/or tributaries during times of connection, i.e. wet season flooding. Spangled perch are known to make general fast migrations to colonise other riverine habitats. They have two types of movement;

1. Migratory behaviour of adults – associated with reproduction
2. Lateral movement (dispersal) of adult and juvenile fish away from dry season refuges and into floodplain habitats (Pusey *et al.* 2004, Marsden and Power 2007).

Migration associated with reproductive behaviour occurs in an upstream direction (generally in the mid-wet season), and in Magela Creek in the Northern Territory, spangled perch have been tracked to move between 8.5 and 9.4 km per day (Bishop *et al.* 1995). Differences in progress rates were noted to occur between size classes of spangled perch because swimming speeds are positively

correlated with body size (Bishop *et al.* 1995). Importantly, spangled perch tend to be found in tributaries and upstream reaches, rather than fast-flowing sections of main channels. In QLD, they were most commonly collected from areas of little or no flow (Pusey *et al.* 2004), and Bishop *et al.* (2001) reported that they do not occur in velocities greater than 0.9 m/s. In a study of stream ecosystem response to coal seam gas water releases in QLD, Takahashi *et al.* (2011) warned that "spangled perch could be affected by increases in flow velocity." However, at this stage, flow velocities in Mar-Two do not appear to be impacting spangled perch sub-adults and adults (see Figure 30). Changes in the abundances of each age-class generally followed the same pattern of change as total abundance of spangled perch in Mar-Two, with the exception of the wet-14, where the increase in total abundance of this time appeared to be influenced by increases in sub-adult and adult spangled perch, rather than all age-classes (Figure 30). This pattern was less apparent in Mar-One, where juvenile spangled perch also increased in abundance in the wet-14 (Figure 30).

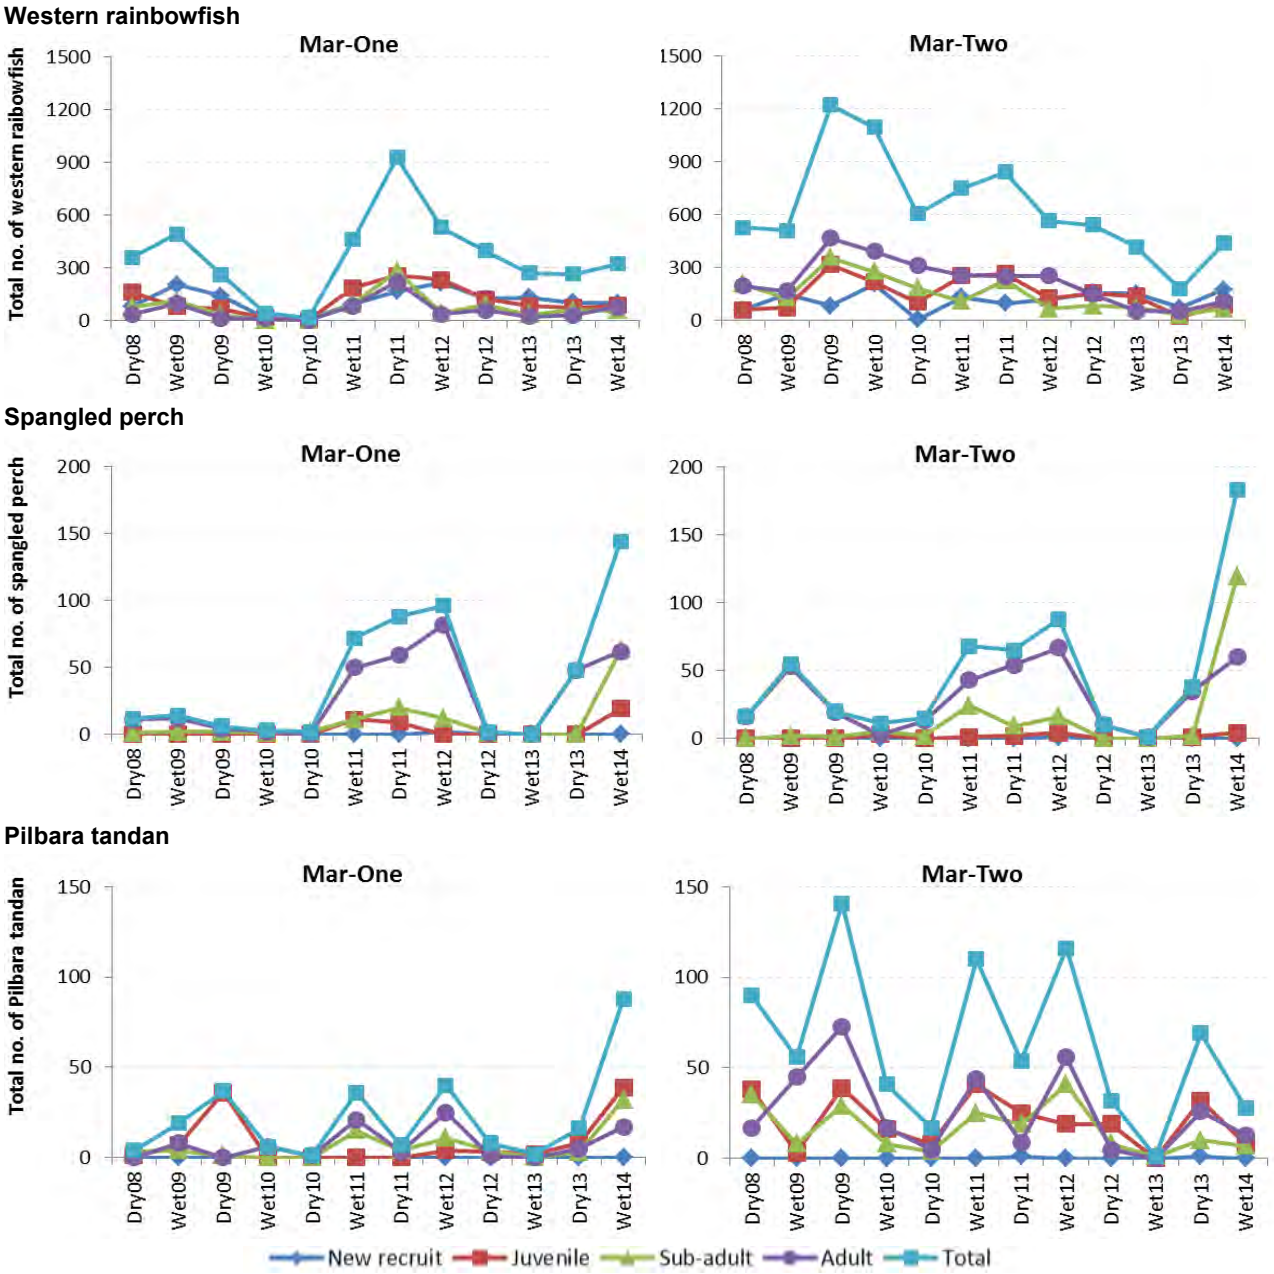

Figure 30. Change in fish abundances of different age-classes of western rainbowfish (top), spangled perch (middle), and Pilbara tandan (bottom) for Mar-One (left) and Mar-Two (right).

Incorporating all Weeli Wolli Creek and Marillana Creek fish age-class abundance data into the analyses, patterns were evident in the dry season constrained CAP plot examining differences between reach (Figure 31). The correlation along both canonical axes was fairly high: CAP1 was 0.83 and CAP2 was 0.68. Upper Weeli Wolli Creek reaches (WW-One, WW-Two and most sites at WW-Three) seemed to cluster separately from the majority of lower Weeli Wolli Creek and Marillana Creek sites, though there was some overlap in ordination space (Figure 31). This was influenced by the differences in abundances of catfish juveniles and sub-adults, and spangled perch adults and juveniles at these reaches (Figure 31). Fish populations of Mar-Two were generally more similar to lower Weeli Wolli Creek populations than the upper Marillana Creek reach (Mar-One). Mar-One fish populations were generally different to all other reaches (Figure 31).

Wet season patterns were also evident in the constrained CAP plot examining differences between reach (Figure 31). The correlation along both canonical axes was again reasonably high: CAP1 was 0.87 and CAP2 was 0.71. There was a longitudinal pattern in Weeli Wolli Creek fish age-class abundance along CAP1 during the wet season, with greater abundances of rainbowfish adults and catfish adults/sub-adults from WW-One & WW-Two influencing the separation with WW-Four (Figure 31). Greater abundances of rainbowfish and catfish juveniles/new recruits from WW-Four also influenced the longitudinal separation of fish samples. Again, Mar-One fish population samples separated from Weeli Wolli Creek reaches, however there was some overlap with Mar-Two sites. There was also some overlap of Mar-Two sites with upper Weeli Wolli Creek sites (Figure 31).

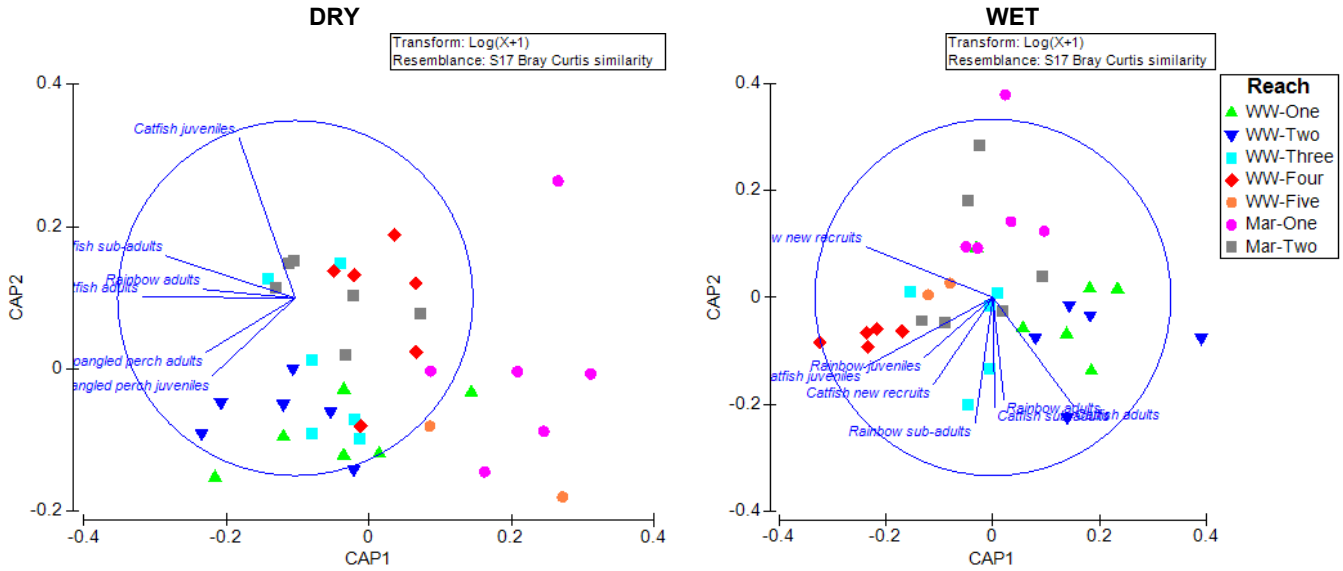

Figure 31. Constrained CAP plots of fish age-class abundance data from Weeli Wolli and Marillana creeks, examining differences between reaches in the dry (left), and wet seasons (right). Vectors of Spearman rank correlations are overlain (correlation > 0.5).

PERMANOVA testing indicated that these patterns were significant. There was a significant difference in fish age-class structures between reach (df = 6, p = 0.002) and year (df = 5, p = 0.005) during the dry season, and there was also a significant difference between reach (df = 6, p = 0.001) and year (df = 5, p = 0.001) during the wet season (Table 15).

Generally, fish age-class structures bore little resemblance to the assemblages present during the initial "baseline" sampling event in either the dry (2008 initial sampling year) or wet season (2009 initial sampling year; i.e. generally less than 20% similarity; Figure 32). However, in Mar-One during the dry season, there was a considerable increase in similarity (~40% increase), i.e. return to more

similar assemblages as those present in 2008. Following the initial change, fish assemblages in Mar-Two remained relatively consistent over time in both seasons (Figure 32).

Table 15. One-factor PERMANOVA results for dry and wet season data, comparing fish age-class abundance between reach and year.

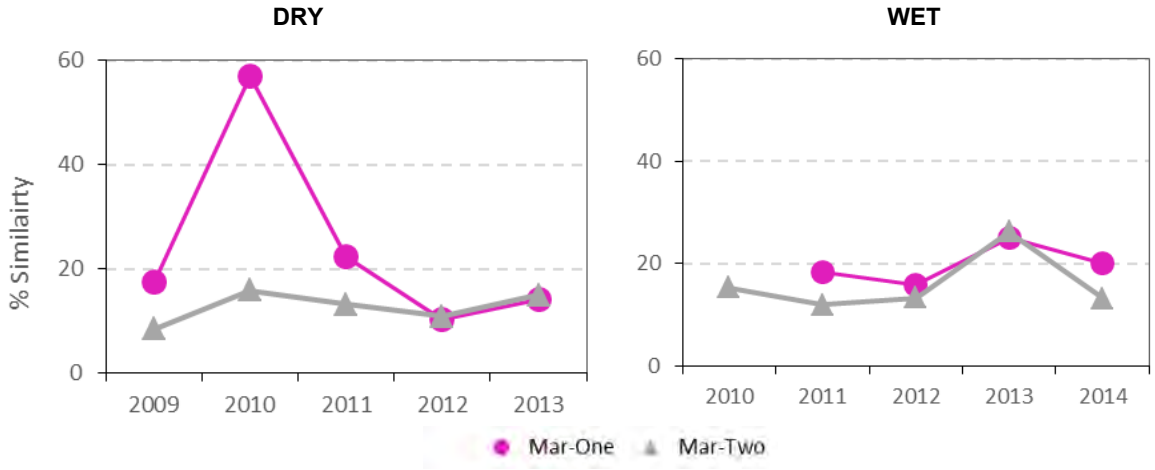

Figure 32. Temporal consistency in similarity (distance to centroid, PERMANOVA) between fish age-class abundance data from initial sampling (2008 in the dry season, 2009 in the wet season) and subsequent sampling events. Distance values are based on percent similarity derived from Bray-Cutis similarity matrices.

4 RISKS IDENTIFIED IN THE HAZARD ANALYSIS

4.1 Eutrophication

Given the elevated nitrate concentrations in the groundwater being discharged, eutrophication was identified as one of the key risks to the aquatic environment in the recent Hazard Analysis for Dewatering Discharge report (WRM 2015a). Nitrate-enriched waters result in eutrophication by fuelling nuisance algal and macrophyte growth (*e.g. Typha*). If growth is excessive/extensive, this may physically smother other life forms, as well as deplete oxygen from the water column due to increased respiration and biological oxygen demand (BOD), leading to anoxia (zero dissolved oxygen) or hypoxia (<20% dissolved oxygen). Increased respiration, particularly at night, is a risk when there is excessive growth of algae and submerged macrophytes, and increased BOD occurs as a result of the breakdown of macrophytes and algae once the plants die-off. The relationship between nitrate-enrichment and enhanced algal growth in freshwaters is well documented, often resulting in very high density/abundance but low species richness (Gorden *et al.* 1982, Townsend *et al.* 2011, Muhid *et al.* 2013). Interestingly, percent algal cover in Mar-Two, downstream of the Rio Tinto's D09 discharge, appeared to follow an inverse relationship with nitrogen concentrations in the most recent sampling rounds of the dry-13 and wet-14, such that algal cover was lower with higher total N (Figure 33). This relationship was not apparent upstream (in Mar-One) during these time periods. While a similar relationship was apparent in the dry-12, prior to the discharge of JSW dewatering water (but not JSE & JC discharge), it was not evident in the wet-13 (Figure 33).

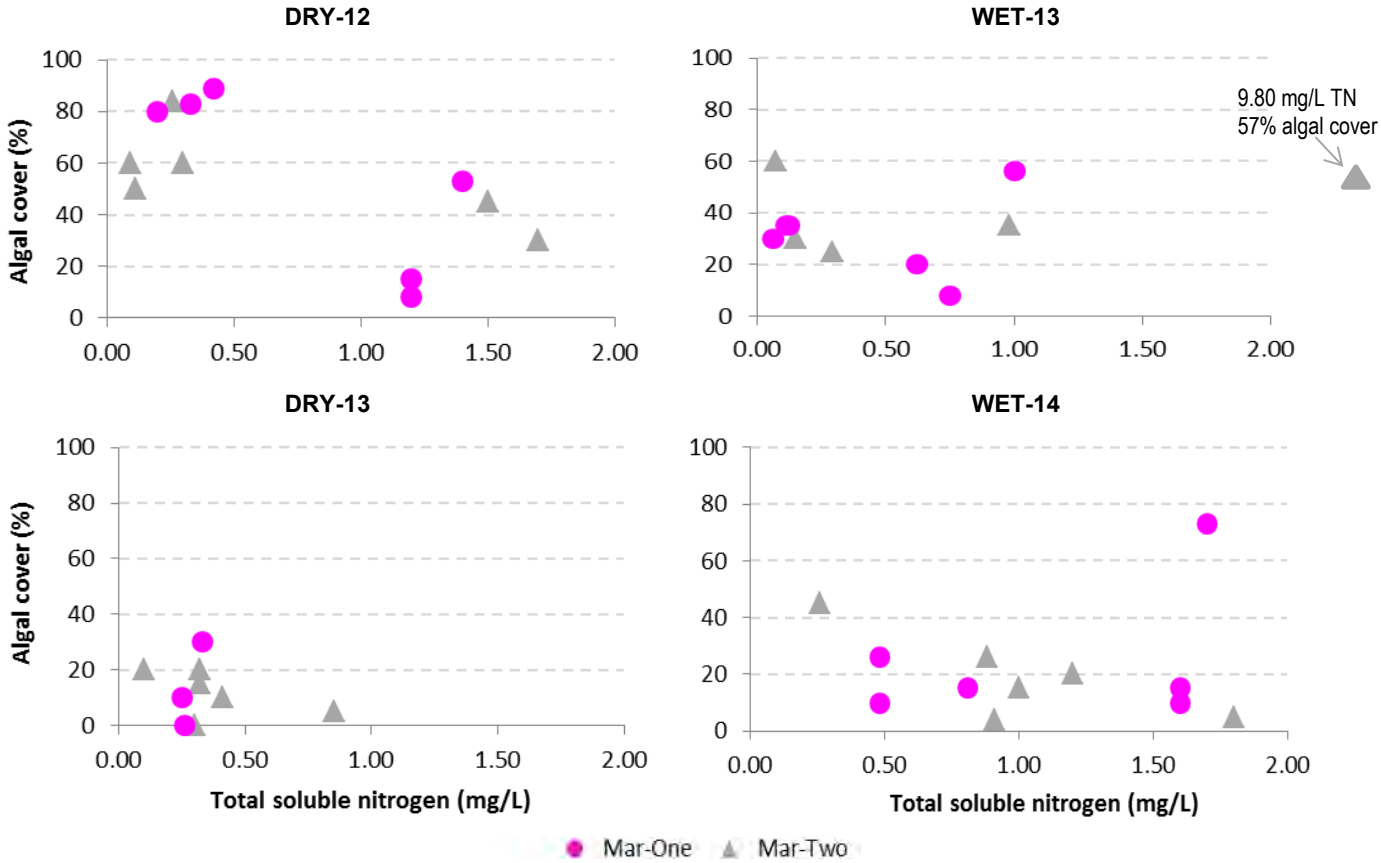

Figure 33. Algal cover (%) versus total soluble nitrogen concentrations (mg/L) along Marillana Creek in the last four sampling events.

The apparent reductions in nitrogen levels recorded in recent sampling events from Mar-Two, coupled with increases in algae and aquatic macrophyte growth may be related to nutrient cycling

within the creek, with nutrients being bound-up in sediments as well as algal and macrophyte growth. Nutrient levels in the water column can often be low, even during algal blooms, as nutrients are tightly cycled and effectively locked-up by the algae itself. There was some evidence for this from studies at Marandoo BWT, where measured concentrations of total dissolved nitrogen and nitrates in the water column rapidly diminished downstream of the discharge point, coupled with increases in algal cover (WRM 2013c). Also, spot measurements of dissolved nutrients in the water column may not pick up any spikes in nutrient levels if and when they are released from algae and sediment. Alternatively, release of nutrients may not occur as a single event, and therefore may not appear as a spike, but instead occur as a slow 'leakage', which is quickly taken up by algae and macrophytes as soon as it becomes available. This is known as tight nutrient spiraling (Solimini *et al*. 2005). The lower algal growth at MAR2-4, where nitrogen levels were highest, may also be a result of the greater flow velocities and high degree of flushing in this area, which is located immediately downstream of the discharge point.

Generally, percent algal cover showed a similar pattern of change over time at all sites within Mar-Two, the lower Marillana Creek reach downstream of Rio Tinto (Figure 34). Within a site, algal growth remained fairly consistent between the wet-10 and dry-11, decreased to the wet-12, increased substantially in the dry-12, and then generally decreased to the dry-13 (Figure 34). There were some increases in algal cover between the dry-13 and wet-14 at sites downstream of the D09 discharge outlet (i.e. MAR2-5, MAR2-8 & MAR2-9), however cover at MAR2-4 and MAR2-6 remained consistent and at MAR2-7 decreased between these time periods (Figure 34). None of the algal cover percentages recorded in the wet-14 were outside values recorded from the creek previously. However, the risk of eutrophication would be highest during periods when natural flow in the creeklines is at its lowest and dewatering discharge constitutes most of the surface water present in channel pools (i.e. the dry season).

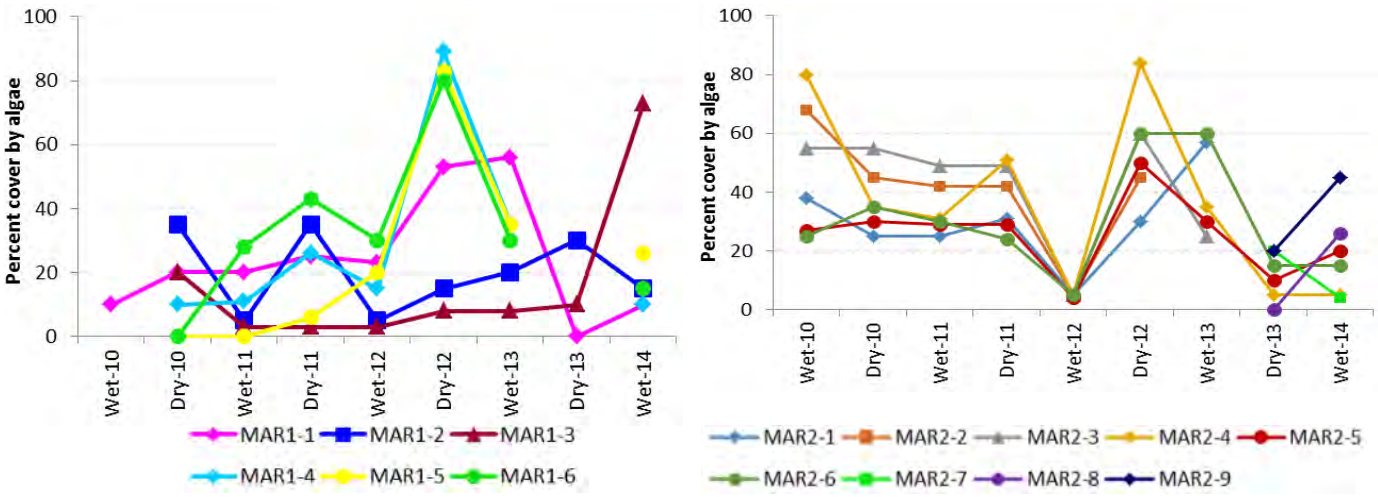

Figure 34. Change in percent algal cover over time at sites within Mar-One (left) and Mar-Two (right).

In contrast, algal growth in the upper Marillana Creek reach (Mar-One) did not show a similar pattern of change over time between sites (Figure 34). For example, algal cover at MAR1-3 saw a substantial increase between the dry-13 and wet-14 which was not seen elsewhere in Mar-One (Figure 34). Aside from the generally high cover of algae recorded at most sites in the dry-12, algal cover was variable amongst sites and over time in Mar-One.

Although algal cover was generally greatest from WW-Five and lowest from Mar-One (Figure 35), overall there was no significant difference in percent algal cover between reach in either season

(Table 16). There was, however, a significant difference in algal cover between year during the dry season (df = 3, p = 0.000), due largely to the high cover recorded during the dry-12 (see Figure 34 & 35, and Table 16). Of importance for the JSW development was the fact that algal cover recorded in the wet-14, following increased discharge from D09, was statistically similar to that recorded during all other wet seasons sampled since 2010 (Table 16).

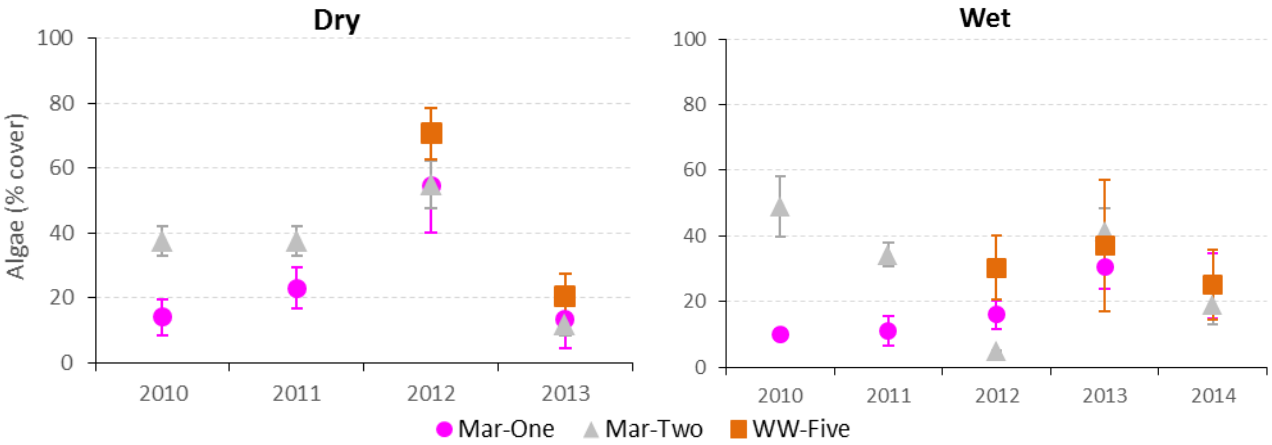

Figure 35. Average percent cover by algae from each reach over time (±se) in the dry season (left) and the wet season (right).

Regression and Spearman Rank Correlation analyses indicated that there was no significant change in percent algal cover over time for either Marillana Creek reach during the dry season (Figure 36). During the wet season, however, there was a significant positive relationship between algal cover and time (Spearman Correlation p = 0.04) in Mar-One (Figure 36). This relationship was not apparent in Mar-Two (Spearman Correlation p = 0.39).

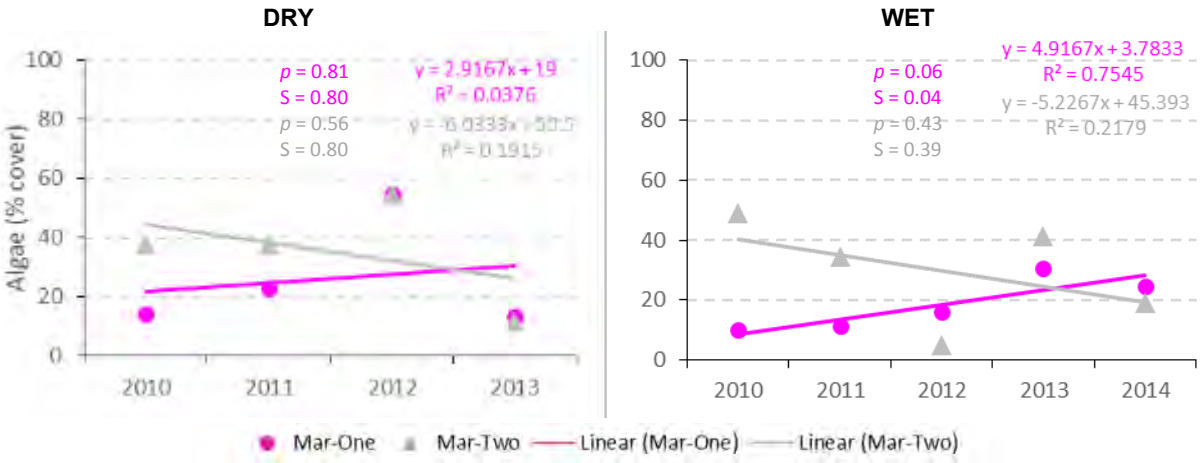

Figure 36. Linear regression plot of algal cover against time during the dry (left) and wet season (right) for Marillana Reaches One and Two. Equations, linear regression p-value, Spearman correlation co-efficient p-value (S) and R^2 values are displayed.

At this stage, the discharge of groundwater with elevated nutrient concentrations from the JSW orebody does not appear to have resulted in eutrophic conditions downstream. However, algal growth patterns and nutrient concentrations downstream of the D09 discharge point will continue to be monitored and assessed in future reports. It should also be noted that the algae currently

recorded from Marillana Creek primarily comprises filamentous algae and/or benthic mats, rather than phytoplankton which is likely to be more responsive to nutrient changes.

Table 16. Two-way ANOVA results comparing percent algal cover (arcsin proportion) between reach and year, for each season. Degrees of freedom, F and p-values are shown. Tukey's *post-hoc* results are presented in ascending order of mean algal cover, with groups with no difference in means joined by a black line

4.2 Calcite precipitate

The Yandi Hazard Analysis also identified a moderate-high risk of in-stream habitat loss due to carbonate (calcite & dolomite) precipitation in Marillana and lower Weeli Wolli creeks (WRM 2015a). WRM have been monitoring the ecological health of Weeli Wolli Creek as part of the "Living Water Survey" since Sep-07, and, in Oct-09 first observed the formation of a precipitate in the creek bed of WW-Two (Weeli Wolli Creek reach two), several hundred meters downstream of the gabion (WRM 2011). The precipitate was initially observed as an armouring or cementing of the creek bed in riffle zones in WW-Two, but has since extended throughout WW-Three, and more recently it has been observed as far downstream as WW-Four, immediately downstream of the confluence with Marillana Creek (see WRM 2014b). Initially the precipitate was only in the fast flowing riffle sections, but it appears gravel runs in WW-Two and WW-Three have also become armoured. The precipitate appears to form at a rapid rate, with leaves and other organic matter being coated before they can breakdown, and so becoming part of the 'cement' (Plate 5). The formation of the calcite precipitate structurally changes the bed of the creek, impacting habitat availability and heterogeneity for macroinvertebrates by infilling interstices and 'cementing' cobbles and pebbles together.

In 2011, a study undertaken by CSIRO found that the precipitate was caused by super-saturation of calcium carbonate in waters downstream of the gabion and degassing of carbon dioxide (CSIRO 2011). Studies elsewhere have reported that for precipitation to occur, the water generally has to be around five to ten times supersaturated with respect to calcite (Hoffer-French and Herman 1989, Chen *et al.* 2004). However, a number of factors are known to affect the rate and location of calcite precipitation, including outgassing of carbon dioxide (i.e. Hoffer-French and Herman 1989, Merz-Preiß and Riding 1999, Chen *et al.* 2004), abiotic environmental conditions such as humidity and

temperature (Andrews 2006) and microbial/biological activity (i.e. Vasconcelos *et al.* 1995, Arp *et al.* 2001, Shiraishi *et al.* 2008). For carbonate deposition (usually as calcite) to occur, kinetic thresholds of mineral formation must be overcome. This means that precipitation often commences in stream channels well downstream of springs, and can continue for a few kilometres thereafter (Liu *et al*. 2006). Many field based studies have shown that outgassing of CO_2 occurs most rapidly in turbulent areas of the stream, such as riffle zones, cascades and waterfalls (Lorah and Herman 1988, Hoffer-French and Herman 1989, Merz-Preiß and Riding 1999). Chen *et al*. (2004) found that the principal cause of precipitation in waterfall areas was due to enhanced inorganic carbon dioxide outgassing due to the sudden hydrological changes which occur in these areas of the creek, rather than any influence from organisms, evaporation or the solid-water interface. Stream turbulence in waterfall zones enhances CO_2 outgassing through physical dispersion of the water, an increase in surface area relative to volume, and the fact that CO_2 can escape across the water-air phase boundary more readily (Drysdale 2001, Chen *et al.* 2004). While the addition of dewatering discharge from Yandi's D06 into Weeli Wolli Creek, and D09 into Marillana Creek (upstream of the Weeli Wolli confluence), may increase flow and thereby add to the turbulence within the creek/s, and hence outgassing of CO_2, the source geology being dewatered at Yandi is considerably different to that around HD1, and does not appear to support groundwater supersaturated with calcium carbonates. If this is the case, then the net result may be dilution of carbonates in Weeli Wolli Creek rather than addition and super-saturation.

Plate 5. Images of the calcite precipitate in Weeli Wolli Creek, showing total armouring of the bed (left) and coating of twigs and debris (right).

At this time, the dewatering-discharge from JSW, JC and JSE does not appear to have resulted in precipitate forming within Marillana Creek. No calcite precipitate has been observed within Marillana Creek, and in fact there is very little bedrock[19] substrate at all (see Figure 37). In multivariate analysis of habitat and substrate characteristics, Marillana Creek sites separated from WW-Two, and some sites in WW-Three, based largely on the lower cover of bedrock at Marillana Creek sites (see Figure 16 section 3.3.2). In addition, there has been no significant change in percent cover by bedrock between years in either the dry or wet season (Table 17), and no significant linear increase in bedrock cover over time in either Marillana Creek reach (Figure 38). Although Mar-Two recorded greater percent cover by bedrock in both seasons (Figure 37), these differences were not significant (Table 17), and the mean cover by bedrock in Mar-Two was low (i.e. average of 0.56% in the dry and 0.21% in the wet).

[19] For the purposes of this study, calcite precipitate was classified as "bedrock" as the armouring of the creek bed creates similar in-stream habitat to bedrock in terms of heterogeneity and diversity.

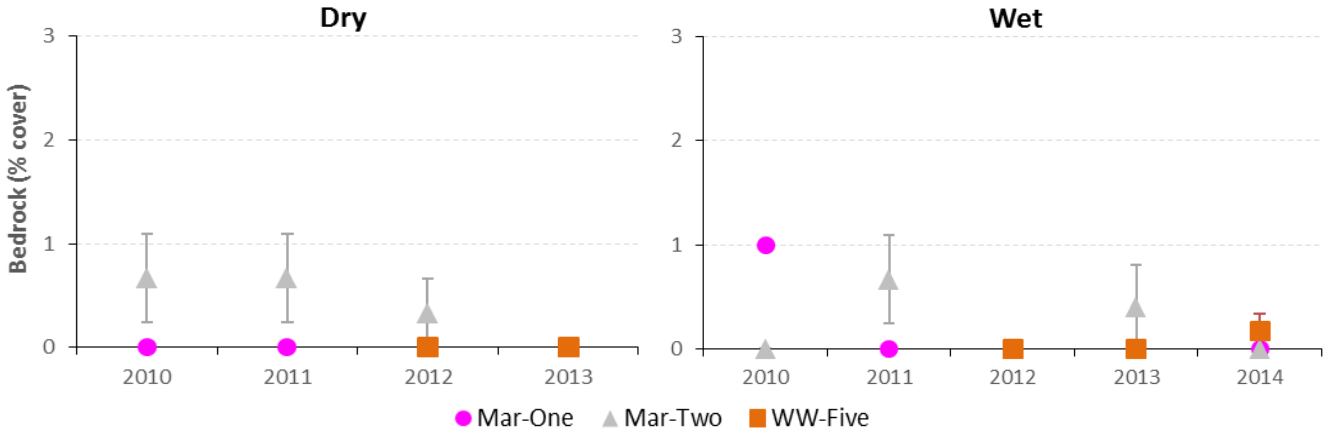

Figure 37. Average percent cover by "bedrock" from each reach over time (±se) in the dry season (left) and the wet season (right).

5 CONCLUSIONS

5.1 General

This report summarises a valuable dataset for assessing cumulative impacts of Rio Tinto developments in the area. This dataset documents the current aquatic ecological values of Marillana Creek, provides a valuable baseline for assessing the impacts of development of the new JSW and Oxbow deposits, and assists in discriminating effects from BHPBIO operations upstream.

Cumulative impacts on the Weeli Wolli Creek system are already becoming evident. However, the extent and nature of these impacts may increase in the future given the expansions at Rio Tinto Yandi, including increased discharge, as well as increased discharge from BHPBIO Yandi. This report outlines current changes to the aquatic environment, some of which are likely climate-related but some of which may be due to mine operations. The main important changes are summarised below.

5.2 Marillana Creek

- There has been a statistically significant decline in wet season pH in Mar-Two over time. However, this only constitutes a change from 8.00 during the wet of 2008 to 7.70 during the wet of 2014. Such a change is unlikely to adversely affect the resident aquatic fauna.
- Water temperature was significantly higher from Mar-Two than Mar-One in both seasons, indicating there may be some effect of the discharge from Rio Tinto's Yandi on downstream water temperature. However, water temperature has not significantly increased over time in either reach. Increased water temperature resulting from discharge of warm groundwater has been reported for Weeli Wolli Creek close to the HD1 discharge point. Although significantly higher than Mar-One (ave. 24.6°C in the dry & 24.7°C in the wet), water temperature at Mar-Two (ave. 26.2°C in the dry & 26.1°C in the wet) was similar to that recorded from Weeli Wolli Creek downstream, i.e. WW-Five (ave. 26.4°C in the dry & 26.7°C in the dry). Therefore, there has been no increase in temperature in Mar-Two above the natural range.
- The discharge of groundwater from the JSW deposit appears to have resulted in elevated nutrient concentrations, with values for nitrogen oxides and total nitrogen exceeding Marillana Creek SSTVs in Mar-Two during the wet season and total phosphorus during the dry. The SSTVs for nitrogen oxides is for protection against eutrophication. Using the new revised toxicity SSTV for nitrate (2.5 mg/L N_NO_3), all N_NOx concentrations were within limits not anticipated to cause toxic effects to aquatic fauna (N_NOx is generally the largest component of N_NO_3 so values can be compared against the toxicity SSTVs). Despite the recent elevated levels of N_NOx and TN, there has been no significant increase in nutrient levels in Marillana Creek (i.e. no significant positive linear relationship with time).
- While there has been no significant increase in dissolved boron concentrations over time in Mar-Two in either season, there was a considerable increase in concentration between the wet-13 and wet-14 which may be related to the discharge at D09.
- Dissolved copper has declined significantly over time in both Mar-One and Mar-Two in the dry and wet seasons.
- Using all water quality data in the analysis, the overall water quality of Marillana Creek was significantly different to that of Weeli Wolli Creek. This remains unchanged since aquatic monitoring commenced.

- Within Mar-Two, water quality has shown decreasing similarity with the "baseline" initial sampling event in the more recent years (2012 & 2013 in the dry & 2013 & 2014 in the wet). This pattern of change was not recorded from Mar-One, upstream on Marillana Creek. In fact, overall water quality in that reach has tended to become more similar to "baseline" condition, particularly during the wet season.
- Percent cover by algae appeared to follow an inverse relationship with nitrogen concentrations in the most recent sampling rounds of the dry-13 and wet-14, downstream of the D09 discharge outlet, such that algal cover was lower with higher total N. This relationship was not apparent upstream (in Mar-One) during these time periods. As data are limited to twice-yearly sampling events, causal relationships between algal growth and nitrogen concentration could not be confirmed within the scope of the current study. However, a possible explanation for the inverse relationship observed at MAR2-4 is that greater water velocities and high degree of flushing in this area, which is located immediately downstream of the discharge point, are physically disrupting algal colonies. Another explanation is that it is related to rapid nutrient cycling within the creek, with nutrients becoming bound-up in sediments and algal and macrophyte growth.
- Eutrophication was highlighted as one of the key risks in the Hazard Analysis (WRM 2015a). Some increase in algal cover was evident at a number of sites in Mar-Two, downstream of the D09 discharge point during the wet-14 (i.e. MAR2-5, MAR2-8 & MAR2-9); however, overall there was no significant increase in algal cover over time in this reach. As there has been only one round of monitoring post commencement of discharge from D09 (i.e. the wet-14), it is too early at this stage to assess the risk of eutrophication. It is expected that risk of eutrophication will be greatest during the dry season when natural flow and water levels are low, and discharge water constitutes much of the water within the creek. This report does not contain dry season data from after the commencement of discharge from D09, and as such, the pattern of change in algal growth (along with nutrient concentrations) will continue to be monitored and assessed.
- Within Mar-Two, there appeared to be a longitudinal gradient of habitat diversity downstream of MAR2-4, with diversity generally decreasing with distance downstream of the D09 discharge outlet. The additional water essentially inundates a greater areal extent of creekline, thus increasing habitat availability and heterogeneity immediately downstream.
- Calcite precipitation was also highlighted as a key risk within the Hazard Analysis. To-date, there is no evidence of increased precipitation along Marillana (or lower Weeli Wolli) Creek associated with the additional discharge from JSW & JSE. Very little bedrock cover has been recorded from Marillana Creek, and there has been no increase in the percent of this cover over time.
- There has been no significant change in microinvertebrate taxa richness over time for either reach in either season, i.e. no consistent increase or decrease in taxa richness. This suggests that the discharge operations at Yandicoogina have not adversely impacted the microinvertebrate taxa richness of the downstream Marillana Creek environment over time.
- The microinvertebrate assemblages of Marillana Creek are significantly different to Weeli Wolli Creek. However, the assemblages of lower Weeli Wolli reach (WW-Five) are more similar to Marillana Creek than upper Weeli Wolli.
- Since the initial change in microinvertebrate assemblages from "baseline" condition they have remained relatively consistent over time in both Marillana Creek reaches in both seasons.
- Although there appeared to be an increase in hyporheos taxa richness over time in both Marillana Creek reaches, this change was not significant. During the dry season, this was

likely due to a considerable decrease in taxa richness between the dry of 2012 and 2013 in Mar-One, and decrease between the dry of 2010 and 2011 in Mar-Two.

- Within the dry-13/wet-14 data, macroinvertebrate taxa richness declined downstream of MAR2-4 and the D09 discharge outlet in both seasons. This longitudinal pattern was not present in either Mar-One or WW-Five. The higher taxa richness at MAR2-4 may have been due to the greater areal extent of habitat associated with the discharge.
- There was no relationship between macroinvertebrate taxa richness and time during the dry season. However, there was a significant positive relationship between taxa richness and time for both Marillana Creek reaches in the wet season. This increase was generally influenced by high numbers of taxa known to be tolerant to disturbance including Diptera (two-winged fly larvae), Coleoptera (beetles) and Hemiptera (true bugs).
- Overall, the macroinvertebrates assemblages of Mar-One and Mar-Two were similar, with considerable overlap in ordination space when compared with upper Weeli Wolli Creek. Downstream of the confluence, assemblages from WW-Four were more similar to Marillana Creek than upper Weeli Wolli Creek.
- In Mar-Two, wet season macroinvertebrate assemblages have remained relatively consistent between 2010 and 2012, following the initial change, with some increase in similarity (i.e. some return to "baseline" condition) after 2012. This pattern was not as pronounced in Mar-One.
- Higher mean abundances of all three fish species were generally recorded from Mar-Two. This is likely due to the more predictable nature of flows in this reach. Discharge from BHPBIO operations upstream of Mar-One appears to be lower in volume and more sporadic than the discharge of Rio Tinto's Yandi operations further downstream, as Mar-One is often dry or appears recently flooded, whilst Mar-Two holds more water consistently. Similarly, WW-Five is highly seasonal, often reduced to small receding pools for most of the year.
- Although western rainbowfish abundances have appeared to decrease over time in Mar-Two during both seasons, this change was not significant.
- Wet season abundances of spangled perch did appear to increase over time in both reaches, however, due to the apparent absence of spangled perch from Marillana Creek in the wet-13, this increase over time was not significant.
- The abundance of Pilbara tandan did not significantly increase or decrease over time at the either Marillana Creek reach in either season.
- Good recruitment of western rainbowfish was observed at Marillana Creek during both seasons. However, no spangled perch new recruits were recorded at any reach in either season, and only one Pilbara tandan new recruit was recorded from Mar-Two in the dry-13. There has been little recruitment of spangled perch and Pilbara tandan in Marillana Creek since monitoring began, with the last major recruitment event occurring in the wet-12. Despite this, numbers of both species are not declining and juveniles are present in most sampling events. This suggests that migration from downstream environments and/or tributaries during times of connection plays an important role in the population stability of spangled perch and Pilbara tandan within Marillana Creek.
- Generally, Marillana Creek fish age-class structures showed reduced resemblance to the initial "baseline" sampling events in the dry 2008 or wet 2009. For rainbowfish and Pilbara tandan, all age-classes have changed in a similar pattern to total fish abundance over time, but for spangled perch there has been a recent increase in sub-adults and adults, but in no other size classes.

5.3 Weeli Wolli Creek

- Higher water temperatures recorded from WW-Two, which may be due to the discharge of warm groundwater by HD1 operations (see WRM 2014).
- No evidence to date that discharge from D06 has resulted in a significant increase in average water temperature in the downstream receiving environment of Weeli Wolli Creek.
- Higher percentage cover by 'bedrock' in WW-Two than any other reach, primarily due to the 'armouring' of the creek bed as a result of calcite precipitate. 'Armouring' appears to be greatest at sites WW2-3, WW2-4 and WW2-5. This precipitate was first observed during sampling in Oct-09 and has subsequently progressed further downstream, and is now well established in WW-Three (WRM 2014), with the first signs of calcite precipitation in WW-Four. Ongoing monitoring will assess calcite development in WW-Five.
- Reduction in total nitrogen and ammonia concentrations since Sep-07, which was attributable in part to the positive effect of flushing, but also nutrient cycling within the creek, with nutrients being bound-up in algal and macrophyte growth (see WRM 2014).
- Increasing homogeneity of water quality along the length of the creek due to dewatering discharge, as evidenced by the significantly higher multivariate dispersion (spread of samples) in Sep-07 compared to recent surveys (see WRM 2014).
- Significantly lower microinvertebrate taxa richness from WW-Two, downstream of the gabion, which likely reflects the high water velocity, and insufficient distance for planktonic fauna to colonise flow from the gabion in this reach (WRM 2014).
- Significantly lower macroinvertebrate taxa richness recorded from WW-Two was likely a result of 'bed-armouring' (calcite precipitate) effectively reducing habitat heterogeneity and therefore available habitat for macroinvertebrates (WRM 2014).
- Changes in macroinvertebrate assemblage structure due to increased abundance of taxa known to prefer faster-flowing habitats. There has also been a loss in seasonality of macroinvertebrate assemblages associated with the continual discharge (WRM 2014).
- Macroinvertebrate assemblages of WW-Five were significantly different to all other reaches in the dry season due to the higher abundances of taxa which prefer slow-flowing waters. This reflects the intermittent nature of this reach, where sites are often reduced to small pools during the dry. As cumulative surface flows from Rio's HD1 and Yandi operations do not currently extend this far, seasonal hydrological differences still influence the assemblage structure. However, during the wet season, assemblages from WW-Five were similar to Marillana Creek assemblages. This indicates that the macroinvertebrate assemblages of lower Weeli Wolli Creek are at times more similar to those of Marillana Creek, likely due to increased flow consistency and habitat heterogeneity of these reaches during the wet season. Once surface flows associated with the discharge extend this far, and there is a hydrological switch to permanent flows, this seasonal signature will likely be lost as has been the case on upper Weeli Wolli Creek.
- No negative influence from Rio Tinto's Yandi discharge has been noted along lower Weeli Wolli Creek (WW-Five) to-date, given surface flows do not currently extend this far. On-going monitoring will allow any future changes to be assessed.

Of considerable concern in relation to cumulative impacts from mining operations and development is the calcite precipitation and resultant 'armouring' of the creek bed which is occurring in Weeli Wolli Creek downstream of the HD1 discharge outlet. As well as the effects to aquatic fauna

diversity, the increase in rate and extent of calcite precipitation in Weeli Wolli Creek will have implications for flow dynamics and flood response. Changes in bed sediment characteristics, reductions in infiltration to the groundwater, and reduced in-stream roughness due to creek bed 'armouring' may result in a decreased ability for the creek to cope with flooding events. When the precipitate was initially observed in October 2009 it was as an armouring of riffle zones only, however, it now appears to be depositing within gravel runs as well (WRM 2015b). Rio Tinto, in collaboration with the CSIRO, are currently undertaking a project to map the precipitate within the creek. This will assist in quantifying the extent of the armouring. Reduced in-stream roughness and reduced infiltration rates are widely known to increase flood energies and stream flow (Baker 1977, Wolman and Gerson 1978). Increased flows and flood energies can negatively impact benthic communities in streams (Resh *et al.* 1988).

Of importance to the Yandi mine is the fact that discharge operations associated with the JSE and JC development, and more recently JSW developments, do not appear to have adversely affected the taxa richness (viz. diversity) of microinvertebrates, hyporheic invertebrates or macroinvertebrates. Although there have been changes in community structure over time, there was no significant negative correlation between taxa richness (hyporheic fauna or micro- and macro-invertebrates) and time. This indicates that the discharge operations to-date have not adversely impacted the diversity of aquatic fauna present in the downstream Marillana Creek environment. In fact, the wet season macroinvertebrate fauna, as well as the abundances of all three fish species may well have benefited (at least in the short-term) from the greater habitat availability, heterogeneity and security provided by Rio Tinto's discharge.

On-going monitoring will allow any future changes to be assessed in the context of the more recent developments.

Upland River[e]	10	5	150	30	6	90-120	6.0-7.5
Lowland River[e]	10	4	200-300[h]	10[b]	10	85-120	6.0-8.0
Lakes & Reservoirs	10	5	350[c]	10[b]	10	90-120	6.0-8.0
Wetlands[3]	10-50[g]	5-25[g]	350-1200[g]	10	10	90[b]-120[b]	6.0-8.0

b = Northern Territory values are 5µgL^{-1} for NO_x, and <80 (lower limit) and >110% saturation (upper limit) for DO;
c = this value represents turbid lakes only. Clear lakes have much lower values;
e = no data available for tropical WA estuaries or rivers. A precautionary approach should be adopted when applying default trigger values to these systems;
f = dissolved oxygen values were derived from daytime measurements. Dissolved oxygen concentrations may vary diurnally and with depth. Monitoring programs should assess this potential variability;
g = higher values are indicative of tropical WA river pools;
h = lower values from rivers draining rainforest catchments.

Table A2-2. Default trigger values for salinity and turbidity for the protection of aquatic ecosystems, applicable to tropical systems in Australia (ANZECC/ARMCANZ 2000).

Aquatic Ecosystem		*Comments*
Salinity	***(µs/cm)***	
Aquatic Ecosystem		
Upland & lowland rivers	20-250	Conductivity in upland streams will vary depending on catchment geology. The fist flush may result in temporarily high values
Lakes, reservoirs & wetlands	90-900	Higher conductivities will occur during summer when water levels are reduced due to evaporation
Turbidity	***(NTU)***	
Aquatic Ecosystem		
Upland & lowland rivers	2-15	Can depend on degree of catchment modification and seasonal rainfall runoff
Lakes, reservoirs & wetlands	2-200	Most deep lakes have low turbidity. However, shallow lakes have higher turbidity naturally due to wind-induced re-suspension of sediments. Wetlands vary greatly in turbidity depending on the general condition of the catchment, recent flow events and the water level in the wetland.

Table A2-3. Trigger values for toxicants at alternative levels of protection (µg/L).

Compound	Trigger values for freshwater Level of protection (% species) 99%	95%	90%	80%

1. Introduction

Rio Tinto Iron Ore (RTIO) is undertaking a Pre-Feasibility Study (PFS) to expand the Yandicoogina Mine (Yandi) to include mining below water table in Pocket and Billiards South (PBS). As part of the PFS, dewatering requirements and potential environmental impacts of dewatering is needed for the Public Environmental Review (PER). A numerical groundwater was selected as the tool to predict the dewatering requirements to meet the A8 mine schedule released in August 2014 and demonstrate the potential cumulative impacts of increased dewatering.

The numerical groundwater model was developed in 2008 for Yandi Operations medium term plan. The model domain was extended to minimise boundary effects from dewatering in Junction South West (JSW) and PBS. Included in the extension was the inclusion of an alluvium layer defined in the 2010 regional groundwater model (RTIO-PDE-0078850). The number of model layer was increased from 7 to 15 to refine the JSW and PBS geology based on the RTIO Vulcan geology block model. The model was calibrated against observed hydrographs from January 1998 to January 2014, a total of 16 years, at monthly stress intervals. The 2012 Australian groundwater modelling guidelines was used to guide the modelling process.

This report presents the conceptual hydrogeological model, model setup, calibration, dewatering requirement prediction and water table drawdown of the new model for the PFS for PBS.

2. Model Domain

The model domain of the conceptual hydrogeological model covers a window from 707338mE, 7480783mN to 725370mE, 7498814mN to 746583E, 7477601mN to 728551mE, 7459570mN in MGA94 Zone50 coordinate system as shown on Figure 1.

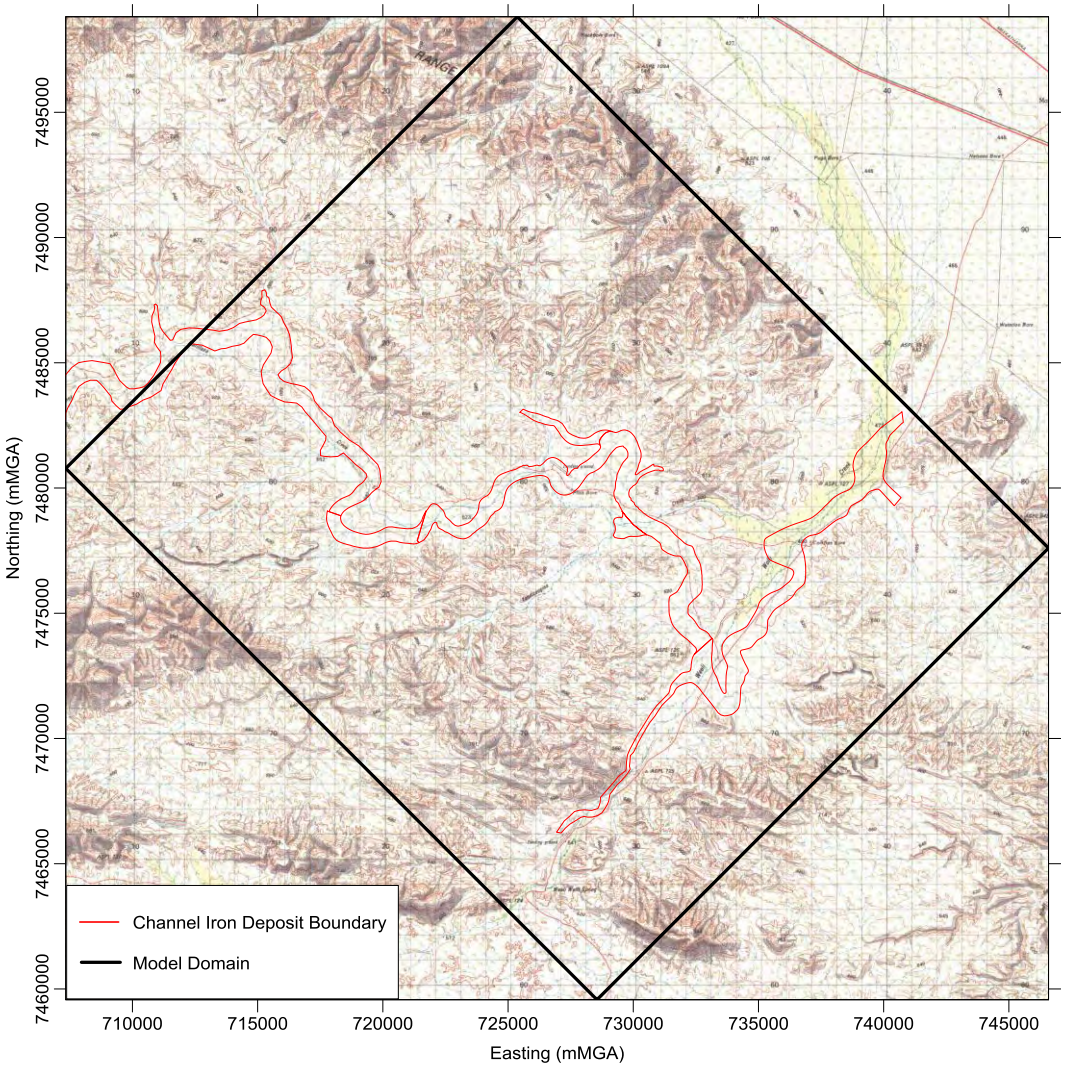

Figure 1. Conceptual Model Domain.

3. Climate

In general, the region is classified as arid-tropical with two distinct seasons; a hot summer extending from October to April and a mild winter from May to September. Average annual rainfall for 1998 to 2013 was 438 mm. Rainfall is episodic and highly variable between years. The majority of rainfall occurs during the hottest months from cyclonic lows with light winter rain in June/July. Due to the low rainfall and brief wet season, watercourses flow, if at all, for only brief periods under natural conditions. Temperature varies from 25°C to 40°C in summer and 10°C to 23°C in winter. Figure 2 shows the seasonal rainfall pattern and averaged monthly maximum and minimum temperatures.

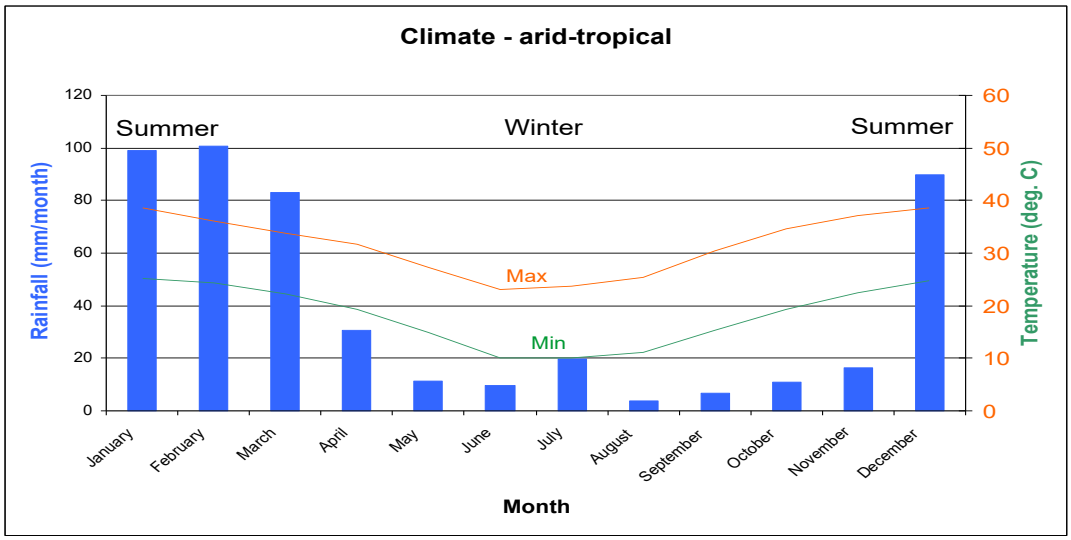

Figure 2. Seasonal Rainfall and Temperature.

The rainfall is episodic and large variations have been observed. Figure 3 shows the average monthly rainfall. It is this high intensity rainfall that poses a risk to mining the PBS.

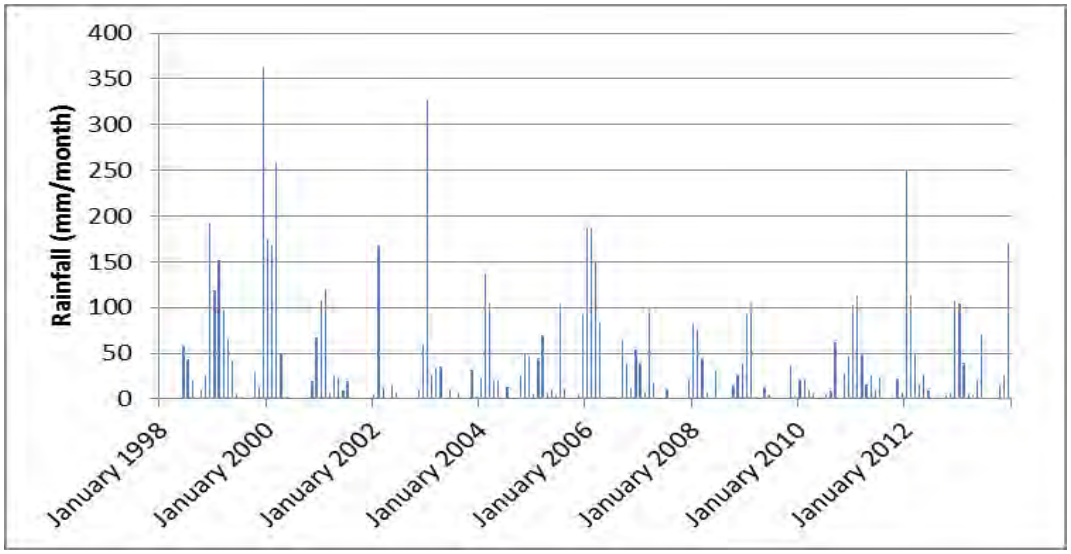

Figure 3. Monthly Rainfall.

Figure 4 shows the seasonal variability of pan evaporation recorded at Yandi weather station. Evaporation is high at about 3,000mm/year in the summer months where availability of water is highest.

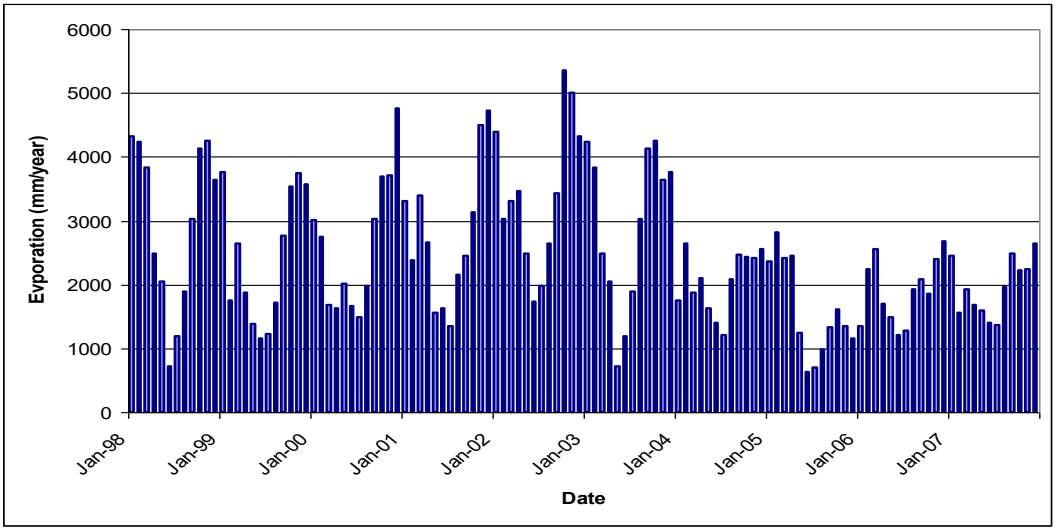

Figure 4. Monthly Pan Evaporation.

4. Geology

The CID is a Tertiary palaeochannel fill deposit, up to 80 m thick and about 500 m wide deposited on the incised Proterozoic basement of the Weeli Wolli and Brockman Iron Formations (Figure 6). The basement consists of inter-bedded banded iron formation, banded chert, shale and dolerite which are relatively less permeable than the CID (Figure 5). However, extensive regional and local fractures within the basement with open fractures and partings parallel to bedding in surface exposures indicates that the basement can transmit and store groundwater where these occur, in addition to the weathered profile. Several large-scale linear structures in the Weeli Wolli Formation are evident from aerial photographs, Landsat images and aeromagnetic maps. These structures trend between north-northeast and east-northeast, and some have surface trace of more than 20 km.

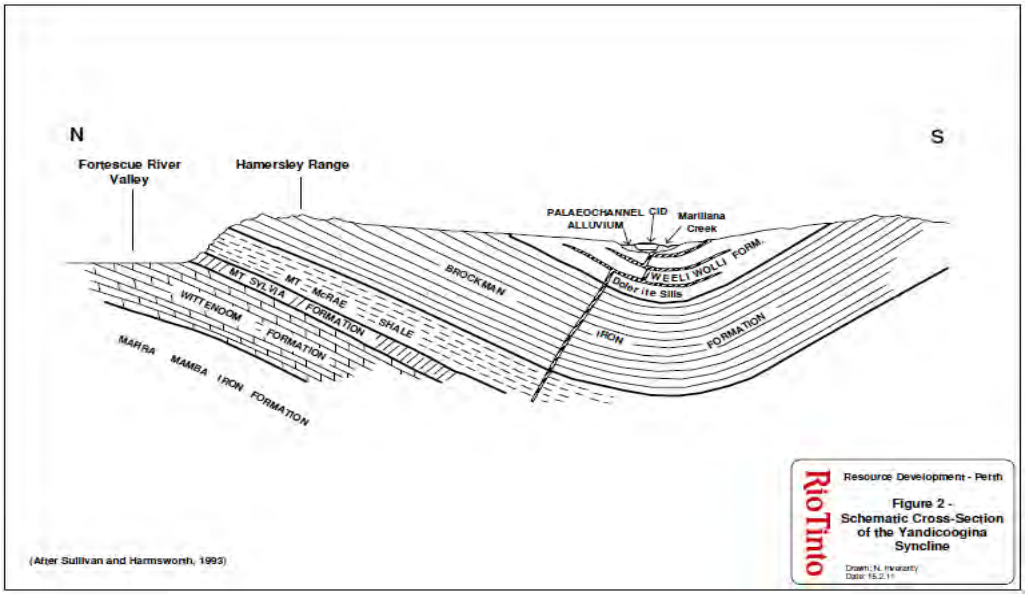

Figure 5. Schematic Cross-Section of the Yandicoogina Syncline.

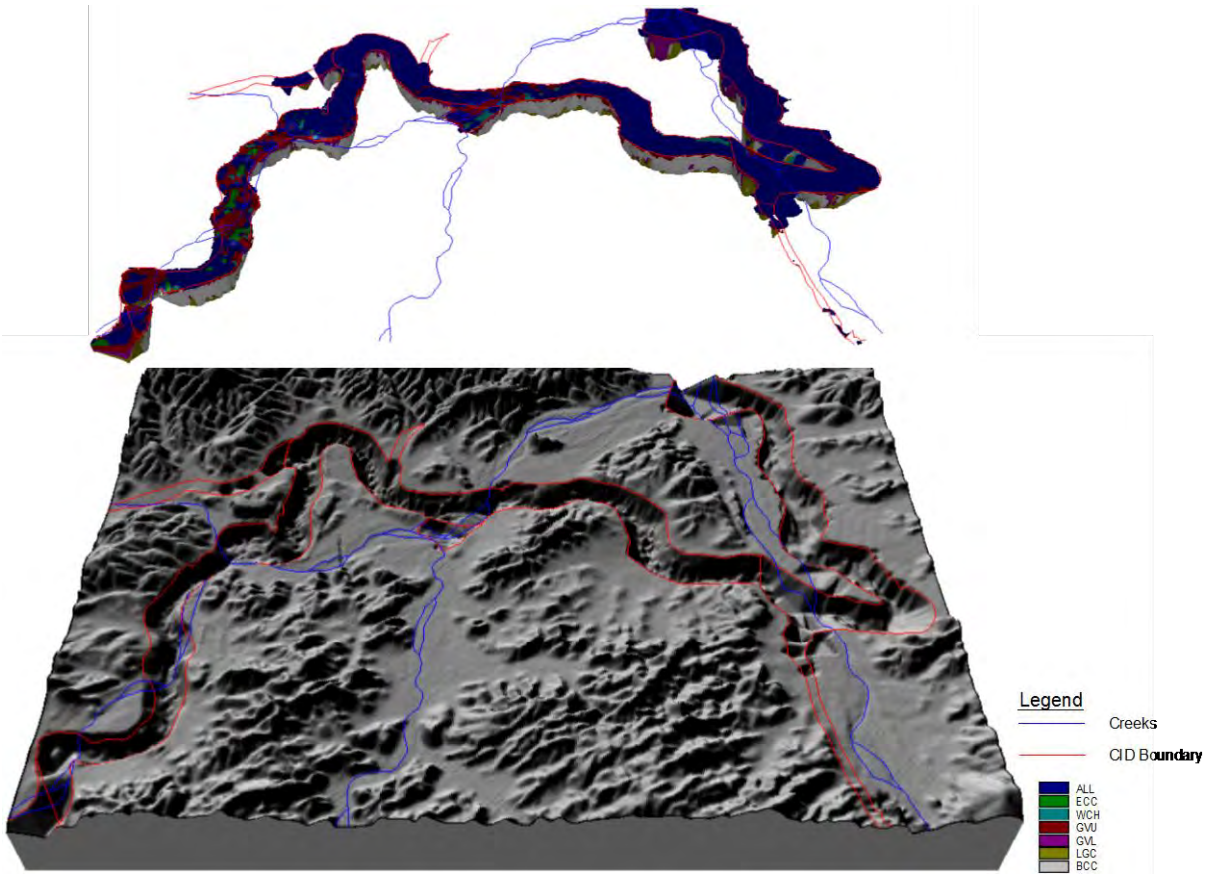

Figure 6. Channel Iron Deposit in Incised Proterozoic Bedrock.

A large east-northeast trending structure crosses Phil's Creek a few kilometres northwest of the Junction Central. Several smaller structures occur between this structure and Marillana Creek in the Junction Central area, and many of them clearly trend into the CID. The northeast trending section of CID at the Junction Central appears to be aligned with one of these structures. Some of the structures are also coincident with current creeks, e.g. Yandicoogina Creek, sections of Marillana Creek, and possibly Weeli Wolli Creek. Sections of the CID that trend in a north-easterly direction may also be aligned with basement structures.

The CID is generally comprised of coarse sand to granule sized placer deposits of predominantly pisoidal granules that have subsequently been cemented in a Geothite matrix. The primary porosity of the original placer deposit has been largely infilled by the goethite cementation of the pisoloid granules. The development of solution features such as vugs and cavities have superseded the interstitial pore space as the primary porosity, with secondary porosity coming from extensive fracturing.

The CID consists of 5 main geo-stratigraphical units within the channel deposit. The uppermost unit consists of recent alluvial (ALL) and the Eastern Clay Conglomerate (ECC). Underlying these, the orebody is comprised of an Upper Vitreous Geothite (GVU) and a Lower Vitreous Geothite (GVL). An upper weathered channel deposit (WCH) overlies the orebody. The orebody is variably broken and vuggy to massive. The GVU and GVL are very similar with GVL generally being less competent and more fractured hence more permeable. The vugs are usually filled with clays which can easily be mobilised. Underlying the main orebody, the Limonite Geothite Clay (LGC) is less

competent than the orebody, being more broken and often has large clay filled or opened cavities that have yielded large volumes of water. It is, however, not continuous throughout the channel. Underlying the CID is a polymictic basal clayey conglomerate (BCC) which can locally provide moderate permeability, but often is clay bound. Figure 7 shows a typical cross-section through the CID.

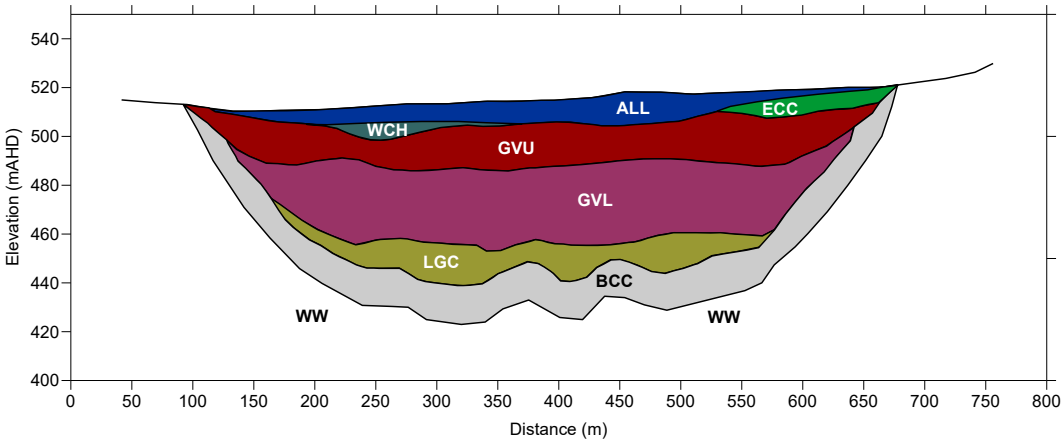

Figure 7. A Typical Cross-Section through the CID.

The creeks lie in narrow strips of unconsolidated Quaternary alluvium consisting of variably sorted material with particle sizes ranging from silt and sand to gravel and boulders. In the Junction Central area the alluvial bed of Marillana Creek is 150 m to 400 m wide, generally broadening in the downstream direction. The thickness of the Marillana Creek alluvium is variable with basement rocks encountered at depths of 5 to 20 m. Very coarse sediments (sand and gravel to boulders) are exposed at the surface and extend to a depth of at least 2 m in alluvium close to the Junction Central area, but finer textured strata (silts and clays) is found at greater depths.

5. Hydrogeology

The groundwater model consists of recharge into the water table from rainfall, leakage from the creeks, aquifer re-injection and throughflow. Discharge occurs through dewatering bores and in-pit sumps, seepage to creeks, evaporation from pools and streams, evapotranspiration from plants and via throughflow.

Rainfall infiltration into the regional water table occurs directly and indirectly. Direct rainfall recharge occurs where rain water infiltrates to the water table close to where the rain drop hits the ground surface. The amount of water reaching the water table depends on the thickness and the conditions of the unsaturated zone. Indirect rainfall recharge occurs where surface flow recharges the aquifers. Leakage from surface run-off into aquifers varies along the creeks. This depends on the vertical permeability of the creek beds, permeability of the receiving aquifers and difference in elevation of the water in the creeks and in the receiving aquifers. Where the creek crosses the CID, leakage may increase due to the relatively more permeable CID aquifer. Surface water recharge occurs along Yandicoogina Creek, Marillana Creek and Weeli Wolli Creek.

Water management at Yandi operations comprises the discharge of surplus dewatering water to previously ephemeral creeks. Both Marillana and Weeli Wolli Creeks are subjected to upstream surplus water discharge activities. Figure 8 and 9 shows hydrograph responses to dewatering and perennial flow in the creeks from the upstream operations. A correlation with rainfall pattern (Figure 10) shows that flow in the creeks is subdued and extends for a longer period; rainwater gets stored in depleted aquifers and seeps from bank storage along the creeks after a rainfall event. Figure 11 shows progressive time lag downstream along the CID from the discharge from Hope Downs 1.

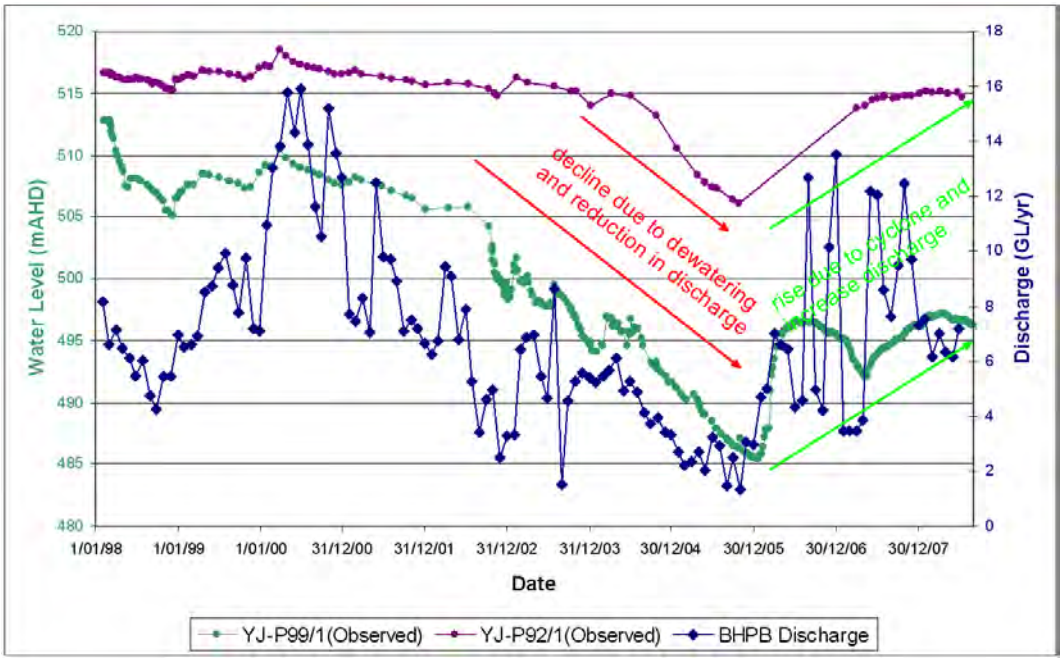

Figure 8. Hydrograph of monitoring bores YJ-P99 and YJ-P92 showing decline due to dewatering and rise due to increase creek flows.

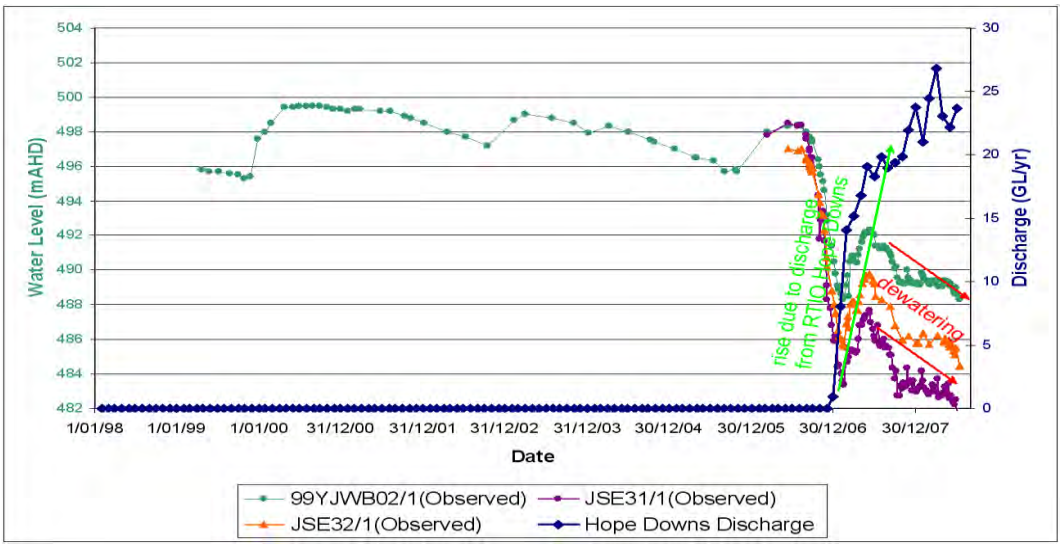

Figure 9. Hydrograph of monitoring bores 99YJWB02, JSE31 and JSE32 showing water level rise due to Hope Downs 1 discharge and decline due to JSE dewatering.

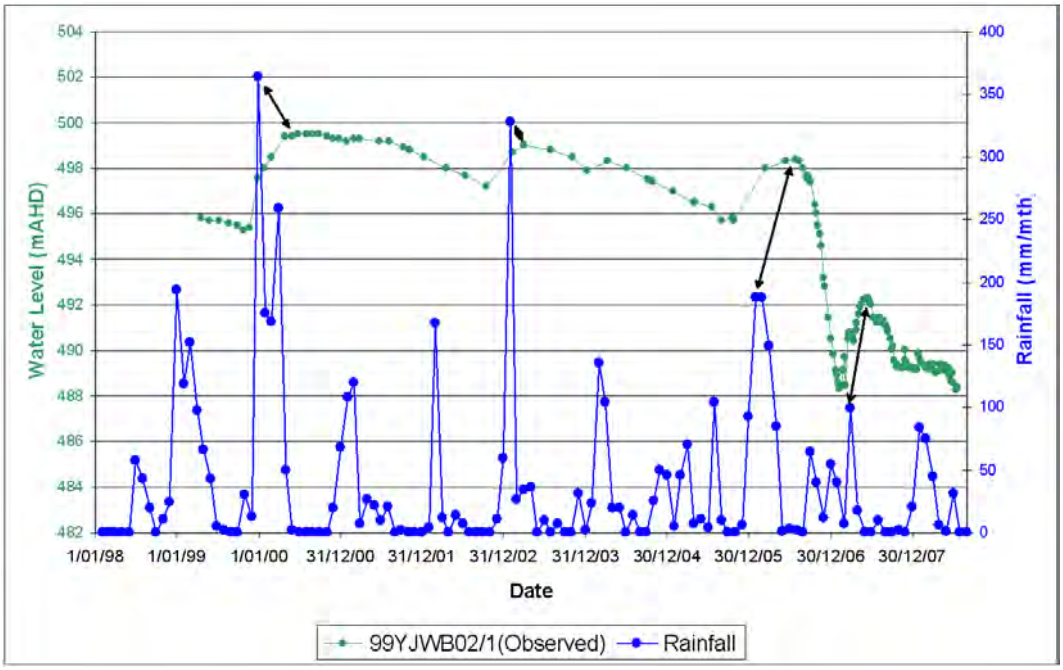

Figure 10. Hydrograph of monitoring bore 99JWB02 showing time lag in water level rise after rainfall events.

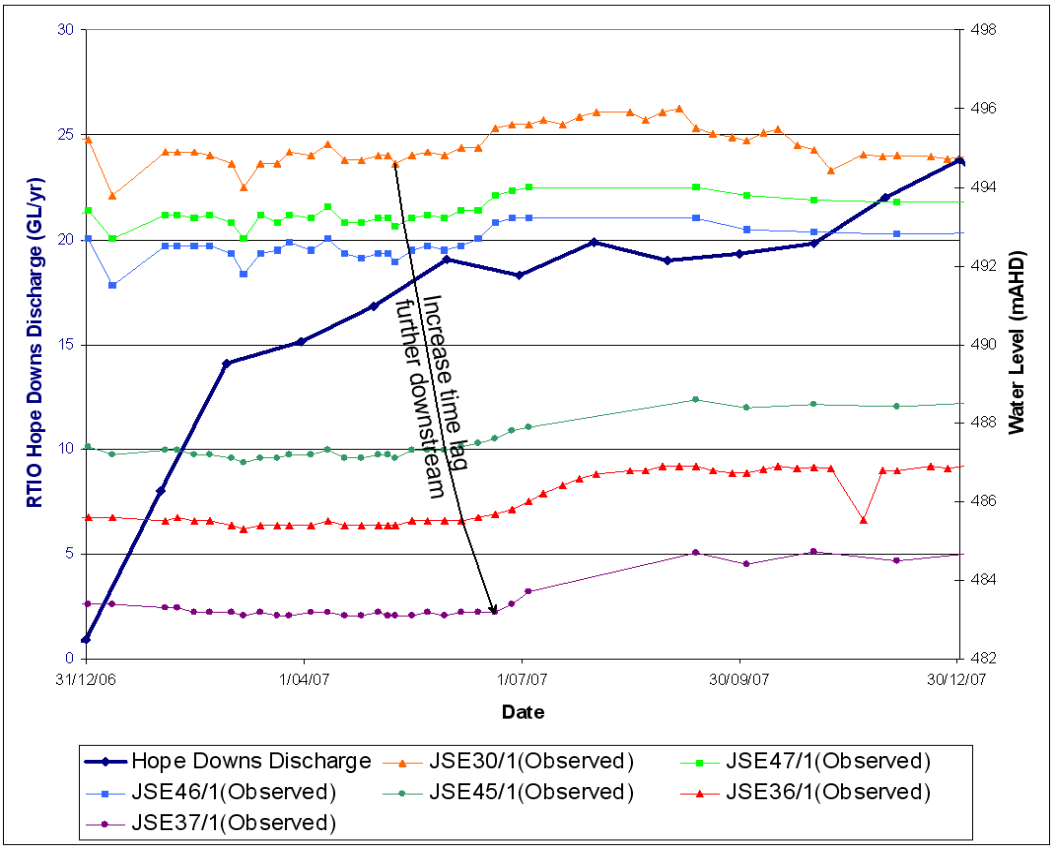

Figure 11. Progressive time lag downstream along the CID from the discharge from Hope Downs 1.

In July 2006 aquifer re-injection commence in Billiards South with dewatering water from JSE. Figure 12 shows monitoring bores in the vicinity of the injection bores mimic the increase in injection with water level rise.

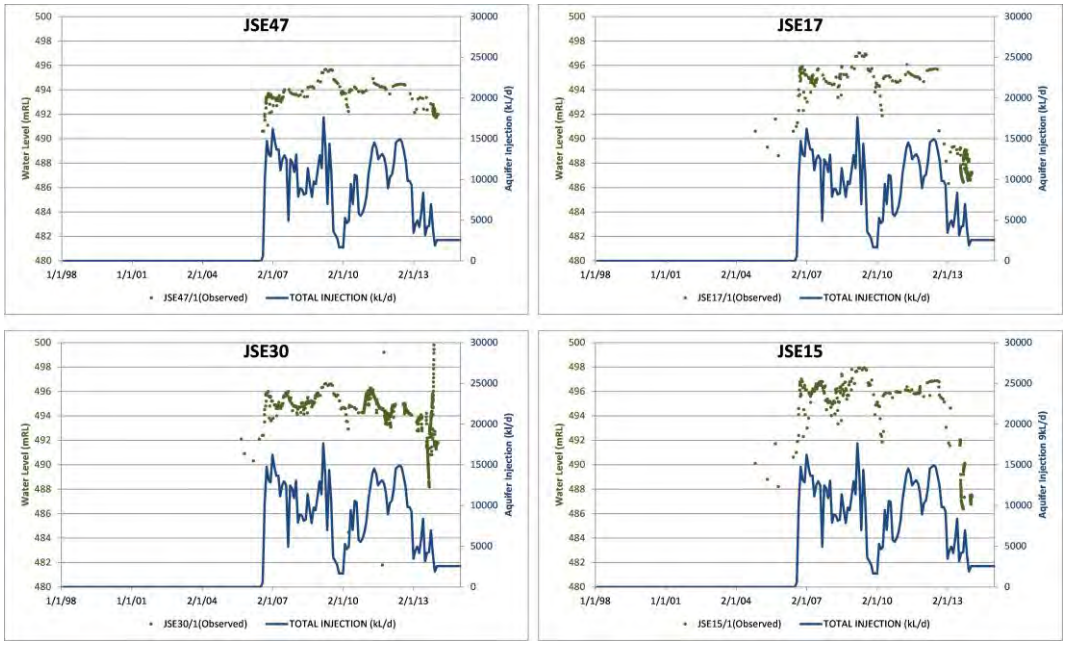

Figure 12 Water level rise in response to aquifer re-injection.

There is a dense network of primary streamlines in the Marillana Creek and Weeli Wolli Creek catchments which developed from the high intensity rainfall, sparse vegetation cover and shallow soils as shown on Figure 13. Marillana Creek and Weeli Wolli Creek drain the main surface water catchment and cross the CID at several places. Marillana Creek drains a catchment of about 2,250 km^2 above its confluence with Weeli Wolli Creek. Weeli Wolli Creek has a catchment of about 1,750 km^2 above the confluence with Marillana Creek. Yandicoogina Creek with catchment area of 200km^2 and Phil's Creek with catchment area of 100 km^2 are major tributaries of Marillana Creek within the model domain.

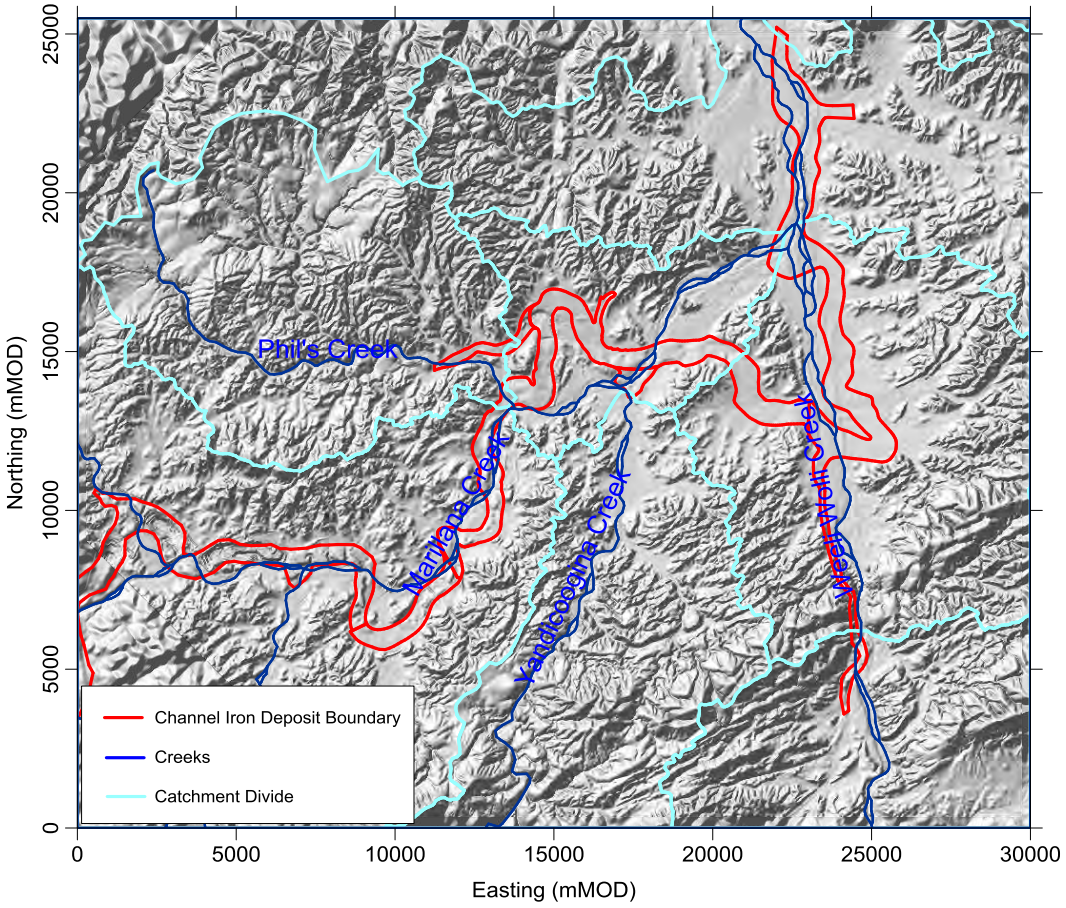

Figure 13. Topography showing dense network of drainage lines developed from intense rainfall on sparse vegetation cover.

Flow rates in the creeks are constantly being modified by BHPB Yandi, Hope Downs 1 and Yandi operations. Groundwater discharge from these operations are adding flow into Marillana and Weeli Wolli creeks making the once ephemeral creek now perennial along the reaches adjacent to mining areas. Yandi Operations discharges groundwater to Marillana Creek from eight (8) discharge outlets. Both Marillana Creek and Weeli Wolli Creek flow to the Fortescue Valley.

Leakage from the creek occurs when water in the creek is higher than the surrounding aquifers. The interconnectivity of the creeks with the CID aquifers mean that increase leakage upstream has the potential to decrease leakage downstream. Dewatering has the potential to increase leakage from the creek within the cone of depression.

Measurements of flow along the creeks have shown reduction in flow rates after the creek crosses the CID. Hydrographs close to the creeks have shown groundwater level rises corresponding to increase creek flows. The formation of braided stream along sections of the creeks meant that the total leakage area could be larger than the observed flowing part of the stream. Seasonally, part of the creek can alternate between a losing stream and a gaining stream depending on the elevation of the groundwater and elevation of the water in the stream. Leakage to and from the creeks depends on the conductance of the material between the creek and the underlying aquifers and the elevation of the creek.

The Yandi Operations in 2013 consist of seven dewatering borefields (JSW, Phils, Marillana, JSE Ridge North, JSE Northern, JSE Central, JSE Southern), a number of in-pit sumps and a re-injection borefield in Billiards. Location of the borefields is shown on Figure 14.

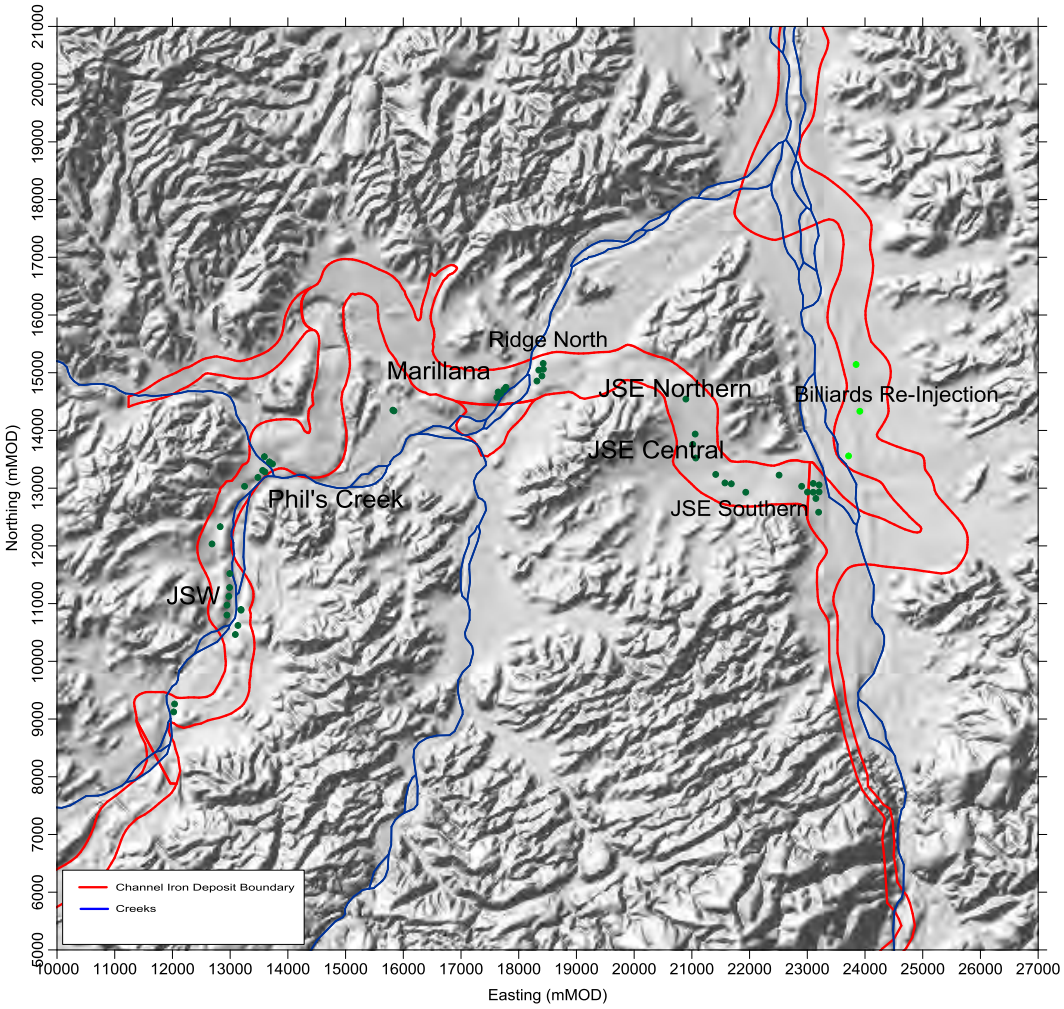

Figure 14. 2013 Borefields.

As part of Yandi Operations, groundwater abstracted from the JSE Southern borefield is being re-injected into the CID aquifer in the Billiards re-injection borefield. Since aquifer re-injection started, groundwater levels in Billiards have risen creating a groundwater mound which may seep back to Weeli Wolli Creek.

Groundwater discharge occurs actively through dewatering bores and in-pit sumps and passively through seepage into creeks, evaporation from pools along the creeks and evapotranspiration from vegetation that rely on groundwater. Areas of major active discharge occurs from the dewatering bores at JSW, Phil's Creek, Marillana, JSE Ridge North, JSE Northern, JSE Central and JSE Southern borefields. Minor discharge occurs from in-pit sumps in Phil's Creek, Hairpin and Waterstand pits, Railway loop borefield and the potable water bores.

The CID, being more permeable than the basement rocks, acts as a conduit for groundwater to flow to Weeli Wolli Creek before ending in the Fortescue Valley.

As part of Yandi's Operations, a wet processing plant was built to wash clays from the ore. Water used in the washing is recycled back to the plant through the waste fines cell (WFC) which is located on the eastern side of the mined out CID east of Phil's Creek borefield and in the Tributary area. Decant sumps located within the WFC pump water back to the plant.

The limited hydrogeological information from the Weeli Wolli and Brockman Iron Formations shows that the general direction of groundwater flow in these units is from the flanks of the catchment towards the valley occupied by Marillana Creek, Weeli Wolli Creek, Phil's Creek, Yandicoogina Creek and the CID before flowing to the Fortescue Valley as shown on Figure 15. Groundwater gradient generally decreases in the CID due to its higher permeability.

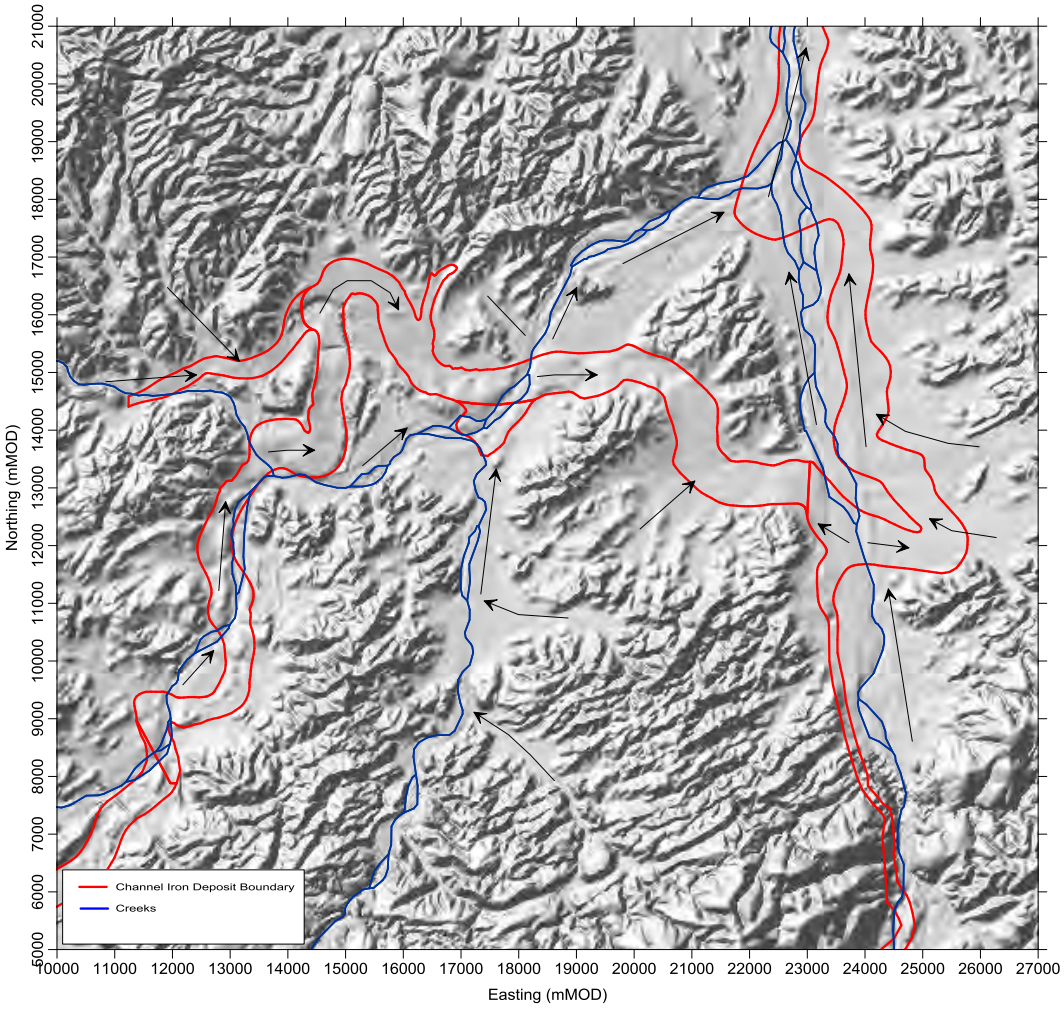

Figure 15. General direction of groundwater flow.

6. Numerical Model Code

The modelling code selected to simulate the groundwater flow condition at Yandi mine was MODSURFACT version 3.0. MODSURFACT is an enhanced version of the widely used United States Geological Survey MODFLOW. MODSURFACT was used mainly to overcome the numerical instability associated with MODFLOW rewetting of dry cells, and better representation of dewatering wells with the Fractured Well Package. The solver selected was PCG5 with adaptive time stepping. MODSURFACT was developed by HydroGeoLogic, Inc. The pre- and post-processor used was Visual MODFLOW version 2011.1 developed by Schlumberger Water Services.

7. Model Setup

The numerical model domain extends 25.5 km north-south and 30km east-west to cover the Channel Iron Deposit (CID) areas and minimise model boundary effects (Figure 16).

MODSURFACT is a finite-difference numerical code that requires the model domain to be discretised into three-dimensional blocks that broadly represent the conceptual hydrogeological model. The model setup consists of 425 rows, 491 columns and 15 layers. Irregular grids were used to capture the required hydrogeological details, maintain numerical stability, and minimise model runtime. The smallest grid measures 31m x 32m and the largest blocks measures 509m x 750m (Figure 16). The top of layer 1 was assigned the elevations of the surface topography and the bottom layer was flat at 250mRL. Variable layer thicknesses were used to capture the geology in the CID as shown on Figures 17 and 18.

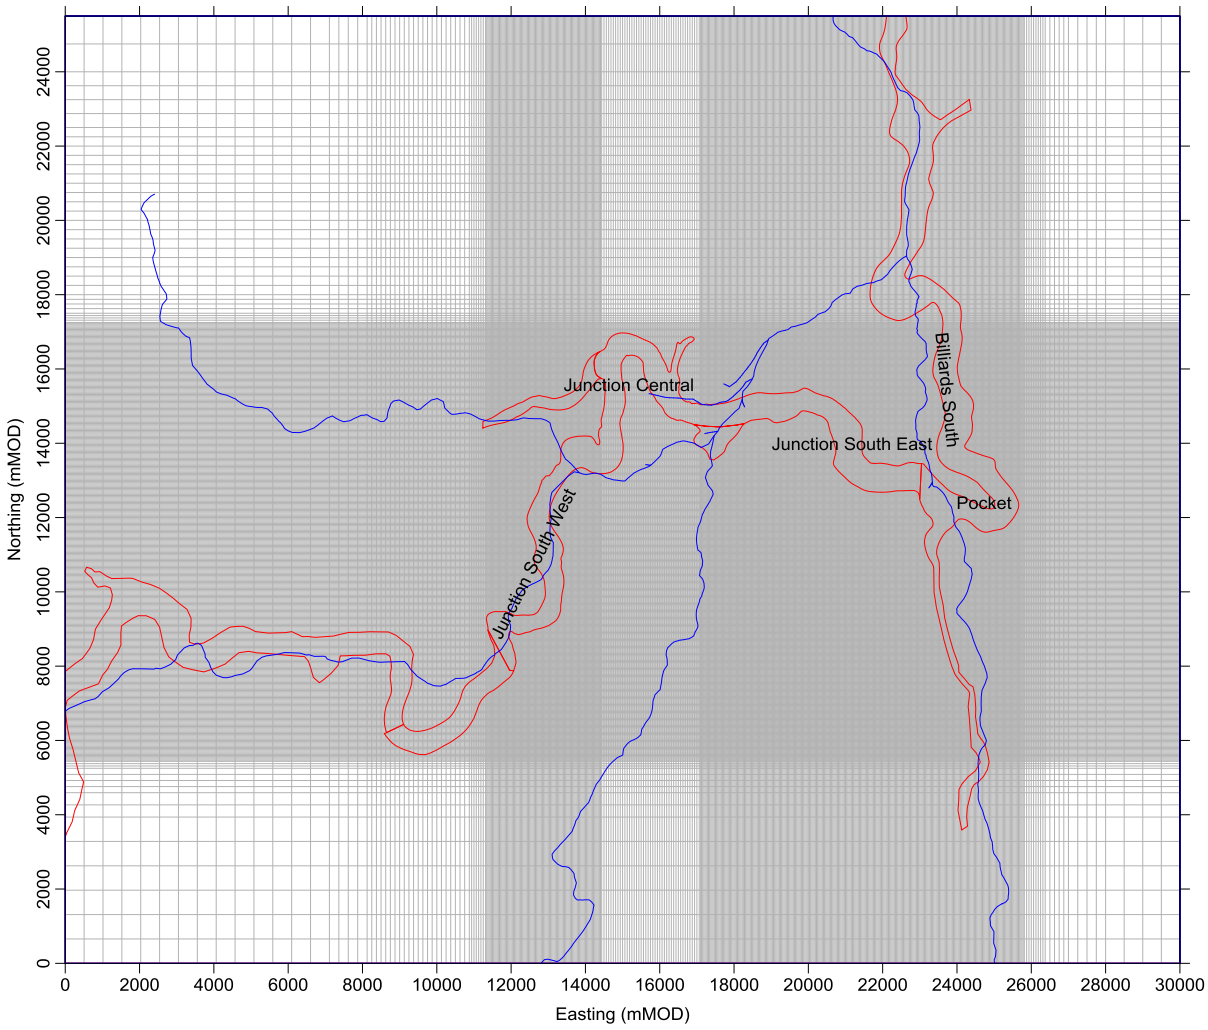

Figure 16. Model Domain and Discretisation.

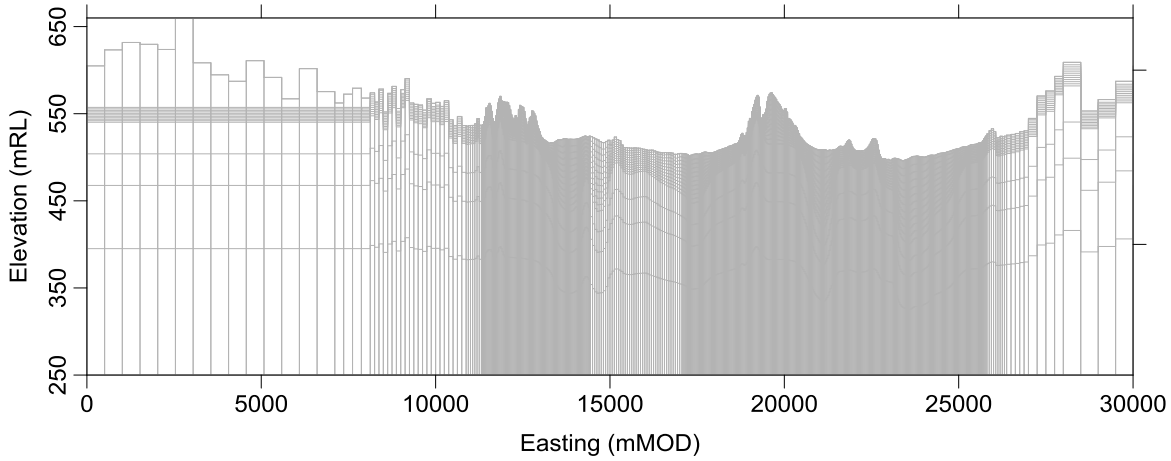

Figure 17. Vertical Discretisation – East West Cross-Section along 13984mN.

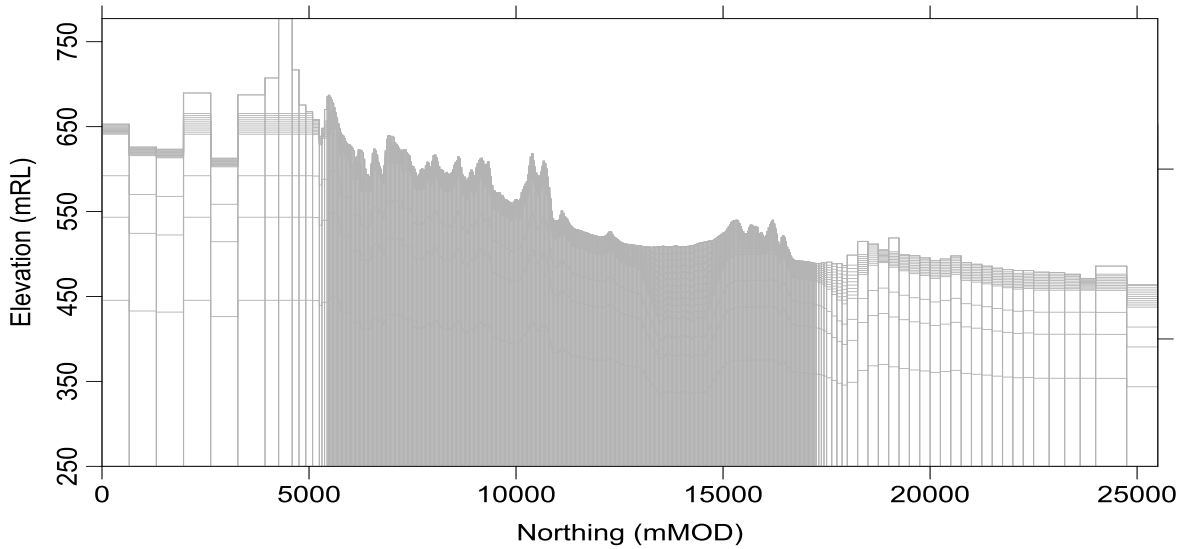

Figure 18. Vertical Discretisation – North South Cross-Section along 21015mE.

Aquifer pumping tests conducted along the CID show there is quite a variation in hydraulic conductivity along the CID as shown in Figures 19 to 22. Figures 23 and 24 show the distribution of the modelled hydrostratigraphic units in layers 1, 3, 6 and 9 and Figures 25 and 26 show cross-sectional views. Based on the interpretations of the aquifer pumping tests analyses and general borelogs interpretations of the competencies of the units encountered, estimates of the conductivity for the different hydrostratigraphic units were assigned to the model by assuming that the GVU is less permeable than the GVL and the GVL is less permeable than the LGC. The hydraulic parameters derived from the aquifer pumping tests were assigned to the numerical model and adjusted, within bounds, in the calibration process to long term pumping.

An aquifer pumping test was conducted in the alluvial in 2009 in bore WB08YJSE002 (Dogramaci and Kirkpatrick, 2010). Analysis of the test shows the hydraulic conductivity of the alluvial to be about 10m/d. Structures outside the CID as evident from aerial photographs, Landsat images and aeromagnetic maps suggest that regionally the basement may be quite transmissive and/or can yield more water than what was observed on a local scale. An equivalent porous media hydraulic conductivity value of 0.5m/d was assumed in the calibration and assumed isotropic.

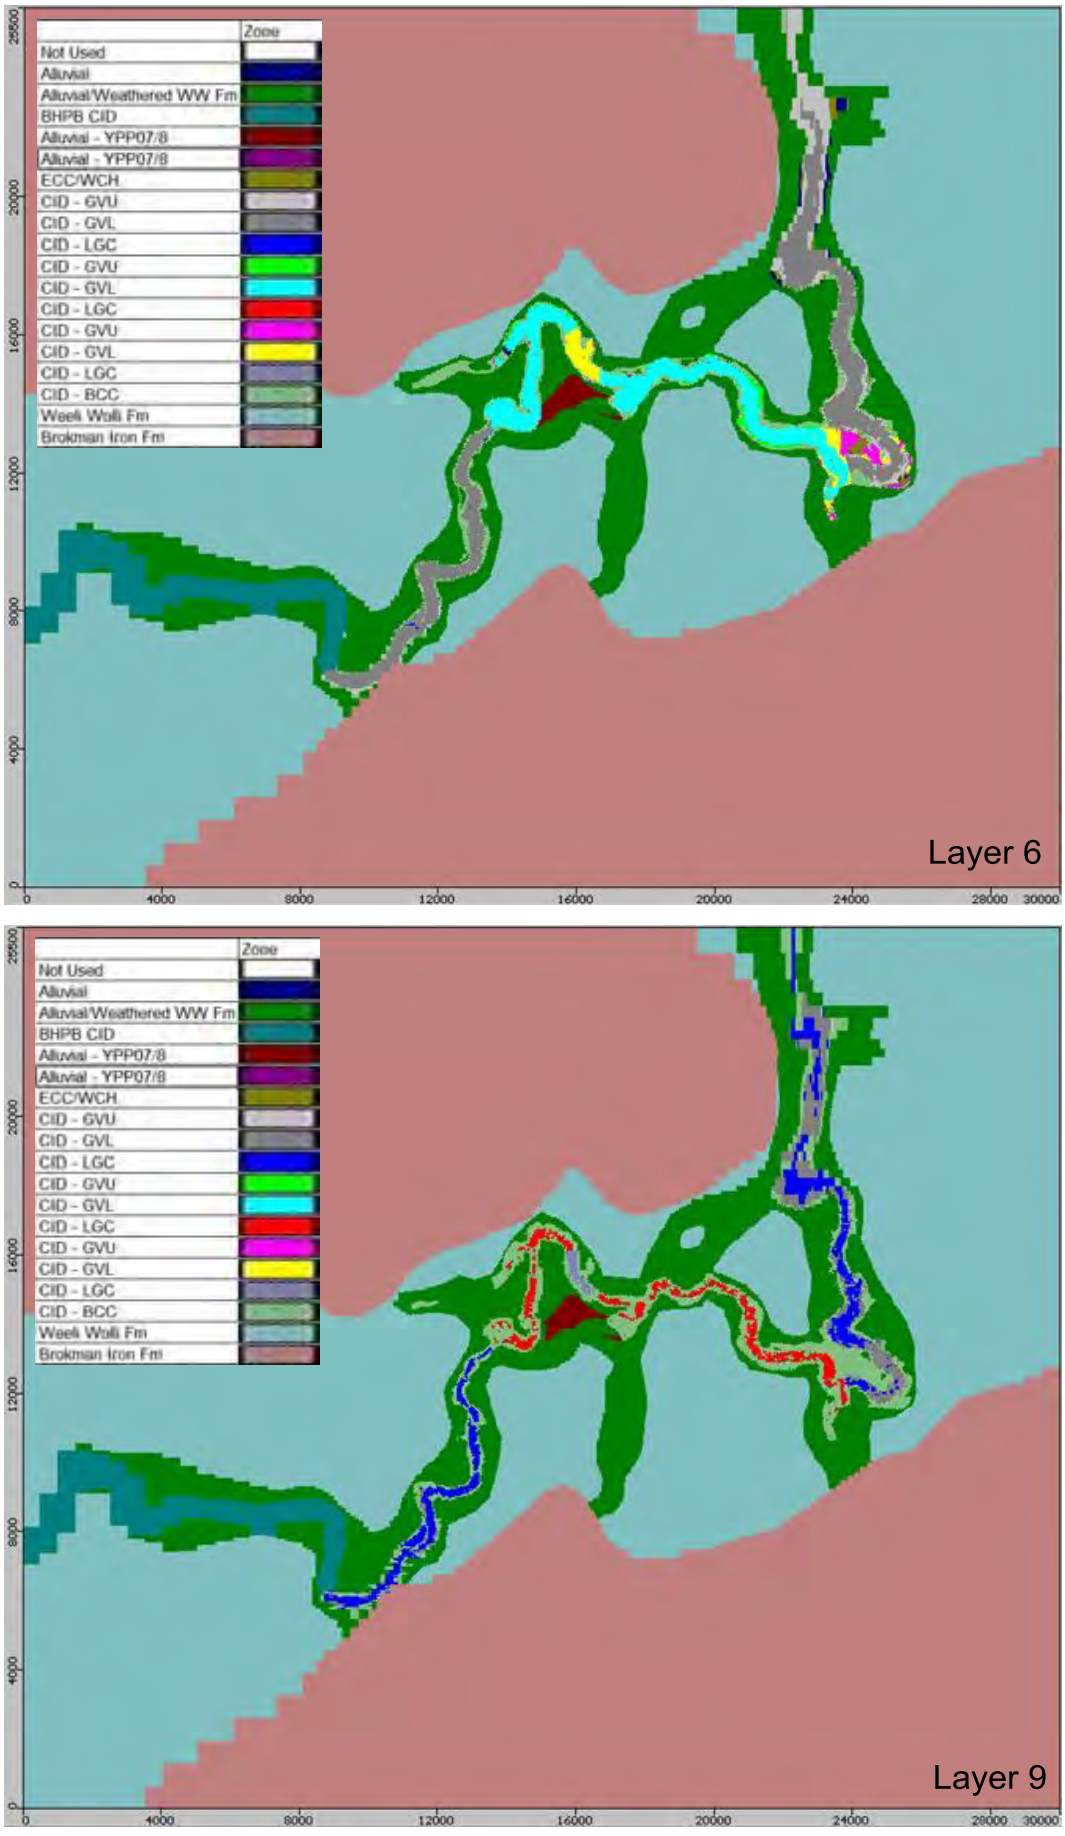

Figure 24. Hydraulic Parameter Zones – Plan View (Layer 6 and 9).

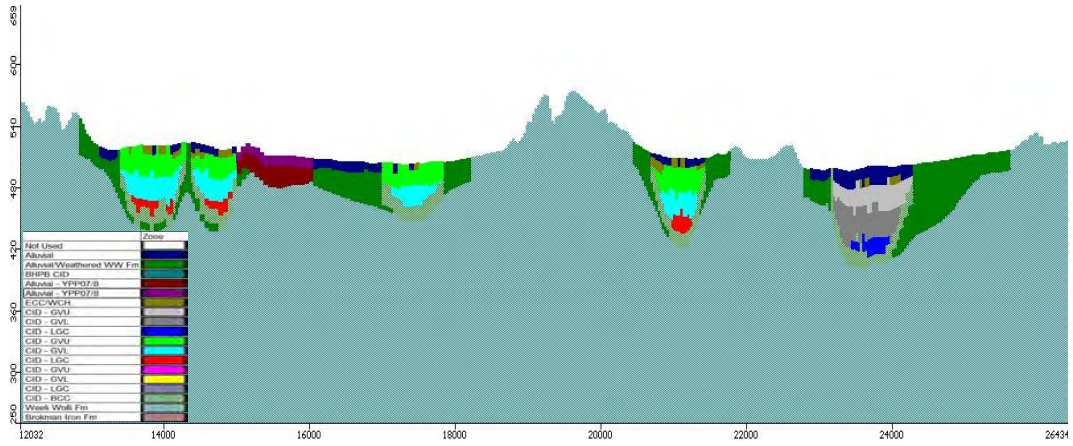

Figure 25. Hydraulic Parameter Zones – East West Cross-Section along Northing 13984mMOD (looking north).

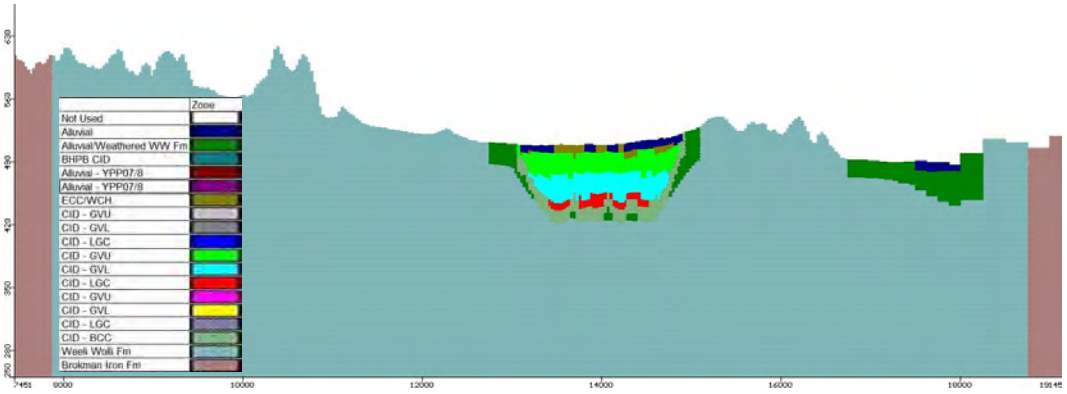

Figure 26. Hydraulic Parameter Zones – North South Cross-Section along Easting 21015mMOD (looking west).

No-flow boundary conditions were assigned to the model boundaries to represent the relatively impermeable Weeli Wolli Formation and Brockman Iron Formation outside the model domain except in the CID. Constant head boundary condition was assigned to the CID upgradient of the mine and MODFLOW drain cells were assigned to the CID down gradient of the mine as shown on Figure 27. This approach facilitates regional groundwater flow from the west and south to the north-north-east matching observations. MODFLOW drain cells were also used in the mined out area at Junction Central to represent in-pit sump pumping.

The upstream assignment of constant heads is recognised as a conservative approach given BHPB dewatering is occurring upstream and will impact the model boundary head over time. However in the absence of BHPB dewatering planning information, a conservative fixed head approach results in RTIO dewatering predictions not being contingent on BHPB meeting their plans.

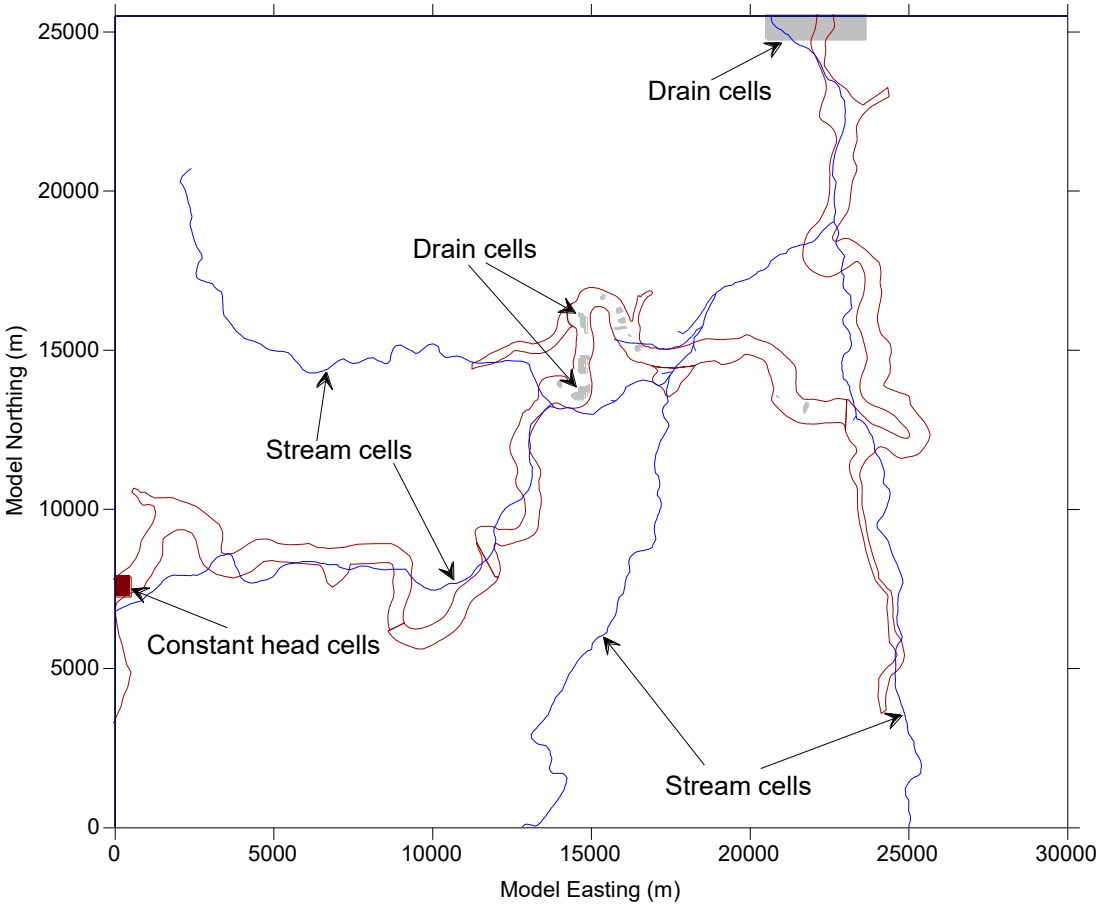

Figure 27. Model Boundary Conditions.

Direct rainfall recharge is represented in the model by MODFLOW recharge cells with selection that recharge enters the highest saturated layer i.e. cells that contain the water table. As direct rainfall recharge to the water table potentially occurs when it rains, measured rainfall were used to temporally vary monthly recharge rates assigned to the MODFLOW recharge cells. This simplified approach scaled the monthly measured rainfall and assumes all infiltration assigned enters the water table. Figure 28 shows the recharge zones assigned to the model based on surface geology and geomorphology. Although this approach is not very accurate in an arid environment, it serves as an approximation of seasonal rainfall recharge. The use of monthly stress period means high intensity rainfall lasting less than a month will be underestimated.

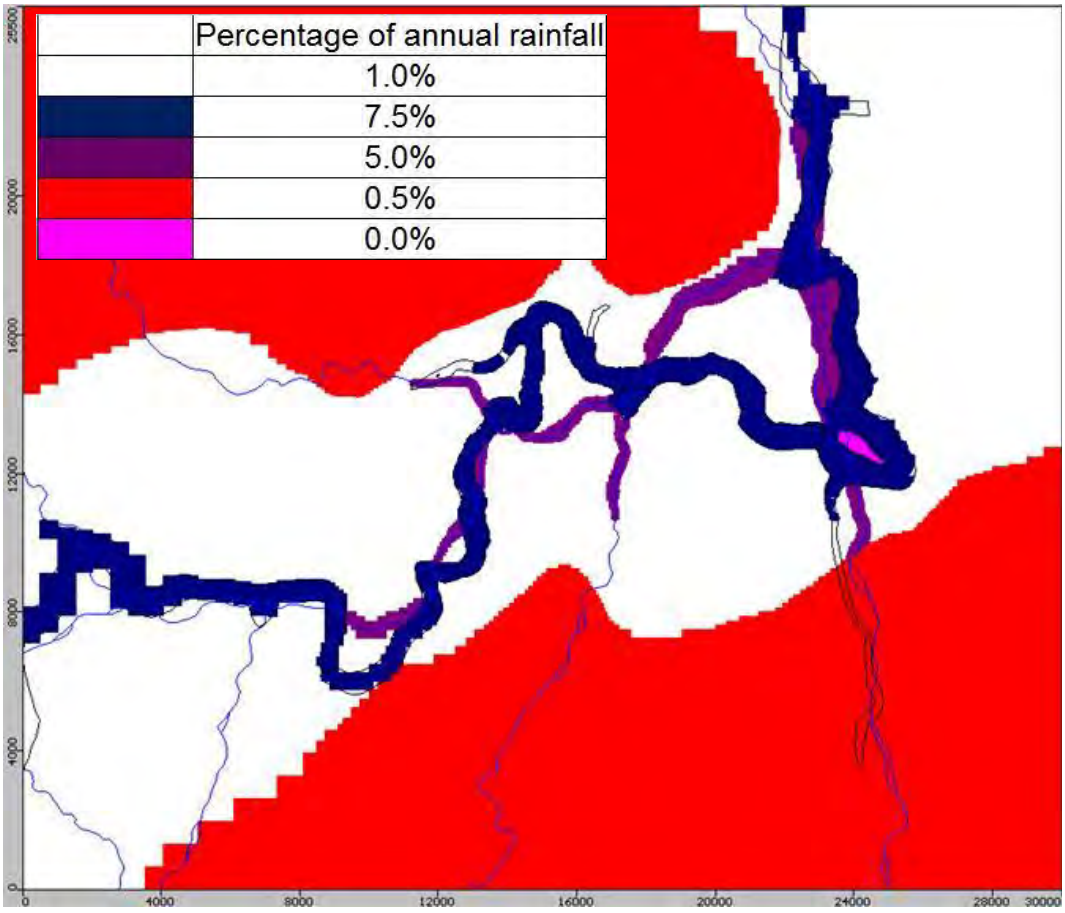

Figure 28. Recharge Zones.

Indirect rainfall recharge from creek leakage was modelled with MODFLOW stream cells. The use of stream cells accounts for losses and gains along the creek i.e. leakage upstream results in reduction in stream flow downstream. This is important in the model because Marillana Creek intersects the CID at a number of places where leakage potentially occurs. Dewatering in the CID has the potential to induce more leakage and hence lessen the amount of water that moves downstream and be available downstream. The rate of leakage is controlled by the streambed conductance of the stream cells. The variability and lack of measured values of the conductance between the creeks and the underlying aquifers has resulted in trial and error adjustment of the streambed conductance in the model calibration. A uniform rectangular stream width of 5m was

assumed and a Manning roughness coefficient of 0.093 was used to calculate the stage height for all the creeks. These values are not meaningful on their own. Current version of MODFLOW has 2 options in treating surface water in the creek. Option 1 is to assign a constant stage height and option 2 uses Mannings coefficients to calculate the stage height based on the equation below.

The depth of water (stage) is calculated based on:

$d = [Qn/ws^{1/2}]^{3/5}$

where

d = depth of water in channel, in metre;

Q = flow in channel in cubic metres per second;

n = Manning's roughness coefficient, dimensionless;

w = width of rectangular channel in metre; and

s = slope of the channel in length per length.

As both options are an imperfect representation of the creek when it floods, option 2 was selected as in part, it allows more water to infiltrate into the aquifers.

Stream cells were assigned to Marillana, Weeli Wolli, Yandicoogina, Phil's Creeks and the eight (8) discharge outlets as shown on Figure 29. Measured discharge rates from the discharge outlets were assigned to the location of the discharge outlets into the highest upstream stream cells. Stream flow in Yandicoogina and Phil's creeks were assumed a function of rainfall, catchment area and runoff assigned to the location shown on Figure 29. Discharge from BHP Billiton Yandi was added to the scaled catchment runoff upstream of the discharge location. Stream flow in Weeli Wolli Creek was modelled with measured flows at Tarina Gauging Station. Bank storage was not modelled.

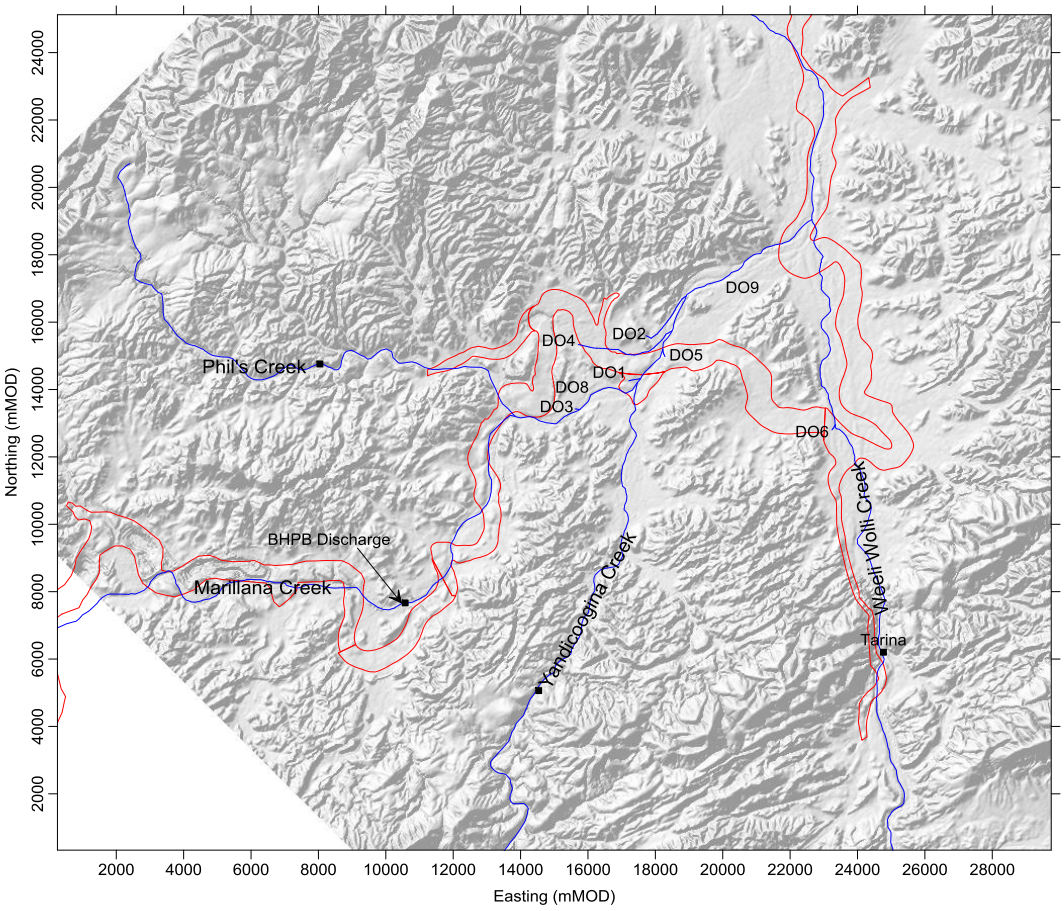

Figure 29. MODFLOW Stream Cells.

Groundwater discharge occurs through evapotranspiration. Evapotranspiration represents the loss of water through uptake by plants. The zoning of the evapotranspiration cells in the model is identical to the recharge cell zoning where groundwater is shallow. This assumes the area with higher recharge has denser vegetation and hence higher evapotranspiration. Extinction depths between 2m to 5m for the evapotranspiration cells were used to broadly represent the effective root depths of the native vegetation. MODFLOW assumes a simplistic approach of linearly reducing the assigned evapotranspiration rate to zero at the extinction depth. Figure 30 shows the evapotranspiration zones.

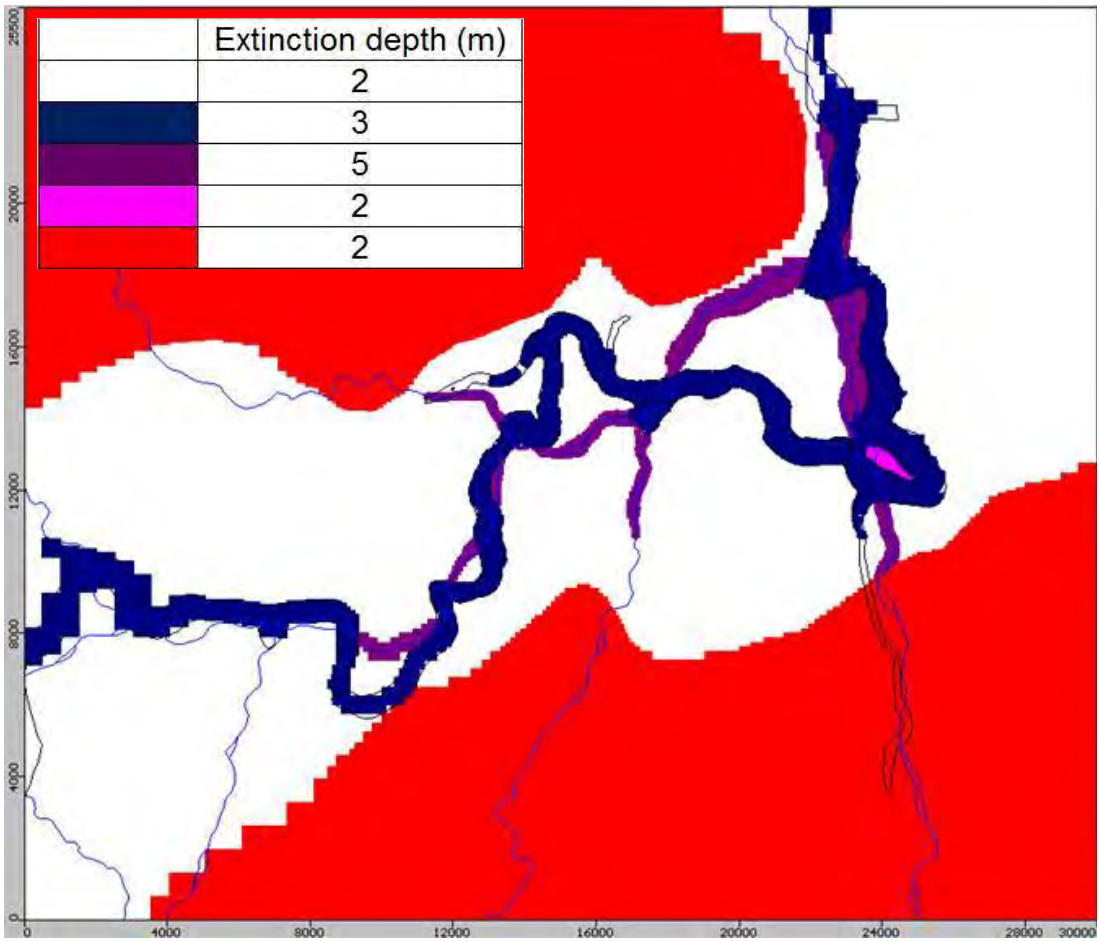

Figure 30. Evapotranspiration Zones.

Indirect discharge occurs through outflow from Weeli Wolli Creek at the model boundary and dewatering bores. MODFLOW drain cells were used in the former. Dewatering and injection bores were modelled with MODSURFACT Fractured Well Package. The package treats the screened section as a highly conductive zone, similar to the behaviour of an actual screen section, in computing inflows into the well from each aquifer intersected. Measured abstraction and injection rates since 1998 were reduced to monthly rates and assigned to the model. The screened intervals were simplified to include the GVL and the LGC layers, however, if these layers are thin then the screened intervals were extended to include the GVU and/or the BCC layers. This assumes that the LGC, being most permeable, can effectively drain the upper layers. Figure 31 shows the location of the dewatering and injection bores assigned to the model since 1998.

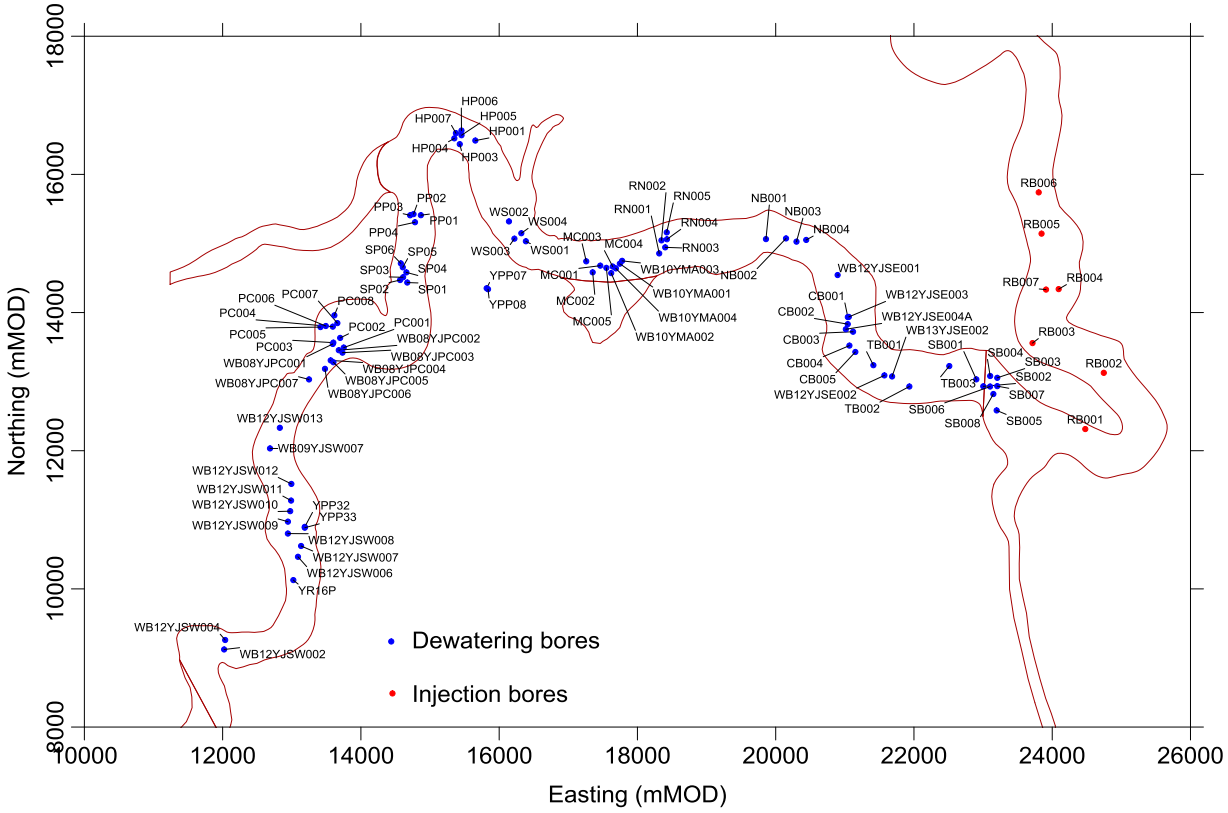

Figure 31. Dewatering and Injection Bores (1998 to 2013).

8. Steady-State Calibration

The model steady-state calibration process adopted involved the establishment of a water level condition consistent with pre-abstraction water level at Yandi. The purpose is to establish an initial/starting water level for the transient calibration consistent with the hydrogeology. Water levels measured pre-1998 was used as target for the steady-state calibration. At RTIO Yandi, this is somewhat compromised by discharge from BHP Billiton Yandi Operations. The dynamic nature of the system to recharge meant that only quasi steady-state conditions exist. Hydraulic conductivity and boundary conditions were adjusted in the calibration process.

Table 1 lists the scaling factors applied to the measured monthly rainfall and Table 2 lists the extinction depths required to calibrate the model.

Table 1. Recharge Zones and Scaling Factors.

Zone	Description	Percentage of annual rainfall
1	Weeli Wolli Formation	1%
2	Channel Iron Deposit	7.5%
3	Alluvial	5%
4	Brockman Iron Formation	0.5%
5	Low permeability WW Fm	0%

Table 2. Evapotranspiration Zones Rates and Extinction Depths.

Zone	Descriptions	Extinction Depth (m)
1	Weeli Wolli Formation	2
2	Channel Iron Deposit	3
3	Alluvial	5
4	Brockman Iron Formation	2
5	Low permeability WW Fm	2

Figure 32 shows the simulated steady-state water table consistent with 1997 water table. Table 3 lists the mass balance from the steady-state model. An inflow/throughflow rate of 3.2 ML/day is in agreement of with an estimated throughflow of 2.5 to 3 ML/day by Peck in 1998.

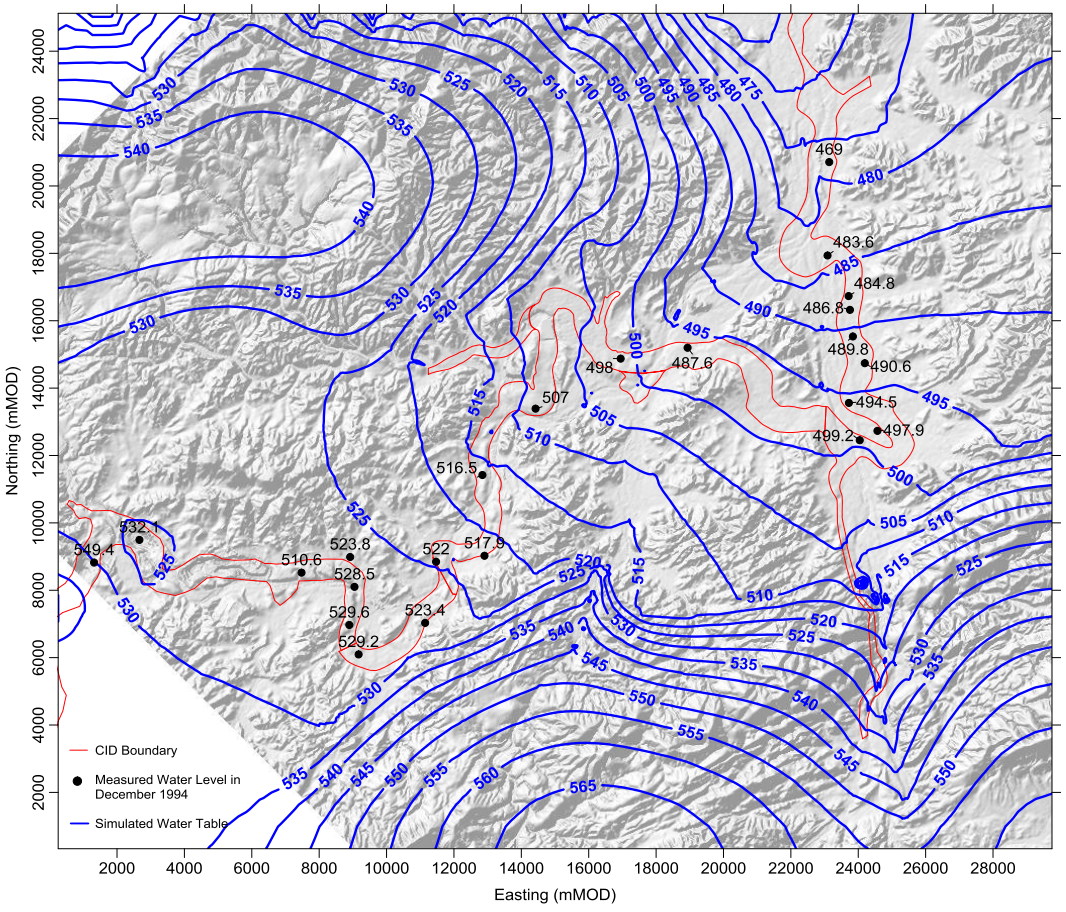

Figure 32. Simulated Steady-State Water Table (mRL).

Table 3. Steady-State Water Balance Summary.

	Volume In		Volume Out	
	Total (kL/day)	**% of Total**	**Total (kL/day)**	**% of Total**
Stream Leakage	138,295	96.5	97,700	68
Recharge	1,768	1.2	0	0
ET	0	0	39,921	27.8
Constant Head	3,239	2.3	30	0
Drain Cells	0	0	6,047	4.2
Total	**143,302**	**100**	**143,668**	**100**

9. Transient Calibration

Following an acceptable match of the simulated steady-state water table with pre-abstraction water levels, the steady-state model was configured with transient conditions by activating all transient parameters and boundary conditions. Historical abstraction, injection and discharge rates, and water levels from observation bores from January 1998 to January 2014 were used in the calibration – a period of 16 years.

Monthly stress periods were used to capture the changes in abstraction, injection, recharge and evapotranspiration rates. Scaling factors for rainfall recharge and stream flows from the steady-state calibration were adopted in the transient calibration. Specific yield and specific storage of each of the hydrostratigraphic units were adjusted, within bounds, in the transient calibration. Calibration was done by comparing simulated hydrographs with measured hydrographs. Figure 33 shows the locations of the calibration bores. Both quantitative (water level matching) and qualitative (trend matching) methods were used to guide the model calibration. Any changes to hydraulic conductivity and boundary conditions require recalibration of the steady-state model. Figures 34 to 40 show simulated versus observed hydrographs in the calibration bores. Observed values are represented by green dots and simulated hydrographs by blue lines.

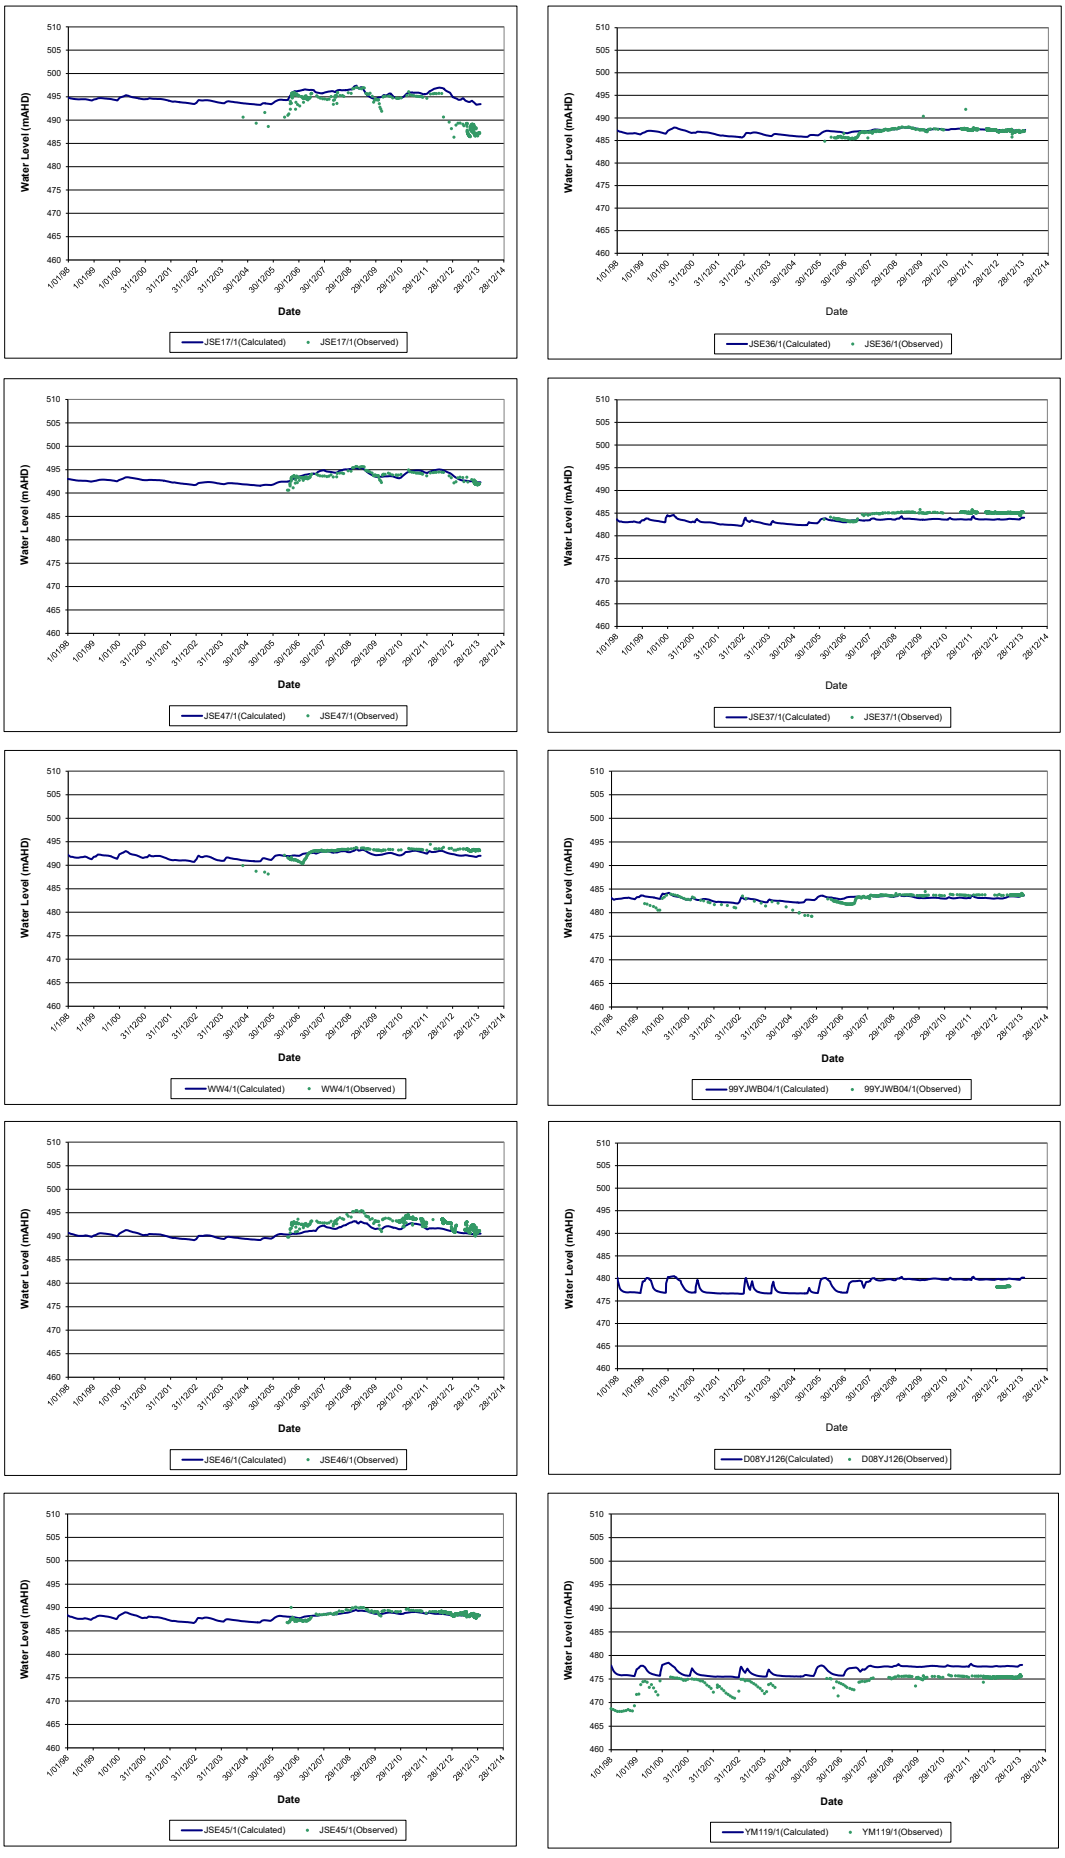

Figure 39. Transient Calibration - Observed versus Calculated Heads.

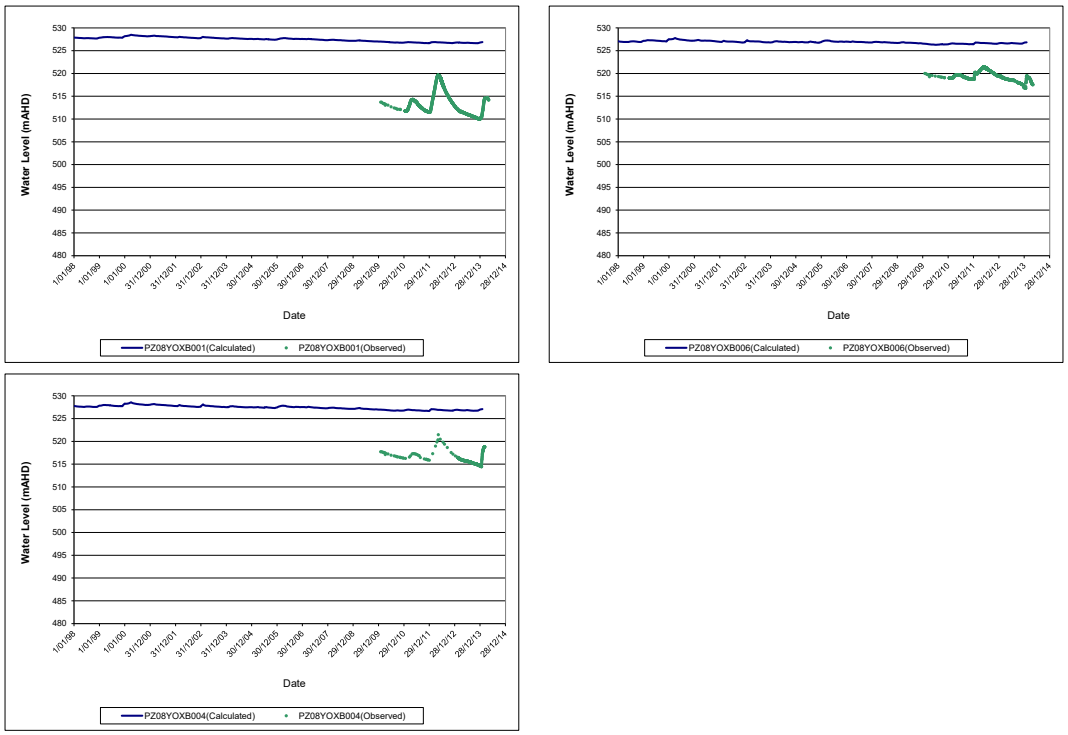

Figure 40. Transient Calibration - Observed versus Calculated Heads.

The simulated hydrographs show the model generally is able to replicate the measured water table over a period of 16 years of dewatering. Where simulated divert from measurements, errors can be attributed to lack of details in the model or measurement error in monitoring water level in the calibration bores and accuracy of the flowmeters. Site has acknowledged that there is insufficient flowmeters in the water circuit to account for all water use on site. Flowmeters once installed were never recalibrated due to operational issues, hence accuracy is compromised. Estimates were made where there is no flowmeter at discharge outlets, sumps and dewatering bores. Overall the transient calibration (TrCal11a_2014.vmf) represents the site hydrogeology very well. The model will need to be recalibrated in the JSW area when more pumping data becomes available. In the Oxbow area, simulated water level is higher than measured. This may be due to dewatering at BHP Billiton Yandi not captured in the model. Table 4 lists the hydraulic parameters derived from the model calibration. The hydraulic parameters were generally similar to the previous model.

The water balance from the transient calibration indicates that increased dewatering at Yandi is coupled with increased leakage from the creeks as shown in Figure 41. This is a function of site water management where the discharge of dewatering surplus to creeks results in recirculation to the aquifer. Figure 42 shows most of the leakage comes from Weeli Wolli Creek with the discharge from Hope Downs 1 from July 2006.

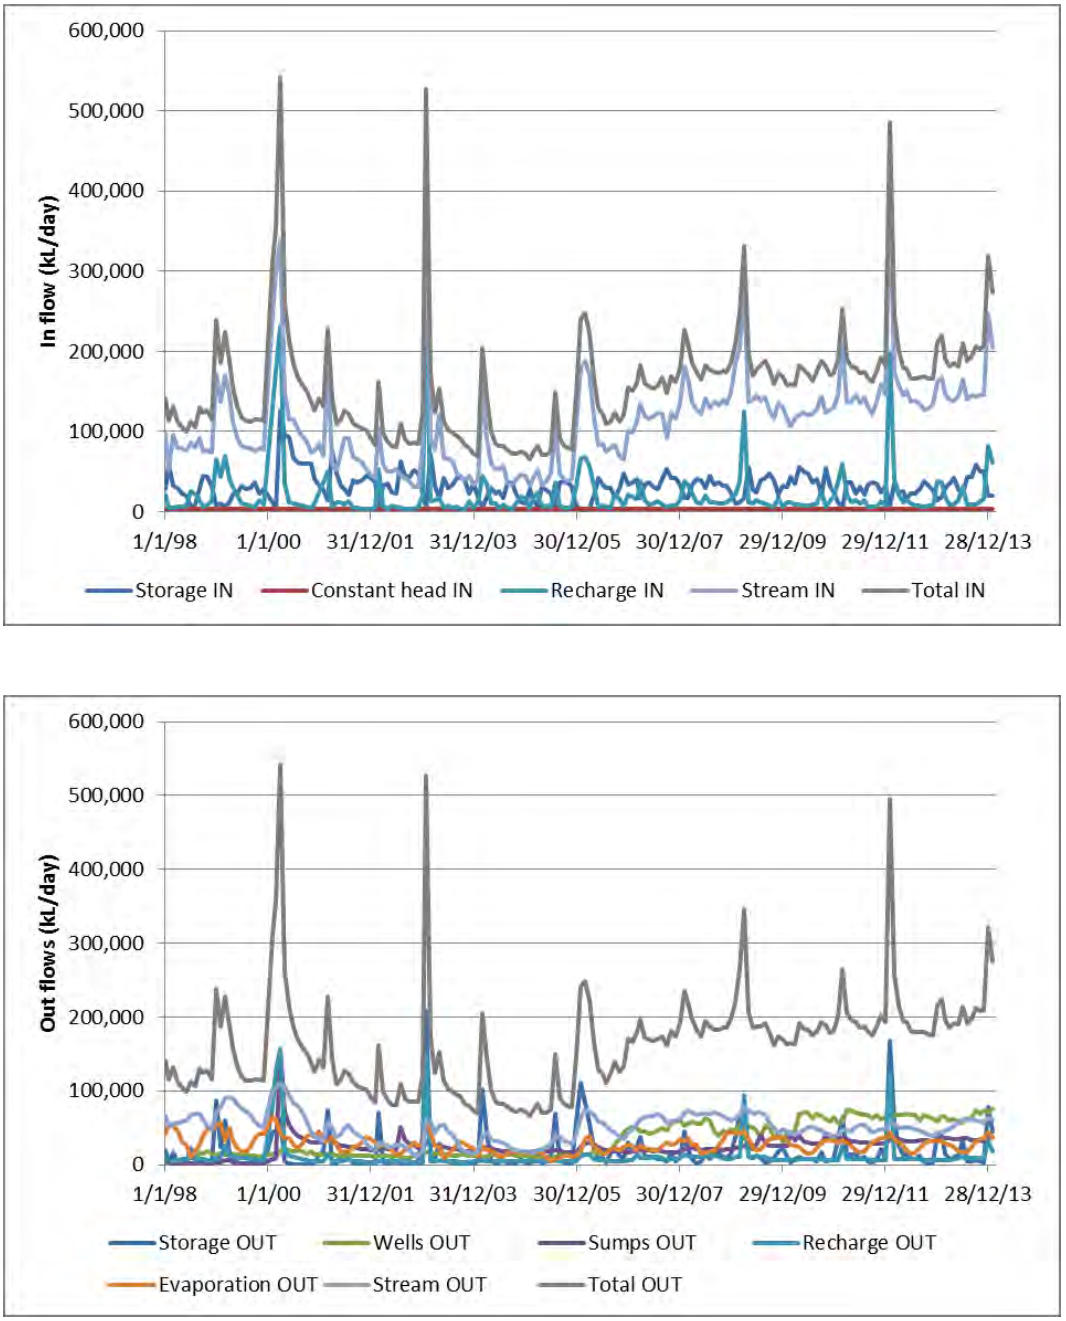

Figure 41. Transient Calibration Mass Balance.

Figure 43 shows the percentage discrepancy errors from the transient model calibration simulation. Percentage discrepancy error below 5% is considered good for complex flow systems.

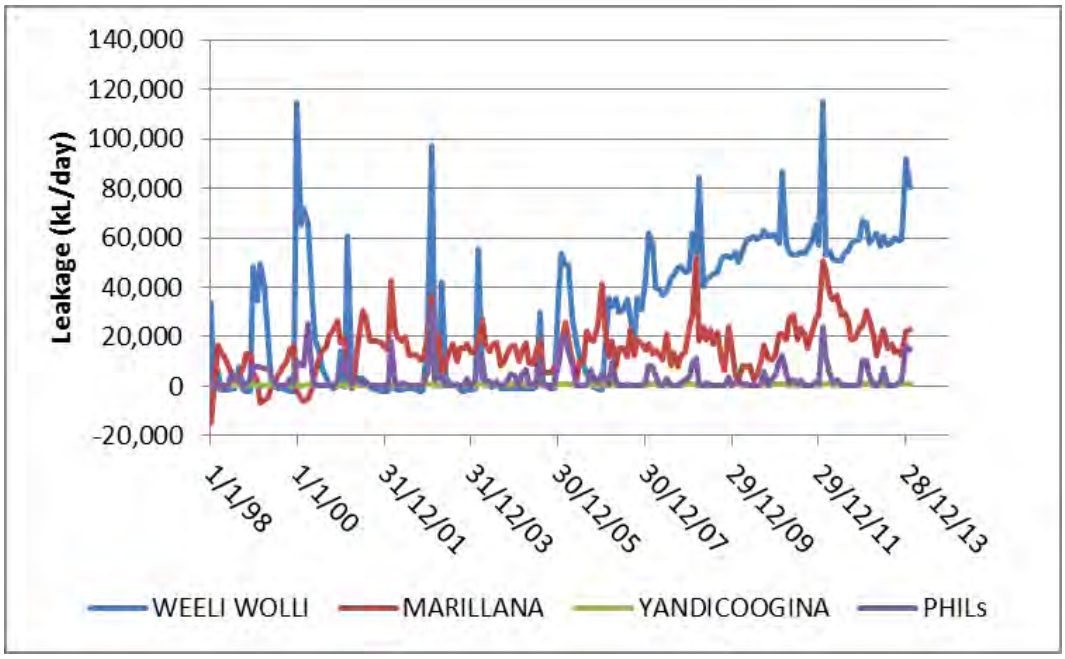

Figure 42. Leakage from creeks.

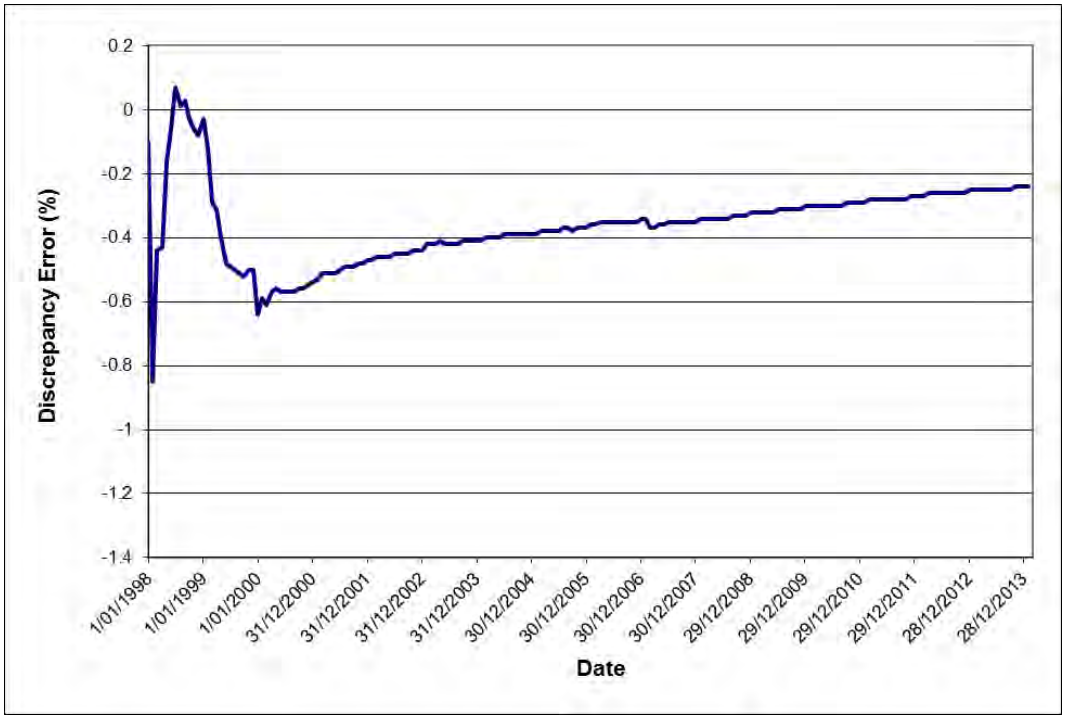

Figure 43. Transient calibration - discrepancy errors.

10. Sensitivity Analysis

Sensitivity analysis was conducted by perturbing the parameters by 20% on either side of the calibrated hydraulic conductivity and 50% on either side of the calibrated specific yield. The results show is the model is not sensitive to hydraulic conductivity of the alluvial at the water supply bores, eastern clay conglomerate/weathered channel deposit and Upper Vitreous Geothite (Figure 44) and specific yield of Limonite Geothite Clay in the Billiards and JSW areas (Figure 45). This implies that these hydrostratigrahic unit parameters can vary without significantly distorting the calibration. These units are identified as potential significant contributing elements to uncertainty in the model predictions and will be tested in the predictive simulations to provide an upper bound of the dewatering requirements as a full suite would take too long and does not add significant value.

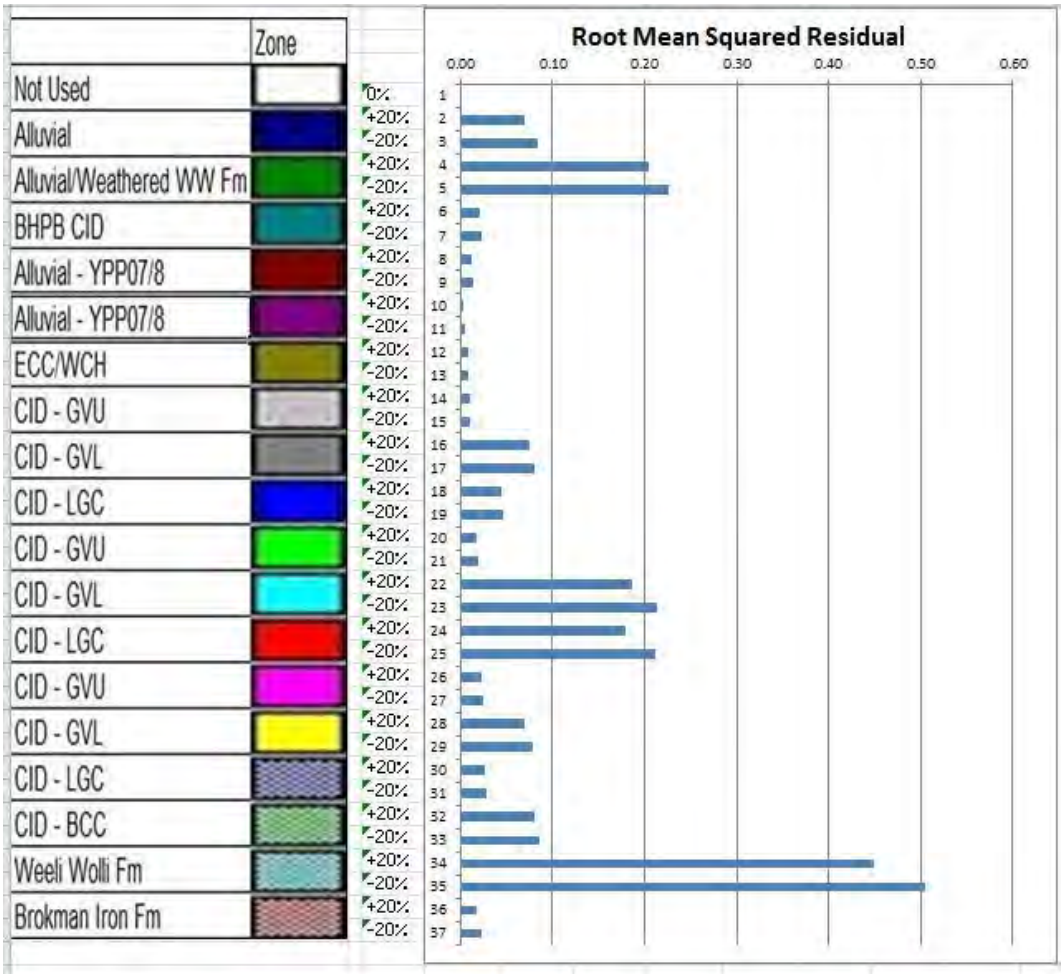

Figure 44. Sensitivity Analysis of Hydraulic Conductivity.

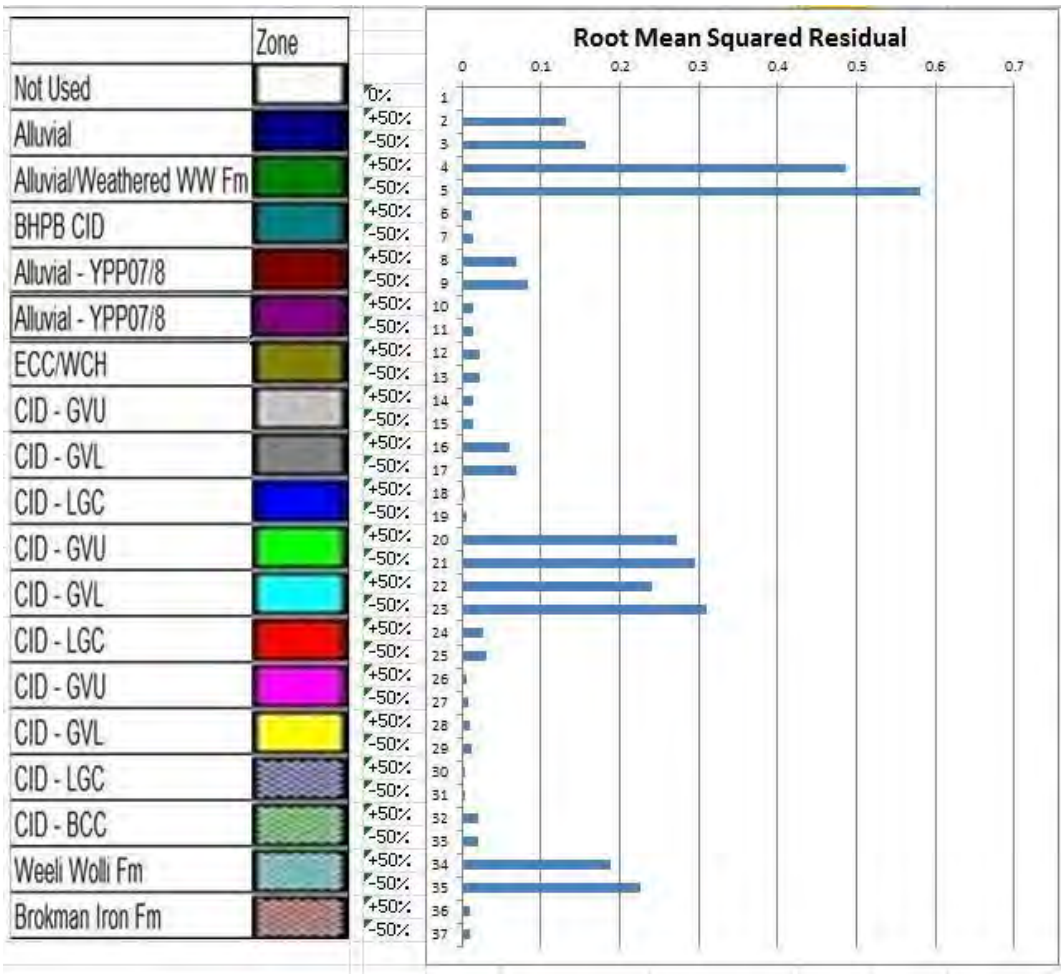

Figure 45. Sensitivity Analysis of Specific Yield.

11. Model Prediction

As part of the PFS for PBS, an estimate of the dewatering requirement is required. Based on the Billiards South A8 mine schedule released in August 2014, the numerical model was configured with predictive conditions to determine the dewatering requirements of the mine as a whole i.e. including Junction Central (JC), Junction South East (JSE), JSW and Oxbow. According to the A8 mine schedule, mining is to commence close to the centre of Billiards South and expand north and south concurrently. Figure 46 shows the start year of mining, Figure 47 shows the end year of mining for each mine block. Figure 48 show the final pit floor elevation. A number of predictive simulations were conducted to optimise the placement of dewatering points. Modelled dewatering points are potential locations for bores not drilled. The number of bores required for each proposed dewatering point depends on the local aquifer yield and bore utilisations.

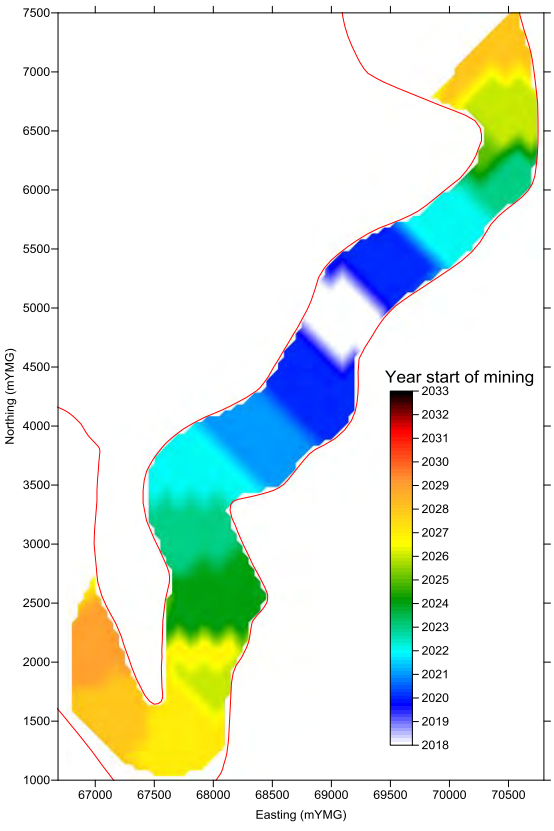

Figure 46. Start year of mining.

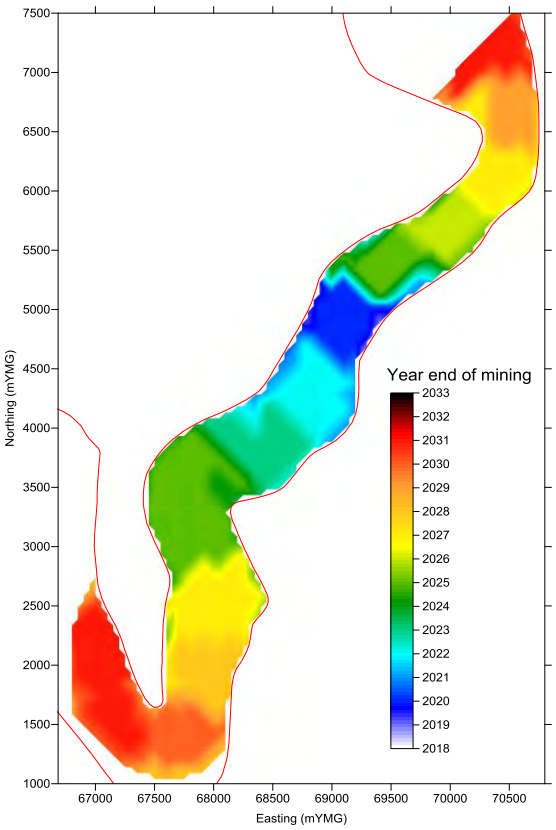

Figure 47. End year of mining.

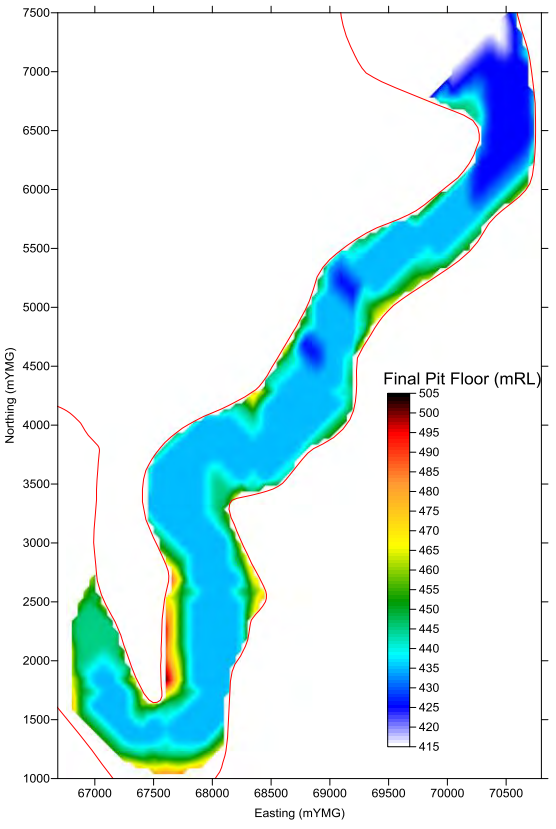

Figure 48. Elevation of pit floor.

For the predictive simulations, flow in the creeks were based on discharge rates from 2009 to 2013, averaged for each calendar month for a year and repeated yearly for the duration of the predictive simulation. Figure 49 shows flows in Marillana Creek at BHPB discharge point and Figure 50 shows flow from Tarina Station into Weeli Wolli Creek.

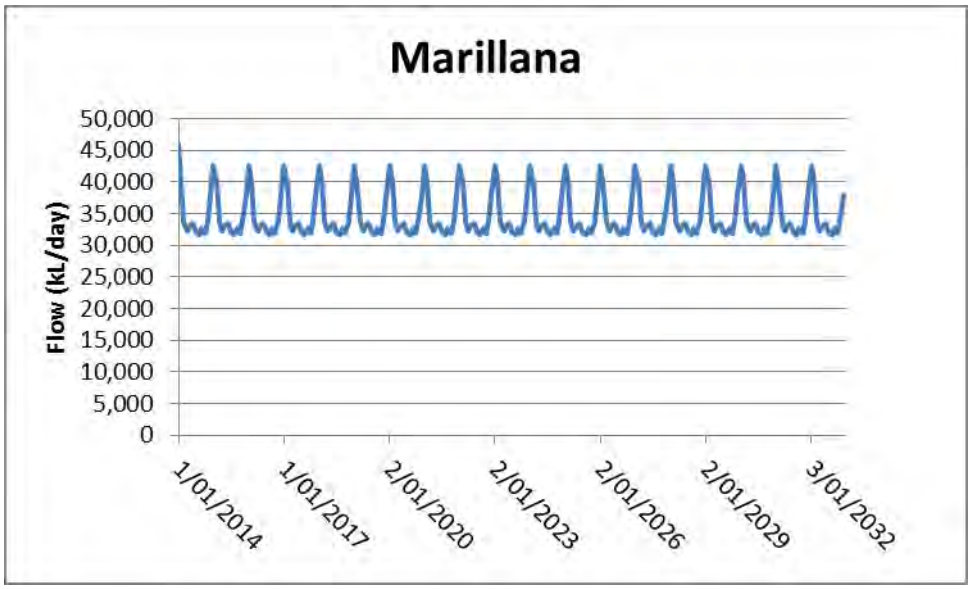

Figure 49. Predictive flow in Marillana Creek.

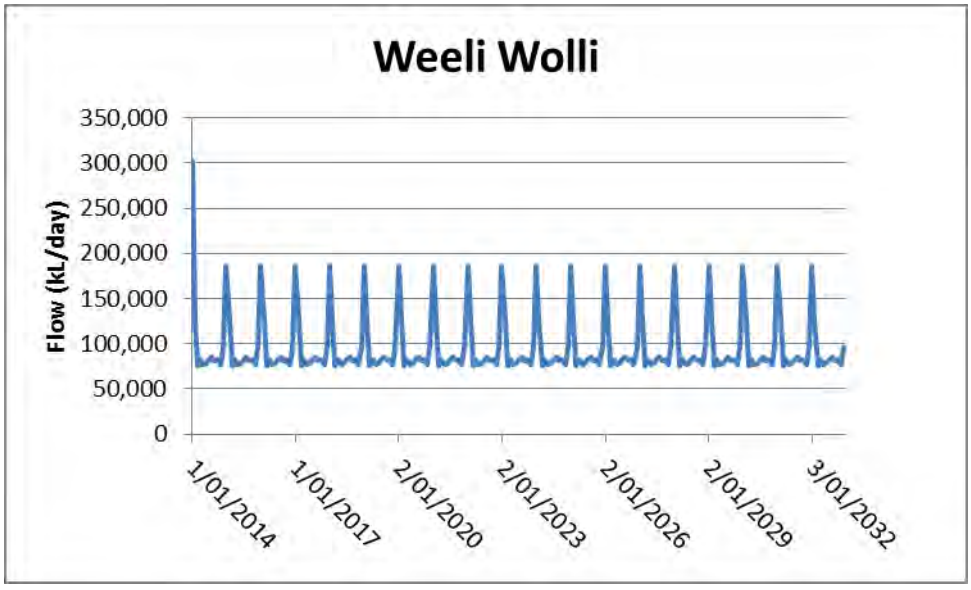

Figure 50. Predictive flow in Weeli Wolli Creek.

To assess the dewatering requirements to meet the mine schedule, thirteen (13) tracking points were assigned to the numerical model, within the CID, to track the decline in water table in response to pumping in the model. Figure 51 shows the location of these points - mainly located close to the deepest part of the pits.

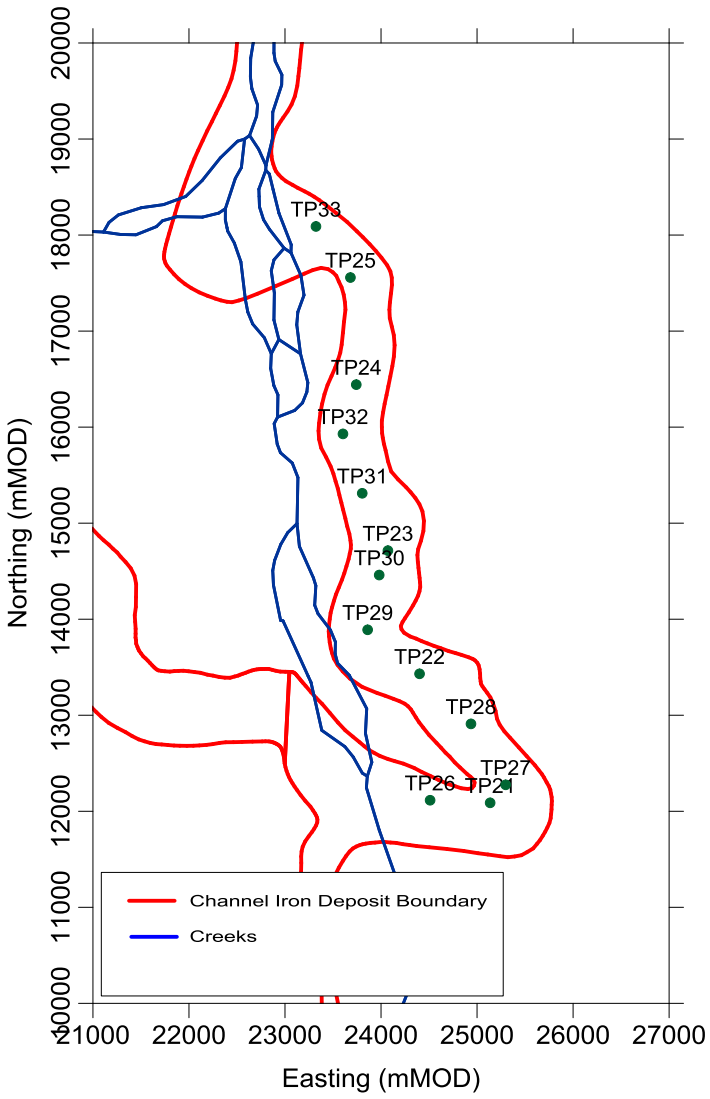

Figure 51. Tracking Points.

Figures 52 to 53 show the simulated water table meeting the mine schedule. Black line shows the bench progression and blue line shows the simulated water table. The yearly bench progression provided is assumed from 1 January to 31 December. This may overestimate advancement of the pit and hence provide a conservative approach in dewatering estimation.

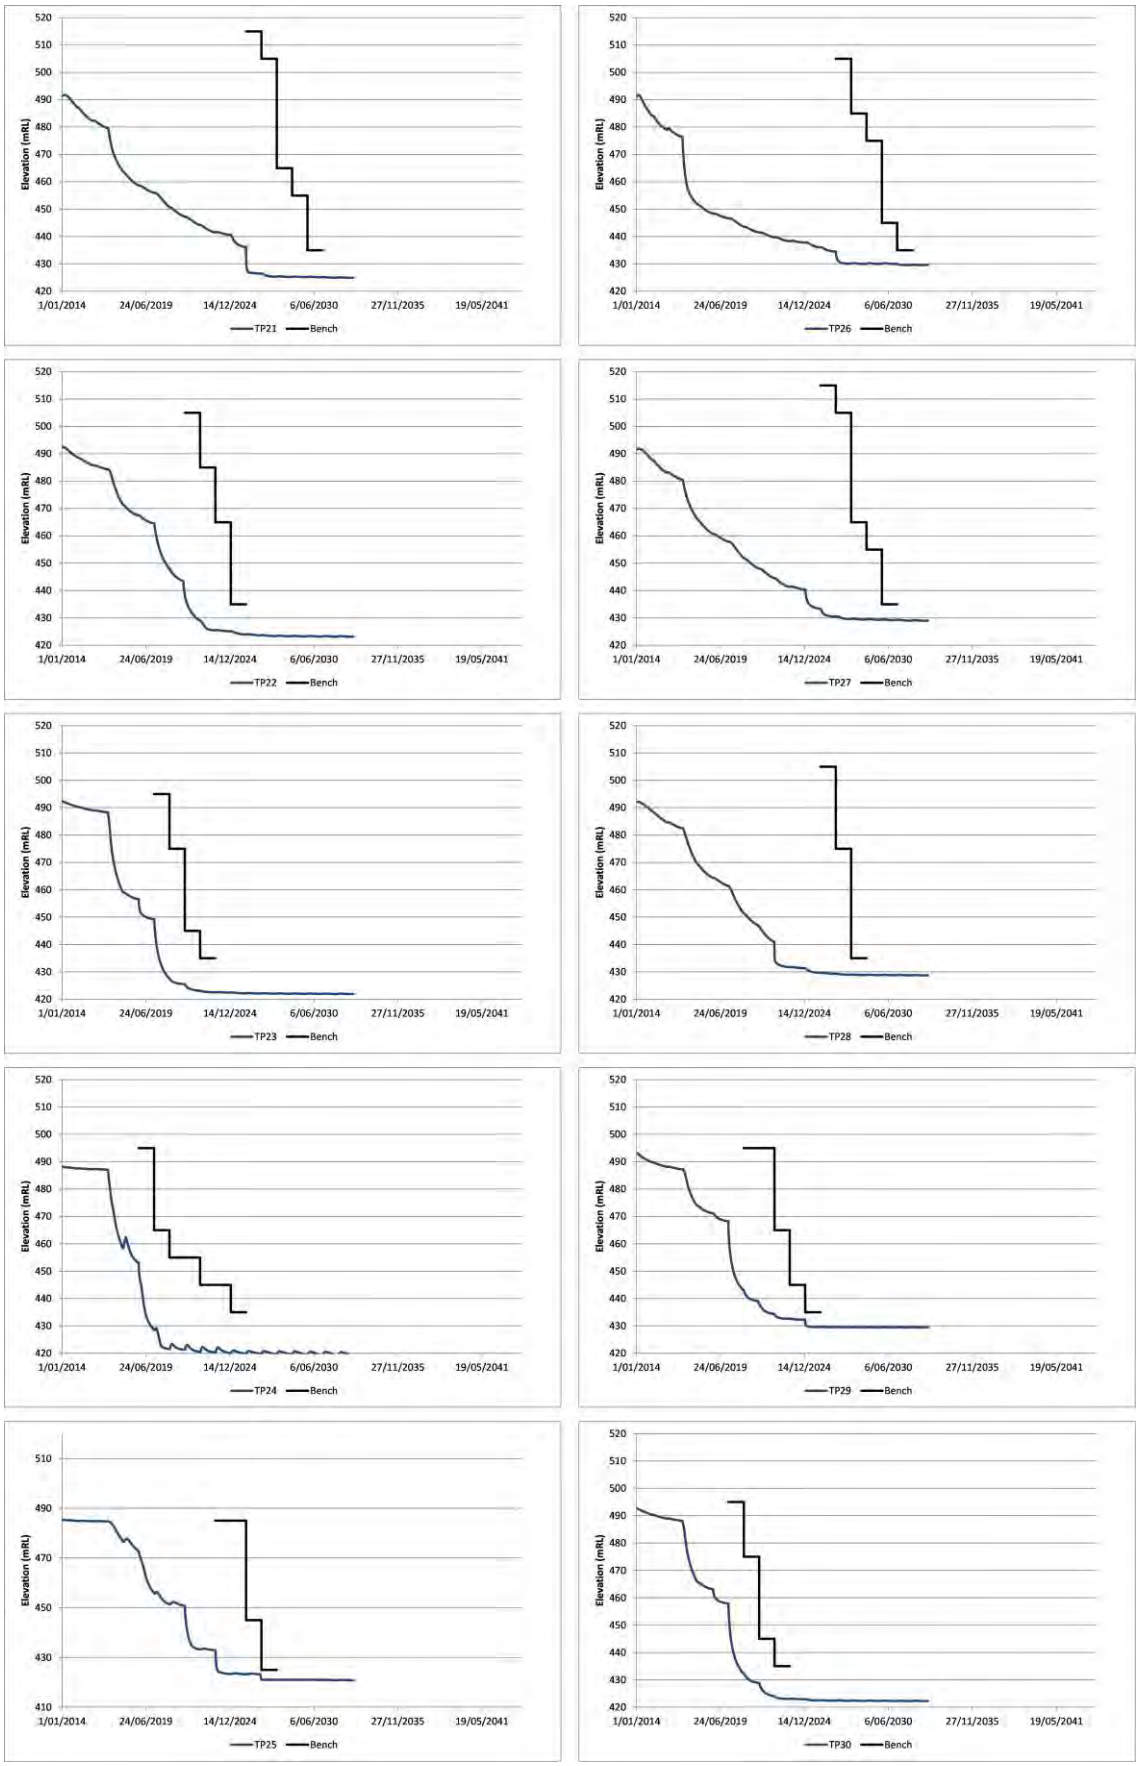

Figure 52. Simulated Hydrographs.

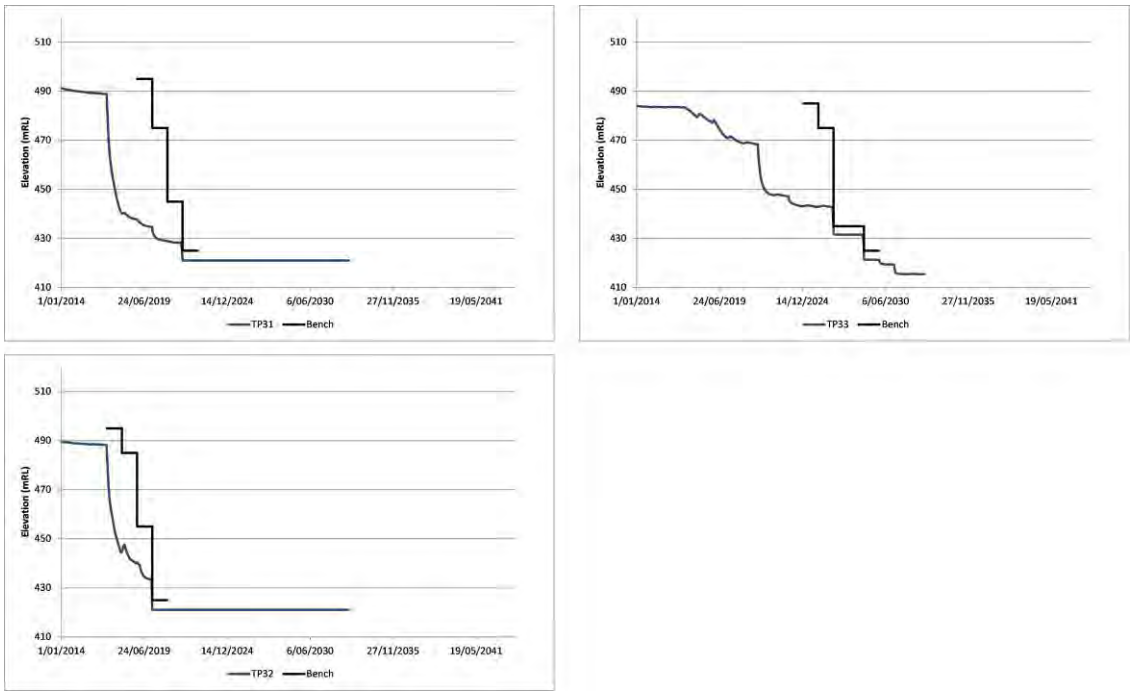

Figure 53. Simulated Hydrographs.

Sumping was required to dewater below the pit floor at tracking point 31, 32 and 33.

The total number of dewatering points is shown on Figure 54. For bores not in the ground already, the dewatering points are the approximate location for the placement of dewatering bores. The number of bores at each of the dewatering point will vary according to the actual bore yield once drilled. Table 5 lists the number of dewatering points in each mining area. Table 6 lists the approximate coordinates of the dewatering points in MGA.

Table 5. Number of Dewatering Points.

Pits	Oxbow	JSW_A	JSW_C	JSE	PBS	Total
Number of dewatering points	9	8	10	24	46	97

The current model assumes the mined out area is being back filled with material similar to the orebody hydraulic parameters and no pit void is being considered due to time constraint for this modelling exercise and the multiple closure scenario options to be investigated.

*Note: * bores already in operation*

Abstraction rates assigned to the model were generally 5,000 kL/day at each dewatering point, however, rate as high as 10,000 kL/day and as low as 2,000 kL/day were used in the model. The model shows the assigned abstraction will decline over time as saturated thickness decreases as a result of dewatering. Figure 55 shows dewatering from Pocket and Billiards South. Spikes in dewatering rate are due to both the initial abstraction rates and activation of the sumps in the model. Figure 56 shows the annualised abstraction. Tracking leakage along Weeli Wolli Creek (Figure 57) shows essentially all flows along the creek gets captured by dewatering at PBS.

Figure 58 shows the contributions from each mining area at Yandi and annualised dewatering is shown in Figure 59.

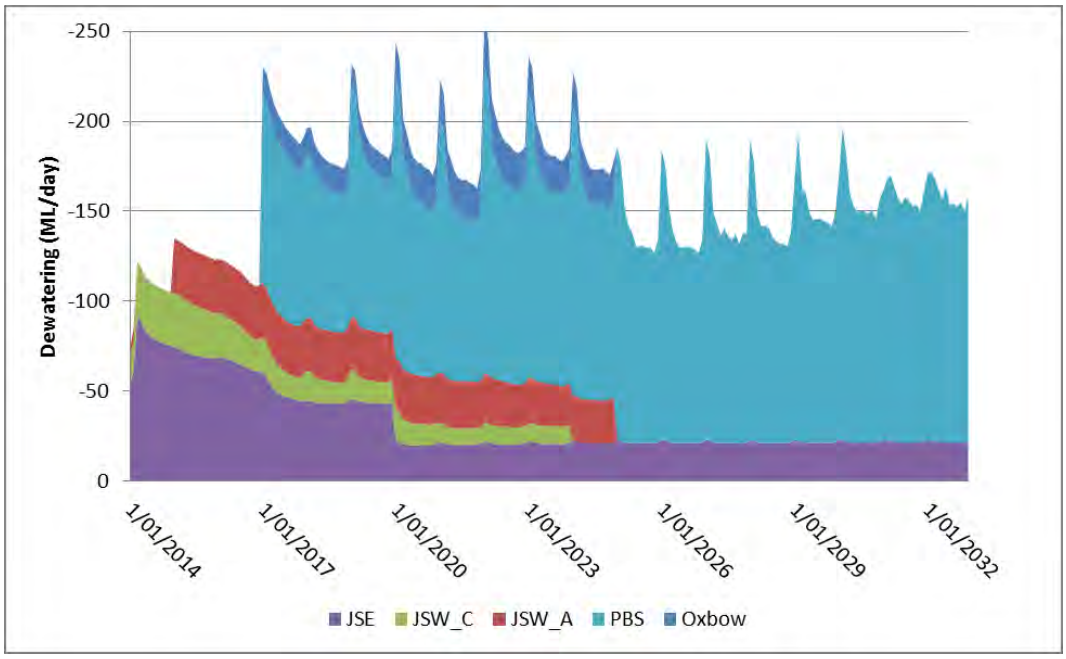

Figure 58. Yandi dewatering.

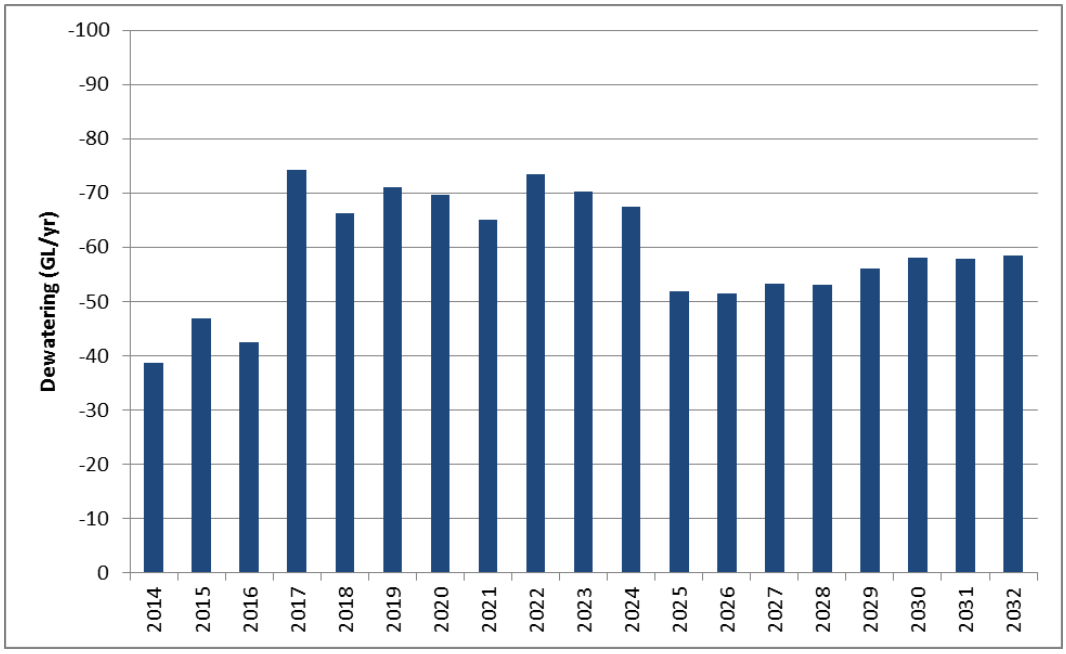

Figure 59. Yandi annualised dewatering.

Figure 60 shows the percentage discrepancy errors from the predictive simulation. A discrepancy error of less than 5% is considered good for such a complex flow systems.

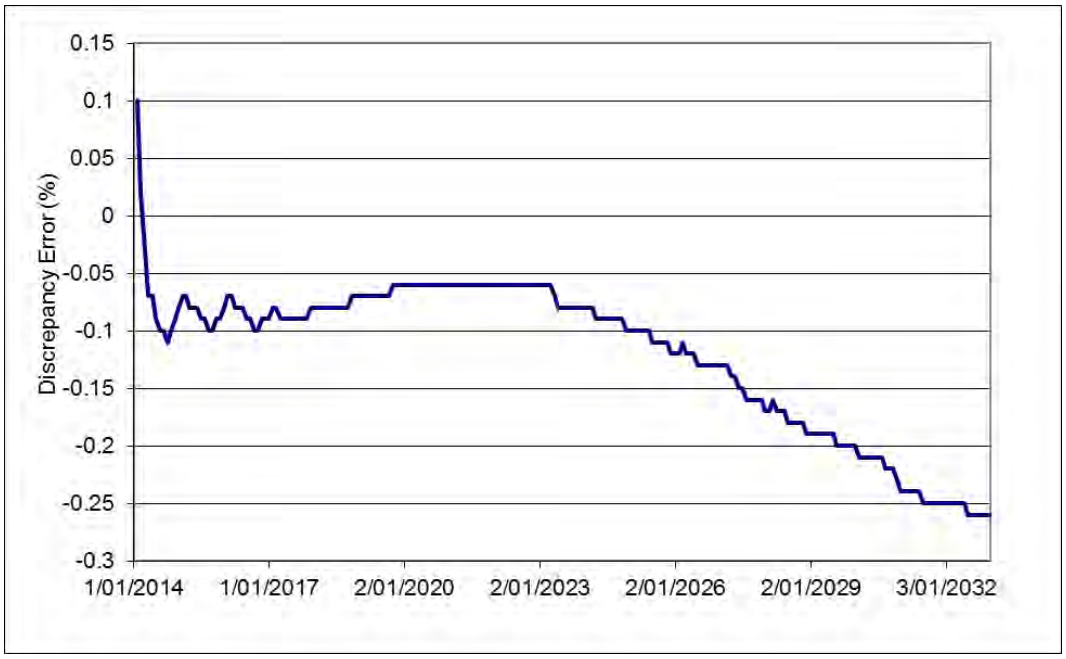

Figure 60. Model discrepancy error.

Potential environmental impacts of dewatering were assessed by assessing the simulated groundwater drawdown from 1997. The model shows the cone of depression from such a large abstraction over such a long time is quite substantial; however, in areas where water table is already deep should have no consequences on the groundwater dependent ecosystems (GDEs). Figure 61 shows the approximate depth to pre-mine water table. Areas with greater than 30m to water table are most unlikely to have any associated GDEs. Figures 62 to 66 show drawdown in December 2017, 2019, 2023, 2027 and 2032 in areas that is less than 30m to pre-mine water table.

12. Predictive Uncertainty Analysis

Based on the sensitivity analysis of the calibrated model, hydraulic conductivity of the GVU was increased to the upper bound value of 5 m/d and specific yield of the LGC was increased to an upper bound value of 0.2. Table 7 shows there is virtually no difference in the dewatering rates and volumes. This indicates that the dewatering predictions are not sensitive to these parameters.

Table 7. Predictive Uncertainty Analysis – Annualised dewatering volume.

	Hy (2 m/d), Sy(0.1)		Hy (5m/d)		Sy (0.2)	
Year	Annual (GL)	Cumulative (GL)	Annual (GL)	Cumulative (GL)	Annual (GL)	Cumulative (GL)

13. Assumptions

A numerical model is a simplified representation of the real world. Assumptions are required in a numerical model due both to the inability to represent the subsurface accurately and as a consequence of the simplified numerical representations of the varied and complex hydrogeological processes i.e. spatial discretisation and temporal discretisation of inputs. The assumptions made for this model include:

- The hydrostratigraphic units are coincident with the geo-stratigraphic units;
- The relative permeability of the GVU, GVL and LGC hydrostratigraphic units;
- The elevation of the base of the CID coincides with the end-of-hole elevation of the resource drilling logs;
- The materials below the resource drilling end of hole logs have similar hydraulic parameters as the basal clayey conglomerate;
- There is CID beneath the buffer zones of the creeks as interpreted from the resource drilling logs;
- Interpolating and/or extrapolating the symmetry of the CID beneath the creeks to fill in data gaps beneath the buffer zones;

- The calculated monthly abstraction rates assigned to the model are representative of the actual abstraction;
- The discretised screened intervals in the model are representative of the actual inflows into the production bore;
- In-pit sumps were adequately represented by MODFLOW drain cells by setting the elevation of the drain cells to the floor of the pit;
- The amount of water discharged into the WFC was completely recovered by the in-pit sumps or evaporated i.e. no net gain or loss hence ignored in the model;
- The width of the creeks was fixed at 5.0m and a manning roughness coefficient of 0.093 accounts for the increased river stage when flows in the creeks increased;
- The slopes and elevations of the creeks can be computed from the topographical data;
- Conductances for the creek beds derived from model calibration are an accurate representation of the conductance between the creeks and the underlying water table aquifers;
- Scaling of monthly rainfall to represent infiltration to the water table is representative of the total rainfall recharge to the aquifers;
- The recharge zones used in the model can adequately account for the total recharge to the aquifers;
- Scaling of monthly rainfall in catchment upstream of BHPB discharge point is a good approximation of the flow in Marillana Creek upstream of the discharge point;
- Scaling of monthly rainfall in catchment upstream of Phil's and Yandicoogina creeks are good approximation of the flow in these creeks;
- Bank storage can be ignored;
- The evapotranspiration zones and extinction depths used in the model adequately account for the total loss of groundwater to the atmosphere;
- Recent interpretation of the pinching out of the Weeli Wolli Formation north, the CID and alluvium directly overlies the BIF and a large mineralised BIF occurs underneath the outwash has insignificant impacts on the model prediction; and
- Predictive boundary conditions were acceptable.

14. Model Limitations

The model is reasonably calibrated in the JC and JSE areas. Limited calibration to stress condition at JSW, Pocket and Billiard South meant that model prediction in these areas will be subject to larger errors. This model represents a possible solution due to the number of unknowns incorporated into the model; but is not the unique solution.

The hydraulic parameters adopted for the Weeli Wolli and Brockman Iron Formations can be subjected to challenge due to the lack of investigation drilling and observation data in

these areas. The values adopted should represent a conservative estimate for dewatering.

The result from this modelling exercise is limited to Pocket and Billiards South PFS and should be review with extended pumping from JSW and Billiards South.

15. Summary

The Yandi 2008 numerical groundwater model domain was limited to mining and dewatering at Junction Central and Junction South East. As part of Yandi's expansion work to include Junction South West and Billiards South, the model domain was extended to minimise boundary effects from dewatering in these areas in the Channel Iron Deposit. The rebuild/update of the model included the alluvium layer defined in the 2010 regional groundwater model (RTIO-PDE-0078850). The number of model layer was increased from 7 to 15 to refine the geology from RTIO Vulcan geology block model.

The model was calibrated in steady-state and transient with abstraction, injection and discharge rates, and water levels from observation bores from January 1998 to January 2014. Both calibrations show the model is broadly representative of the site.

To meet the A8 mine schedule released in August 2014, the predictive model shows annual abstraction peaked in 2017 at about 80 GL per year. Abstraction will be above the current EP Act Part IV approved abstraction rate of 53 GL a year for more than 50% of the time.

Drawdown impact from the dewatering is quite substantial; however, a large portion of it is in areas where the groundwater is very deep.

16. Recommendations

It is recommended that the model be:

- recalibrated at least once a year to maintain currency of the model;
- Refinement in the Billiards North areas for future model calibration;
- Include aquifer pumping tests data from Billiards South;
- Conduct long term aquifer pumping tests in Billiards South and North;
- Stress the aquifers in JSW;
- Continue to monitor water levels;
- Understand leakage from the creeks especially Weeli Wolli and Marillana creeks; and
- Model the creeks with MODHMS 1D channel and 2D overland flow to better represents flood events.

Groundwater Modelling Scenarios 2014 - 2015

During the Pre-feasibility study for Pocket and Billiard South (PBS), a number of groundwater modelling scenarios were developed based on optimisation of the proposed mine plans and schedules throughout 2014 and 2015. Up to 30 mine schedules were modelled.

Examples of the modelling estimates for the whole of Yandi Operations are presented in Figures 1 and 2. Whilst the simulations show annualised dewatering requirements vary in volume and timing of the peak abstraction, the overall peak abstraction for the whole of Yandi Operations for all scenarios modelled remains below 83 GL/a. Figure 3 shows annualised dewatering from PBS.

1.0 Summary

1.1 Background

Rio Tinto proposes to develop two channel-iron deposits at Pocket and Billiard South (the 'study area'), located approximately 7 km east of the existing Yandi mine. Given the proximity of these deposits to Weeli Wolli Creek and the Fortescue Marsh catchment, Biota Environmental Sciences (Biota) was commissioned to conduct a Level 2 seasonal fauna survey. This was focused on addressing knowledge gaps identified by a review of fauna sampling conducted during previous surveys of the study area, to assist with environmental impact assessment (EIA).

The scope of this study was to:

- undertake a Level 2 fauna survey of the study area consistent with relevant Environmental Protection Authority (EPA) Guidance Statements;
- undertake targeted sampling and searches for species of National Environmental Significance (NES) and terrestrial short-range endemic (SRE) invertebrate species;
- document the vertebrate and SRE fauna assemblage within the study area using established sampling techniques;
- identify and assess the local and regional conservation significance of the fauna assemblage and habitats present in the study area;
- identify vertebrate fauna of particular conservation significance, particularly threatened fauna listed under the Commonwealth *Environment Protection and Biodiversity Conservation (EPBC) Act 1999,* Schedule fauna listed under the State *Wildlife Conservation Act 1950*, and species classified as Priority fauna by the Department of Parks and Wildlife; and,
- identify habitats for potential SRE fauna and identify SRE fauna of particular conservation significance.

1.2 Methods

A literature review incorporating searches of databases and previous surveys in the study area locality was conducted to construct a list of species that may potentially occur within the study area. This utilised the following databases and literature:

- NatureMap database;
- the Federal *EPBC Act 1999* Protected Matters database;
- the Atlas of Living Australia; and,
- reports from surveys conducted within 10 km of the study area were used for context in regard to the conservation significance of particular taxa or features.

The fauna survey comprised two phases: the 'wet season' Phase 1 survey was conducted over a 11 day study period, from the 8th until the 18th of March 2014, and the 'dry season' Phase 2 survey was conducted over a 10 day study period from the 10th until the 19th of September 2014.

Phases 1 and 2 employed systematic sampling at 11 trapping sites, consisting of five pitfall trapping grids, four funnel trapping grids and two Elliott trap transects. All pit-trapping sites were open for six to seven nights, resulting in a total trapping effort of 2,070 trap-nights (630 pitfall trapping, 1,014 Elliott trapping and 426 funnel trapping nights).

Systematic avifauna surveys were conducted at trapping sites during both phases; each trapping site was surveyed at least twice during each survey phase, providing a total of 24.5 hours of bird survey time.

Bats were sampled during the survey using echolocation call recordings at 14 locations considered likely to provide foraging, drinking or commuting opportunities for a range of species. Calls were sampled using SongMeter SM2BAT bat detector units, which detect and record ultrasonic echolocation calls emitted by bats during flight. Echolocation recordings were sampled over a total of 36 nights.

In addition to systematic surveying, non-systematic surveying was conducted at 28 locations. The aim was to locate, search and describe habitats that may support fauna of conservation significance, habitat-specific species and species not likely to be trapped. A range of non-systematic techniques were used when conducting these additional searches, including; searching of microhabitats for reptile, frog, avifauna and mammals not commonly recorded through trapping; identification of road kills and other animal remains; opportunistic sightings and records; recording and identification of secondary signs including tracks, scats and diggings; motion camera trapping; nocturnal searches; searches for evidence and secondary signs in suitable NES species habitat; and, audio recording for night birds and amphibian calls using the SongMeter bat detector units configured to record audible noise. The effort from these surveys totalled 17 motion camera trapping days, 15 SM2 recording days, 14 hours (834 minutes) of nocturnal searching, just under five hours (280 minutes) of targeted search time for conservation significant species and just under two hours (110 minutes) search time for avifauna.

SRE fauna sampling was conducted using both systematic (pit-trap transects) and non-systematic (targeted searching) sampling methods. The invertebrate groups targeted during the survey were primarily those considered to potentially support SRE taxa, including:

- Mygalomorphae (trapdoor spiders);
- Diplopoda (millipedes);
- Scorpionides (scorpions);
- Pulmonata (land snails); and
- Pseudoscorpiones (pseudoscorpions).

Thirty sites were searched for SRE fauna, for a total of just over 61 person-hours (3,685 minutes).

Fauna habitats were mapped based on an assessment of the landforms and vegetation in the study area. The fauna habitats present in the study area were Alluvial Plain (Flood Plain), Floodout Plain, Mulga Woodland, Minor Alluvial Fan, Hilltops and Slopes, Pediment and Major Drainage Line. A small area was Disturbed through mining. It was noted that much of the area has been degraded by cattle, particularly riparian vegetation associated with Weeli Wolli Creek, Mulga Woodlands and open grasslands on softer sandy soils such as those of the Urandy land system.

1.3 Vertebrate Fauna Results

A total of 182 vertebrate fauna species from 65 families were recorded during the survey, comprising 14 native non-volant mammals, three introduced non-volant mammals, ten volant mammals, 93 avifauna, 59 reptiles and three amphibians.

1.4 Conservation Significant Vertebrate Fauna

Eight species of conservation significance were recorded in the study area:

- Mulgara, *Dasycercus* sp. (species unconfirmed, most likely *D. blythi*);
- Pilbara Olive Python, *Liasis olivaceus barroni* (Schedule 1, Vulnerable);
- Western Pebble-mound Mouse, *Pseudomys chapmani* (Priority 4);
- Star Finch, *Neochmia ruficauda* (Priority 4);
- Australian Bustard, *Ardeotis australis* (Priority 4);

- Fork-tailed Swift, *Apus pacificus* (Schedule 3, Migratory);
- Eastern Great Egret, *Ardea modesta* (Schedule 3, Migratory); and,
- Rainbow Bee-eater *Merops ornatus* (Schedule 3, Migratory).

In addition, one noteworthy bat species was recorded. Individuals of the isolated Pilbara population of the Chocolate Wattled Bat (*Chalinolobus morio*), were recorded near Weeli Wolli Creek. While this species has a wider distribution in the southwest of WA, its distribution in the Pilbara is separated from other populations, and as a result it is possible that these populations are genetically distinct. Weeli Wolli Creek represents one of only two locations in the Pilbara where this species has been recorded, the other being Marillana Creek.

A further 18 species of conservation significance were identified from database and literature searches as being recorded within close proximity to the study area (within 10 km) or within the locality (within 40 km). Their likelihood of occurrence in the study area was assessed by giving consideration to habitat availability, species distributions and past records. Based on this, seven species were considered likely to occur:

- Orange Leaf-nosed Bat, *Rhinonicteris aurantius* (Schedule 1/Vulnerable);
- Peregrine Falcon, *Falco peregrinus* (Schedule 4);
- Pilbara Barking Gecko, *Underwoodisaurus seorsus* (Priority 1);
- Blind Snake, *Anilios ganei* (Priority 1);
- Ghost Bat, *Macroderma gigas* (Priority 4);
- Bush Stone-curlew, *Burhinus grallarius* (Priority 4); and,
- Common Greenshank, *Tringa nebularia* (Schedule 3, Migratory).

Four species were considered to have the potential for occurrence:

- Northern Quoll, *Dasyurus hallucatus* (Schedule 1/Endangered);
- Australian Painted Snipe, *Rostratula australis* (Schedule 1)
- Grey Falcon, *Falco hypoleucos* (Schedule 1)*;*
- Cattle Egret, *Ardea ibis* (Schedule 3, Migratory);

Six species were considered to be unlikely to occur:

- Night Parrot, *Pezoporus occidentalis* (Schedule 1, Endangered)*;*
- Crest-tailed Mulgara, *Dasycercus cristicauda* (Schedule 1, Vulnerable);
- Bilby, *Macrotis lagotis* (Schedule 1, Vulnerable);
- Short-tailed Mouse, *Leggadina lakedownensis* (Priority 4);
- Long-tailed Dunnart, *Sminthopsis longicaudata* (Priority 4); and,
- Oriental Plover, *Charadrius veredus* (Schedule 3, Migratory).

One species was considered to not occur in the study area:

- Northern Marsupial Mole, *Notoryctes caurinus* (Schedule 1, Endangered);

1.5 SRE Fauna Results

Nineteen mygalomorph spider specimens were collected from the study area. Genetic analysis of the specimens detected five putative species from two families. All species detected have been found previously outside of the study area. Three of the five putative species were considered potential SRE fauna (Idiopidae species ‘I53’, Nemesiidae species ‘N42’ and ‘N44’), while the remaining two species were not considered to represent SREs (Nemesiidae species ‘N16’ and ‘N1’).

One pseudoscorpion specimen was collected from the study area and assigned to *Beirolpium* sp. (family Olpiidae). The SRE status of this taxon is currently undetermined as the group requires further taxonomic investigation, however it has been found previously outside of the study area.

2.0 Introduction

2.1 Project Background and Study Area

Rio Tinto currently operates the Yandicoogina (Yandi) iron ore mine as part of its Pilbara Iron operations. Yandi is located approximately 90 km northwest of Newman in the Pilbara region of Western Australia. The original Yandi mine, Junction Central, started construction in 1997 with the first shipment of ore occurring in 1999.

Rio Tinto is currently undertaking a pre-feasibility study for the potential development of two nearby channel-iron deposits called Pocket and Billiard South (PBS), located approximately 7 km east of the existing Yandi mine (Figure 2.1). Given the proximity of these deposits to Weeli Wolli Creek and the Fortescue Marsh catchment, the proposal was referred under the WA *Environmental Protection (EP) Act 1986* and under the Commonwealth *Environment Protection and Biodiversity Conservation (EPBC) Act 1999*. The proposed development was subsequently deemed to not be a Controlled Action under the *EPBC Act 1999*, but formal environmental assessment will still occur at State level.

A desktop review of the surveys completed in the Pocket and Billiard South area was recently conducted (Biota 2013a) to determine knowledge gaps and whether further work was required to bring the amount of information for the area to a level suitable for environmental impact assessment (EIA) under Part IV of the WA *EP Act 1986*. This review found that fauna sampling in the northern and western portions of the study area, coinciding predominantly with the Newman, McKay and Urandy land systems, was under-represented by existing surveys. As a result, Biota was commissioned to address zoological knowledge gaps outlined in the review, by undertaking a Level 2 fauna survey in the Pocket and Billiard South area. The Pocket and Billiard South study area is approximately 8,640 ha in size and is hereafter referred to as the 'study area'.

2.2 Study Objectives and Scope

This report documents the combined methods, results and key findings of the first phase (Phase 1: 'wet season') and second phase (Phase 2: 'dry season') fauna surveys in the study area in March and September 2014, respectively. The results of the first phase of sampling in the study area were previously presented in an interim report (Biota 2014a). Information presented in the current report has been reviewed and updated as necessary, based on the combined results of the two field surveys.

The scope of the survey was to:

- undertake a Level 2 fauna survey of the study area consistent with relevant EPA Guidance Statements;
- complete targeted searches and non-systematic data collection within habitats suitable for Short Range Endemic (SRE) species or fauna of National Environmental Significance (NES species); and,
- conduct vertebrate and SRE fauna habitat mapping and potential NES species habitat mapping.
- document the vertebrate and SRE fauna assemblage within the study area using established sampling techniques;
- identify and assess the local and regional conservation significance of the fauna assemblage and habitats present in the study area; and,
- identify vertebrate and SRE fauna of particular conservation significance, particularly threatened fauna listed under the Commonwealth *EPBC Act 1999,* Schedule fauna listed under the State *Wildlife Conservation Act 1950*, and species classified as Priority fauna by the Department of Parks and Wildlife.

The survey was planned and implemented in accordance with:

- EPA Position Statement No. 3 – Terrestrial Biological Surveys as an Element of Biodiversity Protection (EPA 2002);
- EPA Guidance Statement No. 56 – Terrestrial Fauna Surveys for Environmental Impact Assessment in Western Australia (EPA 2004); and
- EPA and the then Department of Environment and Conservation (DEC) Technical Guide – Terrestrial Vertebrate Fauna Surveys for Environmental Impact Assessment (EPA and DEC 2010).

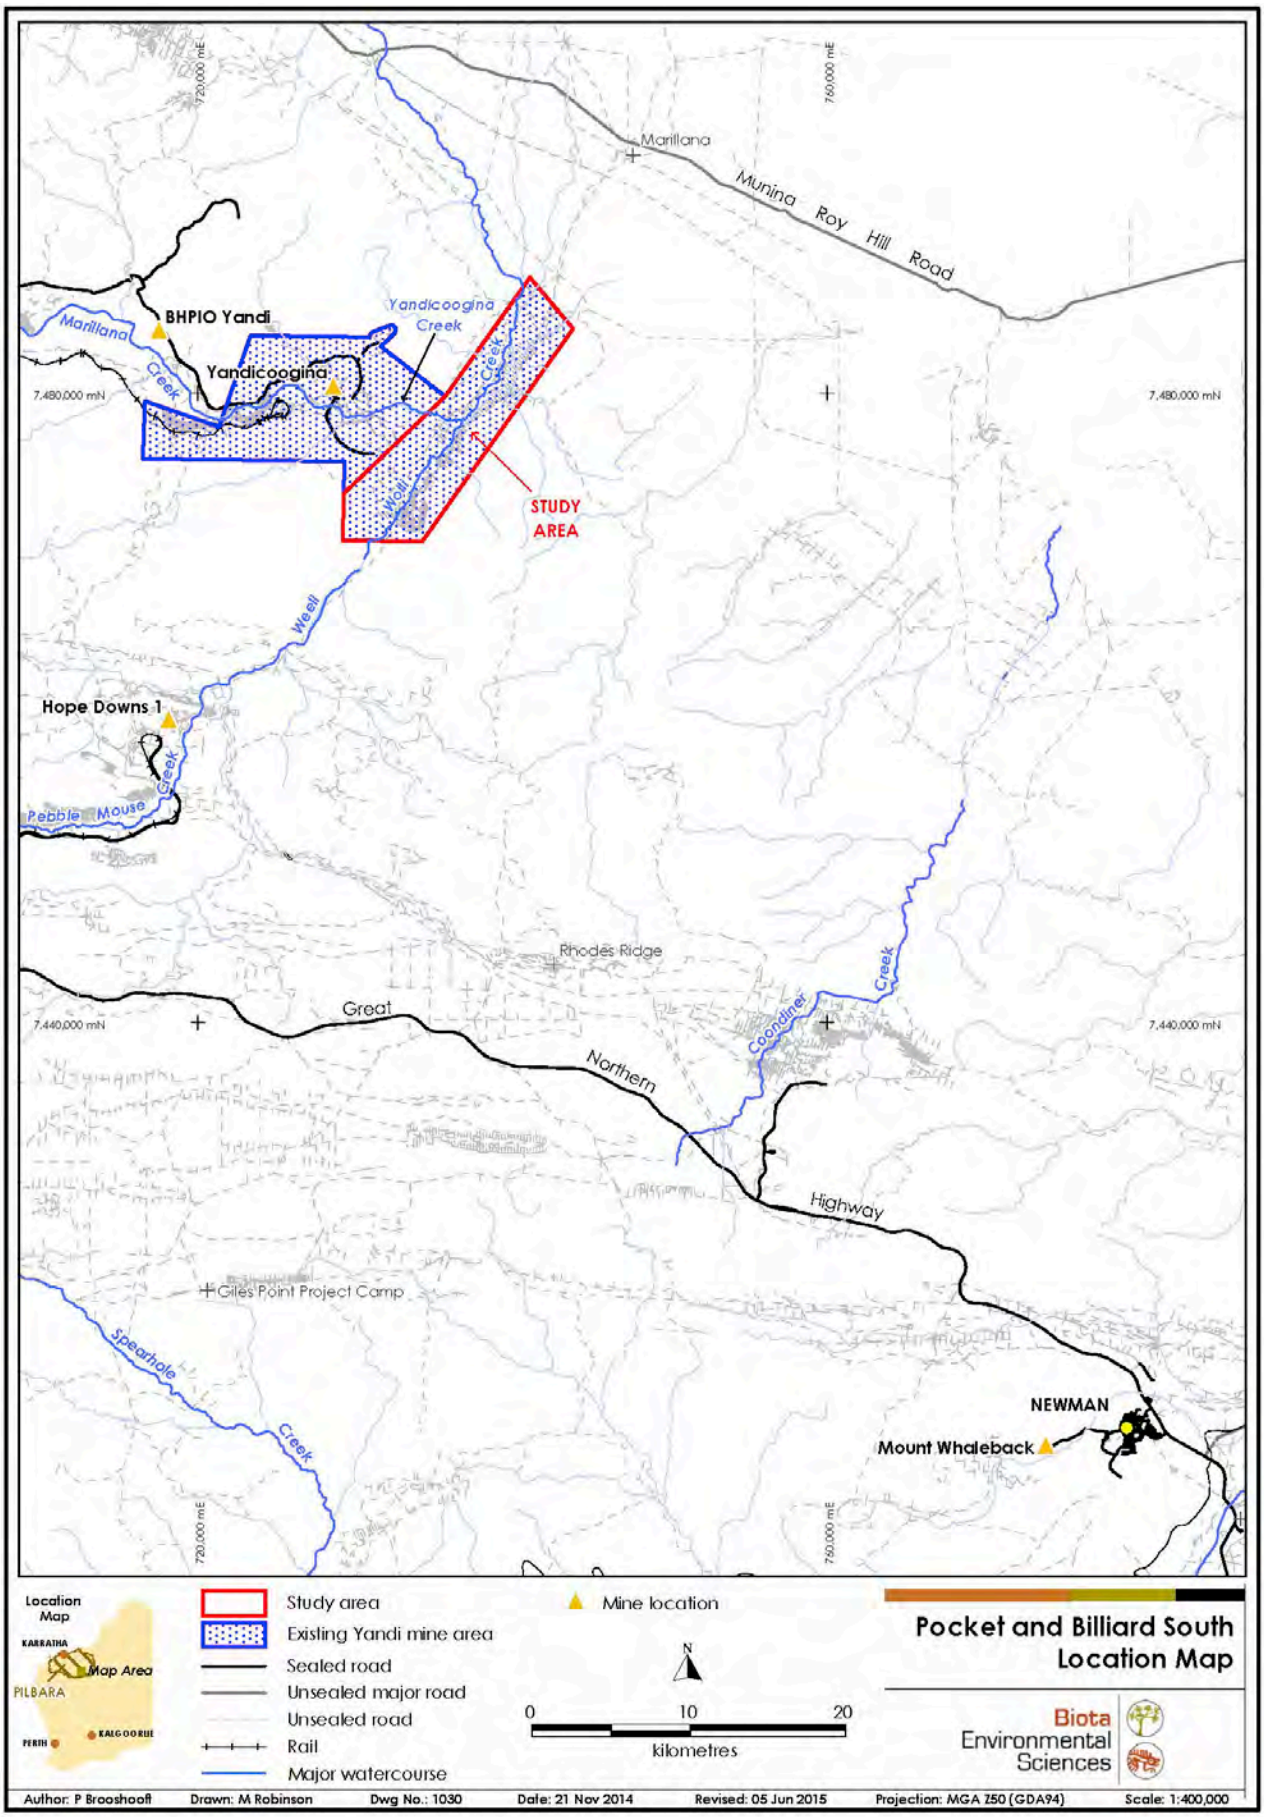

Figure 2.1: Location of the Pocket and Billiard South study area showing the existing Yandi mine.

This page intentionally blank

3.0 Regional Context of Study Area

3.1 IBRA Bioregion and Subregion

The Interim Biogeographic Regionalisation for Australia (IBRA) recognises 89 distinct bioregions and 419 subregions within Australia (Department of Environment 2013). The study area is located at the boundary between two subregions of the Pilbara:

- Hamersley (PIL3): mountainous area of Proterozoic ranges and plateaus with low Mulga (*Acacia aneura*) woodland over bunch grasses on fine textured soils, and Snappy Gum (*Eucalyptus leucophloia*) over *Triodia brizoides* on the skeletal sandy soils of the ranges (Kendrick 2003a); and
- Fortescue Plains (PIL2): alluvial plains and river frontages with salt marsh, Mulga-bunch grass and short grass communities on alluvial plains and River Gum (*Eucalyptus camaldulensis*) woodlands fringing drainage lines (Kendrick 2003b).

3.2 Priority Ecological Communities in the Locality of the Study Area

Four Priority Ecological Communities (PECS) exist within 40 km of the study area:

- Weeli Wolli Spring Community (Priority 1) overlaps the southern section of the study area;
- Fortescue Valley Sand Dunes (Priority 3) lies within 5 km to the north east and north west of the study area;
- Fortescue Marsh (Priority 1) is approximately 20 km north of the study area; and
- Coolibah-Lignum Flats (Priority 3), approximately 40 km southwest of the study area.

Areas surrounding the Fortescue Marsh are also proposed to be excluded from the Marillana Station pastoral lease in 2015 to assist with management of this important ephemeral wetland (Bell et al. 2014).

3.3 Conservation Reserves in the Locality of the Study Area

Karijini National Park (Karijini) is the closest conservation reserve to the study area. The nearest boundary of Karijini to the study area is approximately 64 km to the west.

3.4 Geology

The geological units of the Pilbara have been documented broadly (Thorne and Trendall 2001). These units form the basis for the description of landforms and substrates that underlie the habitats found within the study area. The study area encompasses eight geological units mapped by the Geological Survey of Western Australia (1984). These units are described in and displayed in Figure 3.1.

Table 3.1: Geological units occurring within the study area.

Unit Code	Geological Description	Area (ha)	Percentage of Study Area
Qa	Alluvium: unconsolidated silt, sand, and gravel; in drainage channels and on adjacent floodplains.	2,413	27.9%
PLHj	Weeli Wolli Formation: banded iron-formation (commonly jaspilitic), pelite and numerous metadolerite sills.	2,350	27.2%
Czc	Colluvium: partly consolidated quartz and rock fragments in silt and sand matrix; old valley-fill deposits.	2,337	27.0%
PLHb	Brockman Iron Formation: banded iron-formation, chert, and pelite.	637	7.4%
Qw	Alluvium and colluvium: red-brown sandy and clayey soil; on low slopes and sheetwash areas.	557	6.4%
Czk	Calcrete-sheet carbonate; found along major drainage lines.	341	3.9%
Czp	Robe Pisolite: pisolitic limonite deposits developed along river channels.	4	0.05%
Qs	Eolian deposit-sand; in sheets and longitudinal dunes.	1	0.01%

3.5 Land Systems

Land systems are repeating patterns in the landscape, grouped by topography, soils, and vegetation. These units are mapped by the Western Australian Department of Agriculture (Payne et al. 1988), and provide a broad description of the habitats potentially occurring within the study area. The Pilbara bioregion contains a total of 107 land systems[1], with 63 land systems occurring in the Hamersley subregion and 54 occurring in the Fortescue Plains subregion.

Land system mapping covering the study area has been prepared by van Vreeswyk et al. (2004). The study area intersects five land systems, which are summarised in Table 3.2. These land systems are widespread and extensive in terms of their area within the Pilbara bioregion. Their location in relation to the study area is shown in Figure 3.2.

3.6 Landforms and Surface Hydrology

The study area encompasses the northern portion of the Weeli Wolli Creek valley, where this widens from a shallow gorge to form a true valley, and its associated floodplains and hillslopes.

Drainage within the study area is dominated by Weeli Wolli Creek, which flows in a northeast direction through the Hamersley Range and ends in an alluvial fan. The alluvial fan stretches from the footslopes of the Hamersley Range scarp, across the pediment slope to the edge of the Fortescue Marsh. The confluence of Weeli Wolli Creek and Marillana Creek occurs in the centre of the study area, just behind the scarp of the Hamersley Range. There are numerous floodout areas adjacent to the creeks, and islands in the anabranching creek beds of both creek systems. Following seasonal rainfall, both creek systems often support ephemeral pools of water.

Low crests and hillslopes define the edge of the creek valley. Numerous short minor drainage lines dissect the hills, forming shallow gorges and narrow floodplains before they flow into Weeli Wolli Creek. In an area near the southern end of the eastern boundary of the study area, the creek valley widens considerably and several minor drainage lines flow through a narrow pediment zone before entering the Weeli Wolli Creek floodplain.

[1] This information was obtained by merging the Ashburton land system mapping (Payne et al. 1988) and Pilbara land system mapping (van Vreeswyk et al. 2004), and intersecting this with the Pilbara bioregion (Environment Australia 2000) in ArcView (v. 3.2).

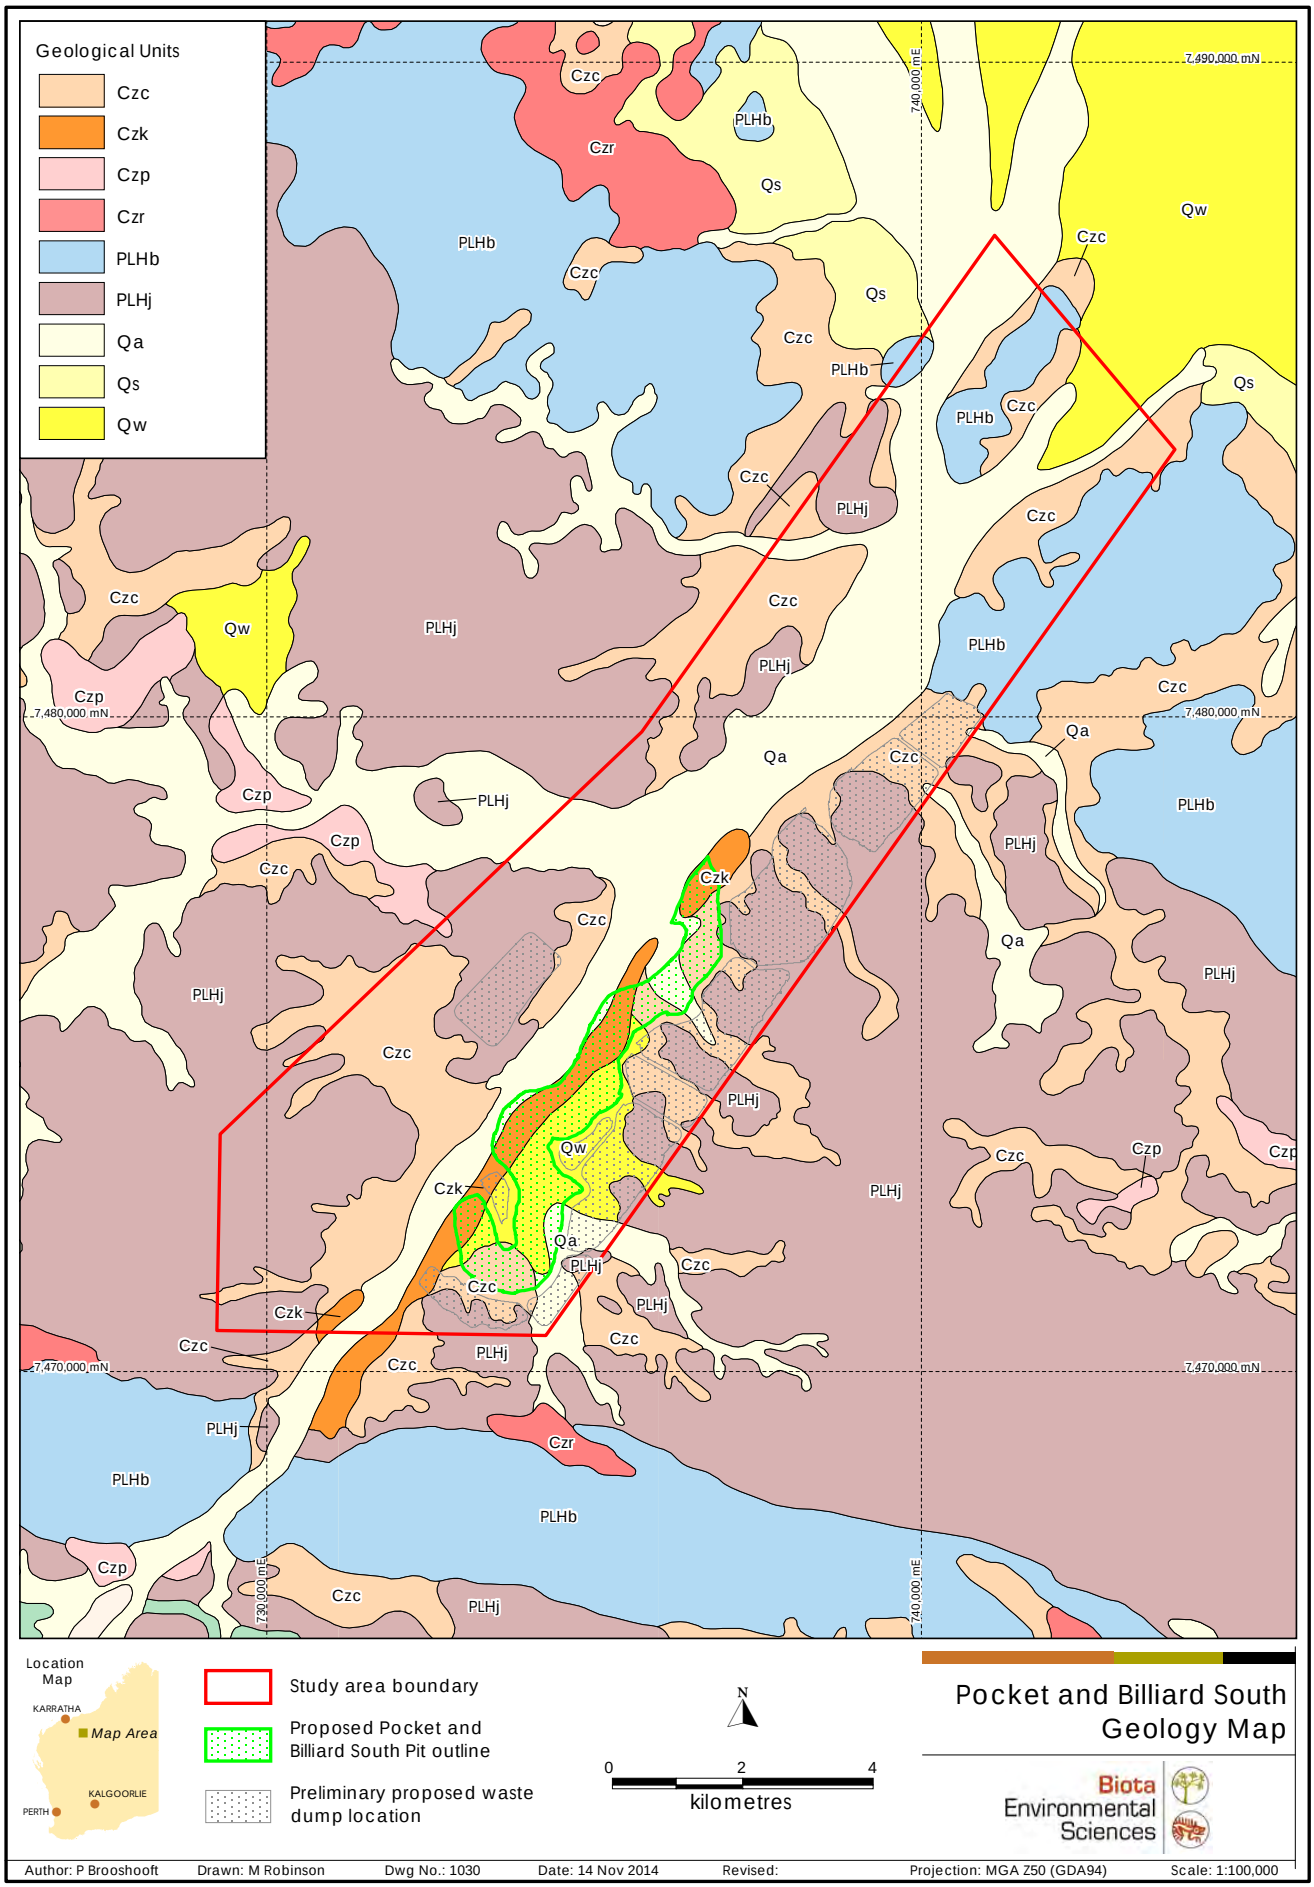

Figure 3.1: Geological units mapped in the vicinity of the study area.

Table 3.2: Extent of land systems in the study area and the percentage this represents of their total extent in the Pilbara bioregion.

Land System	Description (van Vreeswyk et al. 2004)	Total Area of Land System within the Study Area	Percentage of Study Area	Total Area of Land System in the Pilbara	Percentage of Total Land System in Study Area
Boolgeeda	Stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands. Component landforms include low hills and rises (4%), stony slopes and upper plains (20%), stony lower plains (65%), groves (1%), and narrow drainage and channels (10%). Not susceptible to degradation or soil erosion.	2,221 ha	25.8%	961,637 ha	0.2%
McKay	Hills, ridges, plateaus and breakaways of meta-sedimentary rocks supporting hard spinifex grasslands. Component landforms include hills, ridges ad plateaus remnants (60%), breakaways (2%), lower foot slopes (10%), stony plains (20%), and drainage floors (8%). Not susceptible to degradation or soil erosion.	1,455 ha	16.8%	426,145 ha	0.3%
Newman	Rugged jaspilite plateaus, ridges and mountains supporting hard spinifex grasslands. Component landforms include plateaus, ridges, mountains and hills (70%), lower slopes (20%), stony plains (5%), and narrow drainage floors with channels (5%). Not susceptible to degradation or soil erosion.	2,326 ha	26.9%	1,993,745 ha	0.1%
River	Active floodplains and major rivers supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands. Component landforms include sandy levees and sand sheets (15%), upper terraces (5%), floodplains and lower terraces (50%), stony plains (10%), and minor and major channels (20%). Susceptibility to erosion is high or very high if vegetation is removed.	2,142 ha	24.8%	497,421 ha	0.4%
Urandy	Stony plains, alluvial plains an drainage lines supporting shrubby soft spinifex grasslands. Component landforms include stony plains (58%), alluvial plains (35%), and drainage zones and channels (7%). Most of the system is not susceptible to degradation or soil erosion.	496 ha	5.7%	131,975 ha	0.4%

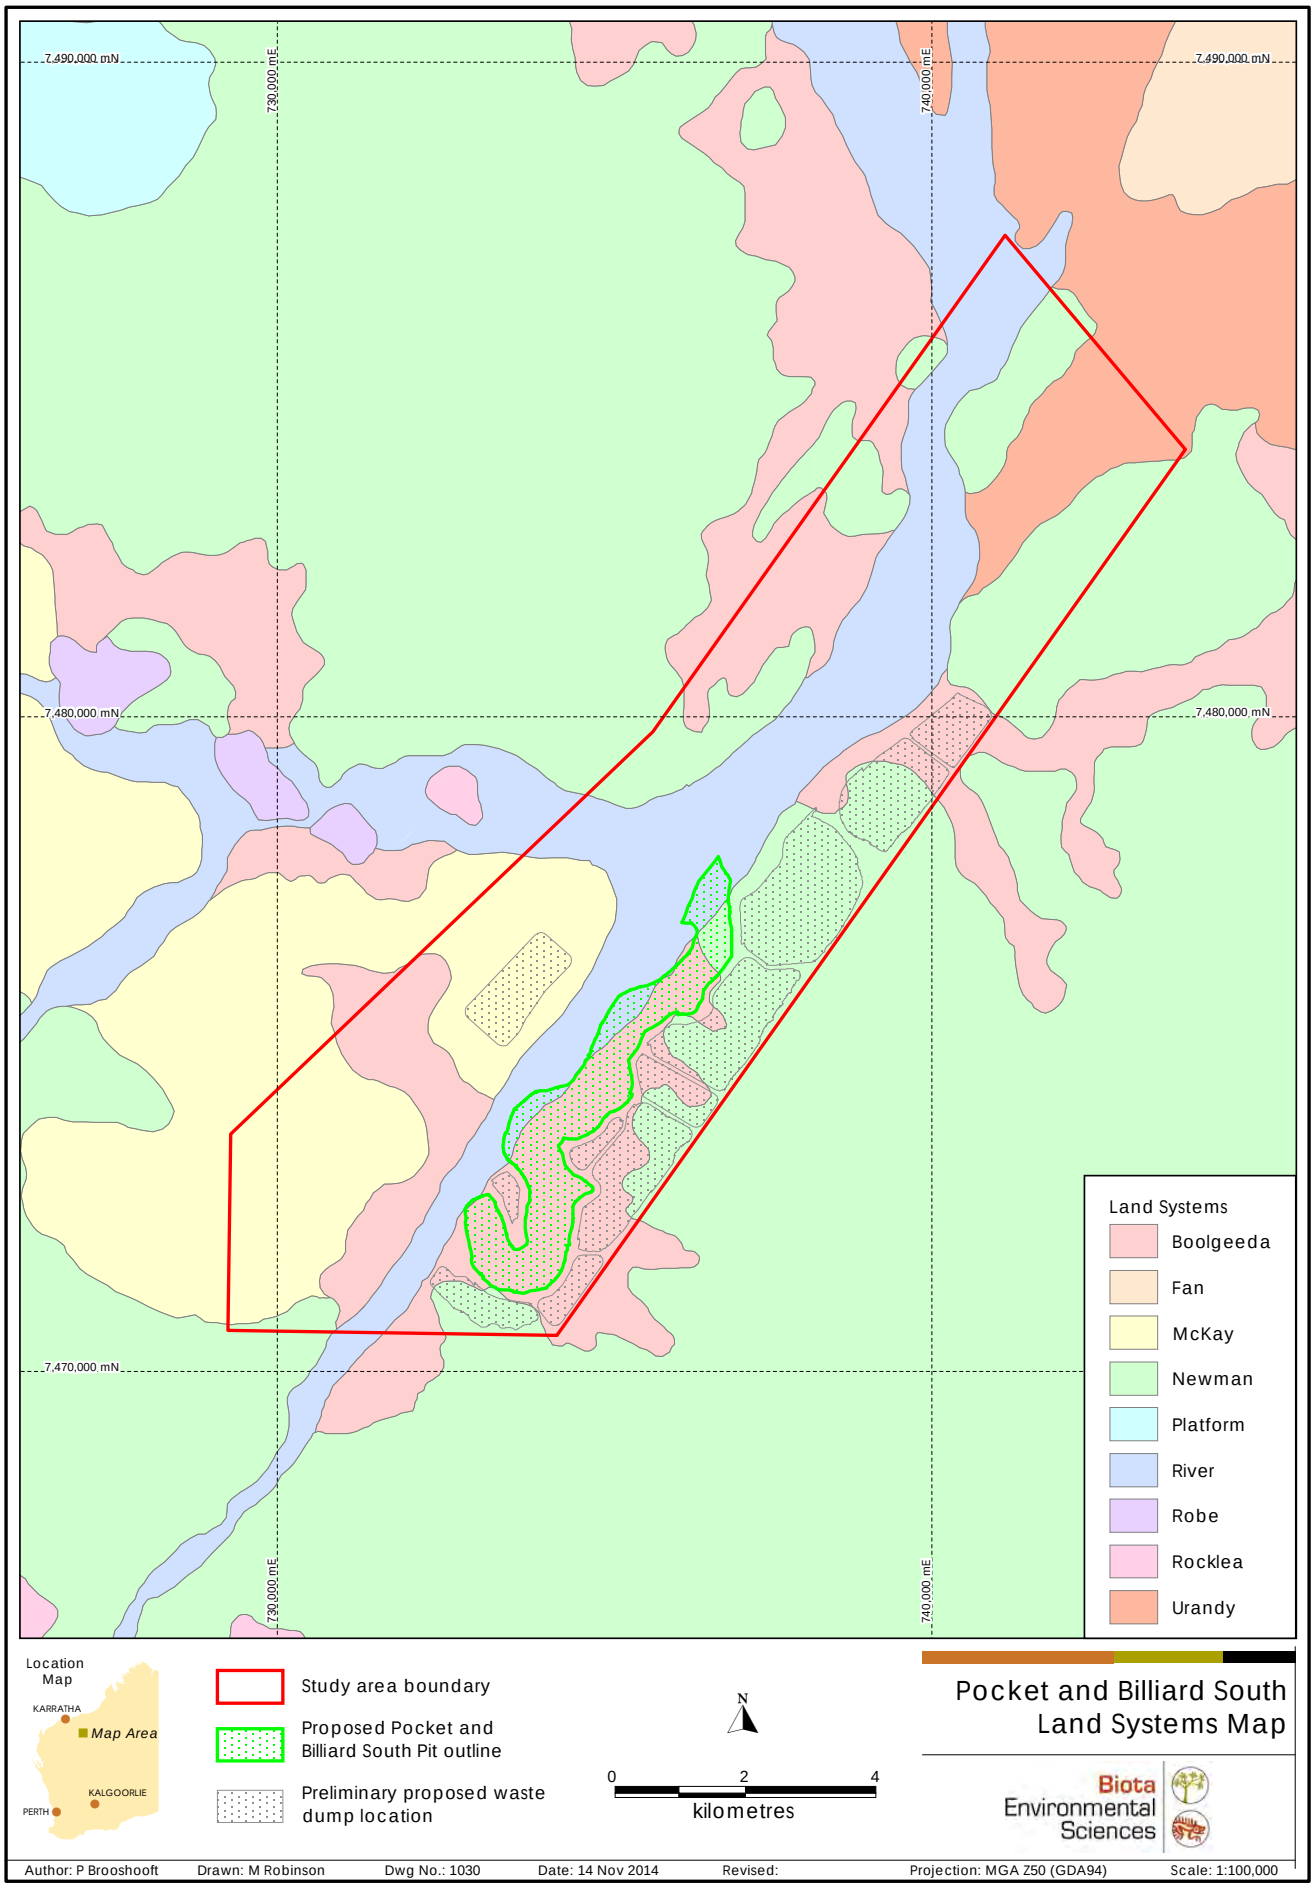

Figure 3.2: Land systems of the locality including the study area.

3.7 Beard's Vegetation Mapping

Beard (1975a, 1975b) described and mapped the vegetation of the Pilbara at a scale of 1:1,000,000. The study area is located on the Hamersley Plateau, which is within the Fortescue Botanical District of the Eremaean Botanical Province as defined by Beard. The vegetation of this province is typically open, and frequently dominated by spinifex, wattles and occasional eucalypts.

Three vegetation units mapped by Beard (1975b) occur within the study area (see Figure 3.3), two of which are essentially the same vegetation type:

- Fortescue Valley 29: Sparse low woodland; Mulga (*Acacia aneura* sens. lat.), discontinuous in scattered groups; and
- Fortescue Valley 82 and Hamersley 82: Hummock grasslands, low tree steppe; Snappy Gum (*Eucalyptus leucophloia*) over Limestone Spinifex (*Triodia wiseana*).

These vegetation units are widespread in the Pilbara bioregion and largely uncleared (see Table 3.3). Given the scale of Beard's mapping, these units only broadly characterise the vegetation of the study area.

Table 3.3: Beard's (1975b) mapping units that occur in the study area and their extent in the Pilbara bioregion (data from Government of Western Australia 2013).

Beard's Vegetation Mapping Unit	Pre-European Extent in the Hamersley or Fortescue Subregion (as relevant)	Current Extent in the Hamersley or Fortescue Subregion (% Remaining)	Extent within the Study Area (% of Total Current Extent in the Hamersley or Fortescue Subregion)
Fortescue Valley 29	893,395 ha	893,222 ha (>99.9%)	4,512.1 ha (0.5%)
Fortescue Valley 82	24,192 ha	24,192 ha (>99.9%)	1,021.8 ha (4.2%)
Hamersley 82	2,177,574 ha	2,165,235 ha (99.4%)	3,105.2 ha (0.1%)

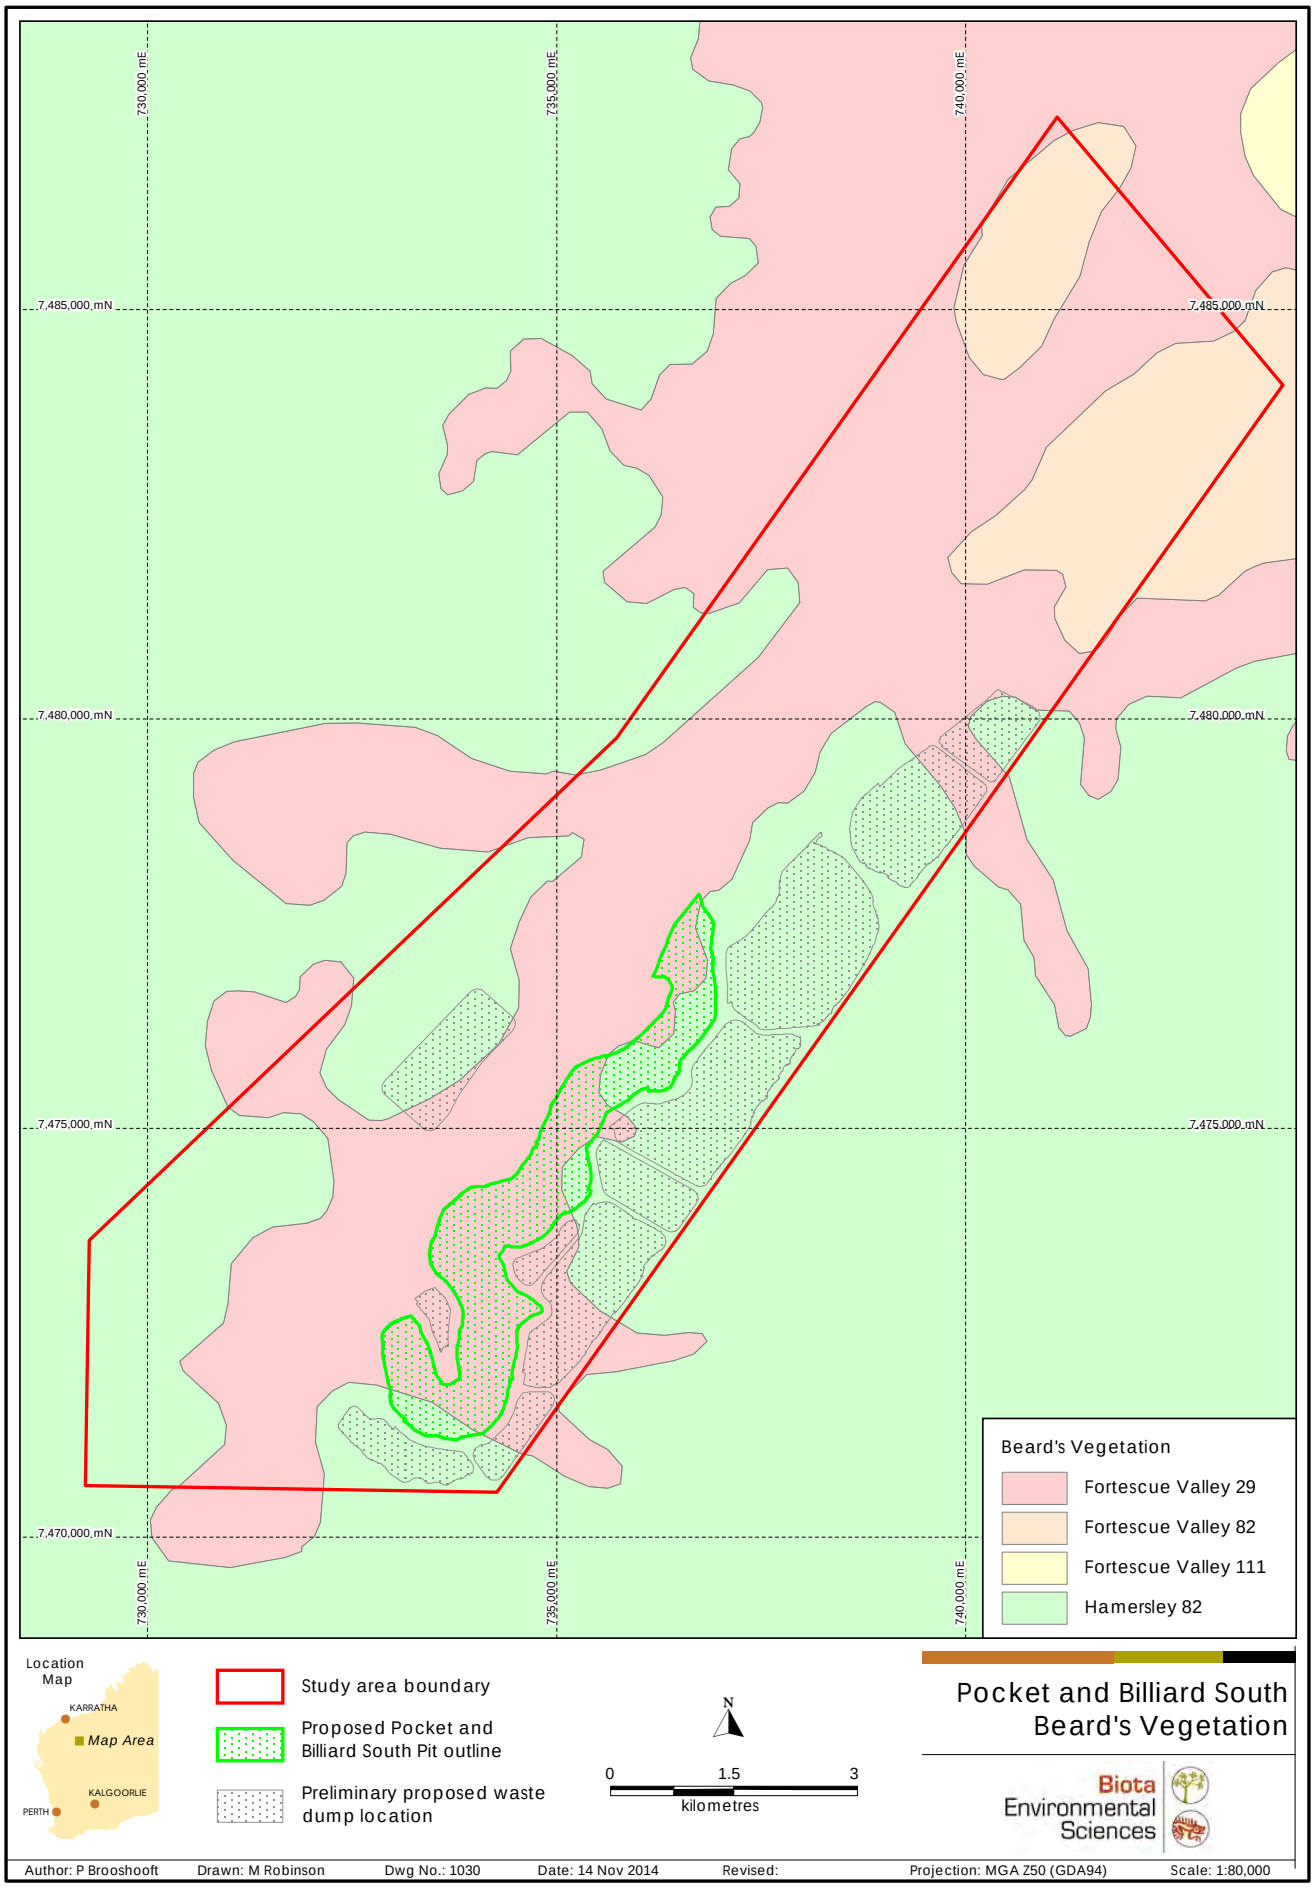

Figure 3.3: Beard's vegetation mapping for the locality including the study area.

3.8 Vegetation of the Study Area

The vegetation of the study area has been mapped previously by Biota (Biota 2014b). Twenty-three vegetation types were described for the study area (Table 3.4).

These vegetation types were broadly associated with the following landforms:

- major creeklines and tributaries;
- minor creeklines, floodplains and valleys;
- hills, ridges and breakaways; and
- plains.

Soils in the study area were generally described as red-brown loams, clay loams or sandy clay loams and were covered with a loose surface layer of stones and pebbles (Biota 2014b). Soils were stonier at the margins of the valley and on the associated footslopes. Heavier soils were found in the lower parts of the valley and in the flood-out areas. Some small areas of light clay supported Mulga woodland on the plains. Soils of the creek beds were a coarse sand-pebble mix.

Table 3.4: Vegetation types described for the study area by Biota (2014b). .

Vegetation Code	Description
Vegetation of Major Creeklines and Tributaries	
C1: EcEvMaMgAc	*Eucalyptus camaldulensis* subsp. *refulgens, E. victrix* woodland over *Melaleuca argentea, M. glomerata, Acacia coriacea* subsp. *pendens* low open woodland
C2: EvChAtuGwTErCYpERItTHt	*Eucalyptus victrix, Corymbia hamersleyana* scattered low trees over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* subsp. *hispidula* tall shrubland over *Tephrosia rosea* var. Fortescue Creeks (M.I.H. Brooker 2186) low shrubland over *Cymbopogon ambiguus, C. procerus, Eriachne tenuiculmis, Themeda triandra* very open tussock grassland
C3: EvAciAcMgCEc	*Eucalyptus victrix* scattered trees over *Acacia citrinoviridis, A. coriacea* subsp. *pendens, Melaleuca glomerata* tall open shrubland over **Cenchrus ciliaris* scattered tussock grasses
C4: EvAciAprAThCEc	*Eucalyptus victrix* open *woodland* over *Acacia citrinoviridis, A. pruinocarpa, Atalaya hemiglauca* low woodland over **Cenchrus ciliaris* tussock grassland
Vegetation of Minor Creeklines, Floodplains and Valleys	
F1: ChAtuGwTp	*Corymbia hamersleyana* scattered low trees to low open woodland over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* tall open shrubland over *Triodia pungens* hummock grassland
F2: AprAciCEc	*Acacia pruinocarpa, A. citrinoviridis* tall open shrubland over **Cenchrus ciliaris* tussock grassland
F3: ElChAtuAaAbGwTspp	*Eucalyptus leucophloia, Corymbia hamersleyana* low open woodland over *Acacia tumida* var. *pilbarensis*, *A. ancistrocarpa, A. bivenosa, Grevillea wickhamii* tall open scrub over mixed *Triodia* hummock grassland
F4: ChAtuAaPcAtenBONeARhPAmTp	*Corymbia hamersleyana* scattered low trees over *Acacia tumida* var. *pilbarensis* tall open shrubland over *A. ancistrocarpa, Petalostylis cassioides, A. tenuissima* open shrubland over *Bonamia erecta* very open herbland over *Aristida holathera* var. *holathera, Paraneurachne muelleri* very open tussock grassland and *Triodia pungens* very open hummock grassland.
F5: ChAciAaAiSENsppTp	*Corymbia hamersleyana* scattered low trees over *Acacia citrinoviridis, A. ancistrocarpa, A. inaequilatera* tall open shrubland over *Senna* spp. open shrubland over *Triodia pungens* open hummock grassland.

Vegetation Code	Description
Vegetation of Hills, Ridges and Breakaways	
H1: ElHcAiGwTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Hakea chordophylla, Acacia inaequilatera, Grevillea wickhamii* tall open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland
H2: ElAiTwTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Acacia inaequilatera* scattered tall shrubs over *Triodia wiseana*, (*T.* sp. Shovelanna Hill (S. van Leeuwen 3835)) open hummock grassland

H5: ElCfERImTHspp	*Eucalyptus leucophloia* subsp. *leucophloia, Corymbia ferriticola* scattered low trees over *Eremophila latrobei* subsp. *filiformis, Senna* spp. scattered shrubs over *Cymbopogon ambiguus, Eriachne mucronata, Themeda* sp. Mt Barricade (M.E. Trudgen 2471), *T. triandra* open tussock grassland
Vegetation of Plains	
P1: ElEgAprAbAaAdTwTpTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia pruinocarpa* scattered tall shrubs over *A. bivenosa, A. ancistrocarpa, A. dictyophleba* shrubland over *Triodia wiseana, T. pungens*, *T.* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland
P2: ChAprAiAsclApaTp	*Corymbia hamersleyana, Acacia pruinocarpa* scattered low trees over *A. inaequilatera, A. sclerosperma* subsp. *sclerosperma, A. pachyacra* tall open shrubland over *Triodia pungens* hummock grassland
P3: AprAciAiAsclTlo	*Acacia pruinocarpa* low open woodland over *A. citrinoviridis, A. inaequilatera, A. sclerosperma* subsp. *sclerosperma* open shrubland over *Triodia longiceps* hummock grassland
P4: AprAsyAiTw	*Acacia pruinocarpa* low open woodland over *A. synchronicia, A. inaequilatera* scattered tall shrubs over *Triodia wiseana* open hummock grassland
P5: ElEgAbAaTb	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia bivenosa, A. ancistrocarpa* open shrubland over *Triodia basedowii* open hummock grassland
P6: AapERfoERl/g	*Acacia aptaneura* low open forest over *Eremophila forrestii* subsp. *forrestii* open shrubland over *E. lanceolata* low open shrubland over mixed very open grassland
P7: ERf/g	*Eremophila fraseri* subsp. *fraseri* open shrubland over mixed very open grassland
P8: EgAiTs	*Eucalyptus gamophylla* scattered low mallees over *Acacia inaequilatera* scattered tall shrubs over *Triodia schinzii* hummock grassland
P9: ChEgAiAaAprPcTb	*Corymbia hamersleyana* scattered low trees over *Eucalyptus gamophylla* scattered low mallees over *Acacia inaequilatera, A. ancistrocarpa, A. pruinocarpa* tall open shrubland over *Petalostylis cassioides* open shrubland over *Triodia basedowii* open hummock grassland

3.9 Fauna Habitats of the Study Area

Fauna habitats of the study area were mapped during the first phase of the survey (Biota 2014a). Habitat mapping was based on Biota's fauna landscape approach (Biota 2013b), which identifies landforms within a broader landscape. Landforms are composed of a mosaic of larger landform patterns (such as flood plains, hills and dune fields) and smaller landform elements (such as a breakaway, cliff or hill slope). The distributions of fauna are typically not limited to specific landform elements, rather fauna may utilise many components of a landform. Therefore, fauna habitats are mapped based on an amalgamation of landform patterns and elements that are considered to represent suitable habitats for species, and in particular, species of conservation significance. This approach formed the basis of NES species habitat mapping, further described in Section 6.6.

Eight fauna habitats were mapped during Phase 1. These habitats are depicted in Figure 3.4 and further described in Table 3.5.

Table 3.5: Landforms and descriptions of fauna habitats within the study area.

Landform Pattern (Data Standard Analogue)	Fauna habitat	Description
Flats	Alluvial Plain (Flood Plain)	An area of land adjacent to a drainage line that stretches from the banks of its channel to the base of the enclosing valley walls. It experiences flooding during periods of high discharge but does not experience a strong current.
Flats	Floodout Plain	A type of alluvial plain that receives water during periods of overbank flow associated with normal or extreme flood events.
Flats	Mulga Woodland	Mulga woodlands at PBS occur on areas of alluvial plain. They are delineated as a discrete fauna habitat because they support a distinct fauna assemblage not present in other habitats within the PBS.
Flats	Minor Alluvial Fan	A large sloping landform element, formed by the deposition of sediment and debris eroded from adjacent upland areas. Alluvial fans usually contain a number of dominant drainage pathways. There is a gradation from coarse material to fine grained material from the outlet point to the end point of the fan.
Hilltops and Slopes	Hilltops and Slopes	Hilltops and slopes make up much of the study area and consist of a number of landform elements, notably (from highest to lowest elevation): Crests, Free Faces, Breakaways (not always present), Transitional Slopes and Foot Slopes.
Hilltops and Slopes	Pediment Slope	The large, gently inclined lower slopes below hills underlain by bedrock at varying depths. Pediments in the PBS vary in width and exhibit sharp breaks of slope between the pediment and the steeper hillside above them. Water passes across the pediment by laminar sheet flow, but if this is disturbed, the flow becomes turbulent and gullies develop.
Drainage	Major Drainage Line	A linear, sinuous open depression forming the floor of the major drainage channel (Weeli Wolli Creek) that is eroded or aggraded (built up) by stream flow. In the PBS this supports taller eucalypts, dense shrublands and reedbeds around water pools that are semi-permanent due to upstream mine dewatering.
Disturbed		Areas of disturbed land originating from clearing.

It was noted that much of the area showed signs of degradation by cattle, particularly riparian vegetation associated with Weeli Wolli Creek, Mulga Woodlands and open grasslands on softer sandy soils such as those of the Urandy land system. Parts of these areas were also heavily affected by introduced weeds such as Buffel Grass (**Cenchrus ciliaris*).

4.0 Methodology

4.1 Desktop Review

4.1.1 Literature Review

A number of vertebrate and SRE fauna surveys have been conducted in proximity to the study area. Table 4.1 provides a summary of surveys reviewed that provide context to the current survey. Reports reviewed were chosen on the basis of data availability and proximity to the study area (all surveys were conducted within 10 km of the study area boundary). The species recorded during the vertebrate fauna surveys, in conjunction with records returned from the database searches detailed in Section 4.1.2, have been compiled to construct a potential species list for the study area, and are presented in Appendix 1.

4.1.2 Database Searches

The following databases were searched to assist in the determination of the potential fauna assemblage of the study area:

1. NatureMap Database (http://naturemap.dpaw.wa.gov.au) (Appendix 2). This database is a joint project of the Department of Parks and Wildlife and the Western Australian Museum (WAM), and represents the most comprehensive source of information on the distribution of Western Australia's fauna and flora. It comprises records from the Fauna Survey Returns database and WA Threatened Fauna database, the WAM Specimen database, and BirdLife Australia's Birdata database. The search was performed on the 31st October 2014 and requested the return of records from a radius of 40 km around a central point within the study area (22°47'08" S 119°18'36" E).
2. The Commonwealth *EPBC* Protected Matters Database (Appendix 3). This database comprises matters of National Environmental Significance protected under the *EPBC Act 1999*, including Threatened Species and Migratory Species. The search was conducted on the 31st October 2014 and requested the return of records from a radius of 40 km around the central point 22°47'08" S 119°18'36" E.
3. The Atlas of Living Australia (ALA) (http://www.ala.org.au/) (Appendix 4). The ALA is a joint project between academic collecting institutions, private individual collectors and community groups. It contains occurrence records, environmental data and images and lists the conservation status of species throughout Australia. This search was conducted on the 31st October 2014 and requested the return of records from a radius of 40 km around the central point 22°47'08" S 119°18'36" E.

Table 4.1: Previous studies conducted within 10 km of the Pocket and Billiard South study area.

4.2 Survey Timing and Weather

4.2.1 Timing

The Pocket and Billiard South field survey was completed over two phases. Phase 1 was conducted over an 11 day study period, from the 8th until the 18th of March 2014, and Phase 2 was conducted over a ten day study period from the 10th until the 19th of September 2014.

4.2.2 Daily Weather Observations

The observations below use daily and long-term rainfall data collected at Marillana weather station (number 5009), located 32 km north of the study area. Temperature data were not available from Marillana, so daily and long-term temperature data from Wittenoom weather station (number 5026), located approximately 94 km northwest of the study area, were used.

4.2.2.1 Phase 1

During Phase 1, minimum temperatures ranged from 24.1ºC to 29.1ºC, while maximum temperatures ranged from 38.9ºC to 41.2ºC (Table 4.2). No rainfall was recorded at Pocket and Billiard South during the Phase 1 survey (Table 4.2).

Table 4.2: Daily meteorological observations for Pocket and Billiard South during Phase 1.

Date	08/03	09/03	10/03	11/03	12/03	13/03	14/03	15/03	16/03	17/03	18/03	Total/ Mean

4.2.2.2 Phase 2

During Phase 2, minimum temperatures ranged from 14.8ºC to 24.8ºC, while maximum temperatures ranged from 33.3ºC to 37ºC (Table 4.2). Again, no rainfall was recorded (Table 4.3).

Table 4.3: Daily meteorological observations for Pocket and Billiard South during Phase 2.

4.2.3 Climatological Data

The Pilbara experiences an arid-tropical climate, with a hot, wet summer between October and April, and a mild, dry winter between May and September. Rainfall in the Pilbara is sporadic and can occur at any time of the year, but heaviest rainfall occurs over the summer months.

Figure 4.1 illustrates the average monthly minimum and maximum temperatures and rainfall of the year preceding the survey as compared with the long-term averages (Bureau of Meteorology

1951-2014). Maximum and minimum temperatures in the year preceding the survey were higher than average long-term temperatures, with the exception of the December-February period where they fall below average (Figure 4.1). The study area received noticeably higher than average rainfall in January prior to the first phase of survey, but February and March were relatively dry (Figure 4.1).

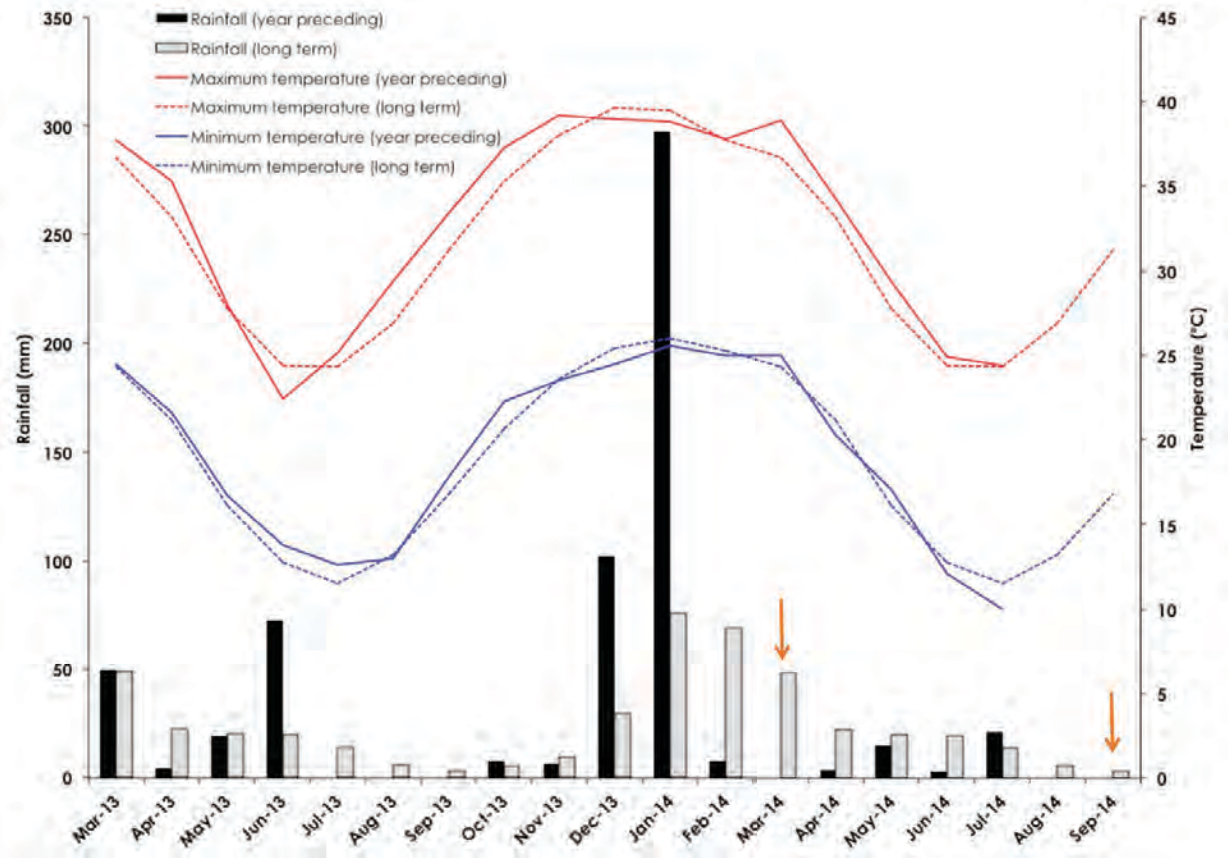

Figure 4.1: Monthly long-term and year preceding the survey climate averages recorded at Marillana (rainfall) and Wittenoom Station (temperature).
Arrows indicate survey timing.

4.3 Vertebrate Fauna Sampling

The vertebrate fauna survey of Pocket and Billiard South consisted of two phases of trapping combined with opportunistic and targeted searching. Figure 4.4 illustrates the distribution of sites sampled across the study area, with each site further detailed in Table 4.4 to Table 4.10.

4.3.1 Systematic Trapping of Vertebrate Fauna

Phases 1 and 2 employed the following trap types as the principal components used to determine species assemblage present in the study area: pitfall traps (bucket and PVC pipes), Elliott box traps, cage traps and funnel traps.

Systematic terrestrial fauna sampling was carried out at 11 sites located in land systems that were not sampled, or were sampled less, during previous surveys in the study area (based on findings of Biota 2013). These trapping sites comprised:

- Five pitfall trapping transects, each consisting of a single row of ten pitfall traps arranged as alternating plastic buckets (20L volume) and PVC pipe (150 mm diameter x 600 mm long), spaced at approximately 10 m intervals and connected with a 100 m long length of 30 cm high flywire fence (see Figure 4.2).

- Four funnel trapping grids, each consisting of 8-10 pairs of funnel traps (i.e. 16-20 traps) placed in pairs at approximately 10 m intervals along a 100 m single length of 30 cm high flywire fence (see Figure 4.3).
- Two Elliott and cage trap transects, each consisting of 25 medium Elliott box traps, ten large Elliott box traps, and four cage traps, spaced at approximately 10 m intervals. Elliott and cage traps were baited with a mixture of peanut butter and oats.

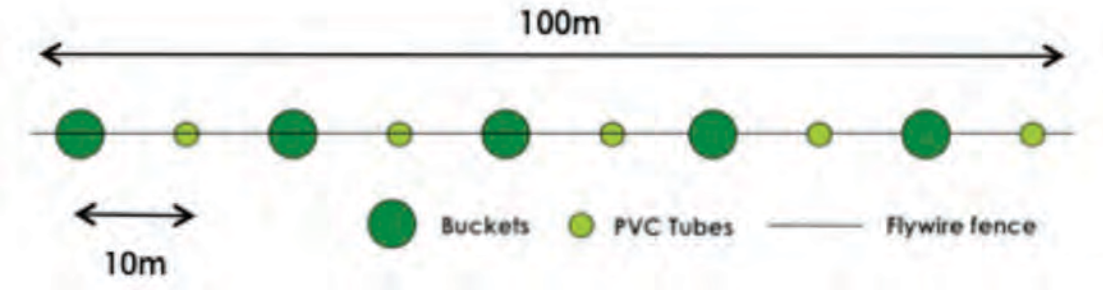

Figure 4.2: Layout of pitfall trapping transects used during the survey.

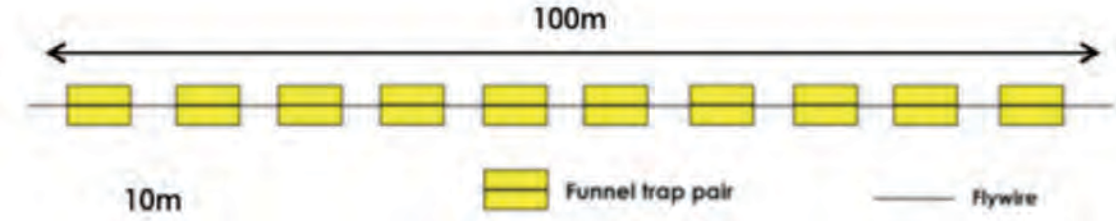

Figure 4.3: Layout of funnel-trapping transects used during the survey.

4.3.2 Avifauna Sampling

Sampling of avifauna was conducted using a combination of techniques including:

- unbounded, habitat-specific area searches (30 minute duration) conducted at each of the systematic trapping sites; and,
- opportunistic observations of birds while traversing the study area.

Forty-five avifauna censuses were completed across the systematic trapping sites, with each site being surveyed at least twice (Table 4.6). Avifauna were surveyed for a total of 1,470 minutes across sites, providing just over 24 hours of dedicated systematic avifauna survey.

Table 4.6: Date and time of avifauna surveys undertaken during the Pocket and Billiard South fauna survey.

4.3.3 Bat Sampling

Bats were sampled during both phases of survey using echolocation call recordings at eight locations. The effort applied to sampling bats during Phase 1 and 2 is detailed in Table 4.7 and Figure 4.4. Bat sampling was also undertaken during a previous survey of the study area which targeted the Northern Quoll (Biota 2014c). Bats were sampled during this survey at six sites, and the results of the survey have been included here (Table 4.7).

Sampling equipment was placed in habitats considered likely to provide foraging, drinking and commuting opportunities for a range of species. Such habitats included cave or rock shelter entrances overlooking valleys/gorges, drainage lines and ephemeral pools of water. The bat habitat at each of the sites is described in Table 4.8.

Calls were sampled using SongMeter SM2BAT bat detector units, which detect and record ultrasonic echolocation calls emitted by bats during flight. The selectable filters and triggers, jumper and audio settings used for the SM2BAT followed the manufacturer's recommendations for bat detection contained in the user manual (Wildlife Acoustics 2010).

Details of calls were analysed by Mr Bob Bullen (Bat Call WA) using methods recommended by the Australasian Bat Society (Australasian Bat Society 2006) in conjunction with available reference data (Bullen and McKenzie 2002, McKenzie and Bullen 2003, 2009) (Appendix 5). Only sequences containing good quality search phase calls were considered for identification.

4.3.4 Non-Systematic Sampling of Vertebrate Fauna

Further habitat assessment and targeted searching for fauna was conducted on foot, often in areas inaccessible by vehicle and not practical for trap installation. These sites were selected when observed traversing the study area. The aim was to locate, search and describe habitats that may support fauna of conservation significance, habitat-specific species and species not likely to be trapped.

A range of non-systematic techniques were used when conducting these additional searches, including:

- searching of microhabitats for reptile, frog, avifauna and mammals not commonly recorded through trapping;
- identification of road kills and other animal remains found during the survey;
- opportunistic sightings and records;
- recording and identification of secondary signs including tracks, scats and diggings;
- motion camera trapping;
- nocturnal searches;
- searches for evidence and secondary signs in suitable NES species habitat; and,
- audio recording for night birds and amphibian calls using the SongMeter II bat detector units configured to record audible frequencies.

The locations of each targeted search site and the effort applied across these sites is detailed in Table 4.9 and Figure 4.4, with each site further described in Table 4.10.

4.3.5 Assessment of Likelihood of Occurrence in the Study Area

In order to determine which vertebrate species of conservation significance had the potential to occur in the study area, consideration was given to the results of the database and literature searches, as well as to the known habitat preferences, distributions and last known records for the species. For each vertebrate species of conservation significance considered as having potential to occur, a set of rankings and criteria was subsequently applied to assess the likelihood of its occurrence within the study area (Table 4.11). Through the remainder of this report, the term "close proximity" has been defined as being within 10 km of the study area, while the broader "locality" comprises the area up to 40 km from the study area.

Table 4.11: Ranking system used to assign the likelihood that a species would occur in the study area.

Rank	Criteria
Recorded	1. The species has been previously recorded in the study area.
Likely to occur	1. There are existing records of the species in close proximity to the study area (within 20 km); and • the species is strongly linked to a specific habitat, which is present in the study area; or • the species has more general habitat preferences, and suitable habitat is present.
May potentially occur	1. There are existing records of the species from the locality (within 40 km), however • the species is strongly linked to a specific habitat, of which only a small amount is present in the study area; or • the species has more general habitat preferences, but only some suitable habitat is present. 2. There is suitable habitat in the study area, but the species is recorded infrequently in the locality.
Unlikely to occur	1. The species is linked to a specific habitat, which is absent from the study area; or 2. Suitable habitat is present, however there are no existing records of the species from the locality despite reasonable previous search effort in suitable habitat; or 3. There is some suitable habitat in the study area, however the species is very infrequently recorded in the locality.
Would not occur	1. The species is strongly linked to a specific habitat, which is absent from the study area; and/or 2. The species' range is very restricted and does not include the study area.

4.4 Short Range Endemic Invertebrate Sampling

SRE fauna sampling of the study area involved both systematic (pit-trap transects) and non-systematic (targeted searching) sampling methods.

Invertebrate groups with potential to contain SREs were targeted, which included the following taxa:

- Mygalomorphae (trapdoor spiders);
- Diplopoda (millipedes);
- Scorpionidae (scorpions);
- Pulmonata (land snails); and
- Pseudoscorpiones (pseudoscorpions).

4.4.1 Targeted Searches

Mygalomorph spider burrows were located visually and were photographed prior to excavation. Holes were dug adjacent to each burrow, allowing the burrow to be followed down with forceps until the spider was located. Collected spiders were preserved in 70% ethanol, with one leg removed and placed in 100% ethanol for molecular studies.

Searches for millipedes, scorpions, land snails and pseudoscorpions were conducted by overturning rocks, foraging through leaf litter or, for scorpions, visually locating burrows.

4.4.2 Sampling Effort

Twenty-three sites were sampled across Phases 1 and 2 (Table 4.12). Searches for SREs were also performed on a previous survey of the study area which targeted the Northern Quoll (Biota 2014c). Habitats located just outside of the study area were searched during the Northern Quoll

survey to provide context to those sampled within the study area. Seven sites were sampled during this survey, and the results have been included here (Table 4.12).

Table 4.12: Short Range Endemic sampling locations during the Pocket and Billiard South fauna survey.

* denotes contextual sites sampled outside of the study area

Sampling sites were spread across the range of landform elements present in the study area (Table 4.13) but searches were targeted towards microhabitats that are considered likely to support SRE fauna. Searches for SRE fauna totalled over 61 hours (3,685 minutes) across the total of 30 sites. The SRE sites sampled are detailed in Table 4.14 and the locations are illustrated in Figure 4.5.

Table 4.13: Number of SRE sampling sites in relation to landform elements present in the study area.

4.4.3 Genetic Analysis

For mygalomorph spiders, species identification on the basis of morphology is not possible in the case of many juvenile and female specimens, as male reproductive parts are typically necessary for taxonomic allocation. In addition, in many cases individuals may be morphologically identical, but represent distinct reproductively isolated species (cryptic species).

To overcome these issues, Biota, the WA Museum and Helix Molecular Solutions (Helix) jointly developed a DNA barcoding approach to delimit species and identify collected specimens (Helix 2012). The aim of this is not to describe species as formal taxonomic entities, but rather, to generate a preliminary taxonomy, consisting of a series of genetically distinct operational units, defined here as species. Extensive molecular work has been conducted on mygalomorph fauna in Western Australia, providing a contextual baseline for the region. This dataset has subsequently provided a molecular framework, from which the potential SRE status of specimens may be evaluated.

The SRE status of species is based on their geographic distributions, which are described by two summary statistics. The first is the 'Maximum Spanning Distance' (MSD), which is the maximum linear distance between two records. The second statistic is the 'Minimum Spanning Area' (MSA), which is the area of the smallest polygon that can be drawn around all of the records. The minimum spanning area can be used as a means for objectively establishing SRE status by comparison against the 10,000 km^2 criterion established by Harvey (2002).

During this survey, 19 specimens (11 from Phase 1, eight from Phase 2) were collected from the study area and were submitted to Helix for molecular analysis. The specific methods used in this molecular analysis are presented in Appendix 6.

4.4.4 Determining SRE Status

Potential SRE specimens were collected in accordance with the SRE criteria outlined in the EPA Guidance Statement 20 (EPA 2009). Table 4.15 details the criteria used to determine the SRE status of putative species.

Table 4.15: Categories of SRE status and defining criteria.

SRE Status	Defining Criteria
Known SRE	• Species, morphotype or genetic type has a documented range of <10,000km^2. • Species, morphotype or genetic type is well collected, with numerous specimens typed and habitat preferences understood.
Potential SRE	• Species, morphotype or genetic type has a documented range of <10,000km^2 but is poorly sampled. • Specimen may not be formally described or assigned to a morphotype / genetic type. • Short-range endemism may be common in genus or family. • May have been collected from restricted, refugial or isolated habitats.
Unlikely to be an SRE	• Species, morphotype or genetic type has a documented range of <10,000km^2 but is poorly sampled. • Specimen may not be formally described or assigned to a morphotype / genetic type. • Short-range endemism is not common in the genus or family. • Specimen was not collected from restricted, refugial or isolated habitats. • Few other individuals of the taxon collected, but records separated by long distances (>100 km).
Not an SRE	• Specimen formally described or assigned to a morphotype / genetic type. • Species, morphotype or genetic type has a documented range of >10,000 km^2.
Undetermined	• Taxa where there is insufficient taxonomic framework available to provide any informed comment on the species-level distribution of the fauna or, therefore, the risk of small-scale spatial restrictions.

4.5 Fauna Survey Team

The fauna survey was conducted under "Licence to Take Fauna for Scientific Purposes" Permit No. SF009991 issued to Dr Stewart Ford (Appendix 7). The survey team for both phases comprised Dr Stewart Ford, Mr Jason Alexander, Mr Andrew Sheppard, Mr Chris Cole, Mr Garth Humphreys and Ms Penny Brooshooft (all of Biota).

Analysis of bat call recordings was completed by Mr Bob Bullen (Bat Call WA). Analysis of audio recordings was completed by Dr Stewart Ford (of Biota). Geographical Information System (GIS) analyses and maps presented in this report were prepared by Mrs Melissa Robinson, Mr Paul Sawers and Ms Kylie Webster.

4.6 Survey Limitations

The following limitations should be recognised with regard to this report:

- Not all sections of the study area were ground-truthed or equally sampled for fauna as this survey targeted areas that were under-represented by fauna sampling during previous surveys of the study area. Parts of the study area were inaccessible by vehicle, and installation and regular checking of fauna traps in these areas would not have been possible. However, habitats potentially supporting different faunal assemblages to those that were systematically sampled were sampled opportunistically on foot, where possible.
- there is only a limited taxonomic framework and ecological knowledge for the majority of potential SRE invertebrates (EPA 2009);
- sampling difficulties exist for potential SRE taxa. For example, mygalomorph spiders are difficult to locate, and accurate morphological identification requires adult male specimens or genetic identification. In addition, weather conditions can affect capture ability; male mygalomorphs are more likely to be captured in pitfall traps following rainfall events, and no rainfall was recorded during both phases of survey; and,
- while the most recent phylogenetic data are presented in this report, molecular work is ongoing and will make use of specimens collected during future surveys in the Pilbara. As additional data are incorporated into the DNA barcoding framework, species' distributions and SRE status may be revised.

5.0 Vertebrate Fauna Results

5.1 Overview

A combined total of 182 species of vertebrate fauna from 65 families (42 avifauna, six mammals, three bat, 12 reptiles and two amphibian) were recorded across both phases of the Pocket and Billiard South survey. Table 5.1 provides a summary of the number of species recorded from each major vertebrate group during each phase of survey.

Table 5.1: Overview of vertebrate fauna recorded from the Pocket and Billiard South study area.

Fauna Group	Number of Species			Overall
	Phase 1	Phase 2	Targeted Northern Quoll Survey	
Native Non-Volant Mammals	12	13	-	14
Introduced Non-Volant Mammals	2	2	-	3
Volant Mammals (Bats)	7	8	10	10
Avifauna	78	74	-	93
Reptiles	54	35	-	59
Amphibians	3	2	-	3
Totals	156	134	10	182

The species composition of the reptile assemblage differed between the two surveys; 19 more reptile species were recorded in Phase 1 than Phase 2. This is often the case with wet season and dry season surveys, and may reflect good conditions during the first phase following significant rainfall in January 2014.

The species composition of other fauna groups did not differ markedly between the two survey phases, although there was a marked decrease in the number of individuals recorded during survey Phase 2, particularly in the reptile assemblage.

The Phase 2 survey added 15 avifauna species, four non-volant mammal species and five reptile species to the inventory. The bat sampling conducted during the targeted Northern Quoll survey (Biota 2014c), recorded one additional species to those recorded during Phase 1 and 2.

5.2 Mammals

5.2.1 The Assemblage – Non-Volant Mammals

Eighteen non-volant mammal species, of which three were non-native, were recorded in the Pocket and Billiard South study area (Table 5.2). Of the six families recorded, the Dasyuridae (carnivorous marsupials) and Muridae (rodents) were the most speciose, each represented by six species. The non-native mammal species were the Camel (*Camelus dromedarius*), Horse (*Equus caballus*) and House Mouse (*Mus musculus*). Non-volant mammals accounted for 9.8% of the species records from the survey.

The most frequently recorded non-volant mammal was the House Mouse; 32 individuals were recorded, accounting for 26% of the total non-volant mammals recorded during the survey. The next most frequently recorded species was the Common Rock-rat with 15 records, accounting for 12.2% of the total mammal records.

5.2.2 The Assemblage – Volant Mammals

Ten bat species were recorded during the fauna survey (Table 5.3). These represented species from three families including two species of sheathtail bat (Emballonuridae), three species of freetail bat (Molossidae) and five species of evening bat (Vespertilionidae). The Northern Freetail-bat (*Chaerephon jobensis*), Gould's Wattled Bat (*Chalinolobus gouldii*) and the Little Broad-nosed

Bat (*Scotorepens greyii*) were the most commonly recorded species, with echolocation records documented at every bat sampling site.

The evening bats (Vespertilionidae) were the most speciose bat family, with five species recorded. Bats represented 5.5% of all vertebrate species recorded within the study area.

5.2.3 Mammals of Conservation Significance

Two mammal species of conservation significance were recorded from the Pocket and Billiard South study area. These were the Mulgara (*Dasycercus* sp.) and the Western Pebble-mound Mouse (*Pseudomys chapmani*). The Mulgara was detected from burrows found, however the species (*Dasycercus blythi* or *D. cristicauda*) that the burrows belonged to is uncertain as no individuals were recorded. However, recent taxonomic and phylogeographic revisions of these species would suggest that *D. blythi* (listed as Priority 4 by the Department of Parks and Wildlife) is the most likely species to occur in the study area. The Western Pebble-mound Mouse is listed as Priority 4 by the Department of Parks and Wildlife. Further details of these records are provided in Section 6.1.

One noteworthy bat species, the Chocolate Wattled Bat (*Chalinolobus morio*), was recorded during Phase 1 at site YBLSM2-03 and during the targeted Northern Quoll survey at sites YBQSM2-03 and YBQSM2-05. This species is not listed as conservation significant as it is common in southwest Australia (Churchill 2008), however an isolated population of this species occurs in the Pilbara in a small area surrounding Weeli Wolli Creek and Marillana Creek (Biota Internal database). Given its geographic separation from the main population in the southwest of WA, the Pilbara population may be genetically distinct. If it is genetically distinct, the Pilbara population may warrant protection as a result of its restricted distribution and apparent habitat specificity.

5.3 Avifauna

5.3.1 The Assemblage

Ninety-three species of avifauna were recorded from the study area, comprising 46 non-passerine and 47 passerine species from 42 families (Table 5.4). Avifauna represented approximately 50.8% of all vertebrate species recorded within the study area.

The Zebra Finch (*Taeniopygia guttata*) was the most abundant species recorded in the study area with 85 records, representing 8.2% of the individuals recorded. The Weebill (*Smicrornis brevirostris*) was the next most commonly recorded species with 78 records, representing 7.5% of total avifauna records. The most speciose family was the Meliphagidae (Honeyeaters and Chats), with 11 records.

5.3.2 Avifauna of Conservation Significance

Five avifauna species of conservation significance were recorded during the survey. These were the Star Finch (*Neochmia ruficauda subclarescens*) and Australian Bustard (*Ardeotis australis*), listed as Priority 4 by the Department of Parks and Wildlife, and the Fork-tailed Swift (*Apus pacificus*), Eastern Great Egret (*Ardea modesta*) and Rainbow Bee-eater (*Merops ornatus*) which are listed as Schedule 3 under the State *Wildlife Conservation Act 1950-1979* and Migratory under the Federal *EPBC Act 1999.*

Further information on these species and other conservation significant avifauna species potentially occurring in the study area can be found in Section 6.1 and 6.2.

Table 5.4: Avifauna species recorded during the Pocket and Billiard South fauna survey.

5.4 Reptiles

5.4.1 The Assemblage

Fifty-nine reptile species from 12 families were recorded during the survey (Table 5.5). The assemblage included nine species of gecko (Carphodactylidae, Diplodactylidae and Gekkonidae), four species of flap-footed lizards (Pygopodidae), six species of dragon (Agamidae), 19 species of skink (Egerniidae, Eugongylidae and Sphenomorphidae), nine species of monitor lizards (Varanidae), two species of blind snake (Typhlopidae), three species of python (Boidae) and seven species of front-fanged snake (Elapidae). Reptiles represented approximately 32.2% of all recorded vertebrate species in the study area.

The fat-tailed gecko (*Diplodactylus conspicillatus*) was the most commonly recorded species with 90 records, accounting for 14.6% of the total reptile records. The next most commonly recorded species was *Ctenotus duricola* with 75 records, accounting for 12.2% of the total reptile records. The Sphenomorphidae family was the most speciose with 11 species recorded.

5.4.2 Reptiles of Conservation Significance

One reptile species of conservation significance was recorded from the study area. This was the Pilbara Olive Python (*Liasis olivaceus barroni*), which is listed as a Schedule 1 species under the State *Wildlife Conservation Act 1950-1979* and Vulnerable under the Federal *EPBC Act 1999.*

Further details of this species and other reptile species of conservation significance potentially occurring in the study area are provided in Section 6.1 and 6.2.

Table 5.5: Reptile species recorded during the Pocket and Billiard South fauna survey.

5.5 Amphibians

5.5.1 The Assemblage

Three amphibian species from two families were recorded during the survey (Table 5.6). The assemblage included two species of tree frog (Hylidae) and one species of ground-dwelling frog (Myobatrachidae).

Table 5.6: Amphibian species recorded during the Pocket and Billiard South fauna survey.

		YBL006P	YBL009E	YBLTarget04	YBLNoct08	YBLOpp
Family/ Species Name	Common Name	P1	P1	P2	P2	P1

Myobatrachidae						
Uperoleia saxatilis	Pilbara Toadlet			•	•	•
Total number of records		1	1	•	•	1 + •
Total number of species		1	1	1	2	3

• denotes calls recorded

The Little Red Tree Frog was the only species recorded at trapping sites, but was not commonly recorded in wet areas along Weeli Wolli Creek. The most abundant frog during both phases of the survey was the Pilbara Toadlet, which was heard chorusing wherever there was water available. The least common species was the Sheep Frog, only one of which was recorded.

5.5.2 Amphibians of Conservation Significance

No amphibian species of conservation significance were recorded during the survey.

6.0 Vertebrate Conservation Significance

Native fauna species that are rare, threatened with extinction, or have high conservation value, are specially protected by law under the WA *Wildlife Conservation Act 1950*. In addition, some of these species are listed for their protection under the Commonwealth *EPBC Act 1999* (see Appendix 8 for statutory framework definitions).

6.1 Conservation Significant Fauna Recorded

The following eight species of conservation significance were recorded in the study area during this survey:

- Mulgara, *Dasycercus* sp. (species unconfirmed, however it is most likely D. *blythi* see Section 6.1.1);
- Pilbara Olive Python, *Liasis olivaceus barroni* (Schedule 1, Vulnerable);
- Western Pebble-mound Mouse, *Pseudomys chapmani* (Priority 4);
- Star Finch, *Neochmia ruficauda subclarescens* (Priority 4);
- Australian Bustard, *Ardeotis australis* (Priority 4);
- Fork-tailed Swift, *Apus pacificus* (Schedule 3, Migratory);
- Eastern Great Egret, *Ardea modesta* (Schedule 3, Migratory); and,
- Rainbow Bee-eater, *Merops ornatus* (Schedule 3, Migratory).

The location of these species is illustrated in Figure 6.1 and detailed descriptions of these species are provided in Sections 6.1.1 to 6.1.4.

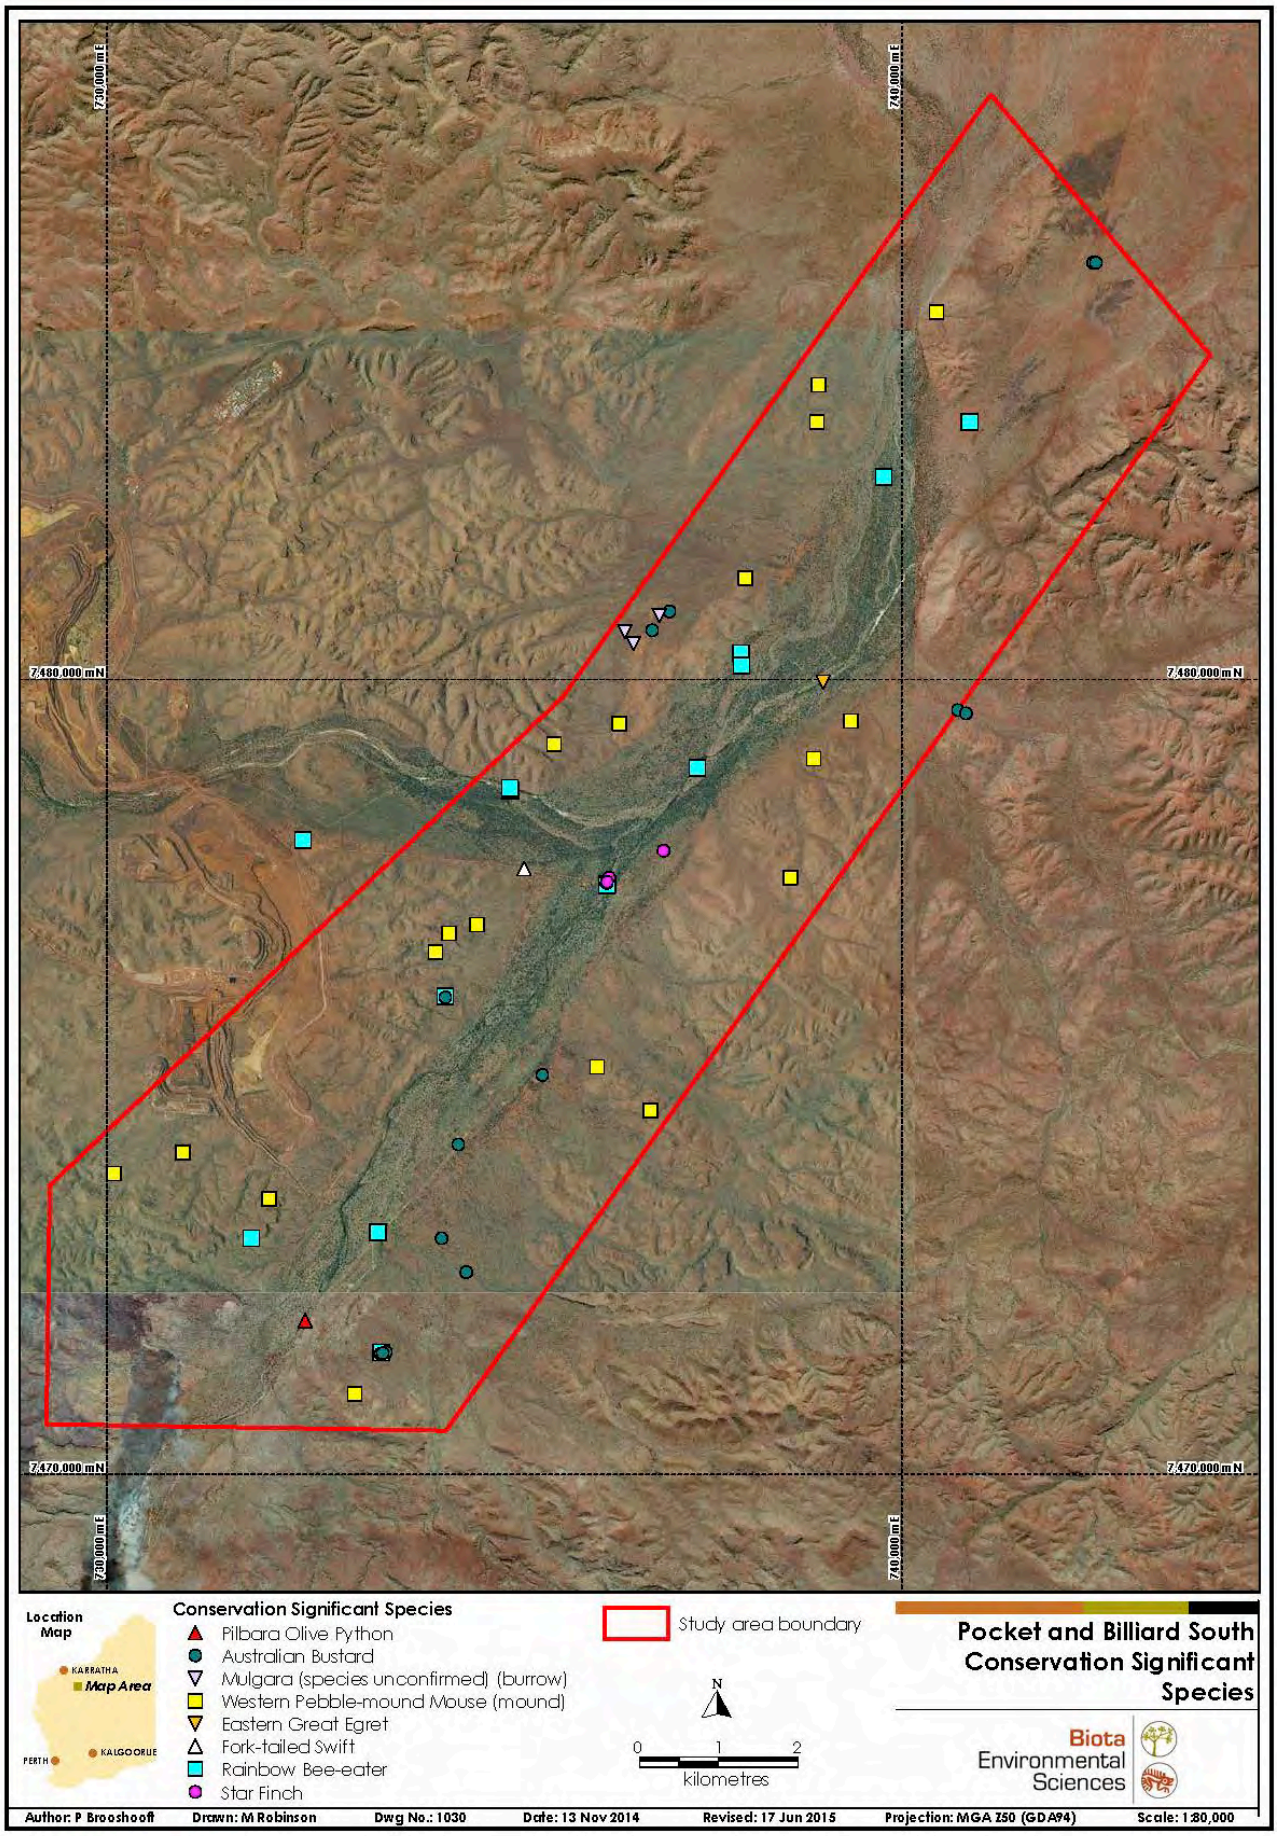

Figure 6.1: Locations of conservation significant fauna recorded during the Pocket and Billiard South fauna survey.

6.1.1 Mulgara, *Dasycercus* sp.

There has been a history of taxonomic confusion within the genus *Dasycercus*. For the last 30 years only a single species, *D. cristicauda*, was recognised; this is listed as Schedule 1 (Vulnerable) under the State *Wildlife Conservation Act 1950-1979* and Vulnerable under the Federal *EPBC Act 1999*. More recent genetic and morphological reviews resulted in the recognition of two species: the Crest-tailed Mulgara, *D. cristicauda,* and the Brush-tailed Mulgara, *D. blythi* (listed as a Priority 4 species by the Department of Parks and Wildlife).

While it is not impossible that *D. cristicauda* could occur in the study area locality, the current reliable data suggest it is much more likely that *D. blythi* is the taxon present. This view is based on the distribution maps of the Australian Museum (van Dyck and Strahan 2008) and Moseby et al. (2012), DSEWPaC's species profiles for the two species (DSEWPaC 2014), and most reliably from recent re-examination and assignment of the WA Museum's collection of *Dasycercus* specimens by taxonomic specialist Pat Woolley. The latter exercise found that all of the Pilbara region vouchers designated as *D. cristicauda* were more properly assigned to *D. blythi* (Biota 2014d).

Mulgara burrows were recorded in both phases of survey (Table 6.2), however no specimens were captured. The burrows were thought to be inactive, as no signs of fresh diggings, scats or tracks were noted. In addition to current views on *Dasycercus* species outlined above, habitat differences may also provide an indication for species identification when used in conjunction with identifications based on morphology (Woolley 2005, 2008, Pavey et al. 2011). Differences in habitat preference have long been recognised (Woolley 2005, 2008) and a study at a point of sympatry of the two species demonstrated discrete habitat preferences (Pavey et al. 2011). In this case, however, it is obviously difficult to ascertain which species (*Dasycercus cristicauda* or *Dasycercus blythi*) the burrows belonged to without captured specimens or tissue, but the habitat present within the study area is more congruous with the preferred habitat of the Brush-tailed Mulgara (*Dasycercus blythi*). This, combined with recent taxonomic revisions of the species, suggest that it is most likely this species that occurs within the study area (see Section 6.1.1.1), however specimens would need to be captured to confirm this.

Table 6.1: Locations of Mulgara burrows found during the Pocket and Billiard South fauna survey.

Site	Latitude	Longitude	Burrow Photograph
YBLMC01	22º45'49"S	119º18'27"E	
YBLMC04/YBLTarget02	22º45'56"S	119º18'13"E	

Site	Latitude	Longitude	Burrow Photograph
YBLMC04/YBLTarget02	22º46'01"S	119º18'16"E	

6.1.1.1 Brush-tailed Mulgara, *Dasycercus blythi*

There has been much taxonomic confusion surrounding the classification of *D. blythi* and *D. cristicauda,* however based on a combination of differences in tail morphology, nipple number (six, not eight), habitat preference and molecular distinction, the species may be identified. This species has a characteristic short tail, which is generally fattened at the base and covered in black hairs for much of its length.

Distribution: This species is known to inhabit spinifex grasslands on sand plains and sandy swale between low dunes from south-western Queensland across the Simpson, Tanami, and Great Sandy Deserts of southern and central Northern Territory and central Western Australia (van Dyck and Strahan 2008, Pavey et al. 2011). It is also known to inhabit areas on gibber (rock and pebble covered flat plains), and is closely associated with gently sloping to flat topographic positions rather than steep-sided sand ridges (Pavey et al. 2011). The presence of *Triodia* hummocks are not a requirement of the Brush-tailed Mulgara habitat (Pavey et al. 2011).

Ecology: The Brush-tailed Mulgara is a medium sized (60 – 110 g) carnivorous marsupial. Little is known about the breeding of this species in the wild, although females in central Australia have been captured in September with up to six young in the pouch. It is thought to be generally solitary, males and females being found in the same burrow only during the mating season.

Likelihood of Occurrence: Mulgara burrows were recorded at sites YBLMC01 and YBLMC04. Previous surveys conducted outside of Rio Tinto scopes of work have recorded active Mulgara diggings, burrows and burrow complexes and individuals in the northwestern section of the study area (S Ford pers. obs.). Despite the inactivity of the burrows, the recordings suggest that Mulgara were recently present (burrows were thought to be at least two months old) within the study area, but may indicate the individuals have moved from the site in search of new resources. Based on habitat preferences and distribution, it was assumed that the burrows recorded during the survey belonged to *D. blythi*; however, without direct captures identification remains uncertain. Previous surveys have recorded the Crest-tailed Mulgara (*D. cristicauda*) within 10 km of the study area (Biota 2002a, 2002b), however current knowledge would suggest that these records were most likely to be *D. blythi* rather than *D. cristicauda.*

6.1.2 Schedule 1 / Vulnerable Species

6.1.2.1 Pilbara Olive Python, *Liasis olivaceus barroni*

Distribution: The Pilbara Olive Python has a known distribution that coincides roughly with the Pilbara bioregion (Environment Australia 2000). It is known from 17 localities in the Pilbara and four areas where reliable populations occur: Pannawonica, Millstream, Tom Price and the Burrup Peninsula. At some of these sites, the species is considered stable and in sizeable numbers (Department of the Environment 2014a).

Ecology: Preferred habitat for the Pilbara Olive Python includes gorges, escarpments, rocky outcrops and water holes where it may find suitable prey that utilise these environments (Department of the Environment 2014a). It seeks shelter in caves, beneath boulders, in pools of water and occasionally in trees overhanging water (Bush and Maryan 2011). It is often associated with ephemeral or permanent water, but may also be recorded in rocky habitats some distance from these features (Biota 2009b). Males were found to travel large distances (Biota 2009b), suggesting that the species can have a large range (estimated between 88 ha and 449 ha) (Department of the Environment 2014a).

Occurrence in study area: This species was observed swimming downstream in Weeli Wolli Creek during the nocturnal search YBLNoct04 (22º50'39"S, 119º15'56"E). It has been recorded in the area previously, with several sightings made at the existing Yandi operations in addition to records from Marillana Creek.

6.1.3 Priority 4 Species

6.1.3.1 Western Pebble-mound Mouse, *Pseudomys chapmani*

Distribution: This species is endemic to the central and eastern parts of the Pilbara including Karijini National Park (Menkhorst and Knight 2011).

Ecology: This species is typically found on stony hillsides with hummock grasslands (Menkhorst and Knight 2011) and is common to very common in suitable habitat within the Hamersley and Chichester subregions of the Pilbara bioregion. The Western Pebble-mound Mouse is well known for its behaviour of constructing extensive mounds of small stones covering areas from 0.5 to 9.0 square meters (van Dyck and Strahan 2008). This mound formation is most common on spurs and gentle slopes where suitably sized stones are present.

Occurrence in study area: Pebble mounds were recorded from 18 locations within the study area. Four mounds appeared inactive, while the rest appeared active (Table 6.2).

Table 6.2: Mounds of the Western Pebble-mound Mouse recorded in the study area.

	Mound Number	Latitude	Longitude	Activity	Mound Photograph

6.1.3.2 Star Finch (western), *Neochmia ruficauda subclarescens*

Distribution: The western subspecies of Star Finch occurs in the north of Western Australia and into the Northern Territory (Schodde and Mason 1999). It remains most common about major watercourses in the tropics and is typically patchy and highly variable in abundance.

Ecology: This species is considered to be resident in most of its range but is generally uncommon and is patchily distributed in the Pilbara. It is typically confined to rushes, reed beds and adjacent vegetation communities along major waterways and permanent pools in the Pilbara where it feeds on seed of sedges. Insects may become a common part of the diet during the breeding season, while in other parts of its range seeds comprise a major part of its diet. This species usually nests in March and April, as seeds are maturing after summer rainfall, and its domed nest is usually built in reeds up to several metres from the ground. The main threat to the species is considered to be overgrazing by stock along waterways, which destroys the riparian vegetation on which they depend (Garnett and Crowley 2000).

Occurrence in study area: This species was recorded at search site YBLBird01 and opportunistically in Phase 2 from reeds and *Typha* sp. and *Melaleuca* sp. vegetation adjacent to a flowing section of Weeli Wolli Creek near site YBLBird01 (Record locations: 22º47'40"S, 119º18'07"E; 22º47'38"S, 119º18'06"E; 22º47'39"S, 119º18'06"E; 22º47'25"S, 119º18'31"E). This species was recorded on both survey phases from the same locality, suggesting that there is a resident

group. It was recorded regularly in the vicinity of Grey's Crossing, both upstream and downstream where the initial discovery was made. Searches at some other reed beds along the creek system were conducted, and call playback was used but elicited no response. This species is thought to be a breeding resident in suitable reed habitat adjacent to waterways within the study area.

6.1.3.3 Australian Bustard, *Ardeotis australis*

Distribution: The Australian Bustard occurs over much of Western Australia, with the exception of the more heavily wooded southern portions of the state (Johnstone and Storr 1998). It is mostly extinct from the settled districts, but common away from settled parts of Western Australia (Pizzey and Knight 2007).

Ecology: Bustards are typically nomadic and occupies large home ranges (Marchant and Higgins 1993) in open or lightly wooded grassland including *Triodia* sandplains (Johnstone and Storr 1998). It is considered scarce to common depending on season and habitat. It has an omnivorous diet and occurs in a relatively broad range of habitats, but is often recorded from recently burnt areas (Marchant and Higgins 1993). This species breeds from March to September and the eggs are laid on bare, preferably stony ground (Johnstone and Storr 1998).

Occurrence in study area: four observations, 12 tracks and one scat of this species were recorded during the field surveys (Table 6.4). This species has also been recorded multiple times from previous surveys within the study area.

Table 6.3: Locations of the Australian Bustard recorded in the Pocket and Billiard South study area.

	Site	Latitude	Longitude	Type of Observation
Phase 1	YBL005P	22º43'22"S	119º21'37"E	Track

6.1.4 Schedule 3 / Migratory Species

6.1.4.1 Fork-tailed Swift, *Apus pacificus*

Distribution: Almost cosmopolitan distribution throughout Australia.

Ecology: The Fork-tailed Swift is most often observed following thunderstorms and cyclonic weather patterns and the associated emergence of invertebrate fauna, which are a food source for this species (Johnstone et al. 2013). Fork-tailed Swifts are thought to be exclusively aerial in Australia as they breed in the northern hemisphere, migrating south to the Australasian region from October to April. Irregular summer visitor to the Pilbara during November to early April (Johnstone et al. 2013).

Occurrence in study area: An opportunistic observation of nine individuals of this species flying overhead was made during Phase 1 (22º47'33"S, 119º17'30"E). This species is expected to be a transient visitor to the study area and does rely on any terrestrial habitats within the study area.

6.1.4.2 Eastern Great Egret, *Ardea modesta*

Distribution: Cosmopolitan distribution throughout Australia.

Ecology: The Eastern Great Egret is largely dependent on the presence of significant water bodies, which may be temporally available in creeklines throughout the Pilbara, following periods of rainfall. These creeklines may attract Eastern Great Egret, particularly when drying pools result in an accumulation of tadpoles and fish.

Occurrence in study area: An opportunistic observation of this species was made during Phase 2 of the survey, when a single bird was observed flying over the creek (22º46'15"S, 119º19'40"E). The lack of observations at other times during the survey suggest that Eastern Great Egret is either uncommon or not regular within the study area.

6.1.4.3 Rainbow Bee-eater *Merops ornatus*

Distribution: This species occurs through the majority of the western third of Western Australia, usually where free water is readily available.

Ecology: This species forages aerially for insects and nests in burrows in the ground (Johnstone and Storr 1998). It occurs in a variety of habitats that are generally well watered, lightly wooded with suitable (sandy) soil for nesting and a tall stratum of vegetation for perching.

Occurrence in study area: This species was observed on numerous occasions opportunistically and whilst conducting systematic avifauna surveys throughout the study area (Table 6.4). This species, which is very common in the bioregion, is likely to be a breeding resident or non-breeding visitor to the region (Johnstone and Storr 1998), with Weeli Wolli Creek providing attractive wetter habitat with ample tall trees from which to forage.

Table 6.4: Locations of Rainbow Bee-eater records in the Pocket and Billiard South study area.

	Site	Latitude	Longitude

6.2 Conservation Significant Fauna Potentially Occurring

Table 6.5 summarises the conservation significant species that have been recorded historically from the study area and from the locality (within 40 km) surrounding the study area. For each species, the likelihood of occurrence currently within the study area was assessed by giving consideration to last known records, distributions and availability of preferred habitat within the study area.

On this basis, the following species were considered likely to occur:

- Orange Leaf-nosed Bat, *Rhinonicteris aurantius* (Schedule 1/Vulnerable);
- Peregrine Falcon, *Falco peregrinus* (Schedule 4);
- Pilbara Barking Gecko, *Underwoodisaurus seorsus* (Priority 1);
- Blind Snake, *Anilios ganei* (Priority 1);
- Ghost Bat, *Macroderma gigas* (Priority 4);
- Bush Stone-curlew, *Burhinus grallarius* (Priority 4); and,
- Common Greenshank, *Tringa nebularia* (Schedule 3, Migratory).

The following species were considered to have the potential for occurrence:

- Northern Quoll, *Dasyurus hallucatus* (Schedule 1/Endangered);
- Australian Painted Snipe, *Rostratula australis* (Schedule 1)
- Grey Falcon, *Falco hypoleucos* (Schedule 1)*;*
- Cattle Egret, *Ardea ibis* (Schedule 3, Migratory);

The following species were considered to be unlikely to occur:

- Night Parrot, *Pezoporus occidentalis* (Schedule 1, Endangered)*;*
- Crest-tailed Mulgara, *Dasycercus cristicauda* (Schedule 1, Vulnerable);
- Bilby, *Macrotis lagotis* (Schedule 1, Vulnerable);
- Short-tailed Mouse, *Leggadina lakedownensis* (Priority 4);
- Long-tailed Dunnart, *Sminthopsis longicaudata* (Priority 4); and,
- Oriental Plover, *Charadrius veredus* (Schedule 3, Migratory).

One species was considered to not occur in the study area:

- Northern Marsupial Mole, *Notoryctes caurinus* (Schedule 1, Endangered);

Table 6.5: Conservation significant species returned from the desktop review and their likelihood of occurrence in the study area.

Class	Conservation Status								
Common Name/ Species Name	WC Act/ DPaW	EPBC Act	NatureMap (<40km)	EPBC PMD*	ALA (<40km)	Records within 10 km	Preferred Habitat	Habitat Available in Study Area?	Likelihood of Occurrence
Mammals									
Crest-tailed Mulgara *Dasycercus cristicauda*	Schedule 1	Vulnerable	-	-		Biota (2002a, 2002b), although see Section 6.1.1	Sand ridges with an understorey dominated by *Triodia.*	✗	Unlikely to occur
Northern Quoll *Dasyurus hallucatus*	Schedule 1	Endangered	✔	✔		Biota (2002a, 2011a)	Many records from the Pilbara bioregion originate from rocky habitats, ridges and free faces particularly when in contact with dense vegetation along drainage areas, and from boulder tors of the Abydos-Woodstock Plain.	✔	May potentially occur
Short-tailed Mouse *Leggadina lakedownensis*	Priority 4		-	-		Biota (2004a, 2005a)	Cracking clay, native grasslands and surrounding habitat.	✗	Unlikely to occur
Long-tailed Dunnart *Sminthopsis longicaudata*	Priority 4					Biota (2004c)	Records have come from plateaus near breakaways and screes, and rugged boulder strewn screes, often in areas with little vegetation.	✔	Unlikely to occur
Bilby *Macrotis lagotis*	Schedule 1	Vulnerable	-	✔	-	-	Sandy soils covered with spinifex grassland (mainly *Triodia basedowii*), with an over-storey of low shrubs dominated by Acacia species.	✔	Unlikely to occur
Northern Marsupial Mole *Notoryctes caurinus*	Schedule 1	Endangered	-	✔	-	-	Well vegetated sand dunes and sandy soils.	✗	Would not occur
Ghost Bat *Macroderma gigas*	Priority 4		✔	-	✔	Biota (2002a, 2012a)	Breakaways adjacent to large drainage lines, deep caves in Banded Iron Formation ranges.	✔ (Foraging)	Likely to occur
Orange Leaf-nosed Bat *Rhinonicteris aurantius*	Schedule 1	Vulnerable	✔	✔		Biota (2013c)(2013b)	Breakaways adjacent to large drainage lines, deep caves in Banded Iron Formation ranges.	✔ (Foraging)	Likely to occur
Reptiles									
Pilbara Barking Gecko *Underwoodisaurus seorsus*	Priority 1		✔			Biota (2012a)	Associated with rocky ridges, slopes and gullies.	✔	Likely to occur
Blind Snake *Anilios ganei*	Priority 1		✔	-	✔	Biota (2004a)(2004b)	Few records, however, occurs in a wide variety of habitats.	✔	Likely to occur
Avifauna									
Night Parrot *Pezoporus occidentalis*	Schedule 1	Endangered		✔		-	Dense, low vegetation often associated with *Triodia* hummock grasslands and areas dominated by samphire or areas where these two habitats are juxtaposed.	✔	Unlikely to occur
Peregrine Falcon *Falco peregrinus*	Schedule 4		✔	-	✔	Ninox (1994) Biota (2004a, 2004b, 2005a, 2013c)	Wide range of habitats including forest, woodlands, wetlands and open country.	✔	Likely to occur
Bush Stone-curlew *Burhinus grallarius*	Priority 4		-	-	✔	Biota (2004a, 2004b)	Sparsely grassed, lightly timbered forest or woodland.	✔	Likely to occur
Grey Falcon *Falco hypoleucos*	Schedule 1		-	-	✔	-	Wide range of habitats in the arid zone but appears to be least rare in lightly wooded coastal and riverine plains.	✔	May potentially occur
Common Greenshank *Tringa nebularia*	Schedule 3	Migratory	✔	-	-	Biota (2013b)	Sheltered coastal habitats and terrestrial ephemeral wetlands.	✔	Likely to occur
Australian Painted Snipe *Rostratula australis*	Schedule 1		✔	✔			Wetland areas with dense screening vegetation.	✔	May potentially occur
Cattle Egret *Ardea ibis*	Schedule 3	Migratory		✔	-	-	Standing shallow freshwater.	✔	May potentially occur
Oriental Plover *Charadrius veredus*	Schedule 3	Migratory		✔	-	-	Numerous, including: open plains, bare, rolling country, muddy or sandy wastes near inland swamps or tidal mudflats, bare claypans, margins of coastal marshes, grassy airfields, lawns and coastal dunes.	✔	Unlikely to occur

* PMD = Protected matters database

6.3 Conservation Significant Species Likely to Occur

6.3.1 Schedule 1 / Vulnerable Species

6.3.1.1 Orange Leaf-nosed Bat, *Rhinonicteris aurantius*

Distribution: While *Rhinonicteris aurantius* occurs from the Pilbara region in Western Australia to Queensland, the Pilbara form is geographically restricted to the Pilbara and Gascoyne regions by a wide expanse of desert (DSEWPaC 2008). Colonies are scattered throughout the landscape and known from mines of the eastern Pilbara, throughout the Hamersley Range and from sandstone formations south of the Hamersley Range (Department of the Environment 2015). Confirmed collections, sightings or records of roost sites are known from Red Hill Station, Turee Creek Station, Klondyke Queen gold mine near Marble Bar, Karratha, Millstream, Tom Price-Marandoo, Comet mine, Bamboo Creek, Copper Hills (near Nullagine) and the Barlee Range Nature Reserve.

Ecology: The Orange Leaf-nosed Bat has short fur, small ears and a distinguishing fleshy, diamond-shaped nose-leaf surrounding the nostrils. The orange fur visible on the front of its body appears darker on the back, where the fur is brown-tipped (Strahan 1995, Department of the Environment 2015). Orange Leaf-nosed Bat are sensitive to human intrusion to their roost (Department of the Environment 2015). The Orange Leaf-nosed Bat is an opportunistic feeder on moths and beetles throughout the year, as well as flying termites during the wet season. Mating occurs in July, followed by a gestation period of five months with single young is born in December or January (Churchill 2008). The Orange Leaf-nosed Bat is a poor thermoregulator and is very susceptible to dehydration. For this reason it requires deep caves, small crevices within deep caves or horizontal mine shafts that have stable, warm and humid microclimates for permanent roost sites (Department of the Environment 2015). For the Orange Leaf-nosed Bat, these parameters are 28-32°C and 96-100% humidity during the dry season (Churchill 2008).

Likelihood of Occurrence: This species may potentially forage within the study area, however it would not be expected to roost in the study area due to a lack of suitable cave habitat. A single call of this species was recorded from a survey approximately 7 km northwest of the study area (Biota 2013c), but no calls were recorded within the study area, despite extensive surveying.

6.3.2 Schedule 4 Species

6.3.2.1 Peregrine Falcon, *Falco peregrinus*

Distribution: The Peregrine Falcon has an almost cosmopolitan distribution across Australia, but is absent from most deserts and the Nullarbor Plain (Johnstone and Storr 1998).

Ecology: This species inhabits a wide range of habitats including forest, woodlands, wetlands and open country (Pizzey and Knight 2007). The Peregrine Falcon, like other birds of prey, is a relatively long-lived species, with low reproductive rates and low population density. These factors, combined with the fact that they are a top end predator and limited by their prey, make them particularly vulnerable to human impact.

Likelihood of Occurrence: This species has been recorded within the vicinity (10 km) of the study area previously (Table 6.5), and large trees adjacent to creekline/riverine areas may provide potential nesting and foraging habitat. The species is considered likely to occur within the study area.

6.3.3 Priority 1 Species

6.3.3.1 Pilbara Barking Gecko, *Underwoodisaurus seorsus*

Distribution: The Pilbara Barking Gecko is a Hamersley Range endemic that was discovered in 2006 but has only recently been described (Doughty and Oliver 2011). It was initially thought to be an isolated population of its more southerly relative, the Barking Gecko *Underwoodisaurus milii* (Menz and Cullen 2006) before morphological and molecular analysis showed it to be taxonomically distinct. To date there are very few records of this species, which occurs in a band

from north of Tom Price in the western Hamersley to West Angelas mine in the south-east (Doughty and Oliver 2011).

Ecology: The habitats used by this species vary in their topography and vegetation but are usually associated with rocky ridges, slopes and gullies.

Likelihood of Occurrence: This species has been recorded within the vicinity of the study area (Table 6.5), and as suitable habitat is present within the study area, this species is considered likely to occur.

6.3.3.2 Blind Snake, *Anilios ganei*

Distribution: This blind snake is poorly collected, being represented by only 39 records throughout Western Australia. This species is distributed from Pannawonica in the west, to Millstream in the north, to Newman in the southeast.

Ecology: The records collected to date indicate that the blind snake may be associated with moist gorges and gullies (Wilson and Swan 2008) but they have also been recorded from mulga woodland and rocky scree slopes. The ecology of this species is poorly known, but it is likely that as with most blind snakes, they would mostly inhabit topsoil, termitaria and ant nests. Blind snake diet typically consists of the eggs, larvae and pupae of ants (Storr et al. 2002).

Likelihood of Occurrence: This species has been recorded previously from within the vicinity of the study area (records from 2004; Table 6.5), and is likely to be present in suitable habitat.

6.3.4 Priority 4 Species

6.3.4.1 Ghost Bat, *Macroderma gigas*

Distribution: Previously distributed across most of inland and northern Australia, but now restricted to the tropical north of the continent (Churchill 1998). Occurs in a broad range of habitats, with their distribution being influenced by the availability of suitable caves and mines for roost sites (Churchill 1998). The distribution of Ghost Bats is fragmented, with each population showing some genetic differentiation (Armstrong and Wilmer 2004, Biota 2004d). Populations in the Pilbara bioregion appear to be isolated from those in the Kimberley and Northern Territory. A study by McKenzie and Bullen (2009) found that the Ghost Bat is more common than previously thought.

Ecology: Ghost Bats are efficient predators of small birds, mammals, reptiles and large insects, and they have highly developed echolocation, visual and hearing systems (Churchill 1998). Vocalisations audible to humans are used in their complex social interactions (Churchill 1998). Bats forage over large distances, with ranges of ~60 ha, and the size of their foraging area is probably inversely related to the productivity of their landscape. Bats are known to have overlapping ranges (Churchill 1998). Scat material from *M. gigas* is quite distinctive and can be used to identify temporary roosts or feeding sites.

Likelihood of Occurrence: This species has been recorded within the vicinity of the study area recently from 9km south (Biota 2012a), where a cave containing scats was located. This species has potential to utilise habitats within the study area, but no potential roost caves were noted.

6.3.4.2 Bush Stone-curlew, *Burhinus grallarius*

Distribution: This species is widespread in Australia and southern New Guinea. It remains common in tropical Australia, but has declined considerably in temperate Australia and has disappeared from many regions (Marchant and Higgins 1993).

Ecology: The Bush Stone-curlew is primarily nocturnal and inhabits sparsely grassed, lightly timbered forest or woodland, often in areas where fallen timber can provide concealment during the day. It is most easily detected by calls, which are given most frequently in Spring (Marchant and Higgins 1993). Breeding season extends from July to January, with eggs laid directly on the ground or in a small scrape (Johnstone and Storr 1998). This species is a generalist terrestrial

feeder, primarily eating invertebrates, particularly beetles, but also small lizards, frogs, snakes, vegetation and seeds (Marchant and Higgins 1993).

Likelihood of Occurrence: This species has been recorded previously from within the vicinity of the study area (Table 6.5) and suitable habitat, such as low open woodlands associated with drainage lines, is available within the study area, therefore this species is considered likely to occur.

6.3.5 Schedule 3 / Migratory Species

6.3.5.1 Common Greenshank, *Tringa nebularia*

Distribution: This species does not breed in Australia, however it occurs in well-watered regions throughout Western Australia (Johnstone and Storr 1998).

Ecology: Found in a wide variety of shallow inland wetlands and sheltered coastal habitat (Johnstone and Storr 1998). It is a visitor to these habitats year round, where it feeds on insects and small molluscs (Johnstone and Storr 1998).

Likelihood of Occurrence: This species has been recorded previously within the vicinity of the study area (Table 6.5), and may be present on occasion in drainage line habitats with water.

6.4 Conservation Significant Species Potentially Occurring

6.4.1 Schedule 1 / Endangered Species

6.4.1.1 Northern Quoll, *Dasyurus hallucatus*

Distribution: The Northern Quoll currently occurs in three broad zones of northern Australia including the Northern Territory, Queensland and the Pilbara. The species occurs in the northerly portion of Northern Territory, with the westernmost records near the WA border and the south-easternmost records from Borroloola (DSEWPaC 2012b). In Queensland, populations of the species have shown a severe decline from their former distribution and are highly fragmented. Records are still known from areas south of Rockhampton, as far north as Cooktown and as far west as near Carnarvon Range National Park (DSEWPaC 2012b). It occurs in all subregions of the Pilbara bioregion, and is also known from a number of offshore islands in Western Australia including Adolphus, Augustus, Berthier, Bigge, Boongaree, Caffarelli, Capstan, Carlia, Dolphin, Hidden, Koolan, Purrungku, Sir Fredrick, Uwins and Wollaston Islands (Biota 2009c); (DSEWPaC 2012b). In the Pilbara, records of the Northern Quoll extend east to the Little Sandy Desert (How et al. 2009) and south to near Newman, but the species is most common in the northern Pilbara closer to the coast.

Ecology: Although known to occur in a variety of habitats across its range, the Northern Quoll is most abundant in rocky country and in open eucalypt forest within 150 km of the coast (Strahan 1983, 1995). In the Pilbara, the Northern Quoll is considered to favour rocky gorges, boulder piles, breakaways and hills (usually of high relief and often along drainage lines) for denning purposes, where it utilises spaces between rocks or in log or tree hollows (Biota 2009c). Previously completed records frequency analysis (Biota 2009a, 2012d) has shown that these critical habitat types are commonly associated with the Capricorn, Macroy, Robe and Newman land systems in the Pilbara bioregion. These land systems include basalt hills, mesas, major drainage channels, low and high plateaux, lower slopes and stony plains (van Vreeswyk et al. 2004). Adjacent plains and vegetated areas provide habitats suitable for foraging and dispersal of young (van Dyck and Strahan 2008), but are considered to be of less importance for the purpose of the species' conservation.

The Northern Quoll is the smallest, most arboreal and most aggressive of the four Australian quoll species (Strahan 1995). It is predominantly a carnivore with a varied diet of small invertebrates and vertebrates, including termites, grasshoppers, beetles, moths, lizards, birds, snakes, small mammals and frogs, as well as figs, other fleshy fruit and carrion (Oakwood 1997, Biota 2010c). In particular, it is known to prey on the Common Rock-rat *Zyzomys argurus* (Strahan 1995); probably

a primary prey item in the Pilbara region (Biota 2013f). Female Northern Quolls seem to outnumber males in most populations. While about one third of females tend to remain in the area they were born, most males disperse by six to eight months of age, and some males in areas are merely transients (Strahan 1983). This species is short-lived, with both sexes reaching maturity at 11 months (Biota 2010c). Male Northern Quolls usually die after one breeding season, which has been documented as May-July in the tropics. This, coupled with the fact that females typically only breed once per year, makes local populations of this species vulnerable to extinction (DSEWPaC 2012b).

Likelihood of Occurrence: There are few records from the locality surrounding the study area (Table 6.5), indicating that while the species may be present, it does not occur in high numbers. Despite targeted surveys within the study area using cage traps (192 total trap nights),Elliott traps (1155 total trap nights) and camera traps (total of 22 trap nights) (Biota 2009a, 2014c), it has not been detected. However, potentially suitable habitat is present within the study area, suggesting that it has potential to occur.

6.4.1.2 Night Parrot, *Pezoporus occidentalis*

Distribution: Very little is known about the distribution of the Night Parrot as only two of the 23 specimens ever collected of this species were from the 20th century; one from the Gascoyne region in WA in 1912 and the other in western Queensland in 1990 (FMG 2005). Several dedicated surveys for the Night Parrot have so far failed to locate a confirmed extant population in the Pilbara, however the species was sighted near Minga Well near the Fortescue Marsh in 2005 (Davis and Metcalf 2008). Its current distribution is thought to be limited to the inland southeast Pilbara and western Queensland (DSEWPaC 2012d).

Ecology: The Night Parrot grows from 22 to 25 cm in length and has a wingspan from 44 to 46 cm. It has a bright green body with black and yellow bars, spots and streaks, bright yellow belly and black wing periphery and tail, which is the same for the male and female parrots (DSEWPaC 2012c). The species is data deficient, but the reliable sightings have recorded birds occurring singly, in pairs and occasionally in small groups of four to eight (DSEWPaC 2012c). The diet of the Night Parrot is thought to comprise grass seeds, especially those of *Triodia*, and green plant material. It is thought to be a nocturnal species, frequenting sources of water at night (DSEWPaC 2012c). Although poorly known, the life expectancy of individuals is estimated at 10 years. The nest is said to be made up of a few small sticks and possibly *Triodia* leaves, built into a tunnel-like structure in a *Triodia* hummock or small bush (DSEWPaC 2012c).

The Night Parrot prefers arid and semi-arid regions characterised by dense, low vegetation (DSEWPaC 2012c). Confirmed records have described the parrot's habitat as *Triodia* grasslands on stony or sandy substrates, particularly when in association with samphire and chenopod shrublands, including genera such as *Atriplex*, *Maireana* and *Bassia,* on the border of salt lakes and creeks (DSEWPaC 2012c)

Likelihood of Occurrence: This species has not been recorded within the study area, or within 40 km of the study area. It is difficult to gauge the probability of this species occurring within the study area given a lack of records, however on the basis of habitat preference, some suitable habitat is present within the study area (see Table 4.9 for locations), suggesting this species has potential to occur.

6.4.2 Schedule 1 Species

6.4.2.1 Grey Falcon, *Falco hypoleucos*

Distribution: The Grey Falcon is endemic to Australia, where it is widespread but rare throughout the arid zone. This species occurs in the northern half of Western Australia, typically north of 26ºS (Johnstone and Storr 1998). It is a resident or nomadic visitor to inland parts of Australia (Pizzey and Knight 2007), but its movements are poorly understood.

Ecology: The Grey Falcon mainly inhabits lightly wooded coastal and riverine plains (Johnstone and Storr 1998) and may also occur near wetlands where surface water attracts prey. In the Pilbara, the Grey Falcon is mostly recorded from the coastal plain between the de Grey and

Ashburton Rivers (Storr 1984). Prey primarily comprises birds, especially parrots and pigeons, taken using high-speed chases and stoops; reptiles and mammals are also taken. It breeds in trees, such as *Eucalyptus* spp., typically in the abandoned nests of crows and butcherbirds (Marchant and Higgins 1993, Johnstone and Storr 1998). Eggs have been recorded in July and August but its breeding season is not certain.

Likelihood of Occurrence: While not recorded in the study area, this species has been recorded within 40 km. This species has potential to hunt in the study area periodically, and could potentially breed in taller eucalypts associated with the Weeli Wolli drainage system.

6.4.2.2 Australian Painted Snipe, *Rostratula australis*

Distribution: This species has been recorded from wetland areas in all states of Australia, although it is most common in eastern Australia (Department of the Environment 2014b).

Ecology: The Australian Painted Snipe is a wading bird with a long, pinkish coloured bill. It is generally observed singly or in pairs. This species generally inhabits shallow terrestrial freshwater wetlands with emergent grasses, sedges, rushes and reeds. Breeding habitat is characterised by shallow wetlands with bare wet mud and small islands within wetlands (Department of the Environment 2014b). The Australian Painted Snipe breeds year round when wetland conditions are favourable (Marchant and Higgins 1993). A substantial and sustained decline in numbers of the Australian Painted Snipe has been observed since the 1950s, and was thought to largely be the result of degradation and alteration of wetland habitats (Garnett and Crowley 2000, Rogers et al. 2005).

Likelihood of Occurrence: While not recorded in the study area, this species has been recorded within 40 km (NatureMap database). Wetland habitats are present year-round, therefore this cryptic species was considered to have potential for occurrence.

6.4.3 Schedule 3 / Migratory Species

6.4.3.1 Cattle Egret, *Ardea ibis*

Distribution: The Cattle Egret is largely associated with pastures and wetlands (Simpson and Day 2004), with scattered records from the Pilbara coming from areas surrounding the Fortescue Marshes and other wetland areas.

Ecology: This species primarily uses shallow open fresh wetlands with low emergent vegetation and abundant aquatic flora. It forages most often away from water in low lying grasslands, pastures and croplands, where it feeds on insects, frogs, reptiles and small mammals (Marchant and Higgins 1993).

Likelihood of Occurrence: this species may utilise damp grasslands adjacent to Weeli Wolli Creek following flooding, but is not expected to be a regular visitor in the study area.

6.5 Conservation Significant Species Unlikely to Occur

6.5.1 Schedule 1 / Endangered Species

6.5.1.1 Northern Marsupial Mole, *Notoryctes caurinus*

Distribution: This species is sparsely distributed across much of arid Australia in sandy desert area (Menkhorst and Knight 2011).

Ecology: This species is adapted to living underground where it burrows through sand. It has no functional eyes, small ear holes and its body is covered in a dense, fine, uniformly golden-brown fur. It primarily lives in sand dunes and sandy soils along river flats, where they forage on ants, beetle larvae and arthropods (Menkhorst and Knight 2011).

Likelihood of Occurrence: There are very few records of this species, with most recorded from over a decade ago from the eastern Pilbara, Gibson Desert and Kimberley region (NatureMap database). Habitat for this species is not present within the study area; therefore this species is unlikely to occur.

6.5.2 Schedule 1 / Vulnerable Species

6.5.2.1 Crest-tailed Mulgara, *Dasycercus cristicauda*

Distribution: This species is known to inhabit the slopes and crests of sand ridges in the southern Simpson Desert and the adjoining Tirari and Strzelecki Deserts in southern Northern Territory and northern South Australia (van Dyck and Strahan 2008). Historic records indicate it occurred from the Canning Stock route in central Western Australia and from Ooldea and along the Nullabor Plain at Fisher and Rawlinna (Pavey et al. 2011).

Ecology: The Crest-tailed Mulgara is generally more brightly coloured and bigger (65 – 185 g) than the Brush-tailed Mulgara, and has a dorsal fin-like crest of the black hairs on the tail (van Dyck and Strahan 2008). Unlike the Brush-tailed Mulgara, this species has eight nipples (Woolley 2005). Little detailed ecological work has been carried out on this species, although it is likely to be similar to the Brush-tailed Mulgara. Previous knowledge suggested that this species is strongly associated with the presence of the sandhill canegrass, *Zygochloa paradoxa*, as burrows were found at the base of this grass (van Dyck and Strahan 2008). Contrary to this, a study by Pavey and colleagues (2011), determined that gradients in *Triodia* cover might be more important than the presence/absence of the canegrass. It appeared that *Triodia*, like canegrass, functioned to stabilise sand required for burrow structural integrity.

Likelihood of Occurrence: Before recent and morphological reviews resulted in the recognition of two distinct species, *D. cristicauda* was recorded from the locality during previous surveys (Biota 2002a, 2002b). Current knowledge would suggest that these records are in fact more likely to be *D. blythi.* The preferred habitat of this species is also not available within the study area, suggesting that it is unlikely to occur.

6.5.2.2 Bilby, *Macrotis lagotis*

Distribution: Historically found across most of arid and semi-arid Australia, the Bilby is now restricted to the deserts of central Australia including the Tanami, Gibson and Great Sandy Deserts, the east Pilbara and south to Warburton in Western Australia. Western Australian populations are found in the inland Pilbara, northern Great Sandy Desert, the south-western Kimberley and the Gibson Desert (DSEWPaC 2012d).

Ecology: The Bilby is a rabbit-sized marsupial covered in long, soft, blue-grey fur and is quite delicate in appearance. Distinguishing features of this marsupial are its large rabbit-like ears, long pointed snout, black tail with a white tip, and delicate hind limbs with the hind foot lacking a first toe (Strahan 1995, Pavey 2006, DSEWPaC 2012d). The species has strong forelimbs with stout claws, making it a powerful burrower and well equipped to dig for food. Their diet typically comprises seeds, bulbs, fruit, insects, larvae and fungi, found primarily through their sharp senses of hearing and smell (Strahan 1995). The occurrence of this species is strongly influenced by the availability of sandy substrates (where burrowing is easier), areas of higher rainfall and higher temperatures (i.e. higher productivity areas and conditions that are unfavourable for foxes), and in some parts of its range, fire age is thought to influence species occurrence (DSEWPaC 2012d). Habitat near areas that have been recently burnt (one year ago or less) appear to be favoured by the Bilby (DSEWPaC 2012d).

Likelihood of Occurrence: There have been no records of this species within the study area or its locality, but potentially suitable habitats are present, particularly sandy areas in the northwest. The lack of records however, despite extensive surveying, suggests that the likelihood of occurrence of this species in the study area is low.

6.5.3 Priority 4 Species

6.5.3.1 Short-tailed Mouse, *Leggadina lakedownensis*

Distribution: Prior to 1997, only two specimens of this species had been collected, however the number of records of this species has increased substantially since this time (Cooper et al. 2003). In Western Australia the distribution includes the Pilbara and Kimberley regions (Menkhorst and Knight 2011).

Ecology: The Lakeland Downs Mouse is known to occur in areas of open tussock and hummock grassland, *Acacia* shrubland and savannah woodland, on sandy soils and cracking clays (Morris et al. 2008). This species has been recorded on cracking clay communities from Cape Preston (60 km west of Dampier) in the west to the northern flanks of the Fortescue Marshes in the east (Halpern Glick Maunsell and Biota 2000). These records suggest that the primary mainland habitat comprises areas of cracking clay and adjacent habitats, although this species has also been recorded from hilltops and sandy coastal areas near Onslow.

Likelihood of Occurrence: This species has been recorded in close proximity to the study area previously (Table 6.5), although very little of its core habitat is present within the study area, and it is therefore considered unlikely to occur.

6.5.3.2 Long-tailed Dunnart, *Sminthopsis longicaudata*

Distribution: The Long-tailed Dunnart inhabits rocky, rugged habitat from the Pilbara and adjacent upper Gascoyne region east to the central Northern Territory and South Australia (Menkhorst and Knight 2011).

Ecology: This species is nocturnal, and its diet includes a variety of invertebrates. Females in captivity give birth to up to five young between the months of October and December (McKenzie et al. 2008). Records of this species have come from plateaus near breakaways and screes, and rugged boulder strewn screes, often in areas with little vegetation. This species was once considered to be rare and possibly threatened, however, research has shown that it is relatively common and widespread but is restricted to a specific habitat (Burbidge 2004).

Likelihood of Occurrence: This species has been recorded in proximity to the study area previously (Table 6.5), however this record was from a decade ago. Preferred habitat of this species is present within the study area, however lack of recent records would suggest that this species is unlikely to occur in the study area.

6.5.4 Schedule 3 / Migratory Species

6.5.4.1 Oriental Plover, *Charadrius veredus*

Distribution: This species is a non-breeding visitor to Australia where it occurs along coastal and inland areas in northern Australia, predominantly north of the Fortescue Marsh (BirdLife Australia 2014).

Ecology: This species prefers open areas such as plains, bare, rolling country, muddy or sandy wastes near inland swamps or tidal mudflats; bare claypans, margins of coastal marshes; grassy airfields, lawns and coastal dune areas (Pizzey and Knight 2007).

Ecology: This species has not been recorded from the study area previously and suitable habitat is largely absent from the study area, only occurring following a fire. The species is thought to be unlikely to occur within the study area.

6.6 NES Species Habitat Mapping

In general terms, the study area was considered to be largely unsuitable for Northern Quoll, with a few small areas found that would have a low likelihood of providing habitat, that is, potential den locations in proximity to water and foraging opportunities (Figure 6.2). The habitat values of the study area as a whole are probably limited to potential dispersal area for Northern Quoll.

The Weeli Wolli Creek system with its series of semi-permanent pools and extensive riparian vegetation represents preferred habitat for Pilbara Olive Python, and this species was recorded in this habitat (Figure 6.2). Preferred habitat in this sense means that it provides areas of shelter in close proximity to foraging areas. During hot and humid conditions, dispersal throughout the study area is possible and, as for Northern Quoll, the study area as a whole is considered to be dispersal habitat for the species.

Weeli Wolli Creek was also considered to be potential foraging habitat for Orange Leaf-nosed Bat, although none were recorded. There was no evidence of roost caves suitable for the species despite extensive searches along the ridgelines of the study area. Consequently, while the study area as a whole could be considered to be dispersal habitat for the species, it was not considered to have any roosting or foraging habitat present. In addition, there is no evidence that a roost occurs within 15 km of the study area (the maximum foraging distance of individuals (Biota 2013h)).

Similarly, the spinifex plains in the north of the study area may represent potential foraging area for Night Parrot, but the spinifex was not old enough to create the large, continuous clumps required to provide suitable nesting locations and the study area as a whole does not provide preferred habitat for the species.

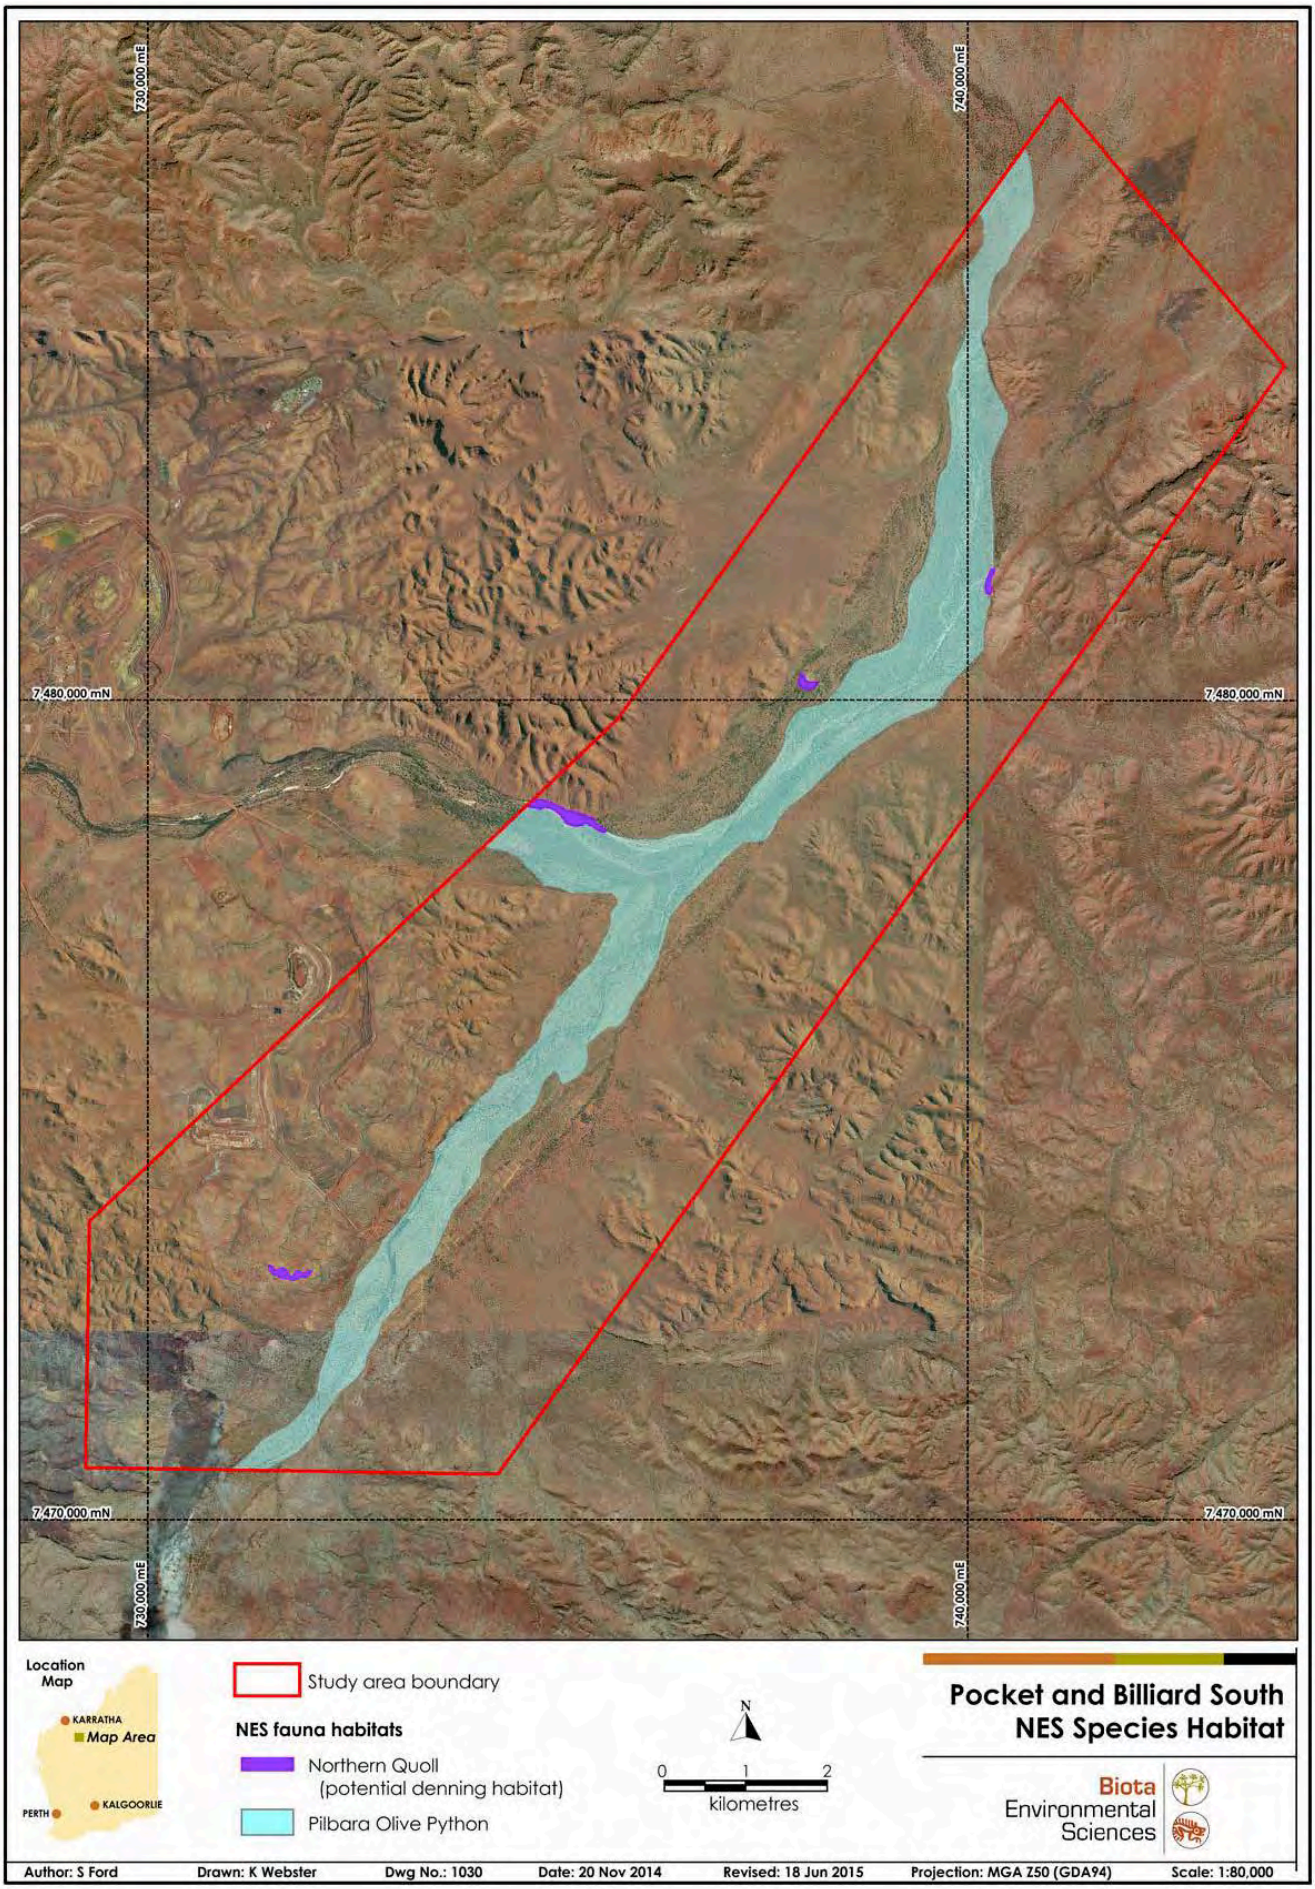

Figure 6.2: NES species habitat mapping.

7.0 Short Range Endemic Fauna Results

7.1 Fauna Recorded in Study Area

The survey recorded taxa from two invertebrate groups: mygalomorph spiders and pseudoscorpions. The locations of these records are illustrated in Figure 7.1.

7.1.1 Myglamorph Species: *Aganippe* 'MYG086'

A previous environmental survey in the north of the study area (URS Australia 2012) reportedly recorded specimens of the potential SRE, *Aganippe* 'MYG086'. Searches during Phase 1 and 2 were performed in the same location as these records were reportedly found in, however no specimens were located. The specimens located during the previous environmental survey had been lodged with the WA Museum, and were submitted to Helix along with specimens collected during this survey for genetic analysis, to assign them to a species (as no genetic material was taken originally). These specimens were successfully sequenced, and were assigned to the species 'I80' (family Idiopidae), which has not been collected previously from the wider Pilbara Mygalomorph study (Helix 2012).

However, upon plotting the locations of these museum specimens (species I80) from museum record coordinates, it was found that they originated 40 km northwest and 60 km east of the study area. Because the species I80 was not detected during this survey, and known records of this species are located some distance outside of the study area in different habitat, it is considered unlikely that this species occurs within the study area.

7.1.2 Mygalomorph Spiders

Nineteen specimens (11 from Phase 1, eight from Phase 2) were collected from the Pocket and Billiards South study area (this study). Genetic analysis of the specimens detected five putative species from two families (Table 7.1).

All species detected have been found previously outside of the study area (Table 7.1).

The Maximum Spanning Distance (MSD), Minimum Spanning Area (MSA) and SRE status of each species is outlined in Table 7.1 and each putative species is further described in Sections 7.1.2.1 - 7.1.2.5. This analysis was based on the locations of all records of this species supplied by the Western Australian Museum.

Table 7.1: Putative species recorded from the Pocket and Billiard South study area.

Family Molecular Species	No of Specimens (Phase)	Sites collected from	No of Sites collected from	Found outside project area?	Maximum Spanning Distance (km)	Minimum Spanning Area (km^2)	SRE Status
Idiopidae I53	3 (P1)	YBLSRE01	1	Y	42.3	0.54	Potential SRE
Nemesiidae N42	2 (P1), 1 (P2)	YBLSRE01, YBL005P, YBLSRE15	3	Y	17.65	106.39	Potential SRE
Nemesiidae N44	2 (P1), 6 (P2)	YBLSRE04, YBLSRE14, YBLSRE19, YBLSRE20	4	Y	20.25	26.47	Potential SRE
Nemesiidae N16	4 (P1)	YBLSRE08, YBLSRE10, YBL007P	3	Y	176.2	14,042	Not an SRE
Nemesiidae N1	1 (P2)	YBLSRE15	1	Y	296.9	14,412	Not an SRE

7.1.2.1 Idiopidae 'I53'

Distribution:
Species I53 is known from four other specimens in the Pilbara; three collected at Yandi (approximately 80.5 km north-northwest of Newman) and one collected from Koodaideri (approximately 122 km northwest of Newman). It currently has a known MSD of 42.3 km and a MSA of 0.54 km^2.

Habitat: Species I53 has been collected from hummock grasslands.

SRE Status: The current known distribution of this putative species is less than 10,000 km^2; therefore it is considered a potential SRE in accordance with the criteria outlined in Table 4.15.

7.1.2.2 Nemesiidae 'N42'

Distribution: This species is known from 20 individuals collected across 11 separate localities between 80 and 90 km northwest of Newman. It has also been recorded within 10 km of the study area during previous surveys (Biota 2011c, 2013e). It has a MSD of 17.65 km and a MSA of 106.39 km^2.

Habitat: Species N42 has been collected from stony plains, ridges, lower slopes and alluvial floodplains.

SRE Status: Based on current records, this species qualifies as a potential SRE.

7.1.2.3 Nemesiidae 'N44'

Distribution: A total of 22 specimens of Species N44 have been collected from the Pilbara region across seven separate locations. It has also been recorded from within 10 km of the study area during a previous survey (Biota 2011c). The records are separated by a MSD of 20.25 km and occupy an area of 26.47 km^2.

Habitat: Species N44 is known from Loamy soils along Weeli Wolli Creek.

SRE Status: Based on the current spread of records, Species N44 qualifies as a potential SRE.

7.1.2.4 Nemesiidae 'N16'

Distribution: Species N16 is broadly distributed through the southern central Pilbara and is known from 221 specimens collected from 184 separate localities that are separated by a MSD of 176.2 km, and has a MSA of 14,042 km^2. This species has been recorded within 10 km of the study area from a number of previous surveys (Biota 2011b, 2011c, 2013c, 2013d).

Habitat: Species N16 have been collected from red shallow loams or red earthy loams in narrow drainage floors and from adjacent landforms (e.g., low slopes and stony plains) where suitable soil profile exists. Associated vegetation units include Acacia woodlands and *Triodia* hummock grasslands.

SRE Status: Species N16 has a distribution larger than 10,000 km^2 and, on that basis, does not qualify as an SRE.

7.1.2.5 Nemesiidae 'N1'

Distribution: Species N1 is known from 108 individuals collected across 71 locations in the Pilbara. It has a MSD of 296.9 km and based on current data, it occupies a MSA of 14,412 km^2. This species has been recorded during a number of previous surveys conducted within 10 km of the study area (Biota 2011b, 2011c, 2013c, 2013d, 2013e).

Habitat: Species N1 is associated with clayey soils in *Acacia aneura* dominated communities as well as clay loams on alluvial fans and broad floodplains.

SRE Status: Species N1 has a distribution larger than 10,000 km^2 and, on that basis, does not qualify as an SRE.

7.1.3 Pseudoscorpions

One pseudoscorpion specimen belonging to the *Beierolpium* genus (family Olpiidae) was recorded during the survey from within leaf litter. This species has been recorded previously during surveys conducted within 10 km of the survey area (Biota 2011b, 2012c, 2013c, 2013d). This group requires further taxonomic investigation before its SRE status can be determined.

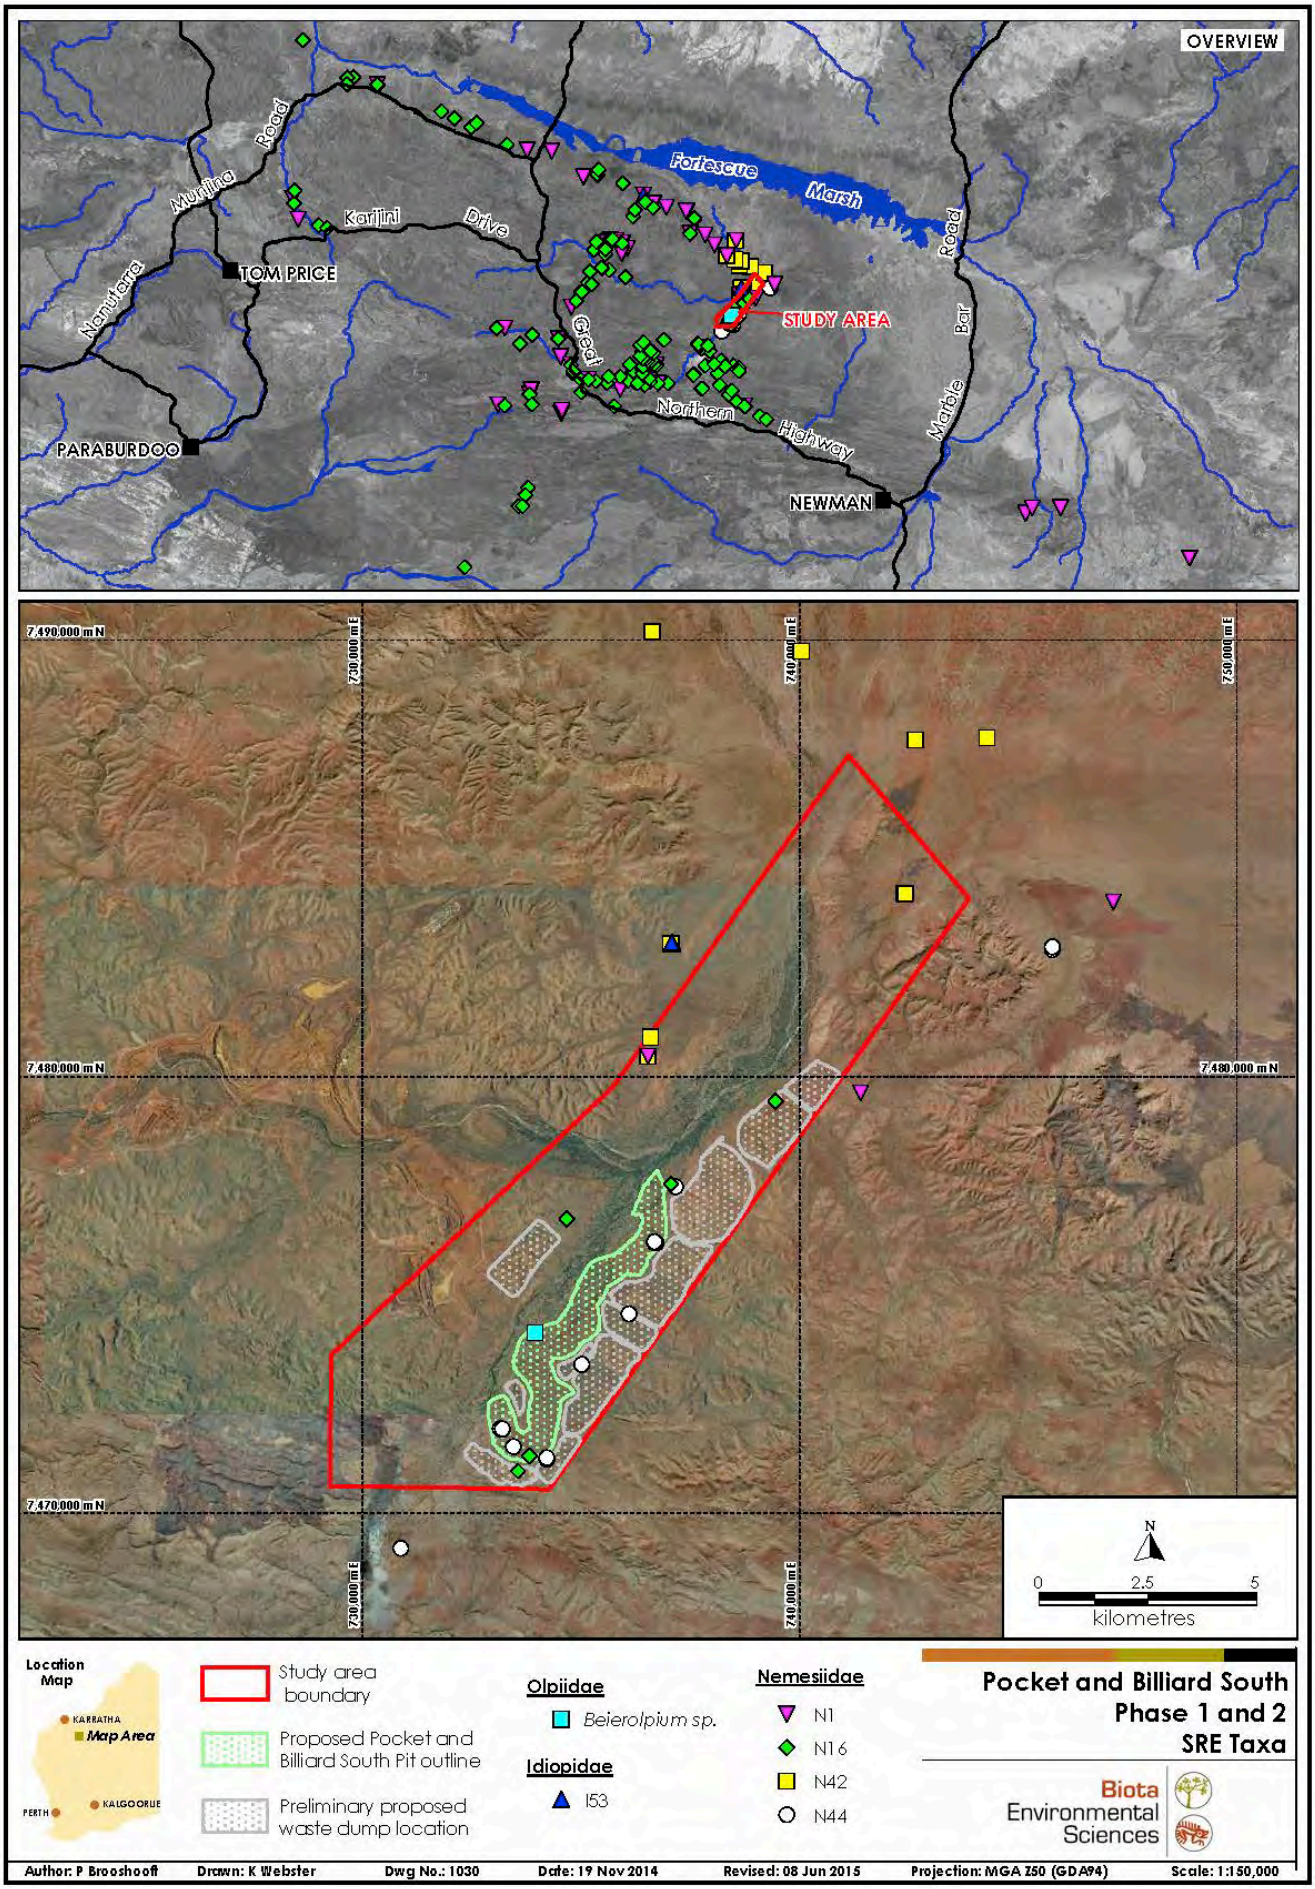

Figure 7.1: Locations of SRE taxa recorded from the Pocket and Billiard South study area.

8.0 Conclusions

The review of the information available for terrestrial fauna within the Pocket and Billiard South study area conducted by Biota (2013a) recommended that additional fauna sampling in the northern and western portions of the study area, coinciding predominantly with the Newman, McKay and Urandy land systems, was required. These land systems do not intersect the Weeli Wolli Creek system. This survey addressed that zoological knowledge gap and added considerably to the understanding of the terrestrial assemblage of the study area, particularly in respect to vertebrate groups such as reptiles, as outlined in a separate report integrating this and other reports on the terrestrial fauna of the study area (Biota 2014e).

Eight conservation significant vertebrate taxa were recorded using survey techniques tailored to each species. Additional trapping effort targeted at Northern Quolls in areas identified as having the greatest potential to support the species continued to be unsuccessful and the study area as a whole was considered to be largely unsuitable for the species, with only minimal potential denning habitat available. Additionally, despite extensive searching, no caves suitable for Ghost Bat or Orange Leaf-nosed Bat colonies were found. While the area represents possible foraging area for these species, the lack of suitable roosts reduces their likelihood of occurrence, and they were not recorded. On the other hand, extensive suitable habitat is available for Pilbara Olive Python in riparian vegetation associated with the Weeli Wolli Creek system and the species has been confirmed as occurring.

Mulgara burrows were recorded within the study area, however no direct captures of species were made, therefore it remains uncertain whether the burrows belonged to the Crest-tailed Mulgara (*Dasycercus cristicauda*) or the Brush-tailed Mulgara (*Dasycercus blythi*). The Crest-tailed Mulgara has previously been recorded within 10 km of the study area, although recent genetic and morphological reviews would suggest these records were in fact more likely to be *D. blythi.* Based on current knowledge of the genetic and morphological differences between the two species, coupled with habitat preferences and distribution, it was assumed that the burrows recorded during this survey belonged to the Priority 4 listed *D. blythi.*

Targeted searches for SRE taxa yielded records of several invertebrate species considered to be potential SREs. All of the taxa recorded have documented distributions that extend outside of the Pocket and Billiard South study area.

9.0 Glossary

ALA	Atlas of Living Australia
Biota	Biota Environmental Sciences
EIA	Environmental Impact Assessment
Elliott Trap	A collapsible aluminium box trap
EPA	Environmental Protection Authority
EPBC Act 1999	Federal *Environmental Protection and Biodiversity Conservation Act 1999*
Helix	Helix Molecular Solutions
IBRA	Interim Biogeographic Regionalisation for Australia
MSA	Minimum Spanning Area
MSD	Maximum Spanning Distance
NES	Species of National Environmental Significance
Non-volant mammals	Ground dwelling mammals
NRS	National Reserve System
Opportunistic record	A species recorded by non-systematic sampling methods
Passerine	Of the order Passeriformes, also known as a perching bird
PBS	Pocket and Billiard South
Study area	The area in which the fauna survey was conducted; Pocket and Billiard South
SM2	A model of Song Meter by Wildlife Acoustics
Speciose	Rich in number of species
SRE	Short Range Endemic fauna
Systematic sampling	Sampling using trapping (including pitfall traps, Elliott traps or funnel traps)
Volant mammals	Bats

Potential Species List Compiled from the Database and Literature Searches

Mammals

Family / Species Name	Common Name	Conservation Status	EPBC PMD	NatureMap + 40km	ALA + 40km	Ninox Wildlife Consulting (1994)	Biota (2002a)	Biota (2002b)	Biota (2004a), Biota (2004b)	Biota (2004a), Biota (2004c)	Biota (2005b)	Biota (2010a), Biota (2010b)	Biota (2009a)	Biota (2011)	Biota (2012a)	Biota (2013b)	Biota (2012b)	Biota (2014c)	This Survey
Tachyglossidae																			
Tachyglossus aculeatus	Short-beaked Echidna			•					•										
Dasyuridae																			
Dasycercus cristicauda	Crest-tailed Mulgara	S1					•	•											
Dasycercus sp. (blythi or cristicauda)	Brush-tailed Mulgara or Crest-tailed Mulgara	P4/S1																	•
Dasykaluta rosamondae	Little Red Kaluta			•	•				•	•		•	•		•	•			•
Dasyurus hallucatus	Northern Quoll	S1	•	•			•							•					
Ningaui timealeyi	Pilbara Ningaui			•	•				•	•		•			•	•			•
Sminthopsis longicaudata	Long-tailed Dunnart	P4								•									
Sminthopsis macroura	Stripe-faced Dunnart			•	•					•					•	•			•
Sminthopsis youngsoni	Lesser Hairy-footed Dunnart			•	•				•	•					•				•
Planigale ingrami	Long-tailed Planigale			•	•										•	•			
Ningaui ridei	Wongai Ningaui			•	•						•								
Pseudantechinus woolleyae	Woolley's Pseudantechinus			•	•													•	
Sminthopsis hirtipes	Hairy-footed Dunnart			•															
Sminthopsis ooldea	Ooldea Dunnart			•	•														
Thylacomyidae																			
Macrotis lagotis	Bilby, Dalgyte	S1	•																
Notoryctidae																			
Notoryctes caurinus	Northern Marsupial Mole	S1	•																
Macropodidae																			
Macropus robustus	Euro			•	•	•			•	•		•			•	•		•	•
Macropus rufus	Red Kangaroo, Marlu			•	•	•			•	•	•	•							•
Petrogale rothschildi	Rothschild's Rock-wallaby			•											•	•		•	•
Muridae																			
Leggadina lakedownensis	Short-tailed Mouse	P4							•	•									
Mus musculus	House Mouse		•	•	•	•	•		•	•			•	•	•				•
Pseudomys chapmani	Western Pebble-mound Mouse	P4		•	•	•				•		•			•	•	•		•
Pseudomys delicatulus	Delicate Mouse									•									
Pseudomys desertor	Desert Mouse			•	•		•		•	•					•	•			•
Pseudomys hermannsburgensis	Sandy Inland Mouse			•	•	•	•		•	•		•	•		•	•		•	•
Zyzomys argurus	Common Rock-rat			•	•	•	•		•			•			•	•	•	•	•
Notomys alexis	Spinifex Hopping-mouse			•	•						•								•
Leporidae																			
Oryctolagus cuniculus	Rabbit		•																
Canidae																			
Canis lupus			•	•		•				•	•				•	•			
Canis lupus dingo	Dingo				•						•						•		•
Vulpes vulpes	Red Fox		•																
Felidae																			
Felis catus	Cat		•	•		•				•	•						•	•	
Equidae																			
Equus asinus	Donkey		•							•		•							
Equus caballus	Horse		•	•						•						•			•
Camelus dromedarius	Dromedary, Camel		•	•		•				•						•			
Bos taurus	European Cattle			•		•					•	•			•	•			

Bats

Psittacidae															
Australian Ringneck	*Barnardius zonarius*			•	•	•	•			•		•	•		•
Mulga Parrot	*Psephotus varius*			•	•		•								•
Budgerigar	*Melopsittacus undulatus*			•	•	•		•	•	•		•	•		•
Bourke's Parrot	*Neopsephotus bourkii*				•				•						
Elegant Parrot	*Neophema elegans*								•						
Night Parrot	*Pezoporus occidentalis*	S1		•											
Cuculidae															
Pheasant Coucal	*Centropus phasianinus*			•	•				•		•				
Horsfield's Bronze-Cuckoo	*Chalcites basalis*			•	•	•		•	•	•	•	•	•		•
Black-eared Cuckoo	*Chalcites osculans*			•			•	•	•	•					•
Pallid Cuckoo	*Cacomantis pallidus*			•	•			•	•	•	•	•			
Strigidae															
Barking Owl	*Ninox connivens*			•	•	•		•		•			•		•
Southern Boobook	*Ninox novaeseelandiae*			•	•	•		•				•	•		•
Tytonidae															
Eastern Barn Owl	*Tyto javanica*			•	•			•							•
Halcyonidae															
Blue-winged Kookaburra	*Dacelo leachii*			•	•	•		•	•	•	•		•		•
Red-backed Kingfisher	*Todiramphus pyrrhopygius*			•	•	•		•	•	•	•	•	•		
Sacred Kingfisher	*Todiramphus sanctus*			•	•	•		•	•	•		•	•		•
Meropidae															
Rainbow Bee-eater	*Merops ornatus*	S3/M	•	•	•	•	•	•	•	•	•	•	•		•
Climacteridae															
White-browed Treecreeper	*Climacteris affinis*						•								
Black-tailed Treecreeper	*Climacteris melanura*				•										
Ptilonorhychidae															
Spotted Bowerbird	*Ptilonorhynchus maculatus*			•	•										
Western Bowerbird	*Ptilonorhynchus guttatus*				•			•				•	•		•
Maluridae															
Splendid Fairy-wren	*Malurus splendens*				•		•								
White-winged Fairy-wren	*Malurus leucopterus*			•		•		•	•	•		•	•		•
Variegated Fairy-wren	*Malurus lamberti*			•	•	•	•	•	•	•	•	•	•		•
Rufous-crowned Emu-wren	*Stipiturus ruficeps*			•				•	•	•					
Striated Grasswren	*Amytornis striatus*			•	•			•	•						
Acanthizidae															
Redthroat	*Pyrrholaemus brunneus*			•	•		•		•						
Weebill	*Smicrornis brevirostris*			•	•	•	•	•	•	•	•	•	•		•
Western Gerygone	*Gerygone fusca*			•	•	•		•	•	•	•	•	•		•
Slaty-backed Thornbill	*Acanthiza robustirostris*			•	•	•	•		•						
Yellow-rumped Thornbill	*Acanthiza chrysorrhoa*			•	•							•			
Chestnut-rumped Thornbill	*Acanthiza uropygialis*			•	•	•	•	•	•	•		•			•
Inland Thornbill	*Acanthiza apicalis*			•	•		•			•		•	•		•
Southern Whiteface	*Aphelocephala leucopsis*			•	•		•		•						
Pardalotidae															
Red-browed Pardalote	*Pardalotus rubricatus*			•	•	•		•	•	•	•	•	•		•
Striated Pardalote	*Pardalotus striatus*			•	•	•	•	•	•		•	•	•		•

Meliphagidae															
Pied Honeyeater	*Certhionyx variegatus*			•					•						
Singing Honeyeater	*Lichenostomus virescens*			•	•	•	•	•	•	•	•	•	•		•
White-eared Honeyeater	*Lichenostomus leucotis*						•								
Grey-headed Honeyeater	*Lichenostomus keartlandi*				•	•		•	•	•	•	•	•		•
White-plumed Honeyeater	*Lichenostomus penicillatus*			•	•	•		•	•	•	•	•	•		•
White-fronted Honeyeater	*Purnella albifrons*					•		•							•
Yellow-throated Miner	*Manorina flavigula*			•	•	•	•	•	•	•	•	•	•		•
Spiny-cheeked Honeyeater	*Acanthagenys rufogularis*			•	•		•	•	•	•	•	•	•		•
Grey Honeyeater	*Conopophila whitei*			•								•			•
Crimson Chat	*Epthianura tricolor*			•	•	•		•	•			•	•		•
Black Honeyeater	*Sugomel niger*			•	•			•	•	•		•			
Brown Honeyeater	*Lichmera indistincta*			•	•	•		•	•	•	•	•	•		•
Black-chinned Honeyeater	*Melithreptus gularis*			•	•			•	•	•		•	•		•
Pomatostomidae															
Grey-crowned Babbler	*Pomatostomus temporalis*			•	•	•		•	•	•	•	•	•		•
White-browed Babbler	*Pomatostomus superciliosus*			•	•		•		•			•			
Eupetidae															
Chestnut-breasted Quail-thrush	*Cinclosoma castaneothorax*			•	•		•		•						
Chiming Wedgebill	*Psophodes occidentalis*			•	•										
Neosittidae															
Varied Sittella	*Daphoenositta chrysoptera*				•		•	•	•	•					
Campephagidae															
Ground Cuckoo-shrike	*Coracina maxima*			•					•			•	•		
Black-faced Cuckoo-shrike	*Coracina novaehollandiae*			•	•	•	•	•	•	•	•	•	•		•
White-winged Triller	*Lalage sueurii*			•	•	•		•	•	•		•	•		•
Pachycephalidae															
Rufous Whistler	*Pachycephala rufiventris*			•	•	•	•	•	•	•	•	•	•		•
Grey Shrike-thrush	*Colluricincla harmonica*			•	•	•	•	•	•	•	•	•	•		•
Crested Bellbird	*Oreoica gutturalis*			•	•	•	•	•	•	•	•	•	•		•
Artamidae															
Masked Woodswallow	*Artamus personatus*			•	•	•			•		•	•	•		•
Black-faced Woodswallow	*Artamus cinereus*			•	•			•	•	•	•	•	•		•
Little Woodswallow	*Artamus minor*			•	•			•		•	•	•	•		•
Grey Butcherbird	*Cracticus torquatus*			•	•	•	•	•	•	•	•	•			•
Pied Butcherbird	*Cracticus nigrogularis*			•	•	•	•	•	•	•	•	•	•		•
Australian Magpie	*Cracticus tibicen*			•	•	•	•	•	•	•	•	•	•		•
Grey Currawong	*Strepera versicolor*						•								
Rhipiduridae															
Grey Fantail	*Rhipidura albiscapa*			•	•		•	•	•	•	•	•	•		
Willie Wagtail	*Rhipidura leucophrys*			•	•	•		•	•	•	•	•	•		•
Corvidae															
Australian Raven	*Corvus coronoides*						•						•		
Little Crow	*Corvus bennetti*			•	•				•		•	•			
Torresian Crow	*Corvus orru*			•	•	•		•	•		•	•	•	•	•
Monarchidae															
Magpie-lark	*Grallina cyanoleuca*			•	•	•		•	•	•	•	•	•		•

Petroicidae															
Red-capped Robin	*Petroica goodenovii*			•	•	•	•	•	•	•	•	•	•		•
Hooded Robin	*Melanodryas cucullata*			•	•	•		•	•	•	•	•	•		•
Western Yellow Robin	*Eopsaltria griseogularis*						•								
Alaudidae															
Horsfield's Bushlark	*Mirafra javanica*			•	•								•		•
Acrocephalidae															
Australian Reed-Warbler	*Acrocephalus australis*			•	•			•					•		•
Megaluridae															
Rufous Songlark	*Cincloramphus mathewsi*			•	•	•		•	•	•	•	•	•		•
Brown Songlark	*Cincloramphus cruralis*			•	•			•	•			•	•		
Spinifexbird	*Eremiornis carteri*			•	•			•	•	•		•	•		•
Hirundinidae															
White-backed Swallow	*Cheramoeca leucosterna*														•
Welcome Swallow	*Hirundo neoxena*				•										
Fairy Martin	*Petrochelidon ariel*			•	•			•		•		•	•		
Tree Martin	*Petrochelidon nigricans*			•	•	•		•	•	•	•	•	•		•
Nectariniidae															
Mistletoebird	*Dicaeum hirundinaceum*			•	•	•	•	•	•	•	•	•			•
Estrildidae															
Zebra Finch	*Taeniopygia guttata*			•	•	•		•	•	•	•	•	•		•
Star Finch	*Neochmia ruficauda*	P4		•	•			•			•				•
Painted Finch	*Emblema pictum*			•	•	•		•	•	•	•	•	•		•
Motacillidae															
Australasian Pipit	*Anthus novaeseelandiae*			•	•	•		•	•				•

[1] For NatureMap's purposes, species flagged as endemic are those whose records are wholely contained within the search area. Note that only those records complying with the search criterion are included in the calculation. For example, if you limit records to those from a specific datasource, only records from that datasource are used to determine if a species is restricted to the query area.

Conservation Codes
T - Rare or likely to become extinct
X - Presumed extinct
IA - Protected under international agreement
S - Other specially protected fauna
1 - Priority 1
2 - Priority 2
3 - Priority 3

Name ID	Species Name	Naturalised	Conservation Code	[1]Endemic To Query Area

4 - Priority 4
5 - Priority 5

[1] For NatureMap's purposes, species flagged as endemic are those whose records are wholely contained within the search area. Note that only those records complying with the search criterion are included in the calculation. For example, if you limit records to those from a specific datasource, only records from that datasource are used to determine if a species is restricted to the query area.

Australian Government

Department of the Environment

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 31/10/14 11:54:24

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Areas:	None
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	8
Listed Migratory Species:	6

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place and the heritage values of a place on the Register of the National Estate.

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	6
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Commonwealth Reserves Marine	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

Place on the RNE:	1
State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	10
Nationally Important Wetlands:	1
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Listed Threatened Species		[Resource Information]
Name	Status	Type of Presence
Birds		
Pezoporus occidentalis Night Parrot [59350]	Endangered	Species or species habitat likely to occur within area
Rostratula australis Australian Painted Snipe [77037]	Endangered	Species or species habitat may occur within area
Mammals		
Dasyurus hallucatus Northern Quoll [331]	Endangered	Species or species habitat likely to occur within area
Macrotis lagotis Greater Bilby [282]	Vulnerable	Species or species habitat likely to occur within area
Notoryctes caurinus Kakarratul, Northern Marsupial Mole [295]	Endangered	Species or species habitat likely to occur within area
Rhinonicteris aurantia (Pilbara form) Pilbara Leaf-nosed Bat [82790]	Vulnerable	Species or species habitat known to occur within area
Plants		
Lepidium catapycnon Hamersley Lepidium, Hamersley Catapycnon [9397]	Vulnerable	Species or species habitat likely to occur within area
Reptiles		
Liasis olivaceus barroni Olive Python (Pilbara subspecies) [66699]	Vulnerable	Species or species habitat known to occur within area

Listed Migratory Species		[Resource Information]
* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.		
Name	Threatened	Type of Presence
Migratory Marine Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Migratory Wetlands Species		
Ardea alba Great Egret, White Egret [59541]		Species or species habitat known to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat likely to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species		[Resource Information]
* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.		
Name	Threatened	Type of Presence
Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba Great Egret, White Egret [59541]		Species or species habitat known to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat likely to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat may occur within area

Extra Information

Places on the RNE [Resource Information]

Note that not all Indigenous sites may be listed.

Name	State	Status
Natural		
Fortescue Marshes	WA	Indicative Place

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Mammals		
Camelus dromedarius Dromedary, Camel [7]		Species or species habitat likely to occur within area
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Equus asinus Donkey, Ass [4]		Species or species habitat likely to occur within area
Equus caballus Horse [5]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		

Name	Status	Type of Presence
Cenchrus ciliaris		
Buffel-grass, Black Buffel-grass [20213]		Species or species habitat likely to occur within area
Parkinsonia aculeata		
Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area

Nationally Important Wetlands [Resource Information]

Name	State
Fortescue Marshes	WA

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World Heritage and Register of National Estate properties, Wetlands of International Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

For species where the distributions are well known, maps are digitised from sources such as recovery plans and detailed habitat studies. Where appropriate, core breeding, foraging and roosting areas are indicated under 'type of presence'. For species whose distributions are less well known, point locations are collated from government wildlife authorities, museums, and non-government organisations; bioclimatic distribution models are generated and these validated by experts. In some cases, the distribution maps are based solely on expert knowledge.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Acknowledgements

This database has been compiled from a range of data sources. The department acknowledges the following custodians who have contributed valuable data and advice:

-Department of Environment, Climate Change and Water, New South Wales
-Department of Sustainability and Environment, Victoria

Document Revision History

Date	Issue	Revision History
2 April 2014	Issue A	Initial draft prepared for Biota
3 April 2014	Issue B	Draft B with initial comments added

Summary
Microbat species presence, with an estimate of activity level, is presented for eight recording nights at Yandicoogina in the Pilbara, WA. Biota Environmental Sciences carried out an echolocation based survey during March 2014. Bat Call WA has reviewed the recordings made and provided species lists for the bats present.

Seven species of echolocating microbats were recorded including rare *Chalinolobus morio*. No Orange Leaf-nosed Bat, Pilbara form (*Rhinonicteris aurantia*) or Ghost Bat (*Macroderma gigas*) calls were detected.

Habitats
Four sites for the survey were chosen by Biota. Details of the sites are presented in Table 1. Three are along the Weeli Wolli Creek riparian zone and the fourth is on Marillana Creek a short distance upstream. The locations of the sites are shown in relation to the locality's features in Figure 1.

Characteristics of the calls recorded are presented in Table 2.

Bat Fauna
A microbat assemblage of seven insectivorous species was confirmed as present at the study sites, Tables 2 and 3. Each of the insectivorous species is has previously been detected along Weeli Wolli Creek. *Chalinolobus morio* is known from this locality and upstream on both Weeli Wolli and Marillana Creeks.

Species activity levels were low to high, which is expected for the study area habitat and the time of year, see criteria below.

Survey Timing, Moon Phase and Weather
The echolocation survey was conducted between 13th and 17th March 2014. Sampling evenings were warm and mostly dry with minimum overnight temperatures around 25^{O}C. Some rain fell on the night of the 16th. The moon in this period was full. These conditions correspond to typical levels of bat echolocation detection for the season.

Survey Team
A team of Biota ecologists conducted the bat sampling work. Bob Bullen of Bat Call WA completed analysis of echolocation recordings.

Sampling
The survey consisted of completing a total of eight overnight bat sound recordings, beginning at twilight, at four locations within the survey area. The recordings were "continuous" (Hyder *et al.* 2010) made using a SM2BAT SongMeter (Wildlife Acoustics Inc, USA). The jumper and audio settings used for the SM2BAT followed the manufacturer's recommendations for bat detection contained in the user manual (Wildlife Acoustics 2010). Selectable filters and triggers were also set using the manufacturer's recommendations, see also Table 4. Table 2 provides details of the methods used by date and site.

For the recordings, once reformatted as .wav files, COOL EDIT 2000 (Now available as AUDITION from Adobe Systems Inc.) was used to display each sequence for identification. Calls were identified manually. Only good quality call sequences were

used. Details of calls analysed are provided in Table 2 as recommended by Australasian Bat Society (ABS 2006). Reference data for the species identified are available in Bullen and McKenzie 2002, McKenzie and Bullen 2003 and McKenzie and Bullen 2009.

Bat activity was then characterised as “Low”, “Medium” or “High” based on the rate of call sequences recorded.

- Low species activity is referred when a species is recorded with call spacing less often than ten minutes,
- Medium species activity refers to call recordings more often than 10 minutes but less often than two minutes apart for a at least an hour followed by sporadic records for the remainder of the session.
- High species activity refers to call recording more often than two minutes apart for at least two hours followed by reasonably regular records for the remainder of the session.

Survey Limitations

The sites surveyed were accessible on foot and the SM2, using an omnidirectional microphone, was set on the ground with the microphone horizontal. Species are unlikely to be under-represented as a result.

Bat species density away from cave or adit entrances is impossible to estimate from echolocation records. Bat activity is therefore substituted as an approximate guide to the relative numbers of each species using the study area.

Re. Report on the molecular systematics of Mygalomorphae from Yandi Billiards

Dear Stewart,

Following is a summary of the results for the Yandi Billiards collections. We detected six distinct genetic lineages in two families of Mygalomorphae (Idiopidae, Nemesiidae). The six Mygalomorphae lineages likely represent five putative species, four of which have been detected previously in the Pilbara.

Thank you once again for collaborating on this project with Helix. We hope we can continue to provide you with useful information, and feel free to contact us if you have any questions or would like to discuss the results in detail.

Sincerely,

Dr. Terrie Finston, Yvette Hitchen and Dr. Jason Kennington
Helix Molecular Solutions Pty Ltd

Background
Extensive molecular work has been conducted on the trap-door spider fauna of Western Australia (Helix 2012a). The resulting dataset provides a molecular framework that can be used to provide a regional context for localised sampling.

The present study involved the collection and sequencing of 66 Mygalomorphae specimens from the Yandi Billiards site in order to assess their relationships to the existing sequencing records for more than 2200 specimens from the Pilbara.

The new Yandi Billiards Mygalomorphae sequences were added to the existing sequence dataset to assign specimens to existing lineages and species or to identify new lineages/species.

Executive Summary
- Sixteen specimens from Yandi Billiards were sequenced for COXI.
- A DNA sequence was obtained from all 16 of the specimens.
- Phylogenetic analysis of the 16 new specimens revealed the presence of six distinct genetic lineages (two Idiopidae and four Nemesiidae).
- The six lineages represent five putative species, four of which have been detected previously in the Pilbara.

Methods
The specimens were sequenced and analysed as previously described (Helix 2012b), with the following changes:

In order to reduce analysis time and to simplify the presentation of results, a preliminary neighbour-joining (NJ) tree was constructed from the 16 new sequences in order to identify the number of unique lineages present. Representatives from each lineage were then used in a model-based phylogenetic analysis along with 76 reference specimens of Mygalomorphae as described below.

Model-based phylogenetic analysis was performed using the lineages of Mygalomorphae detected among the new specimens and a sub-set of reference lineages (N=76) that were selected based on the criteria that they showed ≤15% sequence divergence from at least one of the new lineages. The reference lineages represented two families of Mygalomorphae detected in the Pilbara (Idiopidae, Nemesiidae). Lineages detected in the present study were assumed to belong to a previously detected lineage when they shared a single common ancestor, were well-supported by posterior probabilities (≥0.95), and differed from one another by ≤3% sequence divergence.

Results
Preliminary analysis
The NJ analyses placed the 16 new specimens into six distinct genetic lineages (haplotypes or clusters of highly similar haplotypes separated from other such clusters by long branch lengths; Figure 1). The analysis revealed the presence of two lineages of Idiopidae and four lineages of Nemesiidae. The number of individuals in each lineage ranged from 2 to 5 (Figure 1; Table 1).

Mean genetic distances between individuals within the Yandi Billiards lineages detected in the NJ analysis ranged from 0.0 to 1.2% sequence divergence (Table 2). The two lineages of Idiopidae differed from one another by a mean sequence divergence of 13.6% and the four lineages of Nemesiidae differed from one another by between 3.4 and 20.4% mean sequence divergence (Table 3).

Phylogenetic analyses
Model-based phylogenetic analysis was performed using the six lineages detected among the new Yandi Billiards specimens and 76 reference lineages that were ≤ 15% divergent from at least one of the new lineages (Figures 2; 3). The GTR+G model of sequence evolution was used for the Idiopidae tree and the GTR+I+G model was used for the Nemesiidae tree, with the Idiopidae tree running for 1 $\times 10^6$ generations and the Nemesiidae tree running for 25 $\times 10^6$ generations. Specimens were assumed to belong to the same lineage as a reference

specimen when they shared a single common ancestor, were well-supported by posterior probabilities (≥0.95), and differed from one another by ≤3% sequence divergence.

Of the six Mygalomorphae lineages detected in the present study, two (represented by FY9 and FY5) were placed in well-supported lineages that also contained reference specimens, NO and NR, respectively (Figure 3). The remaining four lineages were assumed to represent new lineages, because they showed >3% sequence divergence from the reference specimens (assigned to the new lineages IEF and IEG (Figure 2) and NIB and NIC (Figure 3).

Genetic differentiation between haplotypes and lineages

The two lineages of Idiopidae differed from the reference specimens by between 4.2 and 16.3% sequence divergence (Table 4). In particular, lineage the new Yandi Billiards lineage IEG showed a relatively high similarity to lineage IBL, differing from that lineage by 4.2% sequence divergence (Table 4).

The four lineages of Nemesiidae differed from the reference specimens by between 2.7 and 24.5% sequence divergence (Table 5). In particular, two lineages showed a high genetic similarity to reference lineages. Yandi Billiards lineage NO differed from the reference lineage of NO by 2.7% sequence divergence, and Yandi Billiards lineage NR differed from the reference lineage of NR by 2.7% sequence divergence (Table 7).

Conclusions

Taxonomic implications

The number of lineages and putative species in each family, as assessed using standard methods (Helix, 2012a), may be summarised as follows:

Idiopidae (two lineages, two putative species)

Eight specimens of Idiopidae were sequenced and all were assigned to new lineages (IEF and IEG). The former lineage was assigned to an existing species I53, while the latter was assigned to a new species, I80.

Nemesiidae (four lineages, three putative species)

Eight specimens of Nemesiidae were sequenced, and four of these were assigned to two existing lineages (NO and NR) and species (N42 and N44 respectively). The remaining four specimens were assigned to two new lineages (NIB and NIC). Both new lineages were assigned to the existing species N16.

Distributions of lineages and species

Both of the lineages of Idiopidae detected at Yandi Billiards were new. One of the lineages was assigned to the previously detected species I53, which has been detected at Koodaideri (Table 6). The remaining species of Idiopidae detected at Yandi Billiards (I80) has not been detected previously.

Two (NO and NR) of the four of the lineages of Nemesiidae collected at Yandi Billiards have been detected previously. Lineage NO has been detected at xxx and lineage NR has been detected at xxz. All four lineages were assigned to species that have detected previously in the Pilbara. Species N16 has been detected at 17 sites in the Pilbara (Table 6). Species N42 has been detected at Jinidi to Mainline Rail and Marillana, and species N44 has been detected at Jinidi to Mainline Rail (Table 6).

In summary, six lineages of Mygalomorphae belonging to two families (Idiopidae and Nemesiidae) were detected at Yandi Billiards. These lineages may be grouped into five putative species, four of which have been detected previously at reference sites and one of which is new.

Re. Report on the molecular systematics of Mygalomorphae from Yandi Billiards phase II

Dear Stewart,

Following is a summary of the results for the Yandi Billiards collections from phase II. We detected three distinct genetic lineages in the family Nemesiidae. The three lineages likely represent three putative species, all of which have been detected previously in the Pilbara.

Thank you once again for collaborating on this project with Helix. We hope we can continue to provide you with useful information, and feel free to contact us if you have any questions or would like to discuss the results in detail.

Sincerely,

Dr. Terrie Finston, Yvette Hitchen and Dr. Jason Kennington
Helix Molecular Solutions Pty Ltd

Background
Extensive molecular work has been conducted on the trap-door spider fauna of Western Australia (Helix 2012a). The resulting dataset provides a molecular framework that can be used to provide a regional context for localised sampling.

The present study involved the collection and sequencing of eight additional Mygalomorphae specimens from the Yandi Billiards site in order to assess their relationships to the existing sequencing records for more than 2200 specimens from the Pilbara.

The new Yandi Billiards Mygalomorphae sequences were added to the existing sequence dataset to assign specimens to existing lineages and species or to identify new lineages/species.

Executive Summary
- Eight specimens from Yandi Billiards were sequenced for COXI.
- A DNA sequence was obtained from all eight specimens.
- Phylogenetic analysis of the eight new specimens revealed the presence of three distinct genetic lineages in the family Nemesiidae.
- The three lineages represent three putative species, all of which have been detected previously in the Pilbara.

Methods
The specimens were sequenced and analysed as previously described (Helix 2012b), with the following changes:

In order to reduce analysis time and to simplify the presentation of results, a preliminary neighbour-joining (NJ) tree was constructed from the eight new sequences in order to identify the number of unique lineages present. Representatives from each lineage were then used in a model-based phylogenetic analysis along with 40 reference specimens of Mygalomorphae as described below.

Model-based phylogenetic analysis was performed using the lineages of Mygalomorphae detected among the new specimens and a sub-set of reference lineages (N=40) that were selected based on the criteria that they showed ≤15% sequence divergence from at least one of the new lineages. The reference lineages represented one family of Mygalomorphae detected in the Pilbara (Nemesiidae). Lineages detected in the present study were assumed to belong to a previously detected lineage when they shared a single common ancestor, were well-supported by posterior probabilities (≥0.95), and differed from one another by ≤3% sequence divergence.

Results
A 686 bp fragment of COXI was obtained from all eight specimens.

Preliminary analysis
The NJ analyses placed the eight new specimens into three distinct genetic lineages (haplotypes or clusters of highly similar haplotypes separated from other such clusters by long branch lengths; YB2-1, YB2-2, YB2-3; Figure 1). The number of individuals in each lineage ranged from one to six (Figure 1; Table 1).

Mean genetic distance between individuals within the Yandi Billiards lineage YB2-1 detected in the NJ analysis was 1.2% sequence divergence; the remaining two lineages contained only single individuals (Table 2). The three lineages differed from one another by between 10.8 and 18.7% mean sequence divergence (Table 3).

Phylogenetic analyses
Model-based phylogenetic analysis was performed using the three lineages detected among the new Yandi Billiards phase II specimens and 40 reference lineages that were ≤ 15% divergent from at least one of the new lineages (Figure 2). The GTR+I+G model of sequence evolution was used for the tree, with the tree running for 25 $\times 10^6$ generations. Specimens were assumed to belong to the same lineage as a reference specimen when they shared a single

common ancestor, were well-supported by posterior probabilities (≥0.95), and differed from one another by ≤3% sequence divergence.

All three Mygalomorphae lineages detected in the present study were placed in lineages that also contained reference specimens. Lineage GT4 was placed in a lineage containing reference lineage NO (=species N42), GT5 was placed in a lineage containing reference lineage NAC (=species N1) and GT8 was placed in a lineage containing reference lineage NR (=species N44; Figure 2).

Genetic differentiation between haplotypes and lineages

The three lineages of Nemesiidae differed from the reference specimens by between 1.1 and 24.7% sequence divergence (Table 4). In particular, all three lineages showed high genetic similarities to reference lineages. Yandi Billiards lineage YB2-2 (represented by GT4) differed from the reference lineage NO by 2.2% sequence divergence, Yandi Billiards lineage YB2-3 (GT5) differed from the reference lineage NAC by 1.1% sequence divergence and Yandi Billiards lineage YB2-1 (GT8) differed from the reference lineage NR by 2.2% sequence divergence (Table 4).

Conclusions

Taxonomic implications

The number of lineages and putative species in each family, as assessed using standard methods (Helix, 2012a), may be summarised as follows:

Nemesiidae (three lineages, three putative species)

Eight specimens of Nemesiidae were sequenced, and all were assigned to three existing lineages (NO, NR and NAC) and species (N42, N44 and N1, respectively).

Distributions of lineages and species

All three of the lineages of Nemesiidae collected at Yandi Billiards during phase II have been detected previously in the Pilbara. Both lineages NO and NR have been detected at Jinidi to Mainline Rail and Yandi Billiards phase I, and lineage NAC has been detected at Marillana and Koodaideri. All three lineages were assigned to species that have detected previously in the Pilbara. Species N1 has been detected previously at 14 sites in the Pilbara (Table 5). Species N42 has been detected at Jinidi to Mainline Rail and Marillana as well as previously at Yandi Billiards phase I, and species N44 has been detected at Jinidi to Mainline Rail as well as previously at Yandi Billiards, phase I (Table 5).

In summary, three lineages of Mygalomorphae belonging to the family Nemesiidae were detected at Yandi Billiards during phase II. These lineages may be grouped into three putative species, all of which have been detected previously at reference sites.

REGULATION 17
LICENCE TO TAKE FAUNA FOR SCIENTIFIC PURPOSES

THE UNDERMENTIONED PERSON MAY TAKE FAUNA FOR RESEARCH OR OTHER SCIENTIFIC PURPOSES AND WHERE AUTHORISED, KEEP IT IN CAPTIVITY, SUBJECT TO THE FOLLOWING AND ATTACHED CONDITIONS, WHICH MAY BE ADDED TO, SUSPENDED OR OTHERWISE VARIED AS CONSIDERED FIT.

DIRECTOR GENERAL

CONDITIONS

1 THE LICENSEE SHALL COMPLY WITH THE PROVISIONS OF THE WILDLIFE CONSERVATION ACT AND REGULATIONS AND ANY NOTICES IN FORCE UNDER THIS ACT AND REGULATIONS.

2 UNLESS SPECIFICALLY AUTHORISED IN THE CONDITIONS OF THIS LICENCE OR OTHERWISE IN WRITING BY THE DIRECTOR GENERAL, SPECIES OF FAUNA DECLARED AS LIKELY TO BECOME EXTINCT, RARE OR OTHERWISE IN NEED OF SPECIAL PROTECTION SHALL NOT BE CAPTURED OR OTHERWISE TAKEN.

3 NO FAUNA SHALL BE TAKEN FROM ANY NATURE RESERVE, WILDLIFE SANCTUARY, NATIONAL PARK, MARINE PARK, TIMBER RESERVE OR STATE FOREST WITHOUT PRIOR WRITTEN APPROVAL OF THE DIRECTOR GENERAL. NO FAUNA SHALL BE TAKEN FROM ANY OTHER PUBLIC LAND WITHOUT THE WRITTEN APPROVAL OF THE GOVERNMENT AUTHORITY MANAGING THAT LAND.

4 NO ENTRY OR COLLECTION OF FAUNA TO BE UNDERTAKEN ON ANY PRIVATE PROPERTY OR PASTORAL LEASE WITHOUT THE CONSENT IN WRITING OF THE OWNER OR OCCUPIER, OR FROM ANY ABORIGINAL RESERVE WITHOUT THE WRITTEN APPROVAL OF THE DEPARTMENT OF INDIGENOUS AFFAIRS.

5 NO FAUNA OR THEIR PROGENY SHALL BE RELEASED IN ANY AREA WHERE IT DOES NOT NATURALLY OCCUR, NOR BE HANDED OVER TO ANY OTHER PERSON OR AUTHORITY UNLESS APPROVED BY THE DIRECTOR GENERAL, NOR SHALL THE REMAINS OF SUCH FAUNA BE DISPOSED OF IN SUCH MANNER AS TO CONFUSE THE NATURAL OR PRESENT DAY DISTRIBUTION OF THE SPECIES.

6 THIS LICENCE AND THE WRITTEN PERMISSION REFERRED TO AT CONDITIONS 3 & 4 MUST BE CARRIED BY THE LICENSEE OR AUTHORISED AGENT AT ALL TIMES FOR THE PURPOSE OF PROVING THEIR AUTHORITY TO TAKE FAUNA WHEN QUESTIONED AS TO THEIR RIGHT TO DO SO BY A WILDLIFE OFFICER, ANY OTHER STATE OR LOCAL GOVERNMENT EMPLOYEE OR ANY MEMBER OF THE PUBLIC.

7 **********ANY INTERACTION INVOLVING GAZETTED THREATENED FAUNA THAT MAY BE HARMFUL AND/OR INVASIVE MAY REQUIRE APPROVAL FROM THE DEPT OF SUSTAINABILITY, ENVIRONMENT, WATER, POPULATION & COMMUNITIES PH 02 6274 1111. INTERACTION WITH SUCH SPECIES IS CONTROLLED BY THE COMMONWEALTH GOVERNMENT'S "ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION ACT 1999" & "ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION REGULATIONS 2000" AS WELL AS DPaW'S WILDLIFE CONSERVATION ACT & REGULATIONS.**********

8 NO BIOPROSPECTING INVOLVING THE REMOVAL OF SAMPLE AQUATIC AND TERRESTRIAL ORGANISMS (BOTH FLORA AND FAUNA) FOR CHEMICAL EXTRACTION AND BIOACTIVITY SCREENING IS PERMITTED TO BE CONDUCTED WITHOUT SPECIFIC WRITTEN APPROVAL BY THE DIRECTOR GENERAL OF DPaW.

9 FURTHER CONDITIONS (NUMBERED 1 TO 4) ARE ATTACHED.

PURPOSE LEVEL 2 FAUNA SURVEY BY SYSTEMATIC TRAPPING (ELLIOTT, FUNNEL AND DRY PITFALL TRAPS), TARGETED TRAPPING AND SEARCHES FOR CONSERVATION SIGNIFICANT SPECIES (NORTHERN QUOLL, ORANGE LEAF-NOSED BAT, PILBARA OLIVE PYTHON, NIGHT PARROT, MULGARA), ECHOLOCATION CALL RECORDERS, HARP NETS, REMOTE CAMERAS, AND SHORT RANGE ENDEMIC (SRE) TARGETED SEARCHES, AT THE YANDI BILLIARDS PROJECT AREA 90KM NORTHWEST OF NEWMAN, FOR RIO TINTO PTY LTD.

WILDLIFE CONSERVATION REGULATIONS 1970

Regulation 17:- Licence to Take Fauna for Scientific Purposes

FURTHER CONDITIONS (OF LICENCE NUMBER SF00 9991)

1. The licensee shall take fauna only in the manner stated on the endorsed Regulation 17 licence application form and endorsed related correspondence.

2. Except in the case of approved lethal traps, the licensee shall ensure that measures are taken in the capture and handling of fauna to prevent injury or mortality resulting from that capture or handling. Where traps or other mechanical means or devices are used to capture fauna these shall be deployed so as to prevent exposure of trapped animals to ants and debilitating weather conditions and inspected at regular intervals throughout each day of their use. At the conclusion of research all markers etc and signs erected by the licensee and all traps shall be removed, all pitfalls shall be refilled or capped and the study area returned to the condition it was in prior to the research/capture program. During any break in research, cage traps should be removed and pitfalls either removed, capped or filled with sand.

3. No collecting is to be undertaken in areas where it would impinge on pre-existing scientific research programs.

4. Any form of colour marking of birds or bats shall only be undertaken in accordance with the requirements of the Australian Bird and Bat Banding Scheme.

5. Any inadvertently captured specimen of fauna which is declared as likely to become extinct, rare or otherwise in need of special protection is to be released immediately at the point of capture. Where such a specimen is injured or deceased, the licensee shall contact Department of Parks and Wildlife licensing staff at Kensington (08 9219 9831) for advice on disposal. Records are to be kept of any fauna so captured and details included in the report required under further condition 6 below.

6. Within one month of the expiration of this licence, the holder shall submit an electronic return detailing the locality, site, geocode, date and number of each species captured, sighted or vouchered during the currency of the licence, into the Department of Parks and Wildlife Fauna Survey Database (FSD). A copy of any paper, report or thesis resulting from the research shall on completion be lodged with the Director General. If a renewal of this licence is required, the licensee shall submit a written progress report for activities undertaken during this licence period prior to the expiry of this licence.

7. Not more than ten specimens of any one protected species shall be taken and removed from any location less than 20km apart. Where exceptional circumstances make it necessary to take large series in order to obtain adequate statistical data the collector will proceed with circumspection and justify their actions to the Director General in advance.

8. All holotypes and syntypes and a half share of paratypes of species or subspecies permitted to be permanently taken under this licence shall be donated to the Western Australian Museum. Duplicates (one pair in each case) of any species collected which represents a significant extension of geographic range shall be donated on request to the Western Australian Museum.

9. To prevent any unnecessary collecting in this State, all specimens and material collected under the authority of this license shall, on request, be loaned to the Western Australian Museum. Also, the unused portion or portions of any specimen collected under the authority of this license shall be offered for donation to the Western Australian Museum or made available to other scientific workers if so required.

Appendix 8

Threatened Fauna Statutory Framework

Commonwealth EPBC Act 1999

Fauna species of national environmental significance are listed under the Commonwealth *EPBC Act 1999*, and may be classified as 'critically endangered', 'endangered', 'vulnerable' or 'lower risk', which are consistent with IUCN categories (IUCN 2013).

Critically Endangered (CR): a taxon is Critically Endangered when it is facing an extremely high risk of extinction in the wild in the immediate future.

Endangered (EN): a taxon is Endangered when it is not Critically Endangered but is facing a very high risk of extinction in the wild in the near future.

Vulnerable (VU): a taxon is Vulnerable when it is not Critically Endangered or Endangered but is facing a high risk of extinction in the wild in the medium-term future.

Lower Risk (LR): a taxon is Lower Risk when it has been evaluated, does not satisfy the criteria for any of the categories Critically Endangered, Endangered or Vulnerable. Taxa included in the Lower Risk category can be separated into three subcategories:

1. Conservation Dependent (CD). Taxa which are the focus of a continuing taxon-specific or habitat-specific conservation program targeted towards the taxon in question, the cessation of which would result in the taxon qualifying for one of the threatened categories above within a period of five years.
2. Near Threatened (NT). Taxa which do not qualify for Conservation Dependent, but which are close to qualifying for Vulnerable.
3. Least Concern (LC). Taxa which do not qualify for Conservation Dependent or Near Threatened.

Migratory species are also protected under the *EPBC Act 1999* as species of national environmental significance (DSEWPaC 2013). Migratory species are those animals that migrate to Australia and its external territories, or pass through or over Australian waters during their annual migrations (DSEWPaC 2013). The list of migratory species consists of those species listed under the following international conventions:

1. Convention on the Conservation of Migratory Species of Wild Animals (Bonn Convention);
2. China-Australia Migratory Bird Agreement (CAMBA);
3. Japan-Australia Migratory Bird Agreement (JAMBA); and,
4. Republic of Korea-Australia Migratory Bird Agreement (ROKAMBA).

Western Australian Wildlife Conservation Act 1950

Classification of rare and endangered fauna under the state *Wildlife Conservation (Specially Protected Fauna) Notice 2013* (State of Western Australia 2013), recognises four distinct schedules of taxa:

Schedule 1: taxa that are rare or likely to become extinct and are declared to be fauna in need of special protection.

Schedule 2: taxa that are presumed to be extinct and are declared to be fauna in need of special protection.

Schedule 3: birds that are subject to an agreement between the government of Australia and the governments of Japan, China and the Republic of Korea relating to

the protection of migratory birds, and birds in danger of extinction, which are declared to be fauna in need of special protection.

Schedule 4: taxa that are in need of special protection, otherwise than for the reasons mentioned above in Schedules (1), (2) and (3).

Department of Parks and Wildlife Priority Fauna

In addition, the Department of Parks and Wildlife maintains a list of Priority species that have not been assigned statutory protection under the *Wildlife Conservation Act 1950*. Species on this list are considered to be of conservation priority because there is insufficient information to make an assessment of their conservation status or they are considered to be rare but not threatened and are in need of monitoring. Under this list, species are classified according to five Priority categories:

Priority One: Taxa with few, poorly known populations on threatened lands
Taxa which are known from few specimens or sight records from one or a few localities on lands not managed for conservation, e.g. agricultural or pastoral lands, urban areas, active mineral leases. The taxon needs urgent survey and evaluation of conservation status before consideration can be given to declaration as threatened fauna.

Priority Two: Taxa with few, poorly known populations on conservation lands
Taxa that are known from few specimens or sight records from one or a few localities on lands not under immediate threat of habitat destruction or degradation, e.g. national parks, conservation parks, nature reserves, State forest, unallocated Crown land, water reserves, etc. The taxon needs urgent survey and evaluation of conservation status before consideration can be given to declaration as threatened fauna.

Priority Three: Taxa with several, poorly known populations, some on conservation lands
Taxa that are known from few specimens or sight records from several localities, some of which are on lands not under immediate threat of habitat destruction or degradation. The taxon needs urgent survey and evaluation of conservation status before consideration can be given to declaration as threatened fauna.

Priority Four: Taxa in need of monitoring
Taxa that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and which are considered not currently threatened or in need of special protection, but could be if present circumstances change. These taxa are usually represented on conservation lands.

Priority Five: Taxa in need of monitoring
Taxa that are not considered threatened but are subject to a specific conservation program, the cessation of which would result in the species becoming threatened within five years.

RIO TINTO IRON ORE

BILLIARDS SOUTH PRE-FEASIBILITY STUDY
Review of Surface Water Modelling

Executive Summary

The present study by Rio Tinto has been undertaken to investigate and develop a concept design for a flood protection levee along Weeli Wolli Creek that would enable the recovery of the Billiards South ore deposit. To support this conceptual review a RORB hydrologic model and TUFLOW hydraulic model have been developed. The work undertaken by Rio Tinto has demonstrated that construction of a levee along Weeli Wolli Creek is feasible and the results have been used to inform the levee design. The RORB and TUFLOW flood modelling results have also been used to inform an ecohydrology study to identify the likely changes to surface water flow regime and the effects on riparian vegetation along Weeli Wolli Creek as a result of development of the Pocket and Billiard South deposits within the Yandicoogina mine.

The results of this peer review indicate suggest that:

- The RORB modelling undertaken is fit for purpose.
- Although some minor improvements can be made to the TUFLOW flood model, the modelling undertaken and results are also considered fit for purpose.

The recommended improvements presented in this report should be implemented during the next phase of the Project to further develop the levee design in more detail.

Disclaimer

This report has been prepared on behalf of and for the exclusive use of Rio Tinto Iron Ore, and is subject to and issued in accordance with the agreement between Rio Tinto Iron Ore and WorleyParsons. APPENDIX A LiDAR METADATA REPORT

APPENDIX B SITE INSPECTION PHOTOGRAPHS

1. INTRODUCTION

Rio Tinto's Yandicoogina Operation is located approximately 80 km northwest of Newman near the intersection of Marillana Creek, Phil's Creek, Yandicoogina Creek and Weeli Wolli Creek (*refer* **Figure 1.1**). The Billiard South Deposit, which incorporates the Pocket Deposit, runs parallel to Weeli Wolli Creek upstream of its confluence with Marillana Creek. Some sections of the deposit also intersect Weeli Wolli Creek itself.

Although the extent of mining will be constrained by the natural flood extent, development of the deposit will have some impact on the riparian zone and has the potential to encroach into the floodplain of the Weeli Wolli Creek if flood protection infrastructure is provided.

A Flood Study has been undertaken by Rio Tinto as part of the Pre-Feasibility Phase of the Project to characterise both the pre-development and proposed operational flow conditions for Weeli Wolli Creek. The Flood Study is based on the results of hydrologic modelling of catchment runoff using RORB and hydrodynamic modelling of flood conditions using the TUFLOW software package. Results from the TUFLOW modelling have been used to assist in the design a flood protection levee for the Pocket and Billiard South Operations. The results have also been used to inform an ecohydrology study which is aimed at identifying the likely changes to surface water flow regime and the effects on riparian vegetation along Weeli Wolli Creek as a result of development of the Pocket and Billiard South deposits.

An independent review of the RORB and TUFLOW flood modelling has been requested due to the location of the proposed development within the floodplain and the potential risks associated with the flooding of Weeli Wolli Creek. This report documents the outcomes of a review of the RORB and TUFLOW flood modelling undertaken by Rio Tinto.

2. PREVIOUS INVESTIGATIONS

A number of previous studies have been undertaken that relate to management of water and the environment in Weeli Wolli Creek, Marillana Creek and Yandicoogina Creeks as a result of the nearby mining operations. The most relevant of these, and the subject of this review, are:

- *'Weeli Wolli Creek Ecohydrology - Yandicoogina Pocket and Billiard South Pre-Feasability Study'* (*Rio Tinto, 2015*); and,
- *'Weeli Wolli Creek Hydrology and Floodplain Assessment - Yandicoogina Billiard South Order of Magnitude Study'* (*Rio Tinto, 2013*).

A number of other hydrologic and hydraulic modelling investigations have also been carried out in the vicinity of the site. Each of the studies that have involved hydraulic modelling is discussed in the following sections.

2.1 IRON VALLEY PROJECT SURFACE WATER STUDY (URS 2012)

URS was commissioned by Iron Ore Holdings Ltd to undertake a surface water assessment for the Iron Valley Tenement, which is located near to the Billiards Deposit and Weeli Wolli Creek. The purpose of the study was to undertake modelling of the works that would be required to protect the operation of the mine form flooding and stormwater. The investigation involved the development and application of a 2D hydraulic model using the TUFLOW software.

2.2 YANDI SUSTAINING PROJECT DETAILED HYDROLOGY (STORMWATER) STUDY (BG&E 2012)

BG&E Pty Ltd was engaged by Rio Tinto Iron Ore to undertake a detailed stormwater study for the Yandi Sustaining Project. The investigation involved the development of a two-dimensional hydraulic model of Marillana Creek upstream of its confluence with Yandicoogina Creek. The model was developed using MIKE 21 and used a 5 m rectangular grid. The terrain was based on LiDAR data, while surface roughness was delineated from available aerial photography. Structures such as culverts were modelled as linked MIKE 11 1D elements.

2.3 WEELI WOLLI CREEK HYDROLOGY AND FLOODPLAIN ASSESSMENT - YANDICOOGINA BILLIARD SOUTH ORDER OF MAGNITUDE STUDY (RIO TINTO 2013)

This study was undertaken by Rio Tinto to determine the flood extents and hydraulic characteristics of flood flows in the vicinity of the Billiards South Deposit. Options for positioning flood protection levees to enable the recovery of ore from the Billiards South Deposit are discussed. The hydraulic modelling that was developed as part of this investigation is discussed in further detail in **Section 2** of this report.

The modelling undertaken as part of this study led to the identification of recommendations for the location and extent of levees that would be required to protect the mine from flooding.

Three levee options were investigated and are referred to as the Pillar Levee, the Maximum Extraction Levee and the Conservative Extraction Levee. The location and extent of each of the three levee options is shown in **Figure 1.1** and are described as follows:

- The Pillar levee option, which could be constructed in conjunction with either the conservative or the maximum recovery levees to protect the Pocket mining operation on the Western side of the Weeli Wolli Creek floodplain. Depending on the option chosen this levee would have an average height of between 1.3 m and 2.8 m.
- The Conservative Extraction Levee which extends along the eastern side of Weeli Wolli Creek with an average crest height of 3.1 m.
- The Maximum Extraction Levee which facilitates the maximum recovery of the Billiards South ore deposit. This levee would be 4.1 m high on average and would require nearly twice the volume of fill to construct relative to the Conservative Extraction Levee.

In all scenarios an allowance for 0.5 m of freeboard was incorporated into the levee crest height.

2.4 WEELI WOLLI CREEK ECOHYDROLOGY - YANDICOOGINA POCKET AND BILLIARD SOUTH PRE-FEASABILITY STUDY (RIO TINTO 2015)

This pre-feasibility study built on the understanding of the hydrologic and hydraulic processes developed as part of the *'Weeli Wolli Creek hydrology and floodplain assessment - Yandicoogina Billiard South Order of Magnitude Study'* (*Rio Tinto 2013*). It involved more detailed flood modelling to assess each of the three levee options considered by Rio Tinto in its 2013 Report. However, in this phase of investigation, the Pillar Levee is always considered in conjunction with one of the levees on the eastern side of Weeli Wolli Creek.

In this investigation, four options for crossing Weeil Wolli Creek are considered as summarised below:

- The conservative and Pillar Levee with eight 3.6 m diameter pipe culverts in the low flow channel and two 2.1 m diameter pipes in the high flow channel.
- The conservative and Pillar Levee with a 22 m wide 3.6m high box culvert bridge in the low flow channel and two 2.1 m diameter pipes in the high flow channel.
- The maximum recovery and Pillar Levee with eight 3.6 m diameter pipe culverts in the low flow channel.
- The conservative and Pillar Levee with a 22 m wide 3.6m high box culvert bridge in the low flow channel.

In all cases some flow over the road way is intended during flood events.

3. HYDROLOGIC MODELLING

Rio Tinto prepared the study report (RTIO-PDE-0117748_Weeli Wolli Creek hydrology and floodplain assessment) dated 17 December 2013 which documents the outcomes of RORB runoff routing modelling and TUFLOW 2D hydraulic modelling (Rio Tinto, 2013). The modelling was undertaken to define the hydrological regime and natural flow conditions of the creek and to investigate conceptual flood mitigation options to facilitate safe mining of the Billiard South deposits within the Weeli Wolli Creek floodplain.

RORB is considered to be an appropriate software package for modelling flood hydrology as it is event based rather than a continuous simulation model. The RORB runoff routing software was originally developed by Eric Laurensen and Russell Mein at Monash University and is widely used throughout the Australia.

3.1 CATCHMENT AND NETWORK DELINEATION

The Weeli Wolli Creek catchment includes the catchment of Marillana Creek, the main tributary of Weeli Wolli Creek. The GIS-based delineations of the model catchment, its subcatchments and the connecting stream network were checked by comparing them with watersheds and streamlines generated from ASTER digital elevation data. The ASTER GDEM is a product of METI and NASA. **Figure 3.1** shows the modelled subcatchments and stream network overlaid with the ASTER-based subcatchment and streamline delineations. While there were several discrepancies, the most significant were attributed to errors in the ASTER generated delineation and none were considered to be significant in affecting outcomes from the RORB model. **Table 3.1** summarizes the subcatchment comparisons.

The routes of the link-node routing network, representing the dendritic stream flow lines, were also confirmed initially by comparison with the ASTER-based streamlines. Significant discrepancies were verified by reference to Google Earth imagery. All of the significant discrepancies in the network were attributed to lack of channel definition in the ASTER DEM. The network routes used in the model were therefore verified.

In the RORB model network there appeared to be a number of redundant nodes located at subcatchment outlets. While the presence of these subcatchment outlet nodes, where located near the edge of the Billiard deposit, may have provided information on local subcatchment flood flows entering the mine, the redundant nodes higher in the Marillana Creek and Weeli Wolli catchments appeared to add unnecessary complexity to the model. Ultimately, however the presence of these nodes would not adversely affect the results obtained from the model.

The storage characteristics used for the Munjina Claypan could not be verified due to a lack of detailed topographic and definition data available to the reviewer.

Table 3.1 Assessment of Subcatchment Delineation

Sub-catchment	Area (ASTER), km²	Area (Model), km²	%Diff	Comments	Model Status
M01	106.63	105.13	1.4%		OK.
M02	252.30	258.66	2.5%	5.4km² less subcatchment at ASTER watershed.	OK.
M03	242.62	247.35	1.9%	6.9km² extra subcatchment at ASTER watershed.	OK.

WW20	29.71	33.91	12.4%	5.3km² subcatchment correctly included at eastern and southern watershed. 1.1km² subcatchment correctly excluded (refer to WW19)	OK.
WW21	42.00	41.97	0.1%		OK.
TOTALS	3987.5	4006.3	0.5%	Very good overall comparison of catchment areas.	OK.

3.2 MODEL CALIBRATION

The Initial Loss (IL) – Continuing Loss (CL) loss model adopted for calibration is consistent with guidance in Australian Rainfall and Runoff for the Pilbara Region. Calibration was based on a number of observed flood events using gauged streamflow records from Flat Rocks (708001) on Marillana Creek and from Tarina (708013) and Waterloo Bore (708014) on Weeli Wolli Creek. Corresponding rainfall data for those events was obtained from records for Munjina (505004), Flat Rocks (505011), Wonmunna (507012), Tarina (505040) and Waterloo Bore (505041). Rainfall records from Munjina (in the upper reaches of Marillana Creek) and Wonmunna (in the upper reaches of Weeli Wolli Creek) do not appear to have been used in the calibration. Rainfall from the remaining three stations appears to have been distributed to the modelled subcatchments based on Thiessen polygons (Voronoi tessellation) constructed from the gauge locations.

Flood events from 25 February 1995, 8 January 1997, 15 December 1999 and 25 January 2003 were used for model calibration, with a further gauged event from 1 March 2009 used for validation. The estimated annual exceedance probability (AEP) of the floods produced by these events ranged from 50% (1/3/2009 at Flat Rocks gauge) to 1% (12/12/1999 at Tarina gauge).

The four input values used in the RORB calibration process were kc (an empirical coefficient representing the relative delay time of the catchment), m (the reach storage exponent), IL and CL. For this study, a value of 0.8 was adopted for m, in accordance with the recommendations of the RORB User Manual and guidance from Australian Rainfall and Runoff (AR&R).

Examination of the calibration plots presented in the Weeli Wolli Creek hydrology and floodplain assessment report (Rio Tinto, 2013) indicated that the calculated peak flows were well matched with the observed values. Hydrograph shapes generally appeared to be well matched, with consistent trends in both rising and falling legs of the hydrographs at the gauged locations. Times-to-peak was compared well in the modelled results.

Two of the calibration models, chosen arbitrarily, were examined in more detail to test the sensitivity of the calibration to each of the parameters in isolation.

3.2.1 December 1999 Calibration

The December 1999 event at Flat Rocks (10% - 5% AEP) yielded calibration values of 19, 80 and 14.8 for kc, IL and CL respectively. The flow peaks were well-matched with only slight lag in timing of the modelled peak. The model appeared to be relatively insensitive to moderate changes in IL, possibly due to the significant losses and buffering effects of storage upstream at the Munjina Flats. The model appeared responsive to changes in both kc and CL, with the storage exponent m fixed at 0.8. Hydrograph shapes were reasonably consistent with the observed curve at Flat Rocks exhibiting the greater volume.

At Tarina gauge (2% - 1% AEP), the calibrated values were 21, 45 and 11.1 for kc, IL and CL respectively. The magnitude and timing of the flow peaks were well-matched. The model at this site appeared sensitive to changes in kc, less sensitive to IL and very sensitive to changes in CL. Modelled hydrograph shapes and volumes were reasonably consistent.

At Waterloo Bore gauge (5% - 2% AEP) the values were 19, 105 and 5.5. The magnitude and timing of the flow peaks again were well-matched. At this site, the model was sensitive to changes in kc and CL and again appeared less sensitive to IL.

Overall the calibrated hydrographs appeared to be a good match to the observed flows. The parameters kc and CL appeared to have greatest influence on the modelled flows.

3.2.2 February 1995 Flood Calibration

At Flat Rocks (5% - 2% AEP) the calibration yielded values of 9, 20 and 5.2 for kc, IL and CL respectively. The flow peaks were well-matched with only slight lag in timing of the modelled peak.

While the model appeared to be insensitive to IL values below 50mm and only moderately sensitive to kc, it exhibited significant response to changes in CL.

At Tarina gauge (20% AEP), the calibrated values for kc, IL and CL were 28, 70 and 8.7. The magnitude and timing of the flow peaks were well-matched. The model at this site appeared somewhat sensitive to changes in kc, insensitive to IL below 50mm and sensitive to changes in CL. Modelled hydrograph shapes and volumes appeared to be reasonably consistent.

At Waterloo Bore gauge (5% AEP) the values were 21, 54 and 0. The magnitude of the flow peaks again were well-matched, however the observed flows seemed to lag behind the modelled curve. While the rising limbs of the hydrographs were similar, the modelled recession limb occurred more rapidly than the observed resulting in some underestimation of flow volume. At this site, the model appeared to be sensitive to changes to all parameters, kc, IL and CL.

For this event, the calibrated hydrographs appeared to be a reasonable match to the observed flows.

3.2.3 Verification Run

The verification run (1 March 2009 event) using the adopted parameters (based on averages from the various calibration runs) exhibited good agreement between the observed peak flow values and the calculated peak flows at each gauge site. Rate of rise of the main hydrograph peaks were reasonably well approximated and volumes of flow appeared consistent for each gauged site.

3.2.4 Calibration of IL and CL

Rather than using the calibrated values for the loss parameters IL and CL, which were determined from observed storm and flood data, these parameters were recalibrated for design storms events of a range of AEP's. The values of the parameters IL and CL were recalibrated to match the peak flows at the gauge sites with the expected peak flow values determined from annual series flood frequency analysis (FFA) of the observed streamflow datasets.

It was evident that there were no distinct trends the calibrated values of either IL or CL with observed event AEP, so recalibration of these parameters against the FFA expected flow values would appear appropriate to reflect the likely variability of both IL and CL with storm (and hence flood) AEP.

Comparison was made in the Weeli Wolli Creek hydrology and floodplain assessment report (Rio Tinto, 2013) with model results at the gauges determined using the published loss values recommended in AR&R. The report concluded that use of the AR&R values tended to overestimate the flood peaks determined for this catchment. This conclusion is supported on the basis of the FFA results presented figures 8-4 (Flat Rocks), 8-5 (Tarina) and 8-6 (Waterloo Bore) of the report (Rio Tinto, 2013).

Ultimately the ranges of the loss values adopted for the design flood simulations (see Table 8-3 of Rio Tinto, 2013) are reasonably consistent with the ranges of values determined in the calibration of observed events.

3.3 RARE DESIGN FLOOD ESTIMATION

For estimation of rare flood events (0.5 to 0.05% AEP) adoption of areal design rainfalls using the published CRC-FORGE data for Western Australia would appear appropriate, particularly where design durations are 24-hours or longer, as appears to be the case at each of the gauge locations (see Tables 8-3 and 10-3 of Rio Tinto, 2013) and at principal points of interest at Billiard South and the Marillana Creek confluence (see Table 9-1 of Rio Tinto, 2013). The recalibrated loss parameters for the design rare events are substantially lower than those used for the 1% AEP design modelling which is more likely to overestimate than underestimate the resulting flood flows and again is considered to be a reasonable approach for the purposes of design.

4. HYDRAULIC MODELLING

Rio Tinto developed a 2D hydrodynamic model that has been used to assess potential levee options aimed at protecting mining operations associated with the Billiards South Deposit. The hydrodynamic model was developed using the TUFLOW software which is a GIS driven 2D hydraulic modelling package that is widely used within Australia and around the world to simulate flooding. GIS tools are used to process the available base data, such as LiDAR derived terrain information or vegetation mapping, into a model capable of accurately simulating a variety of flood events.

4.1 BASE DATA

The TUFLOW model was developed using LiDAR derived terrain data, vegetation mapping and aerial photography. This data was used in conjunction with ground based survey, site inspections and historic records of previous flood events to create a model capable of reliably simulating flood behaviour along Weeli Wolli Creek and its floodplain.

4.1.1 LiDAR

The LiDAR data used as a basis for the TUFLOW model was captured by Fugro Spatial Solutions Pty Ltd. The data was captured between the 12th December 2011 and the 17th May 2012 by an aircraft flying at approximately 1400 m above ground level. The full metadata report is reproduced in **Appendix A**.

In conjunction with the aerial survey, Fugro Spatial Solutions Pty Ltd collected 57 ground control points, of which 3 points are within the model domain. Comparisons between the LiDAR and the ground control points show the standard deviation of returns is 0.09 m vertically and 0.18 m horizontally. The average vertical deviation is 0.055 m, while the maximum vertical error is +0.143 m. This suggests that there are no systematic errors in the LiDAR data set, and that the LiDAR data provides a reliable representation of the terrain.

However, LiDAR may not always accurately capture features underneath heavy vegetation, in steep or enclosed terrain, or where there may have been buildings or standing water. These features may be of greater hydraulic interest. Due to the location of the ground control points comparisons between ground control points and the terrain surface produced by the LiDAR data do not always give a good indication of the suitability of the data for hydraulic modelling.

A sample of the LiDAR data that has been used to develop the TUFLOW model is shown in **Figure 4.1**. A detailed examination of high resolution contours shows that the creek and overbank floodplain are clearly resolved in the LiDAR data set.

There are some areas where vegetation may be confusing the interpretation of the laser returns, however these areas are limited in extent and do not materially affect the resolution of the waterways or other hydraulic features.

Areas that were covered with water at the time of the data collection would have been filtered from the laser returns, and hence no terrain data is available in these locations. Subsequent processing was undertaken using interpolated data to fill in these areas. However, the waterways were substantially dry during the survey collection, and so there are only limited areas where data is missing for this reason and where interpolation was required.

4.1.2 Aerial Photographs

Aerial photographs were available for use in developing the TUFLOW model. These photos are visible in **Figure 1.1**. A broader scale photograph with a 0.5 m resolution was used to aid model development, together with a photograph extending over the Billiards South Deposit which has a 0.3 m resolution. Metadata is not available to indicate the time or date of capture.

These photographs clearly show features within the Weeli Wolli Creek floodplain. Floodplain features such as vegetation, roads, creeks and waterway extent and structures are all clearly visible across the modelling domain.

4.1.3 Site Inspection

Multiple site inspections were undertaken by Rio Tinto staff in and around the TUFLOW model domain area. Site inspections were undertaken on the following days:

- 24th June 2014
- 25th June 2014
- 2nd July 2014
- 11th July 2014
- 12th July 2014
- 13th November 2014

A range of Site Photos was gathered during the site inspections. Some of these are contained in **Appendix B**, which also includes a map showing the location and orientation of each photo. Most of these photos are concentrated around the Billiards South deposit, and show in channel, overbank and overland floodplain areas. They have been used in conjunction with the aerial photographs, publications documenting floodplain roughness and previous experience to determine appropriate energy loss coefficients for use on the Weeli Wolli Creek floodplain.

4.1.4 Historic Flood Level Information

No historic flood level information is available for Weeli Wolli Creek or its tributaries Marillana Creek or Yandicoogina Creek. It is noted that significant flooding did occur in January 2012, however no flood marks were recorded in the vicinity of the Billiards South Development. Without records of historic floods it is not possible to undertake reliable calibration of the flood model.

4.2 MODEL SETUP

Two versions of the TUFLOW hydraulic model were developed by 2D modelling specialists within Rio Tinto. The model used for the *Weeli Wolli Creek Hydrology and Floodplain Assessment – Yandicoogina Billiard South Order of Magnitude Study*, is based on a 40 m grid. The model was developed using TUFLOW version 2013-12-AC-iDP-w64, which is a double precision, 64 bit version of the software.

A separate a 5 m grid based TUFLOW model was developed for the *Weeli Wolli Creek Ecohydrology - Yandicoogina Pocket and Billiard South Pre-Feasibility Study*. Two versions of the TUFLOW modelling software were used in this study. TUFLOW version 2013-12-AC-iDP-w64 was used where the model includes the crossing of Weeli Wolli Creek. Where the model does not include the creek crossing, version 2013-12-AC-iSP-w64 was used with the GPU solver. The GPU solver operates using a different numerical scheme to the regular version of TUFLOW, and as such has different requirements.

4.2.1 Model Configuration and Parameters

For the most part model parameters have been left as the default values for version 2013-12-AC-iDP-w64. In general, the default values within TUFLOW are set to produce reasonable simulation results, and as such, there is often little reason to vary from these defaults. The default configuration for all TUFLOW settings is documented in BMT WBM (*2010*). However the timestep, cell wet / dry depth and eddy viscosity have all been explicitly set in the set-up file.

The 40 m model time step has been set at 10 seconds, which results in a maximum Courant number of 3.05 for the 0.2% AEP base case simulation. Mass errors are also less than 1% once starting conditions are allowed for. Both of these values are within the guidelines advised by the TUFLOW manual. There is no other evidence of numerical instabilities in the modelling, and hence the selected timestep can be considered appropriate.

The 5 m model time step has been set at 1.25 seconds with the creek crossing, which results in a maximum Courant number of approximately 3.05 as before for the 0.2% AEP base case simulation. Mass errors are also still less than 1% once starting conditions are allowed for, which indicates that the selected time step is appropriate. The versions of the model without the creek crossing have used adaptive timestepping.

The cell wet / dry depth is set at 0.002 m, which is the recommended value for main stream flood simulations, although it is greater than the minimum value of 0.0002 m. As a result cells will drop out of the simulation once the depth of water is less than 0.002 m, and this may contribute to the mass error. However, with the exception of direct rainfall simulations, the default value of 0.002 m is normally appropriate. As stated above the mass balance does not present a concern.

The Smagorinsky turbulence model has been used to simulate the hydrodynamic viscosity. This is a Large Eddy Simulation (LES) turbulence model that is commonly adapted for flood and estuary models, and calculates the effect of eddy viscosity from the local velocity field in the model. The recommended values have been used in the turbulence model, with a constant co-efficient of 0.1 and a Smagorinsky coefficient of 0.2.

Due to the coarse (40 m) grid, the effects of eddy viscosity are not expected to be a major factor in the simulated hydrodynamics. As the Smagorinsky turbulence model calculates the effect of eddy viscosity form the velocity field, there is little reason to change the coefficient from the recommended default values in most circumstances. However, the 40 m grid may be supressing the calculation of viscosity effects.

4.2.2 TUFLOW Model Terrain Resolution

The terrain used by the TUFLOW model is based on the LiDAR data-set discussed in **Section 4.1.1**. TUFLOW samples the terrain at half the grid resolution to allow for cells to be partially blocked. As a 40 m grid has been used, TUFLOW effectively samples the terrain at 20 m intervals. With the 5 m grid the floodplain is sampled at 2.5 m intervals.

Figure 4.2 shows a comparison of the difference in a cross section located across the main channel of Weeli Wolli Creek, as well as a side tributary, near the Pillar Levee. The LiDAR data used to make this cross-section is shown in **Figure 4.1**.

From this comparison it is evident that the 40 m TUFLOW model has not been able to sample the details of the main channel as well as the main channel. The depth of the main channel is reduced, while the channel bank heights and steepness are also reduced. The smaller side tributary is not captured by the TUFLOW model. Flatter overbank areas are however reproduced reasonably well by the TUFLOW model.

As a result of the differences in the terrain between the available LiDAR and the 40 m grid TUFLOW model, the 40 m grid TUFLOW model may not have the ability to accurately capture the impacts on the hydrodynamics of in channel flow as well as the impacts of small features such as road embankments.

However, once flooding covers the floodplain to a substantial depth, the TUFLOW model does captures the flow area available across the entire floodplain.

These issues are addressed with the 5m grid TUFLOW model. **Figure 4.2** shows that most of the detail of the floodplain is captured by the 5 m grid.

4.2.3 Model Representation of Proposed Levees

As 40 m grid resolution TUFLOW model has sampled the terrain on a 20 m interval, it is possible for the simulation grid to sample the terrain either side of narrow structures such as the proposed levees. As a result there are circumstances where the proposed levees may not be properly represented in the model.

In the post development modelling, the levees have been incorporated as 'thin' lines. These lines raise the elevation in a continuous string in a path defined by the line. The crests of the levees have been raised above the simulated terrain by a uniform amount. Inspection of the post-development model shows that there are no gaps where water may flow through the levee.

However, this approach may not capture the side slopes of the levee embankment. The effect of the not fully representing the side slopes of the levees is expected to be minor in terms of its impact on flood levels. However, it may mean that the velocity information extracted from the model is less reliable that desired for use in designing scour protection systems that may be required, especially where high velocity conditions exist. It may be appropriate to refine the model in these areas when and if it is used to provide criteria for levee and scour protection system design.

4.2.4 Model Representation of the Creek Crossing

The crossing of Weeli Wolli Creek has used 1D elements linked to the 2D model domain. This approach allows the energy losses associated with the structure to be carefully controlled. The 1D results show the simulation to be stable, and as such the model is accurately simulating the structures that have been specified.

As the culverts are modelled in 1D, entry and exit losses are assigned to the inlet and outlet of the culverts. A value of 0.5 has been used for the inlet losses, while a value of 1.0 has been assumed for the exit loss. These are typical loss energy loss values and are appropriate in the majority of circumstances.

However, for some inlet and outlet arrangements it is recommended that these losses be adjusted (*Queensland Department of Energy and Water Supply, 2013*). For example, in cases where the pipe inlet protrudes from the embankment, the inlet loss should be increased. In cases where the flow leaving the outlet is constrained, there may be scope to decrease the loss values.

In addition to inlet an outlet losses, TUFLOW applies a contraction coefficient to the pipe or culvert inlets to account for the effects of the vena-contracta. For circular pipes a contraction coefficient of 1.0 has been used. For the box culvert sections a height contraction of 0.6 and a width contraction of 0.9 has been applied. As these are large culverts these values may be more conservative than required.

4.2.5 Boundary Conditions and Model Extent

The location of the boundary conditions is shown in **Figure 4.3**. All inflow boundaries are flow hydrographs exported from RORB, while both of the outflow boundaries are normal depth boundaries where the energy slope has been specified.

The downstream boundaries are located over 10 km from the Billiards South deposit, while the upstream boundary is over 1km from the end of the proposed levee. The two downstream boundaries both contain bends which result in flow running parallel to the boundary for a distance.

The boundaries should be located such that the flow is approximately perpendicular to the boundary. However, in this instance this does not appear to have affected the results at Billiards South.

A plot of the water level profile through the model domain for the 0.5% AEP flood is shown in **Figure 4.4**. The energy slope is approximately equal to the water surface slope, and this is shown to be approximately equal to the bed slope. Such conditions suggest that using a normal depth boundary at the downstream end of the model is appropriate.

The bed slope is uniform throughout the model domain, with a slope of 0.0026. This compares with an energy slope of 0.00286 and 0.00295 used in the model. As the water surface profile is reasonably uniform throughout the model domain, and as the sites of interest are sufficiently far from the downstream boundaries the modelled boundary slopes are reasonable.

Downstream of the Billiards South development there is a proposed Fortescue Metals Group (FMG) development. As part of this development a levee is to be constructed, and this may create a backwater that will affect the Billiards South development. As **Figure 4.4** shows the backwater for the 0.5% AEP does not extend to the Billiards South Levee.

4.2.6 Effect of Grid Resolution

While the initial modelling has been undertaken using a 40 m grid, recent modelling has been conducted using a 5 m grid. The reduction in grid size has resulted in changes to both flood level and flow velocity. This change may be as a result of any or all of the following factors:

- Increased definition of the terrain allowing greater conveyance in the identified water ways and defined flood channels
- Increase in the definition of the terrain effectively increases roughness
- Improved definition of the velocity field affecting the calculation of viscosity effects and allowing the formation of eddies.

The impact on peak flood levels is shown in **Figure 4.5**. The reduction in grid size has resulted in a mean increase of 0.1 m, although the water levels are reduced by up to 0.5 m and are increased by up to 0.5 m. Along the length of the proposed levee (*maximum extraction option*) the peak flood levels are increased by up to 0.1 m. The largest variations are noted where Marillana Creek enters the model domain.

The variations in water level, combined with differences in the terrain used in the simulation, have resulted in areas becoming inundated which were not previously inundated, while some areas which were inundated are now no longer inundated as shown by the yellow and purple mapping in **Figure 4.5**.

The impact that the reduction in grid size has had on velocity is shown in **Figure 4.6**. **Figure 4.6** shows that across the majority of the floodplain the impact on velocity is extremely minor. However, there is a notable change in the vicinity of the main channels.

The standard deviation in velocity as a result of the reduction in grid size is 0.28 m/s, while the maximum change in velocity is 4.1 m/s. Along the levee (*maximum extraction option*), the velocities may be increased by up to 0.7 m/s or reduced by 1.0 m/s as a result of the reduction in grid size.

As the velocity along the levee varies between 1.4 m/s and 4.8 m/s (*Maximum Recovery Levee with Pillar Levee Option*), the variation in velocity associated with the different grid size may alter the type and extent of the scour protection required along the levee embankment. It is recommended that velocity and shear stress criteria adopted for design of the levee and associated scour protection be based on the results of simulations undertaken using the 5 m grid resolution TUFLOW model.

4.2.7 Model Roughness

Model roughness has been determined based on Land Unit Classifications (*Van Vreeswyk et al., 2004*), aerial photographs, and literature (*Arcement & Schneider, 1989*). The roughness distribution is shown in **Figure 4.7**.

The site inspection photographs (*refer* **Appendix B**), along with the aerial photographs show that the creek channel contains only minimal vegetation at the northern portion of the of the model domain where Weeli Wolli Creek flows towards Fortescue Marsh (*refer* **Photo B1).** However the vegetation that is present consists of mature trees that will have a disproportionate effect on flow due to their location and rigidity**.** Further south, nearer the Billiards development area, the creek resembles a pool and riffle system, with gravel bars and some vegetation separating present between pools of standing water. In all instances there is significant vegetation, though not excessively thick, on the creek banks.

The floodplain is covered with vegetation that varies from moderate, which is inclusive of grasses and shrubs but very few trees, to thick with a substantial number of trees (*refer* **Photo B6).** Gulleys and other watercourses attract a greater density of vegetation. Due to the terrain, vegetation in these areas will have a greater influence on flood flows and hence the roughness should be weighted accordingly.

It is understood that the roughness delineation used has been based on vegetation mapping. The use of vegetation mapping has enabled the floodplain roughness to be mapped in detail. Major hydraulic features such as the creek channel, thick overbank and moderate overbank vegetation are all delineated. Graded roads are also included in the roughness distribution used. A small area of the model domain has not been assigned a roughness values, and this area will be assigned a value of 0.045 as this is the default roughness set in this particular model.

However, the roughness does not always follow the patterns of vegetation visible in the aerial photographs. Along the creek channel the creek and immediate overbank areas are commonly covered by the same roughness polygon, which will apply the same roughness to the relatively clear creek channel and relatively heavily vegetated creek banks. In other instances it is apparent that there are flood channels that have been swept clear of vegetation that are included within polygons that correspond to thick vegetation.

Table 4.1 lists the materials roughness values adopted and the apparent conditions that each refers to, based on overlaying the roughness distribution over the aerial photographs (*refer* **Figure 4.7**). Also listed for comparison is the expected range that the roughness co-efficient would fall in for a 2D model from the Australian Rainfall (ARR) and Runoff Project 15 Stage 1 and 2 Draft Report (*Babister & Barton 2012*).

From **Table 4.1** is apparent that in many instances the adopted roughness co-efficients fall below the range recommended by ARR Project 15. The ARR Project 15 Stage 1 and 2 Draft Report does not specify what roughness value should be used for a given set of conditions, but rather, it gives the range of values used by water resources engineers to achieve calibration over a variety of other 2D numerical flood models in Australian catchments.

It is not necessary for the adopted roughness co-effients to fall inside range nominated by ARR in every instance. However any instance where the adopted value does fall outside of the nominated range should be carefully justified. Consideration should be given to other factors which may be altering roughness calibration process, for example, hydrologic factors, the presence or absence of hydraulic structures or changes in the nature and type of vegetation.

For the comparison, the modelling undertaken as part of BG&E (*2012*) applied a roughness co-efficient of 0.08 for densely vegetated areas, 0.06 for moderately vegetated areas, 0.05 for lightly vegetated areas, and 0.04 for cleared areas. As the model domain used in BG&E (*2012*) is located very close to the model domain used by Rio Tinto (*2013*), and both are 2D modelling studies, the roughness values are comparable between the two models. The modelling undertaken in URS (2012) applies a uniform roughness of 0.04 across waterways and the floodplain. However the modelling approach is not comparable as Rio Tinto (*2013*) has delineated the roughness based on the vegetation present while URS (*2012*) have not.

Sensitivity tests with a higher roughness demonstrated that increasing the roughness coefficients do have a significant effect on flood levels. **Figure 4.8** shows the impact that a 20% increase in roughness has on the 0.5% AEP flood levels. Along the length of the proposed levee the water level increased by up 0.4 m. However, the range recommended by ARR is in many instances more than 20% greater, and hence the results of this sensitivity test may understate the effect that a revised roughness will have on flood levels.

Table 4.1 COMPARISON BETWEEN BILLIARDS TUFLOW MODEL AND ARR PROJECT 15 RECOMMENDED RANGE

Roughness co-efficient	TUFLOW Material IDs	Description	ARR Recommended Range
0.022	24	Unsealed Roads	0.02 to 0.03
0.025	16	Non- floodplain areas with some minimal vegetation (grassed)	0.03 to 0.05
0.028	20, 23	Non- floodplain areas with minimal vegetation (grassed)	0.03 to 0.05
0.030	4, 7, 14	Non- floodplain areas with moderate vegetation (shrubs)	0.05 to 0.07
0.032	19	Mine site – roads and materials stockpile (industrial, not conducive to flood conveyance)	0.2 to 0.5
0.035	3, 6, 21	Creek channels and immediate overbank area with vegetation	0.04 to 0.1
0.040	13, 18	Floodplain areas with moderate vegetation (shrubs)	0.05 to 0.07
0.045	2, 9, 25	Floodplain areas with moderate vegetation (shrubs)	0.05 to 0.07
0.047	11, 12	Floodplain areas with thick vegetation (trees)	0.07 to 0.12
0.050	1, 8, 17, 22	Floodplain areas with thick vegetation (trees)	0.07 to 0.12
0.052	10	Floodplain areas with thick vegetation (trees)	0.07 to 0.12
0.055	5	Floodplain areas with thick vegetation (trees)	0.07 to 0.12
0.060	15	Floodplain areas with thick vegetation (trees)	0.07 to 0.12

4.2.8 Hydraulic Structures

The modelling produced by Rio Tinto contained no hydraulic structures such as culverts of bridges. In the base case modelling, there is a road that crosses Weeli Wolli Creek, however **Photo B4** shows this road crossing to be by way of a ford, and as such no hydraulic structure is present.

No structures have been incorporated into the post development modelling either. While it is proposed to construct a crossing of Weeli Wolli Creek to connect to the Existing facilities at the Yandicoogina Mine, the details of this crossing are yet to be determined.

Some sensitivity testing has been undertaken on the effect that the crossing may have on the TUFLOW model results. The potential impacts of the crossing are shown in **Figure 4.9**. The inclusion of the crossing has increased water levels upstream of the bridge by as much as 1.5 m. The extent of the impact is however limited.

4.3 REVIEW OF RESULTS

4.3.1 Flood Level and Velocity

A review of base case results has been carried out, with an example of the velocity and depth shown in **Figure 4.10**. In all cases the results were as expected, with greatest velocities and greatest depths noted in the creek channels.

WaterRide has been used to examine the flows through the model. Hydrographs are consistent with expectations through the model. Some attenuation is noted due to storage effects in in the flood plain; however mass is conserved throughout the model domain.

4.3.2 Impact of the Levees

The impact of the maximum recovery levee and Pillar levee on flood levels during the 0.5% AEP event is shown in **Figure 4.11**. The construction of both levees may increase flood levels by up to 2.4 m. The construction of both levees creates a funnel through which the floodwater is forced.

Due to the effect of funnelling the flow between the levees, velocities are increased by up to 3 m/s in the vicinity of the Billiards development (*refer* **Figure 4.12**). As velocity in this area is between 2 m/s and 3 m/s the effect of the levees has been to double the velocity while also increasing the depth by up to 50%.

As a result, the model will have a greater sensitivity to the effect of roughness. In the St Venant's equations, depth reduces the effect of roughness by the 4/3rd power. Velocity however increases the effect of roughness with the 2nd power. In a natural channel this will result in changes in water level due to variations in roughness that are greater than sensitivity testing on the base case would suggest.

5. CONCLUSIONS

5.1 SUMMARY

The present study by Rio Tinto has been undertaken to investigate and develop a concept design for a flood protection levee along Weeli Wolli Creek that would enable the recovery of the Billiards South ore deposit. A RORB hydrologic model and TUFLOW hydraulic model have been developed to support this conceptual review.

The work undertaken by Rio Tinto has demonstrated that construction of a levee along Weeli Wolli Creek is feasible and the results have been used to inform the levee design. The flood modelling results have also been used to inform an ecohydrology study to identify the likely changes to surface water flow regime and the effects on riparian vegetation along Weeli Wolli Creek as a result of development of the Pocket and Billiard South deposits.

The results of this peer review indicate that although some minor improvements could be made to the flood model(s), the 5 m grid TUFLOW model is considered to be 'fit for purpose'. Furthermore, the results that have been derived from the modelling are considered to provide a reliable representation of flow conditions during major flooding of Weeli Wolli Creek, and are therefore suitable for the assessment of environmental impacts and for use in the development of concept designs for the proposed flood protection levee. The minor improvements to the model that are outlined in this report can be implemented during the next phase of the Project to further support the detail design of the levee.

5.2 'FIT FOR PURPOSE' ASSESSMENT OF TUFLOW MODEL

5.2.1 Model Set-up

A peer review of the TUFLOW hydraulic model(s) developed by Rio Tinto has established that the models are based on reliable data. LiDAR terrain data, aerial photographs and site inspection photographs have all been used to assist in developing the TUFLOW model and in the determination of key model parameters such as roughness. Examination of this base data sources it to be of a good quality and to be representative of the Weeli Wolli Creek and its floodplain.

The TUFLOW model that has been developed from these data sources is, for the most part, set up in accordance with the recommendations made by BMT WBM (2010). Where model parameters are unspecified the appropriate TUFLOW default settings are used. Where model parameters have been specified these are within the range expected for a model of this type. While the location of the downstream boundary could be improved this does not have a notable impact on the modelling results at the Billiards South Levee for those design flood scenarios that have been tested.

The original modelling was based on a 40 m grid. This grid resolution compromised the ability of the TUFLOW model to reliably simulate the hydrodynamics in some areas. The 40 m grid did not allow the terrain to be sampled correctly, and as a result the depth of the

main channel that was simulated is less than it should be. However, the development of a finer resolution TUFLOW model based on a 5 m grid addressed this issue.

Sensitivity testing undertaken by Rio Tinto showed that reducing the model resolution from 40 m to 5 m increases peak flood levels throughout the model domain. Along the proposed levee, the reduction in grid size results in an increase in peak 1% AEP flood level of 0.1 m, on average.

Velocities are also changed, with increases of up to 0.7 m/s and decreases of up to 1.0 m/s noted in the vicinity of the Billiards South development. This change in velocity may influence the design of the required scour protection.

Where there is a crossing of the Weeli Wolli Creek included in the model, a linked 1D element has been used. The general arrangement and operation of these structures in the simulation is satisfactory, and can be considered to serve as an accurate representation of the structure that has been specified. However, once further details regarding the specific design of these crossings is known, values for the entry loss, exit loss and flow contraction should be reviewed.

5.2.2 Model Parameters

The model roughness used in TUFLOW can have a significant effect on the flood level results. The roughness used for this project has been assigned on the basis of vegetation mapping, and clearly delineates major features such as the creek channels or pockets of thick vegetation. This is appropriate provided consideration is given to whether the adopted grid resolution suitably “picks-up” vegetation or obstructions that are smaller than the model grid. For example, in the creek channel it is possible that each grid cell has captured part of the creek channel and part of the overbank area. A roughness that accounts for this partial obstruction should be derived.

The method for estimation of roughness coefficients used in this study is based on Arcement & Schneider (*1989*). Arcement & Schneider (*1989*) break down the selection of roughness into the following components:

- A base value for a straight, uniform and smooth channel in natural materials
- A correction for the effect of surface irregularities
- A correction for variations in the size and shape of the channel cross-section or floodplain
- A correction for obstructions in the channel or floodplain
- A correction for the effect of vegetation in the channel or floodplain
- A factor applied for the sinuosity of the channel.

The base roughness values have been determined appropriately from site inspection and the coefficients developed by Arcement & Schenider (*1989*) have been applied. Therefore, roughness parameters adopted in the modelling are considered to be ‘fit for purpose’ for

environmental impact assessment and for the provision of parameters (*e.g., velocity and shear stress*) that will be required to inform the levee design at a pre-feasibility level.

5.3 RECOMMENDATIONS FOR FUTURE STUDIES

It is recommended that the following data be gathered, if available, for use in validating the results of the flood modelling:

- Stream gauging data for Weeli Wolli Creek.
- Available flood level marks from any significant flood events.

If available, this data should be used to validate the flood model for existing scenario conditions.

For future work is recommended that the TUFLOW modelling be modified in the following ways:

(i) All simulations aimed at deriving hydraulic parameters for levee design should be based on application of the 5 m grid TUFLOW model. .

(ii) The downstream boundary conditions should be moved closer to the site of interest to reduce simulation run time.

(iii) The model roughness values should be revisited to ensure alignment with recommendations made in the ARR Project 15 Stage 1 Report and Stage 2 Draft Report, and should be re-assessed for the area within 500 metres of the flood protection levee to ensure the coefficients recommended by Arcement & Schneider (*1989*) have been employed. The levee design should be re-evaluated during the next phase of the project based on the results of this more detailed assessment of roughness values.

(iv) The Creek Crossing should be reviewed and the TUFLOW model updated as required once details of the proposed crossing design are made available.

Processing / Derivation Lineage	**Ground Classifications** Fugro Spatial Solutions Pty Ltd aim is to select those points that are part of a clean ground surface, which might not be 100% of the ground hits. This results in a cleaner dataset, without compromising on terrain detail and accuracy. Ground filtering algorithms, tailored for this project, data type and terrain type, are applied to the full dataset. The ground filtered dataset is then visually checked by an operator, and incorrectly classified data is corrected or the ground filtering algorithm is adjusted and then visually checked. For the verification of the ground classifications, intensity imagery is used as a backdrop image. All data was reviewed for ground classification at level 2 classification. **Classified point cloud las 1.2** A merge of ground and non-ground data, in LAS file format. Ground in class 2 and non ground in class1. Classification 2 for ground has been performed. **Ground in DGN and XYZ** This dataset consists of every point that is part of the classified ground surface. The data is level 2 classified. **Bare Earth DEM in DGN** A 5m DEM has been generated from the LiDAR ground surface. The method of deriving the height for each grid point is by triangulation between the three nearest LiDAR ground points. **Model Keypoints in DGN and XYZ** A resampled ground dataset, consisting of only those points that actually contribute to the shape of the terrain (+/- 15cm), with a minimum point density of 1 point every 10m. **Contours 50cm in DGN** From the model keypoints, triangles are built. At 0.5m intervals in height, points or interpolated points on triangle edges with the same height are connected using smoothed curved lines. The lines for each height interval are then merged to become the final contours. **Note:** Returns on water have not been removed from the (classified) point clouds. Gridded datasets have been interpolated across voids (up to 500m in diameter) caused by either no-return due to water bodies, or removal of buildings, vegetation or other above ground features. Contour datasets are interpolated across voids, and contours across water bodies have not been removed or clipped. All data has been cut into 1km tiles, where the file name prefix corresponds with the Lower Left coordinate of the block.

Limitations of Data	This data has not been field tested for completeness or accuracy.
Conditions of Supply	1. This Metadata file is always to be stored with the unaltered data contained in this volume. 2. Any supplied data is to be used only for the purpose for which it was commissioned and in accordance with the terms of engagement. 3. Use of any supplied data for purposes other than those stated is entirely at the risk of the Client.

1.0 Summary

Rio Tinto's Yandicoogina (Yandi) iron ore project is located approximately 90 km northwest of Newman, in the Pilbara region of Western Australia. Since its construction in 1997, the Yandi project has expanded from the original mine at Junction Central to a number of other developments including Junction South East, Junction South West and Oxbow. Hamersley Iron Pty Ltd – Yandi Pty Ltd (Hamersley Iron) plans to further sustain the operations at Yandi mine. This includes the development of the Channel Iron Deposits at Pocket and Billiard South (PBS), located approximately 7 km east of the existing Yandi mine, and within the existing Yandi Operations development envelope (as per Ministerial Statement 914). The proposed PBS development is being formally assessed under the WA *Environmental Protection Act 1986* at a Public Environmental Review level of assessment.

Biota Environmental Sciences was commissioned in 2014 to integrate the existing vegetation and flora data for the Yandi PBS area into the wider dataset for the broader Yandi locality, to produce a supporting document for the environmental impact assessment of the PBS development. This report documents the combined results of the PBS Level 2 vegetation and flora survey, together with 14 other separate studies located within the Yandi integration development envelope (the 19,351 ha area as per Ministerial Statement 914, which is hereafter referred to as the study area).

Detailed vegetation mapping had already been prepared for over 63% of the study area. Vegetation types described from different surveys were standardised and the mapping was extended over the entire study area in order to produce a single consolidated vegetation map. A total of 30 vegetation types have been described for the study area. These vegetation types are associated with four landscape categories: major creeklines and tributaries; minor creeklines, floodplains and valleys; hills, ridges and breakaways; and plains. Most of the vegetation was in Excellent to Good Condition, except for the creekline and floodplain vegetation; this ranged from Very Good to Very Poor, as some areas were affected by weed invasion and minor disturbance from cattle.

None of the vegetation types observed in the study area represent Threatened Ecological Communities or Priority Ecological Communities. Vegetation similar to that recorded for the study area is well represented in the broader locality. Four riparian vegetation types (C1, C2, C3 and C5) represent good condition riparian vegetation associated with Marillana Creek and Weeli Wolli Creek, which are two of the major ephemeral creek systems in the locality. These vegetation types are considered to be of local conservation significance.

A total of 548 native vascular flora taxa from 173 genera and 53 families have been recorded from the study area to date. This species richness is within the range expected for an area of this size in that locality.

One Threatened species, *Lepidium catapycnon,* was recorded from the study area. A total of 4,211 individuals of this species were recorded from 81 locations, forming 11 separate populations. It occurred on rocky hills and slopes, with the majority of the populations being recorded from vegetation type H1. Additional habitat suitable for *L. catapycnon* occurred in the study area, not all of which has been systematically searched, and it is possible that other populations occur. All hills and slopes of the study area could comprise suitable habitat for *L. catapycnon*, especially areas that have been burnt recently or have a substrate of rocky ironstone shale, however vegetation type H1 remains the most prospective unit for this species. The majority of the proposed PBS development will be located in valleys and drainage areas, rather than on the hills and slopes.

Five Priority flora species were recorded from the study area:

- *Rostellularia adscendens* var. *latifolia* (Priority 3) has been recorded from three locations on a floodplain (vegetation type F1), comprising a total of 13 individuals in two populations. One of these populations (two individuals) has since been cleared.
- *Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3) was recorded from three locations, comprising a total of five individuals in two populations. One population was recorded from the bank of Marillana Creek, which has since been cleared (number of individuals for this population not supplied), and the remaining population was recorded from a rocky ridgeline (vegetation type H5).
- *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) (Priority 3) was recorded from one location on a plain adjacent to Marillana Creek (vegetation type P2). The number of individuals at this location was not recorded.
- *Goodenia nuda* (Priority 4) was recorded from 21 locations on floodplains (vegetation type F1), creeklines (vegetation type C2) and plains (vegetation type P6, P2 and P3), with a total of 154 individuals forming 11 separate populations.
- *Rhynchosia bungarensis* (Priority 4) was recorded from two locations, which represented one population in vegetation type P5. The number of individuals was not recorded, and one of these locations has since been cleared.

One additional Priority flora species, *Stylidium weeliwolli* (Priority 2), may potentially occur in the study area in the wetter areas along Weeli Wolli Creek or Marillana Creek (vegetation type C1). While it has not been recorded from the study area to date, there is a known population 1.3 km west and the suitable habitat in the study area has not been systematically searched through its entirety. As *Stylidium weeliwolli* is a very small annual herb, additional survey effort under optimal conditions would be required to determine whether it is present in the study area.

A total of 36 introduced flora species (weeds) have been recorded from the study area. Weeds were most densely distributed around areas of development and disturbance, and along creeklines and floodplains in the study area. **Argemone ochroleuca* (Mexican Poppy) is the only species listed as a declared pest for WA under the *Biosecurity and Agriculture Management Act 2007*. **Cenchrus ciliaris* (Buffel Grass) was the most prolific weed observed in the study area. This species formed dense populations along sections of creek banks and floodplains, frequently in association with **Cenchrus setiger* (Birdwood Grass). Both **Cenchrus* species are serious environmental weeds.

2.0 Introduction

2.1 Project Background

Hamersley Iron currently operates the Yandi iron ore mine as part of its Pilbara Iron operations. The Yandi mine is situated approximately 90 km northwest of Newman in the Pilbara region of Western Australia (Figure 2.1). Construction of the original Yandi mine, Junction Central (YJC), started in 1997 with the first shipment of ore occurring in 1999. An expansion to existing mining developments was approved in 2005 in the form of Junction South East (JSE). A number of other expansions have subsequently been approved, including at the Junction South West (JSW) and Oxbow deposits (YOX) (Figure 2.1). The Yandi operations have been approved under Ministerial Statement 914 (MS914).

Hamersley Iron plans to further sustain the operations at the Yandi mine. The proposed expansion includes the Channel Iron Deposits at PBS, located approximately 7 km east of the existing Yandi mine within the existing Yandi Operations development envelope (as per MS914; see Figure 2.1). A level 2 vegetation and flora survey has already been completed over the proposed PBS development area (Biota 2014a). The proposed PBS development is now being formally assessed under the WA *Environmental Protection Act 1986* at a Public Environmental Review (PER) level of assessment. In order to assist with the environmental impact assessment (EIA), Biota Environmental Sciences (Biota) was commissioned to integrate the Yandi PBS vegetation and flora surveys into a broader reference framework for the wider locality.

The combined extent of the different mining developments represents the overall Yandi integration development envelope as specified under MS914, which is hereafter referred to as the study area (see Figure 2.1). The study area covers a total of 19,351 ha.

2.2 Purpose and Scope of this Report

This report has been prepared as a supporting document for an EIA of the Yandi PBS development. It consolidates all data from the individual studies completed for various components of the broader Yandi study area into a consistent format, and provides a structured framework and integrated summary of the data from the individual studies. In this form, the entire dataset from the Yandi surveys can be analysed together to provide a more informed view of the botanical values of the overall study area. Consequently, combined records of flora species of conservation significance and the potential impacts of development of the PBS deposits can be placed into a better context to support the forthcoming EIA.

Additionally, vegetation mapping that has been prepared for different parts of the study area at different times and at different scales was reviewed and revised where necessary, so that one consolidated map could be presented for the entire study area. The description of vegetation types in the study area has been strengthened through the analysis of a larger floristic dataset.

The following tasks were specifically required to be completed for this study:

- identification of all relevant surveys completed to date within the integration study area;
- integration, mapping unit standardisation and spatial joining of vegetation mapping completed for the Yandi PBS survey area (Biota 2014a) with existing recent vegetation mapping of the broader Yandi locality;
- examination of older vegetation mapping from the broader Yandi locality to assess whether it could be aligned with the integrated map for the study area;
- specific mapping and area estimates of riparian vegetation types across the entire extent of the study area;

- re-analysis of all flora quadrat data from the PBS survey area and comparison of the wider Yandi locality quadrat dataset with selected data from other sites in the broader subregion to place these floristic groups into better context; and
- collation and updating of all records and mapping of Threatened and Priority flora and introduced flora (weed) populations from the integration study area[1].

[1] The framework for conservation significance ranking of species in Western Australia is provided in Appendix 1.

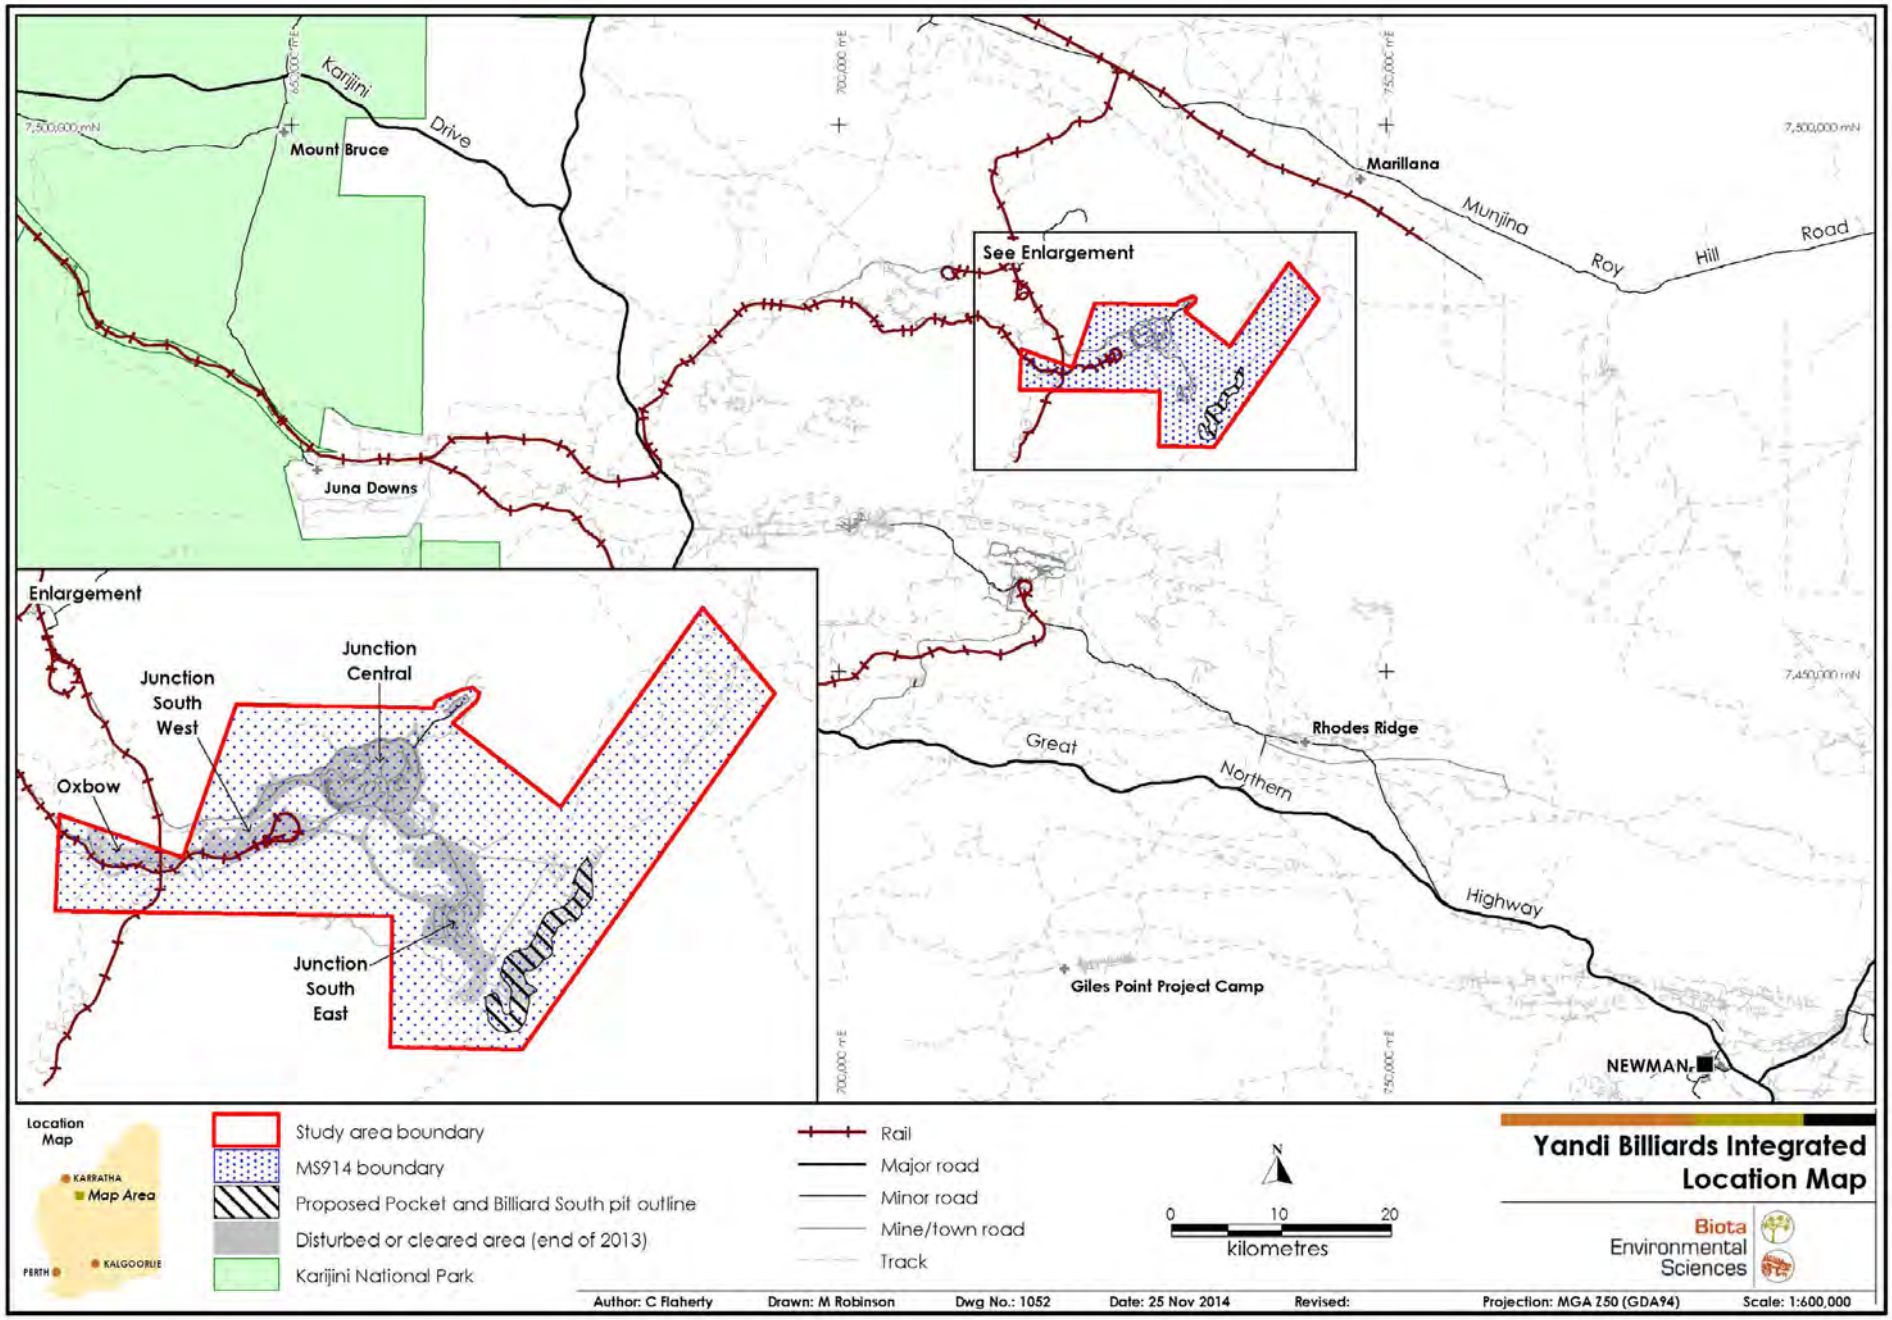

Figure 2.1: Location of the study area and the MS914 boundary.

This page intentionally blank.

3.0 Methodology

3.1 Survey Data Used

The collated Yandi vegetation and flora data used in this report were sourced from 15 separate studies, some of which involved multiple survey phases. The spatial extent of these survey areas is displayed in Figure 3.1. Note that "survey area" has been used to refer to these individual areas within the broader study area.

Table 3.1 provides a brief description of each survey and summarises the data available from each survey that contribute to the overall dataset for the study area. A review of the combined data from these surveys shows that:

- 12,226 ha (63%) of the study area has been subject to detailed vegetation and flora surveys, which have included detailed vegetation mapping and establishment of quadrats[2] and relevés to validate the vegetation types (Biota 2005, 2009a, 2009b, 2010a, 2011a, 2014a, 2014b, 2014c);
- 2,880 ha (15%) of the study area has been subject to historical vegetation and flora surveys, for which vegetation mapping was completed, however the descriptions provided are at a very broad scale and there are no quadrat data available to validate the vegetation types (Mattiske 1995a, 1995b, 1995c);
- 1,533 ha (8%) of the study area remains unsurveyed; and
- 2,711 ha (14%) of the study area is cleared or disturbed[3] (see Figure 3.2).

Some survey areas overlap and in some cases vegetation mapping presented in the individual reports have been updated and integrated in subsequent reports. Where survey areas overlap, the most recent revisions of mapping boundaries are presented. The method of integration of existing data into a consolidated vegetation map of the study area is detailed in Section 3.5.

Details on the individual survey teams and weather conditions are provided in the relevant reports for the surveys listed in Table 3.1. A summary of the survey methods used and the combined sampling effort is provided in Section 3.3.

3.2 Additional Flora Data Sourced for the Study Area

In addition to the vegetation and flora data obtained from the studies outlined in Section 3.1, a search of Rio Tinto's internal flora database was requested for the study area.

Any additional records of introduced flora (weeds) and conservation significant flora from surveys not reviewed in this report (e.g. from non-baseline surveys such as weed monitoring and rare flora clearances) are also listed in this report in order to present a comprehensive and up-to-date record of flora for the study area.

2 Some of which have been seasonally sampled.

3 This estimate was based on the Rio Tinto December 2013 disturbance layer and does not include additional areas mapped as disturbed within individual survey areas, which are included in Section 4.3.

Table 3.1: Summary of Yandi vegetation and flora surveys contributing to the overall Yandi Integration study area dataset.

Study (Reference)	Area Surveyed Within Study Area (Total Area of Survey)	Survey Description Survey Timing (Conditions for Plant Growth[4])	Available Data
Yandi Billiards – Phase 1 and Phase 2 (Yandi PBS) (Biota 2014a)	8,640 ha (8,640 ha)	Two phase (seasonal) vegetation and flora survey of the PBS survey area to expand the existing data for the area to a Level 2 standard. 8 – 20 March 2014 (favourable); 7 – 11 July 2014 and 14 July 2014 (favourable).	• Quadrats/relevés/mapping notes. • Conservation significant flora and weeds. • Detailed vegetation mapping. • Vegetation condition assessment. • Species list.
Yandi JSW/Oxbow Vegetation and Flora Integration Report (Biota 2014b)	2,133 ha (2,192 ha)	Integration of existing data with a further botanical survey to provide additional information on the values associated with the JSW and YOX survey areas. 27 February – 4 March 2012 (favourable).	• Quadrats/relevés/mapping notes. • Conservation significant flora and weeds. • Detailed vegetation mapping. • Vegetation condition assessment. • Species list.
Yandi Additional Areas (Biota 2014c)	2,807 ha (2,828 ha)	Establish additional quadrats to validate vegetation mapping of additional areas around the JSW and YOX deposits to match the project footprint. 12 – 18 June 2012 (favourable).	• Quadrats/relevés/mapping notes. • Conservation significant flora and weeds. • Detailed vegetation mapping. • Vegetation condition assessment. • Species list.
Yandicoogina Additional Vegetation Mapping (Biota 2011a)	2,806 ha (3,030 ha)	Mapping of additional areas around the JSW and YOX deposits to match the project footprint. 29 November – 3 December 2010 (unfavourable).	• Mapping notes. • Detailed vegetation mapping. • Conservation significant flora and weeds. • Vegetation condition assessment. • Species list.
Vegetation and Flora Surveys of the Oxbow and Junction South West Deposits, near Yandicoogina (Biota 2010a)	YOX: 665 ha (725 ha) JSW: 1,460 ha (1,460 ha)	Two phase (seasonal) vegetation and flora survey of the JSW and YOX survey areas. YOX: 27 July-6 August 2008 (unfavourable); 3-9 June 2009 (favourable). JSW: 4 – 16 June 2007 (unfavourable); 27 July – 6 August 2008 (unfavourable); 3 – 9 June 2009 (favourable).	• Quadrats/relevés/mapping notes. • Conservation significant flora and weeds. • Detailed vegetation mapping. • Vegetation condition assessment. • Species list.
A Flora and Vegetation Survey of the Billiards Deposit, near Yandi (Biota 2009a)	1,512 ha (1,512 ha)	Two phase (seasonal) vegetation and flora survey of the Billiards survey area. 11 – 20 June 2007 (unfavourable); 27 July – 6 August 2008 (unfavourable); 3 – 9 June 2009 (favourable).	• Quadrats/relevés/mapping notes. • Weed records. • Detailed vegetation mapping. • Vegetation condition assessment. • Species list.

[4] Determined by assessing the amount of rainfall received prior to the survey dates; listed as "unknown" if rainfall data from Marillana Station (the closest recording station to the study area) were not available for the specific survey period.

Study (Reference)	Area Surveyed Within Study Area (Total Area of Survey)	Survey Description Survey Timing (Conditions for Plant Growth[4])	Available Data
Yandicoogina Waste Dumps, Topsoil Stockpiles and Haulroads Native Vegetation Clearing Permit Report (Biota 2009b)	406 ha (406 ha)	Single phase vegetation and flora survey of four development areas to support a Native Vegetation Clearing Permit. 4 – 7 September 2008 (unfavourable).	• Conservation significant flora records. • Detailed vegetation mapping. • Vegetation condition assessment. • Species list.
Vegetation Mapping and Rare Flora Searches of Yandi Backfill Hill (Biota 2005)	189 ha (189 ha)	Vegetation mapping and systematic rare flora searches of the Yandi Backfill Hill survey area. 31 May – 2 June 2005 (unfavourable)	• Detailed vegetation mapping. • Vegetation condition assessment. • Species list.
Yandi Expansion Vegetation and Flora Survey (Biota 2004a)	2,245 ha (2,245 ha)	Single phase vegetation and flora survey of the Yandi Expansion area, near the YJC deposit. 30 August – 5 September 2004 (unfavourable)	• Quadrats/relevés. • Conservation significant flora and weeds. • Detailed vegetation mapping. • Vegetation condition assessment. • Species list.
Flora and Vegetation Survey of the Hope Downs Rail Corridor Extension through the Hamersley Range (Biota 2004b)	1,492 ha (3,977 ha)	Single phase vegetation and flora survey of the Hope Downs Rail Corridor Extension through the Hamersley Range. April 2003 (favourable)	• Quadrats. • Weed records. • Detailed vegetation mapping. • Species list.
Vegetation and Flora of the Hope Downs Rail Corridor from Port Hedland to Weeli Wolli Creek (Biota 2002)	805 ha (2,774 ha)	Single phase vegetation and flora survey of the Hope Downs Rail Corridor from Port Hedland to Weeli Wolli. 25 April – 14 May 2001 (favourable) 29 May – 10 June 2001 (favourable)	• Quadrats. • Weed records. • Vegetation mapping. • Species list.
Hope Downs Rail Corridors Biological Surveys (Halpern Glick Maunsell 2000a)	2,594 ha (16,420 ha)	Single phase vegetation and flora survey of the Hope Downs Rail Corridors. 25 November – 3 December 1999 (unfavourable)	• Quadrat. • Vegetation mapping. • Species list.
Flora and Vegetation: Yandicoogina Junction Area (Mattiske 1995a)	3,591 ha (3,745 ha)	Single phase vegetation and flora survey of the YJC survey area. January and March 1994 (unknown) February 1995 (unknown)	• Detailed vegetation mapping.
Flora and Vegetation: Northern Transport Corridor, Yandicoogina Junction Project Area (Mattiske 1995b)	3,035 ha (24,703 ha)	Single phase vegetation and flora survey of the Yandi Northern Transport Corridor. February 1995 (unknown)	• Detailed vegetation mapping.
Flora and Vegetation: Southern Transport Corridor, Yandicoogina Junction Project Area (Mattiske 1995c)	2,450 ha (30,103 ha)	Single phase vegetation and flora survey of the Southern Transport Corridor. January and March 1994 (unknown) February 1995 (unknown)	• Detailed vegetation mapping.

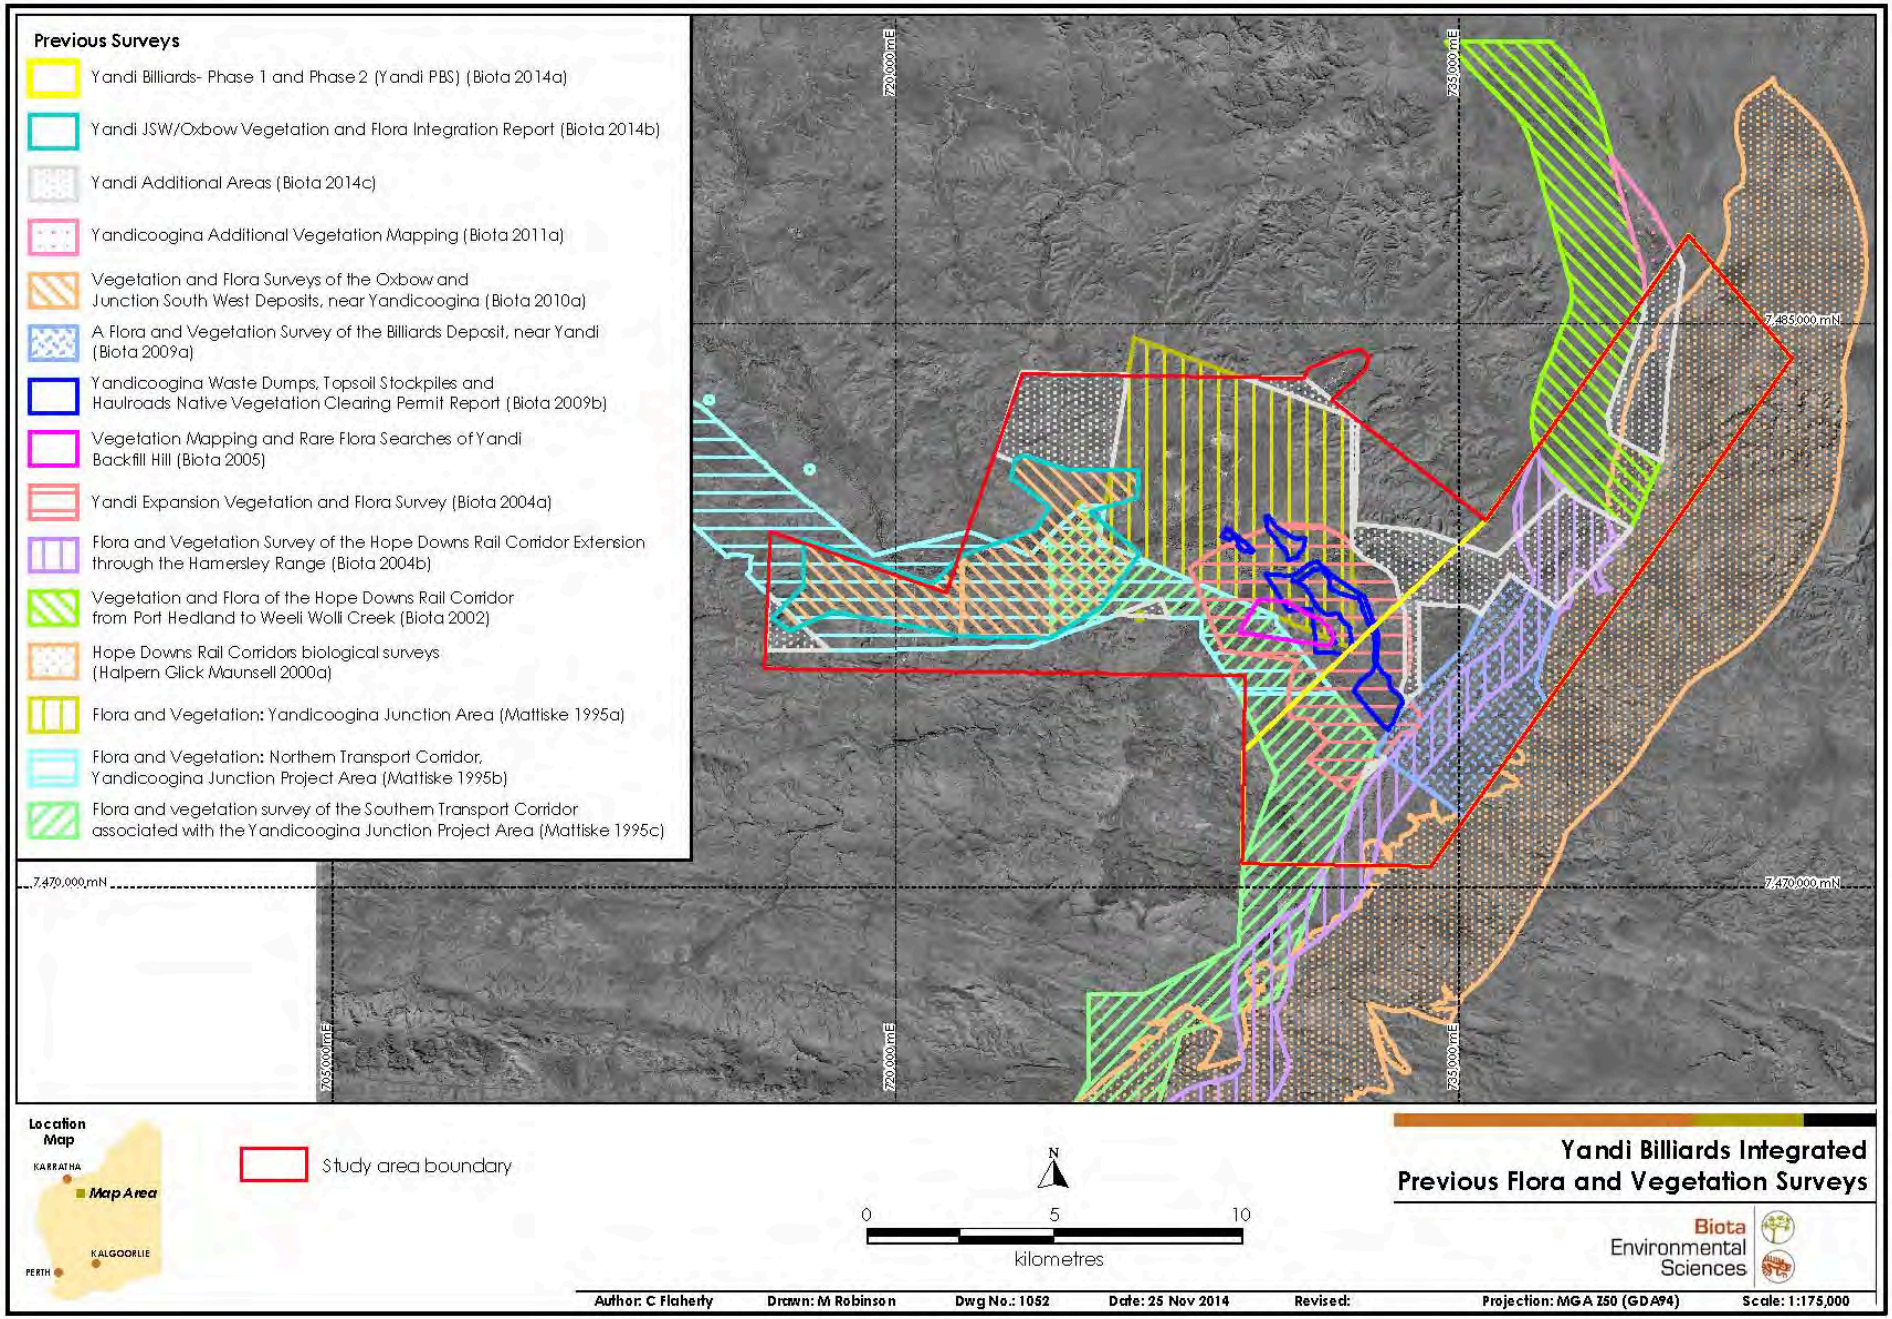

Figure 3.1: Flora and vegetation surveys conducted over the study area.

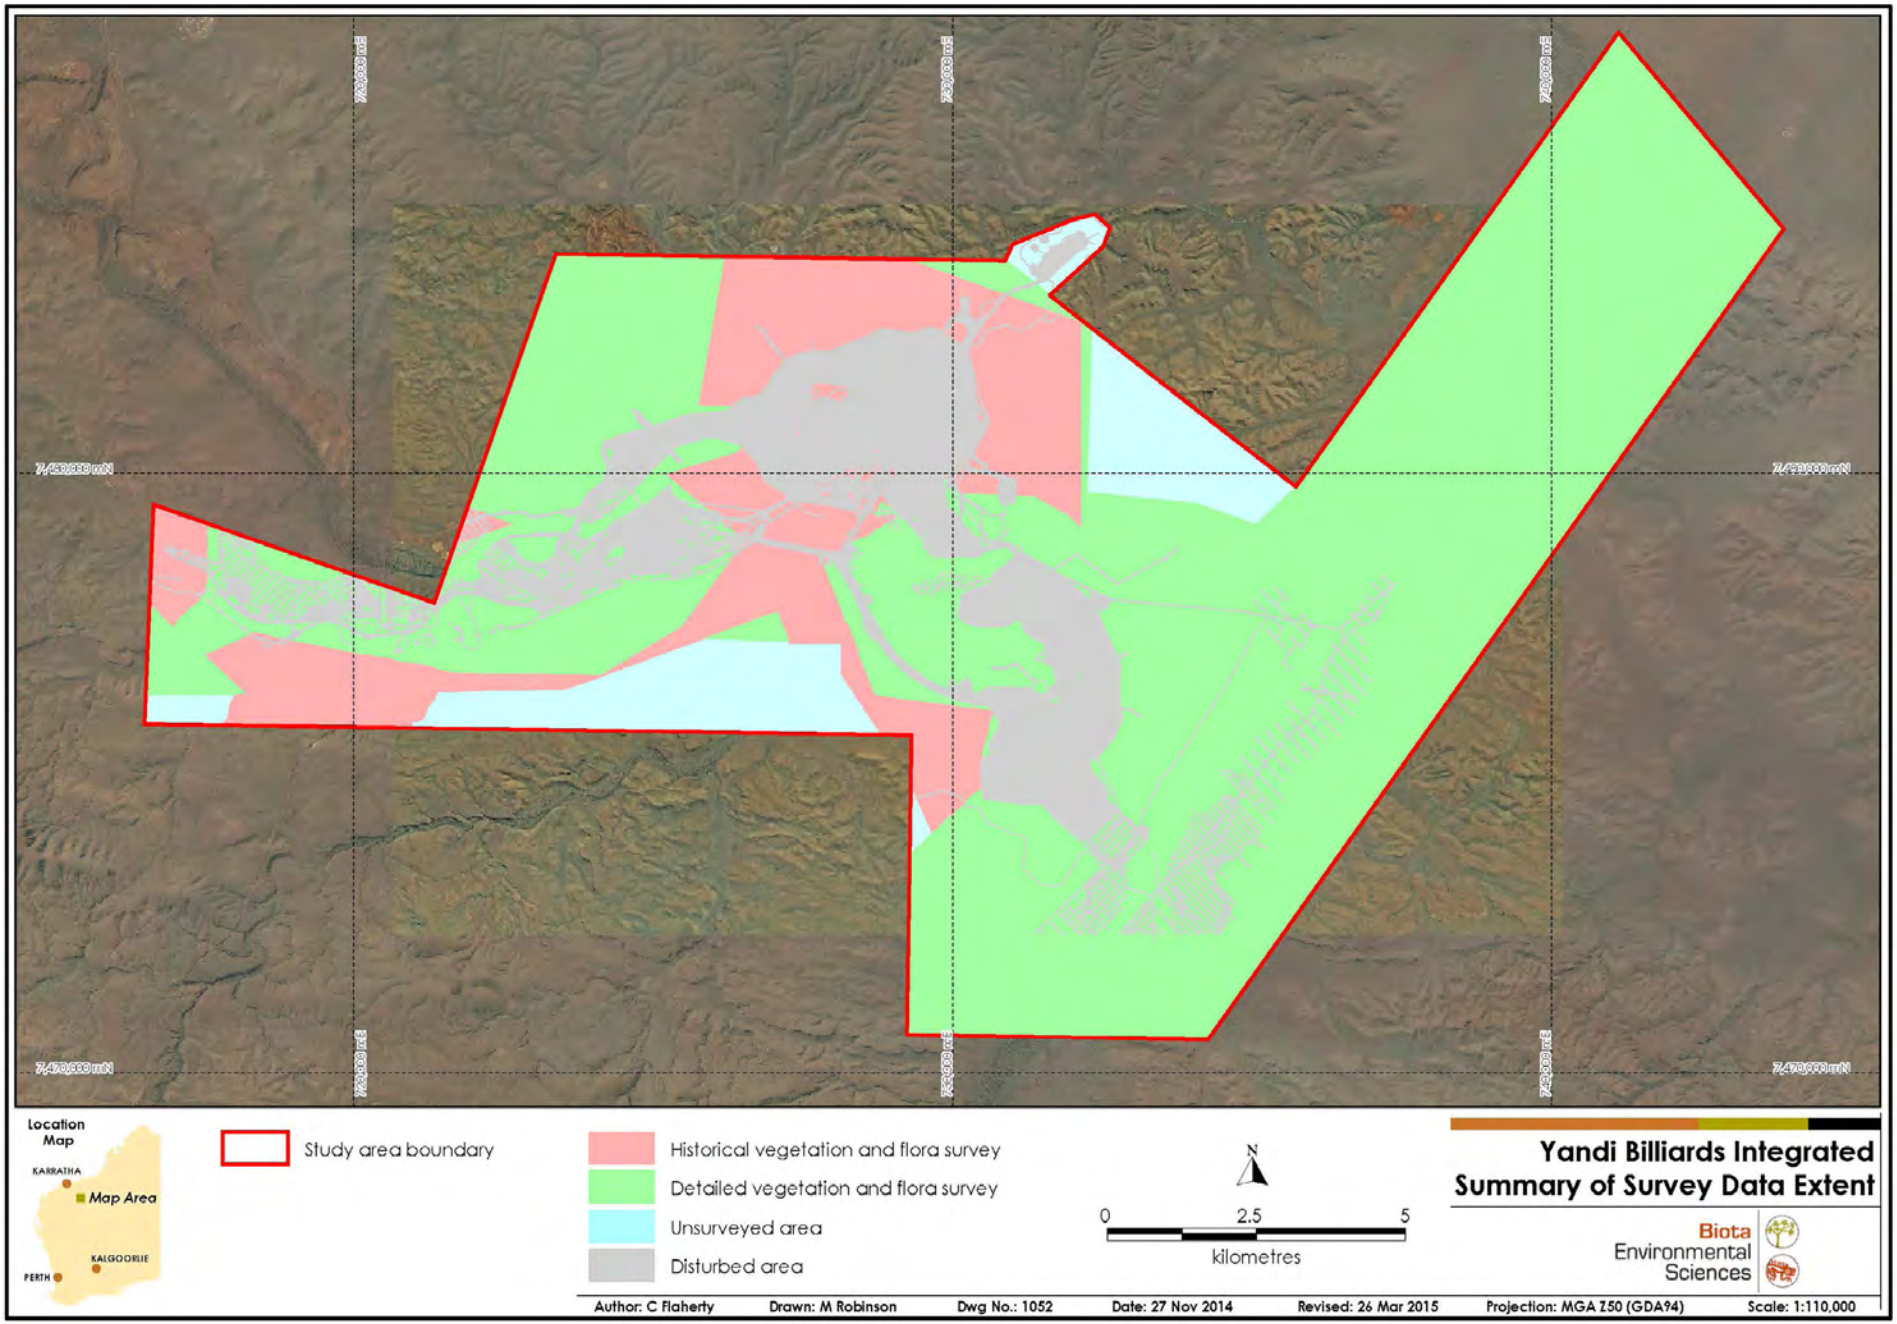

Figure 3.2: Different levels of survey effort across the study area.

3.3 Summary of Survey Methods

The vegetation and flora surveys completed by Biota within the study area used essentially the same sampling methods. This approach comprised a combination of qualitative description and mapping of vegetation types and vegetation condition (Section 3.3.1), systematic sampling of flora using standard floristic survey quadrats (Section 3.3.2), and targeted searches and opportunistic sampling for additional flora, particularly species of conservation significance and weeds (Section 3.3.3).

The field surveys were generally completed in accordance with relevant Environmental Protection Authority (EPA) policies and guidelines, specifically:

- EPA Position Statement No. 3: "*Terrestrial Biological Surveys as an Element of Biodiversity Protection*" (EPA 2002); and
- EPA Guidance Statement No. 51 "*Terrestrial Flora and Vegetation Surveys for Environmental Impact Assessment in Western Australia*" (EPA 2004).

A statement of limitations is provided in Section 3.7.

3.3.1 Vegetation Description and Mapping

Detailed vegetation mapping was completed over nine separate surveys and extends over 12,226 ha (63%) of the study area (see Section 3.1).

Vegetation types identified from aerial photography were ground-truthed during foot traverses in the respective survey areas. The boundaries of the survey area were uploaded onto hand-held Global Positioning System (GPS) units to ensure that the correct areas were traversed. Vegetation descriptions for each vegetation type observed in the field were recorded at all quadrats and relevés (see Section 3.3.2), and also in a series of mapping notes[5]. Typical information recorded at the mapping note locations included notes on the habitat, landscape and vegetation type, usually with a representative photograph and often with opportunistic specimen collections to supplement the species list. Over 600 mapping notes have been made during the recent surveys at Yandi (see Table 3.1 in Section 3.1). Locations of these mapping notes are presented in Figure 3.3.

Vegetation descriptions for the study area were based on the height and estimated cover value of dominant species using Aplin's (1979) modification of the vegetation classification of Specht (1970) (see Appendix 2). Descriptions were made for each vegetation type observed in the field, and vegetation boundaries identified from aerial photography were ground-truthed during foot traverses through the survey area.

The vegetation types were described at the sub-association level (level VI as per the National Vegetation Information System, or NVIS)[6]. The sub-association level includes information about the dominant growth form, height and cover for up to five species in all layers/sub-strata observed (e.g. *Eucalyptus victrix, Corymbia hamersleyana* scattered low trees over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* subsp. *hispidula* tall shrubland over *Tephrosia rosea* low shrubland over *Cymbopogon ambiguus, C. procerus, Eriachne tenuiculmis, Themeda triandra* very open tussock grassland).

Similar vegetation descriptions were grouped to establish the vegetation types for the study area. Vegetation descriptions that shared a suite of perennial species with a similar range of cover values were considered to be alike.

---

5 Mapping notes are sampling sites conducted over an area of smaller scale than a quadrat or relevé; these notes are typically brief, with only dominant and commonly associated species being recorded. Mapping notes are taken primarily during foot traverses of an area, with the objective of detecting boundaries and changes in vegetation types.

6 http://www.environment.gov.au/erin/nvis/publications/avam/section-2-1.html

Two coding systems are presented in this report to refer to the individual vegetation types:

1. An alphabetic code was assigned to represent the dominant flora species from the tallest stratum to the lowest stratum. Each dominant species was given a unique code by using an abbreviation of the genus to capital letter(s) followed by an abbreviation of the species to lower case letter(s) (e.g. EvAciAcMgCEc denotes a vegetation type dominated by *Eucalyptus victrix, Acacia citrinoviridis, Acacia coriacea* subsp*. pendens, Melaleuca glomerata and *Cenchrus ciliaris*). This coding enables vegetation types from different studies to be quickly compared, however it can sometimes result in long and unwieldy codes.
2. To aid interpretation, each vegetation type was also assigned an alpha-numeric code as a unique precursor to the species-driven code (e.g. C3: EvAciAcMgCEc for the third creekline sub-association). This short code is used to refer more simply to the individual vegetation types in this report.

Although some of the vegetation types were first drafted in the field, the majority of the vegetation mapping was completed in the office after the fieldwork was completed. Field data and aerial imagery were studied to determine boundaries of vegetation types, which were then mapped to an appropriate scale. The maps were created and consolidated using GIS software (QGIS and MapInfo), and point locations of sampling sites, conservation significant flora and weeds were added. All maps in this report were produced by Melissa Robinson (Biota) using the MapInfo package (version 11).

Summarised descriptions of the vegetation types are provided in Appendix 3, while their distribution is mapped in Appendix 4.

3.3.2 Establishment and Assessment of Flora Quadrats and Relevés

Permanently marked quadrats (flora sampling sites of a fixed area) were preferentially used as the primary method to gather quantitative data on floristic composition. Most quadrats established were 50 m x 50 m in size. This quadrat area of 2,500 m^2 is recognised as providing an adequate sample of species presence for Pilbara vegetation, and is the standard quadrat size for botanical survey work in the region (Clarke 2009). Where a square quadrat was unsuitable for capturing the vegetation type (e.g. along narrow creeklines), a rectangular quadrat of equivalent area (e.g. 25 m x 100 m) was established instead. In most cases, the quadrats were permanently marked using steel fence droppers on at least three corners. An optical square and measuring tapes were used to accurately position the quadrat boundaries.

In cases where quadrats could not be established (e.g. due to the small size or irregular shape of the habitat), these locations were instead surveyed as relevés. A relevé is an unbounded flora sampling site with a similar area to a standard quadrat; essentially the same information is recorded as for a quadrat, however the sampling of flora is typically not as thorough. Relevé sampling was usually undertaken if the vegetation type had a linear or irregular shape (e.g. along creeklines), making establishment of a standard quadrat in a single vegetation type difficult.

The following information was recorded for each quadrat and relevé (raw data are appended to each of the relevant survey reports):

- Location: Universal Transverse Mercator (UTM) coordinates in WGS84 datum in Zone 50, recorded to an accuracy of typically ±5 m using a handheld GPS unit; coordinates were recorded for all four corners of a quadrat and for the centre point of a relevé;
- Vegetation description: a broad description based on the height and estimated cover value of dominant species (Aplin 1979; see Appendix 2);
- Habitat description: a description of the landform and other relevant habitat details (e.g. aspect);
- Broad soil type: a description of the soil colour, texture and any stony surface mantle;
- Fire history: approximate time since last fire, where applicable;

- Vegetation condition ranking: considering evidence of grazing, physical disturbance, weed invasion etc. (after Trudgen 1988; see Appendix 2);
- The estimated percent foliar cover of each flora species present within the quadrat, or in the vicinity (within a ~30 m radius) of the centre point of the relevé; and
- A colour photograph of each site (usually taken from the northwest corner of a quadrat).

Data are available from a total of 209 quadrats and 35 relevés that have been sampled in the study area. A summary of the quadrats and relevés in the study area is provided in Table 3.2, while their locations are indicated in Figure 3.3 and on the vegetation maps in Appendix 4. Due to the overlap of some of the 15 survey areas, some sampling sites were presented in more than one of the survey reports. Quadrat and relevé numbers in Table 3.2 have been assigned based on the source survey during which each site was initially established. Therefore for some of the surveys, this does not reflect the total number of quadrats that were located within the survey area as described in the original report. Mattiske (1995a, 1995b, 1995c) established a total of 296 sites, however only a subset of these were located within the study area. As no data were provided in the respective reports, these sites have not been considered further in this report.

A subset of 83 quadrats (approximately 40% of the quadrats sampled in the study area) were effectively seasonally sampled; that is, surveyed over two phases, with at least one survey phase completed when conditions were favourable for plant growth (i.e. following adequate rainfall). Some quadrats previously established by Biota (2009a, 2010a) were sampled over two phases, however both seasons were unfavourable for plant growth. These quadrats were not considered as being effectively seasonally sampled, as it is likely that some species would not have been present or identifiable at the time of both survey phases (e.g. annual daisies that would germinate mostly after late winter rains, other herbs, annual grasses, etc.). Some quadrats were established during one survey and resampled during a different survey. The numbers presented in Table 3.2 display the seasonally sampled quadrats in each of the source survey areas, regardless of whether resampling occurred during the source survey or a separate survey.

Thirty-one quadrats and one relevé have subsequently been cleared for mine expansion or establishment of roads or drill tracks (see Section 4.3).

Table 3.2: Total number of quadrats and relevés located in the study area that were established during each survey.

Survey Area (Reference)	Survey Code	Number of Quadrats		Number of Relevés
		Not Seasonally Sampled	Seasonally Sampled	
Yandi Billiards (PBS) (Biota 2014a)	BIL	19	30	7
Yandi JSW/Oxbow Integration (Biota 2014b)	YVI	15	0	1
Yandi Junction South West (Biota 2010a)	YSW	15	4	1
Yandi Oxbow (Biota 2010a)	OXB	0	11	0
Yandi Billiards (Biota 2009a)	YBI	15	21	15
Yandi Additional Areas (Biota 2014c)	YAQ	21	7	5
Yandi Expansion (Biota 2004a)	YEX	33	6	6
Hope Downs Rail Corridor Extension through the Hamersley Range (Biota 2004b)	HDA	6	3	0
Hope Downs Rail Corridor from Port Hedland to Weeli Wolli Creek (Biota 2002)	H	1	1	0
Hope Downs Rail Corridors Biological Surveys (Halpern Glick Maunsell 2000a)	WW	1	0	0
	Total	126	83	35

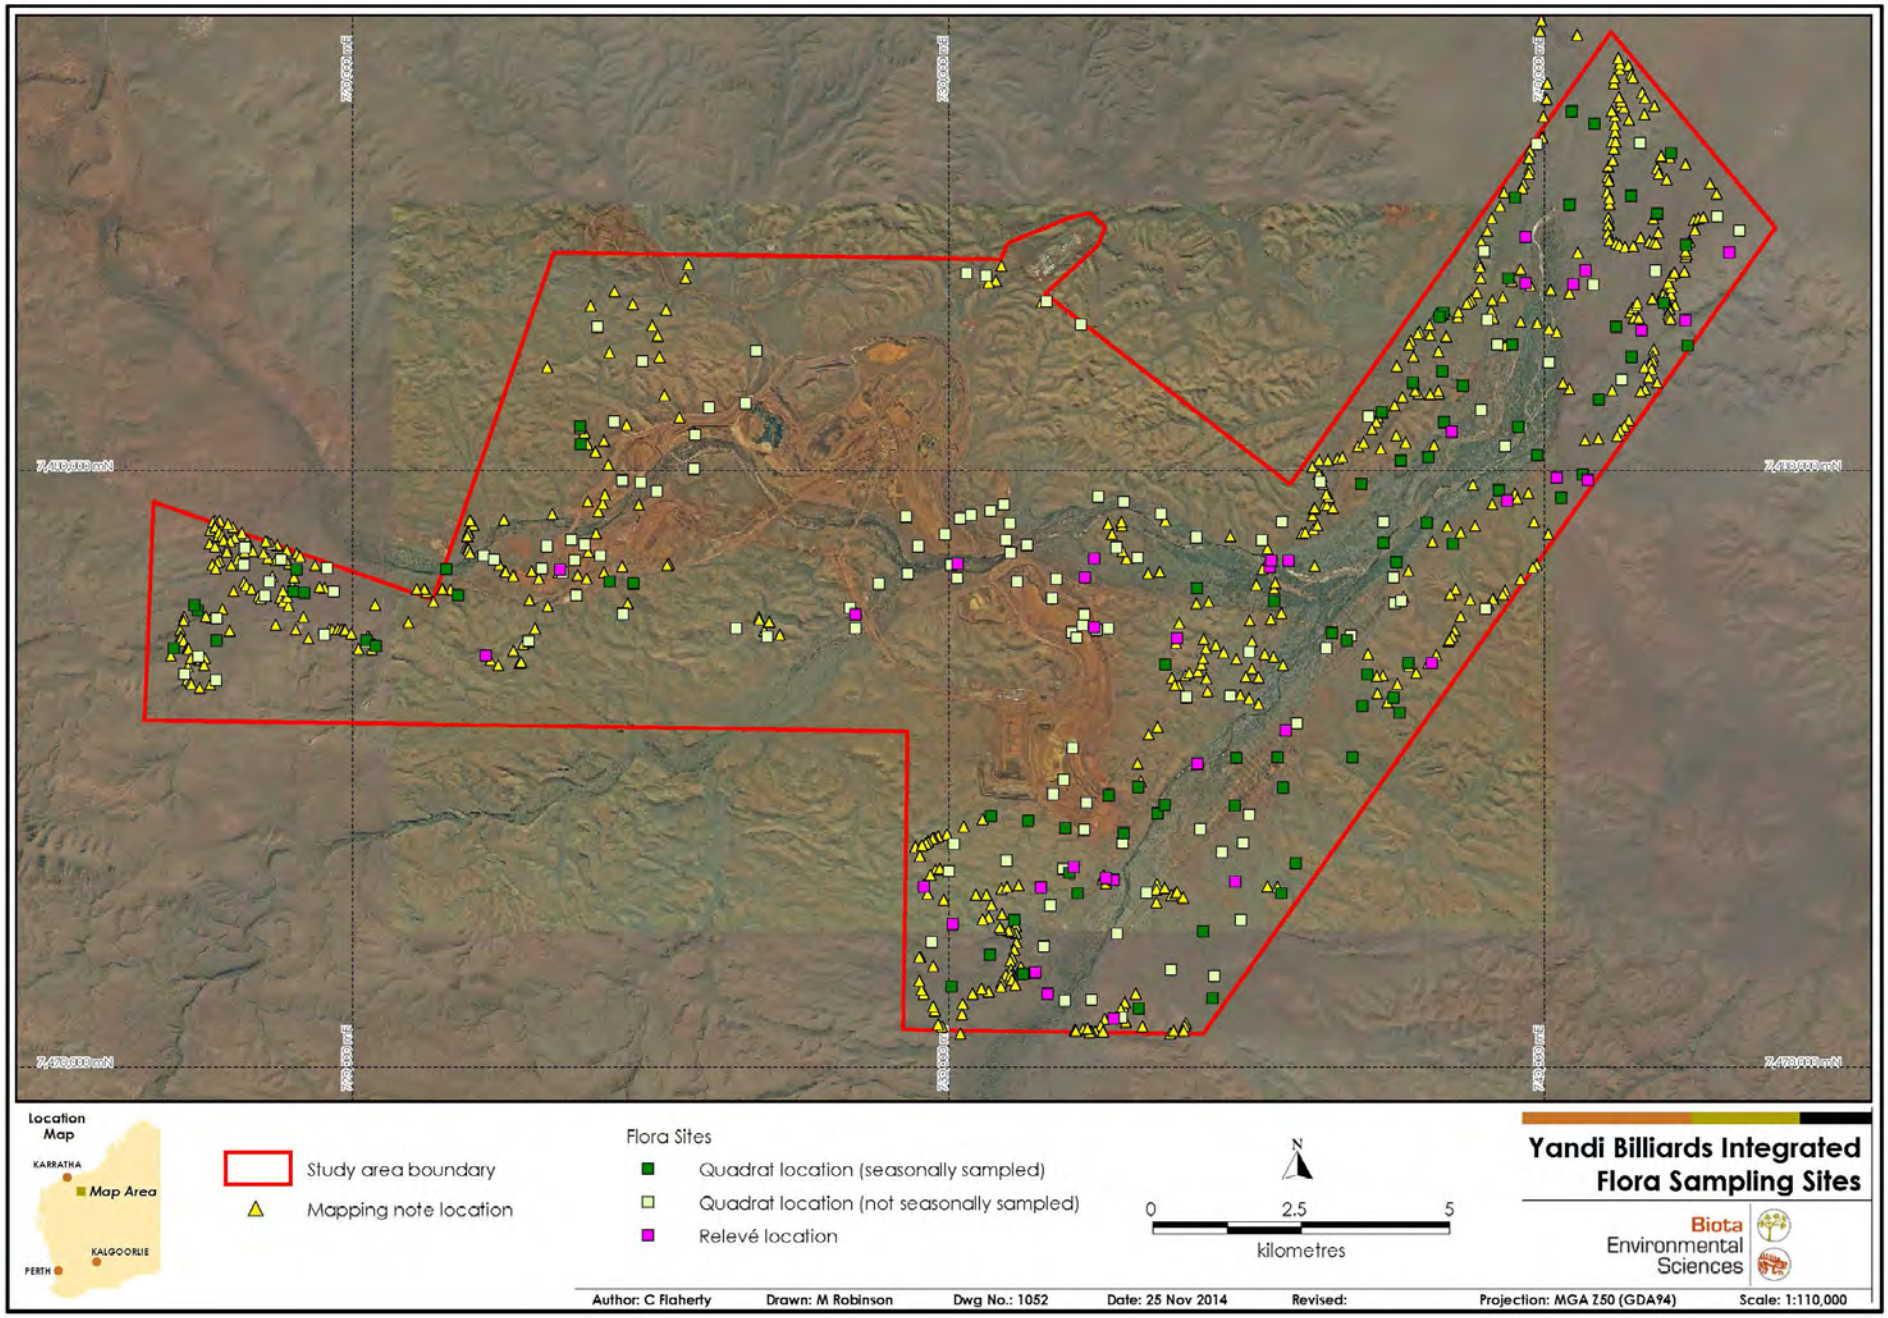

Figure 3.3: Quadrat, relevé and mapping note locations in the study area.

3.3.3 Targeted Searches for Conservation Significant Flora and Weeds

Searches for conservation significant flora were not conducted systematically over the entire study area. Only one of the surveys that was reviewed for the study area (a survey of Yandi Backfill Hill; Biota 2005) included systematic searches for conservation significant flora (see Section 3.1).

However, all surveys reviewed for this report included opportunistic searches for conservation significant flora. These were conducted within quadrats and relevés, and during foot traverses while conducting vegetation mapping and travelling between sites. Track logs of foot traverses are only available for the most recent survey in the study area and are provided in the relevant report (Biota 2014a). Another indication of the proportion of the study area that was assessed opportunistically is provided by the spatial coverage of the quadrats, relevés and mapping notes recorded during the field surveys (see Figure 3.3).

All locations of conservation significant flora were recorded using a GPS unit (WGS84 datum). Wherever possible, the number of individuals, habitat and associated plant species were also recorded. Voucher specimens were collected for confirmation, and also for lodgement with the WA Herbarium (as appropriate).

Similar information was recorded during the foot traverses for introduced flora species (weeds), and any additional native flora species that had not been previously recorded in the area were noted as opportunistic collections. A list of all vascular flora species recorded in the study area is provided in Appendix 5.

3.4 Specimen Identification, Nomenclature and Data Entry

Identification of vascular flora specimens was conducted in the field or in the office following the field survey. In cases where a plant specimen was common and known to the botanist, the identification was confirmed and noted in the field. If the species was difficult to determine without microscopic examination, belonged to a recognised species complex, was poorly collected or otherwise unusual, a voucher specimen was collected.

Voucher specimens were identified by using flora keys, consulting appropriate publications, checking voucher reference collections, and comparing the specimens to the collections held at the WA Herbarium. Biota botanists identified most specimens, the majority of which were confirmed by Michi Maier, with external assistance sought as necessary. Data from older surveys in the study area were reviewed, and specimen identifications were checked and amended as necessary to reflect recent taxonomic changes. Various taxonomic specialists were consulted to provide assistance or confirm the identifications of difficult plant groups (see Table 3.3).

Table 3.3: Taxonomic specialists that have identified difficult taxa from the study area.

Specialist (Affiliation)	Taxa Examined	Survey/s
Malcolm Trudgen (M.E. Trudgen and Associates)	Fabaceae, Poaceae, Malvaceae and other difficult taxa	All surveys
Bruce Maslin (WA Herbarium)	*Acacia.*	Biota (2002, 2004b)
Bryan Simon (Queensland Herbarium)	*Triodia, Cymbopogon, Aristida* and *Eriachne*	Biota (2002)
Lyn Craven (Australian National Herbarium, Canberra)	*Halgania*	Biota (2004b)
Allen Lowrie	*Stylidium*	Biota (2002)
Leigh Sage (Department of Parks and Wildlife)	*Goodenia*	Biota (2002)
Paul G. Wilson (WA Herbarium)	Asteraceae and Chenopodiaceae	Biota (2002)
Ryonen Butcher (WA Herbarium)	*Tephrosia*	Biota (2014a)
Andrew Perkins (WA Herbarium)	Conservation significant species and atypical specimens of various taxa	Biota (2014a)

Nomenclature was checked against the current listing of scientific names recognised by the WA Herbarium. All data were entered into a Microsoft Access Vegetation Database structure held internally at Biota. The database model employed by Biota was developed by Ted Griffin (private consultant) at the request of Malcolm Trudgen (M.E. Trudgen and Associates).

3.5 Mapping Integration and Standardising of Vegetation Types

In order to prepare an integrated map based on all of the vegetation mapping available for the study area, it was necessary to attempt to standardise some of the vegetation types that were described in the different surveys by the different authors. As Biota had conducted the majority of the survey work in the study area in a consistent way, and given that for most areas the vegetation types used across the different projects were kept consistent, Biota's more recent mapping units were used as the basis for the vegetation mapping over the entire study area.

Some vegetation mapping completed by Biota (2000, 2004a, 2005, 2009b) was revised and updated where necessary. The changes made were generally minor and included some amendments to a few vegetation descriptions, so that they reflected the vegetation types used consistently over the study area; and some changes to mapping boundaries, so that the vegetation units displayed seamlessly across the boundaries of the different survey areas. It was necessary to update a number of vegetation descriptions due to some updates made to the identification of *Triodia*: specimens that were previously thought to be *Triodia lanigera* in the Yandi area have been re-identified as *T. basedowii,* while the taxon previously designated by the informal name "*Triodia* aff. *basedowii*" is now recognised as *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835).

The areas of historical mapping by Mattiske (1995a, 1995b, 1995c) were reviewed, however it was determined that it was not possible to integrate this mapping with the more recent, detailed mapping of the surrounds completed by Biota. Some of the historic vegetation types were described at a considerably broader level than the vegetation types described more recently for the study area (e.g. 'Low shrubland of mixed *Acacia* species' (Mattiske 1995a), which is a broad floristic formation equivalent to NVIS Level III). Additionally, some of the mapping boundaries appeared to be spatially inaccurate, as they did not correspond to the landforms apparent on aerial photography. While numerous flora sites were sampled during these surveys, no data were provided in any of the reports. As these areas of historical vegetation mapping could not be validated with any quantitative flora site data, we were unable to accurately translate these vegetation types to the corresponding more detailed units used for the study area. For these reasons it was decided that the historical mapping would not be presented or further discussed in this report.

Instead the existing detailed mapping and corresponding vegetation types were extended over these areas through a desktop exercise using aerial photography and information from the surrounding areas that had been mapped. This was also done for the areas where no mapping had been completed, in order to produce a single consolidated vegetation map for the entire study area. The extended vegetation mapping should provide a reasonable indication of vegetation in these areas. However, mapping boundaries would need to be ground-truthed in the field and flora quadrats would need to be established to support the vegetation types mapped, in order for this mapping to be considered suitable to support an EIA (as outlined in Guidance Statement No. 51 of EPA 2004).

The consolidated vegetation map for the study area is presented in Appendix 4. Not all surveys within the study area were completed at a Level 2 standard (as outlined in EPA 2004) and vegetation mapping was completed with varying levels of survey effort across the study area. A discussion of the level of confidence in the vegetation mapping presented in this report is provided in Section 4.2.

3.6 Floristic Analysis

In order to examine the relationships between the floristic composition of the sampling sites in the study area compared to a selection of sites from the broader locality (within 100 km of the study area), cluster analyses were carried out using the PRIMER software package. The dataset included 868 quadrats and 101 detailed relevés, comprising:

- 209 quadrats and 21 relevés assessed within the current study area by several studies (including Halpern Glick Maunsell 2000a, Biota 2004a, 2009a, 2010a, 2014a, 2014b, 2014c); together with three additional quadrats in close proximity that were treated as "inside the study area" for the purposes of the current analysis: YVI03 (40 m outside), YAQ28 (60 m outside) and YAQ26 (420 m outside);
- 16 quadrats and three relevés from the Hamersley Range section of the Hope Downs rail corridor (Biota 2004b);
- 26 quadrats and one relevé from the Chichester Range section of the Hope Downs rail corridor (Biota 2004c);
- 41 quadrats and one relevé from the Juna Downs section of the Hope Downs rail corridor (Biota 2006a);
- 13 quadrats from Rio Tinto's Bellbird – Juna Downs rail corridor (Biota 2008), and 15 quadrats from an addendum to this corridor (Biota 2009c);
- 348 quadrats and 23 relevés from various survey areas associated with Koodaideri, including the Koodaideri Lease Area, Western Rail Corridor, Southern Infrastructure Corridor and Northern Extension (summarised in Biota 2012a);
- 52 quadrats and 13 relevés from Fortescue Metal Group's Stage A rail corridor (Biota 2004d);
- nine quadrats and 10 relevés from BHP Billiton's Jinidi-Mindy survey area (Biota 2011b);
- 67 quadrats and eight relevés from BHP Billiton's Southern Flank-Jinidi survey area (2012b);
- 24 quadrats and 16 relevés from Deposits E and F at West Angelas (Biota 2006b);
- 35 quadrats from the West Angelas gas plant and pipeline corridor (Biota 2010b); and
- 10 quadrats and five relevés from Deposit F at West Angelas (Biota 2014d).

A full list of the sites and their source studies is provided in Table 1 in Appendix 8, with each site within the study area attributed with its alpha-numeric vegetation code (Section 3.3.1) and broad habitat. Note that five sites sampled in the locality were excluded from the dataset after an initial screening analysis, as they were found to be significant outliers that precluded presentation of the analysis results for the remaining sites. These outlier sites were HDDRELG in a herbland on a granite outcrop (Biota 2004c); FMG15 and FMG16 in samphire shrublands associated with the Fortescue Marsh, FMG61 in a *Triodia longiceps* hummock grassland on a low-lying plain containing patches of clay, and FMG20f in a mixed herbland on a clay plain (all from Biota 2004d).

A combined species list was created from all of the sites and reviewed for errors or inconsistencies in nomenclature. Both annual and perennial vascular flora species were included. The data were screened to remove or take into account records with the potential to substantially bias the results. This included:

- Weed species other than **Cenchrus* were excluded, as these were often linked to location (particularly the presence of disturbance factors, such as cattle) rather than specifically to the vegetation type. **Cenchrus ciliaris* and **C. setiger* were retained and were combined and treated as "**Cenchrus* spp.", as these provided a significant cover in some areas and now formed part of the vegetation structure.
- Fungi and non-vascular flora records were excluded from the dataset, as these were not systematically sampled.
- Records that could represent different taxa across multiple projects (e.g. "*Euphorbia* sp.") were excluded.

- Where it was considered that multiple taxa may represent the same species, these were all referred to a single taxon identification code in the dataset, and thus treated as a single entity in the subsequent analyses. For example, the records of sterile soft spinifex that were assigned to *Triodia* sp. (*epactia/pungens*) were amalgamated with *T. epactia* and *T. pungens*; records of *Scaevola parvifolia* and its two subspecies were amalgamated, as there appeared to be crossover of characters; and all forms of Mulga (*Acacia aneura* complex) were referred back to the species in the broad sense, as names from old projects were not consistent with the recent taxonomic revision by Maslin and Reid (2012).
- Finally, singleton species (those occurring in only one site) were removed to reduce noise in the dataset, unless they were characteristic of a particular habitat (e.g. *Astrotricha hamptonii*).

Where a site had been sampled more than once, the Phase 1 and Phase 2 data were amalgamated. Where the estimated cover value for a particular species differed between survey phases, the larger of the two estimates was retained.

For the resulting list of species, two matrices were then generated:

- percentage foliar cover of each species at each site; and
- presence / absence of each species at each site.

Two additional matrices were generated from the above by removing annual species that would only be recorded under optimal sampling conditions. These matrices were used to investigate potential bias in the dataset caused by sampling during different seasonal conditions for different projects.

The screened site by species data were imported into PRIMER. Percentage foliar cover values were square-root transformed to reduce the influence of high abundance species on the similarity analyses. A resemblance matrix was then constructed using the Bray-Curtis similarity index, which produces a similarity value for all pairs of sites based on their species composition and transformed abundances.

The resultant resemblance matrix was then run through PRIMER's CLUSTER routine, using group average linkage to construct a dendrogram grouping the survey sites into clusters based on similarity in species composition. Two analyses were run, the first including data for both perennial and annual flora species, and the second using data for perennial species only. Analyses were run using all sites from the study area, and using all sites in the dataset. The resemblance matrix was used to generate Non-metric Multi-Dimensional Scaling (NMDS) ordination plots to assist with visualising the groupings amongst sites based on flora composition. Due to the size of the dataset (969 sites), site clusters were not tested for significance using the similarity profile permutation test (SIMPROF) and it was not possible to reproduce the dendrogram from the overall analysis. Representative outputs are instead presented as NMDS plots in Appendix 8. The full outputs from the analyses are available for inspection if required.

3.7 Limitations of this Study

As this report collates data from 15 studies, the limitations outlined in the reports for each individual study also apply here. The main limitations affecting the study that should be taken into account include:

- Some sections of the individual survey areas were not ground-truthed or systematically sampled. The habitats and vegetation types within each survey area were therefore not equally sampled, and sampling effort was not equal amongst the contributing surveys (see Section 3.1 and Figure 3.2). This particularly applies to the areas indicated as 'Low - moderate' and 'High' vegetation mapping confidence in Figure 4.1.
- EPA Guidance Statement 51 (EPA 2004) states that a Level 2 vegetation and flora survey should comprise a seasonal survey component. Not all of the component surveys within the study area included a seasonal component to meet Level 2 standards (see Table 3.1 and Figure 4.1), and

resampling of existing quadrats was therefore a key task for the more recent survey work. Over the entire study area, approximately 40% of the quadrats established have been effectively seasonally sampled (see Section 3.3.2 and Figure 3.3), and the more recent component surveys generally have a higher proportion (e.g. approximately 56% of quadrats within the PBS survey area have been resampled). While resampling of all established quadrats would be ideal, it has been acknowledged that a 'High' level of satisfaction can be reached from resampling a proportion of quadrats (approximately 25–50%) if the initial survey was completed under appropriate seasonal conditions (EPA and DEC 2012, p. 123). The level of quadrat resampling within the study area is therefore adequate.

- Survey timing has a significant effect on the flora species recorded from any area. The various studies were conducted at different times of year and following different rainfall regimes. While most of the survey work included at least one phase that followed adequate rainfall, the timing of some of the surveys was not optimal for recording annual or cryptic perennial species (see Table 3.1).
- While some opportunistic records of fungi were made (see species list in Appendix 5), fungi and non-vascular flora were not specifically surveyed, as is typical for surveys of this nature.
- The vegetation types for the individual survey areas were defined through a combination of quadrat and relevé data, mapping notes recorded in the field, and the interpretation of aerial photography. Interpretation of vegetation from aerial photography can be difficult and mapping notes are recorded as point data, which provide only an indication of vegetation boundaries. The existing mapping therefore provides a spatial representation of the vegetation of the individual survey areas, and vegetation boundaries should be treated as indicative rather than absolute.
- Vegetation mapping has been extrapolated to unsurveyed sections of the study area. Vegetation boundaries were based on landforms apparent on aerial photography, combined with information inferred from nearby areas of vegetation mapping. Vegetation types and mapping boundaries in these areas have not been ground truthed, and should only be used to provide a general indication of the vegetation in these areas (see Section 4.2 for a broad indication of the level of confidence in the vegetation mapping).
- Vegetation type C1 includes riparian vegetation of the wettest parts of the local creek systems, but does not distinguish between areas dominated by *Melaleuca argentea* and *Eucalyptus camaldulensis.* The former species occurred in stands along Marillana Creek and Weeli Wolli Creek but was not continuous through this vegetation type.
- The majority of the information presented in this mapping integration has been acquired post-mining. Consequently, the vegetation types present and their spatial extent are likely to have been altered through clearing for mining development and the effects of mine water discharge into the local creek system.
- Four vegetation types (H8, H9, H10 and H11) were described from a single quadrat only. These vegetation types have a very small area of representation (see Appendix 4).
- The results of the floristic analysis reflect the dataset utilised, and analysis using different or additional sites may result in a somewhat different interpretation. Quadrat data for the Pilbara region is typically patchily distributed and concentrated in development areas, and not all vegetation types are equally well sampled.

4.0 Vegetation of the Study Area

4.1 Overview of Vegetation Types

Four landscape categories were identified for the study area:

- major creeklines and tributaries;
- minor creeklines, floodplains and valleys;
- hills, ridges and breakaways; and
- plains.

A total of 30 vegetation types were mapped for the study area over the four landform categories. Some of the older vegetation types were updated to an equivalent unit so that mapping was kept consistent over the entire study area (see Section 3.5). All vegetation types are summarised in Appendix 3 (for full descriptions, refer to the individual supporting survey reports).

4.1.1 Major Creeklines and Tributaries

A total of five vegetation types mapped in the study area were associated with creeklines that supported true riparian vegetation, as characterised by the presence of the tree species *Eucalyptus camaldulensis* (River Red Gum), *E. victrix* (Coolibah) and/or scattered stands of *Melaleuca argentea* (Cadjeput). This vegetation was associated with Marillana Creek and Weeli Wolli Creek, which represent two major, regionally significant creeklines in the Pilbara. Weeli Wolli Creek is situated adjacent to the proposed PBS area, while Marillana Creek flows through the YJC, JSW and YOX developments. The confluence of the two creeks is situated immediately to the north of the proposed PBS development.

The wettest parts of these creeklines supported vegetation type C1, which comprised riparian woodlands containing varying proportions of *Eucalyptus camaldulensis* subsp. *refulgens* and/or scattered stands of *Melaleuca argentea,* sometimes with *E. victrix* also present. A tall shrubland of species such as *Melaleuca glomerata* and *Acacia coriacea* subsp. *pendens* (Weeping Wirewood) was typically also present, and patches of *Typha domingensis* (Bulrush) and sedges such as *Cyperus vaginatus* (Stiff-leaf Sedge) often occurred in these areas.

The scoured, rocky beds of the major creeks supported occasional trees of *Eucalyptus victrix* and shrubs of *Acacia citrinoviridis* (River Jam), *A. coriacea* subsp. *pendens* and *Melaleuca glomerata* (vegetation type C3). Buffel Grass (**Cenchrus ciliaris*) also occurred in these areas as scattered individuals, while the low shrubs *Indigofera monophylla* and *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) were common.

Major tributaries of Marillana and Weeli Wolli Creeks (vegetation types C2, C4, C5 and some parts of C3) supported *Eucalyptus victrix* low trees, occasionally with *Corymbia hamersleyana* (Hamersley Bloodwood) in the upstream reaches of vegetation type C2. A tall shrub or low woodland stratum typically consisted of mixed *Acacia* species, *Grevillea wickhamii* (Wickham's Grevillea) and occasionally *Atalaya hemiglauca* (Whitewood). Vegetation types C2 and C5 supported several native species of tussock grasses in the understorey, while C3 and C4 were dominated by **Cenchrus ciliaris*.

4.1.2 Minor Creeklines, Floodplains and Valleys

A total of five vegetation types were associated with minor creeklines, floodplains and valleys in the study area.

Minor creeklines and the smaller tributaries of Marillana and Weeli Wolli Creeks (vegetation types F1 and F3) were typically in better condition than the main channels, with **Cenchrus ciliaris* being

considerably less abundant or absent. The floristic composition of these smaller creeklines varied depending on their location and size. The overstorey typically comprised scattered trees to a low open woodland of *Eucalyptus leucophloia* (Snappy Gum) or *Corymbia hamersleyana* over an open to closed tall shrubland of mixed species such as *Acacia tumida* var. *pilbarensis* (Pilbara Pindan Wattle), *A. ancistrocarpa* (Fitzroy Wattle), *A. bivenosa* (Two-veined Wattle) and *Grevillea wickhamii*. The understorey of these creeks varied from grasslands dominated by *Eriachne tenuiculmis* and *Themeda triandra* (Kangaroo Grass), to hummock grasslands dominated by *Triodia pungens* (Soft Spinifex) or various other spinifex species, particularly *T. wiseana* (Limestone Spinifex) and *T.* sp. Shovelanna Hill (S. van Leeuwen 3835).

Floodplains of Marillana and Weeli Wolli Creeks had a substrate of sandy or silty loams and supported open to dense woodlands dominated by *Acacia citrinoviridis* over an understorey of **Cenchrus ciliaris* tussock grassland (vegetation type F2). **Cenchrus ciliaris* formed dense infestations in vegetation type F2, affecting the overall condition of this vegetation (see Section 4.3). Other typical trees and shrubs in these areas included occasional *Acacia pruinocarpa* (Western Gidgee) and *Atalaya hemiglauca*. Some of the floodplains provided habitat for the Priority flora species *Rostellularia adscendens* var. *latifolia* (Priority 3) and *Goodenia nuda* (Priority 4) (see Section 5.4.2). Other floodplain vegetation types in the study area were associated with more minor creeklines, or with floodouts and valleys, which were often fed by minor creeklines that flowed through low hills (vegetation types F4 and F5). These vegetation types typically comprised a *Corymbia hamersleyana* low open woodland over a mixed *Acacia* shrub stratum with *Triodia pungens* hummock grasses and common tussock grasses including *Aristida holathera* var. *holathera* and *Paraneurachne muelleri* (Northern Mulga Grass).

4.1.3 Hills, Ridges, Gorges and Breakaways

A total of 11 vegetation types were associated with hills, ridges, gorges or breakaways in the study area.

The low stony hills had a near-continuous surface cover of cobbles, pebbles and gravel over sandy loams, and were generally dominated by hummock grasslands of *Triodia wiseana* and/or *T.* sp. Shovelanna Hill (S. van Leeuwen 3835), with the latter tending to be more dominant on elevated hill crests. Occasional low trees and shrubs were present including *Eucalyptus leucophloia, Hakea chordophylla, Acacia inaequilatera* (Baderi) and *Grevillea wickhamii*. The two major hill and hillslope vegetation types (H1 and H2) covered approximately 96% of the hills mapped for the study area and 45% of the entire study area. These vegetation types were also the main habitat for the Threatened species, *Lepidium catapycnon* (see Section 5.4).

Other vegetation types that were recorded less broadly through the hills, ridges, gorges and breakaways of the study area included:

- Some hilltops and slopes had a distinct shrubland stratum of *Acacia arida* (vegetation types H3 and H4). *Eucalyptus leucophloia* was the dominant tree species in vegetation type H3 and *Corymbia hamersleyana* was the dominant tree species in vegetation type H4.
- Several rocky ridges and breakaways situated on large rocky hills were mapped separately (vegetation type H5). This vegetation was characterised by very steep, often vertical, rocky slopes and rocky outcrops with skeletal soil. *Eucalyptus leucophloia* and *Corymbia ferriticola* were found growing out of crevices in the rocks. *Eremophila latrobei* subsp. *filiformis* and several species of *Senna* formed a shrub stratum. Several species of native tussock grasses were present in the understorey, including *Themeda* sp. Mt Barricade (M.E. Trudgen 2471), a species typically restricted to rocky habitats. The Priority 3 species *Sida* sp. Barlee Range (S. van Leeuwen 1642), which has a similar preferred habitat comprising skeletal soil in rocky areas, was also recorded from this vegetation type (see Section 5.4.2).
- *Acacia bivenosa* was found occasionally as an open shrubland on some slopes and hilltops, along with *Eucalyptus leucophloia* and *Triodia wiseana* (vegetation type H6).

- Low stony hills fringing Marillana Creek supported *Eucalyptus leucophloia* scattered low trees over an *Acacia pruinocarpa* tall open shrubland and a mixed hummock grassland of *Triodia wiseana* and *T. pungens* (vegetation type H7).
- A tall shrubland of *Acacia monticola* (Gawar) was found on a single area of hillslope (vegetation type H8), occurring over a mixed hummock grassland of *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) and *T. wiseana*.
- Two gorges in the study area were sufficiently large to map separately (vegetation type H9). These were dominated by *Corymbia hamersleyana* low trees over a shrub layer of *Gossypium robinsonii* (Wild Cotton), *Androcalva luteiflora* (Yellow-flowered Rulingia), *Acacia tumida* var. *pilbarensis*, *Grevillea wickhamii* and tussock grasses including *Themeda triandra* and *Cymbopogon ambiguus* (Scentgrass).
- *Eremophila fraseri* subsp. *fraseri* (Burra) was found on some isolated low hills, where it occurred over *Triodia pungens* with either *Acacia inaequilatera* (vegetation type H10) or *Grevillea pyramidalis* subsp. *leucadendron* (Caustic Bush) (vegetation type H11).

4.1.4 Plains

A total of nine vegetation types were associated with stony plains of the study area.

Vegetation occurring on the pebbly to stony plains typically comprised scattered low trees to a low open woodland of *Corymbia hamersleyana* or *Eucalyptus leucophloia*, sometimes with *E. gamophylla* (Twin-leaf Mallee), over scattered shrubs to an open shrubland of various wattle species, particularly *Acacia ancistrocarpa, A. bivenosa, A. citrinoviridis, A. inaequilatera*, *A. pachyacra, A. pruinocarpa, A. pyrifolia* (Ranji), *A. sclerosperma* subsp. *sclerosperma* (Limestone Wattle) and *A. synchronicia* (Bardi Bush) (vegetation types P1 to P5 and P9). The understorey was typically a hummock grassland, with *Triodia pungens, T. longiceps* (Giant Grey Spinifex), *T. wiseana* or *T. basedowii* (Lobed Spinifex; formerly identified as *T. lanigera*) dominating different areas. Some areas of plains in the study area provided habitat for Priority flora including the Priority 3 species *Themeda* sp. Hamersley Station (M.E. Trudgen 11431), and *Goodenia nuda* and *Rhynchosia bungarensis* (both Priority 4).

Other vegetation types that occurred over the plains in the study area included:

- The *Acacia "aneura"* (Mulga) complex was dominant in one vegetation type (P6) that occurred in several stands across the alluvial plains adjacent to Weeli Wolli Creek. Mulga species also occurred as scattered individuals (i.e. as a non-dominant species) over the plains and some hillslopes in the study area. Vegetation type P6 was dominated by shrubs of *Acacia aptaneura*[7], *Eremophila forrestii* subsp. *forrestii* and *E. lanceolata* and mixed grasses including *Triodia longiceps*, *Aristida pruinosa* (Gulf Feathertop Wiregrass) and sometimes **Cenchrus ciliaris* and **C. setiger* (Birdwood Grass). Several populations of the Priority 4 species, *Goodenia nuda,* were located in this vegetation (see Section 5.4.2).
- *Eremophila fraseri* subsp. *fraseri* (Burra) was a dominant shrub on some small areas of plain with a calcrete substrate (vegetation type P7). These areas supported either a mixed tussock grassland, with the dominant species comprising *Aristida contorta* (Bunched Kerosene Grass), *Enneapogon polyphyllus* (Leafy Nineawn), *Eragrostis eriopoda* (Woollybutt Grass) and *Paraneurachne muelleri* (Northern Mulga Grass), or a *Triodia wiseana* hummock grassland.
- *Triodia schinzii* was present along with *Eucalyptus gamophylla* and *Acacia inaequilatera* in one area of gently sloping pediment slopes at the base of a range of low hills (vegetation type P8).

[7] All Mulga specimens collected from the previous surveys were assigned names based on the recent taxonomic revision completed by Maslin and Reid (2012); older specimens were re-determined as necessary.

4.2 Vegetation Mapping Confidence

The various surveys completed previously in the study area utilised differing methodologies and had differing levels of survey effort. In addition, some areas of mapping were prepared solely from interpretation of aerial photography in combination with information extrapolated from adjacent mapping, and have not been ground-truthed. This results in variable levels of confidence (see Figure 4.1) in the final integrated vegetation map generated for the study area (as presented in Appendix 4).

Figure 4.1 provides a broad indication of our level of confidence in the accuracy of the vegetation mapping presented in this report. This is a function of various factors including the age of the mapping, the level of survey effort completed and the amount of site data available to validate the vegetation types and boundaries. The areas indicated in Figure 4.1 as a 'Very High' level of mapping confidence correspond to surveys that were completed at a Level 2 standard (as outlined in EPA (2004) Guidance Statement No. 51) and which included a seasonal component.

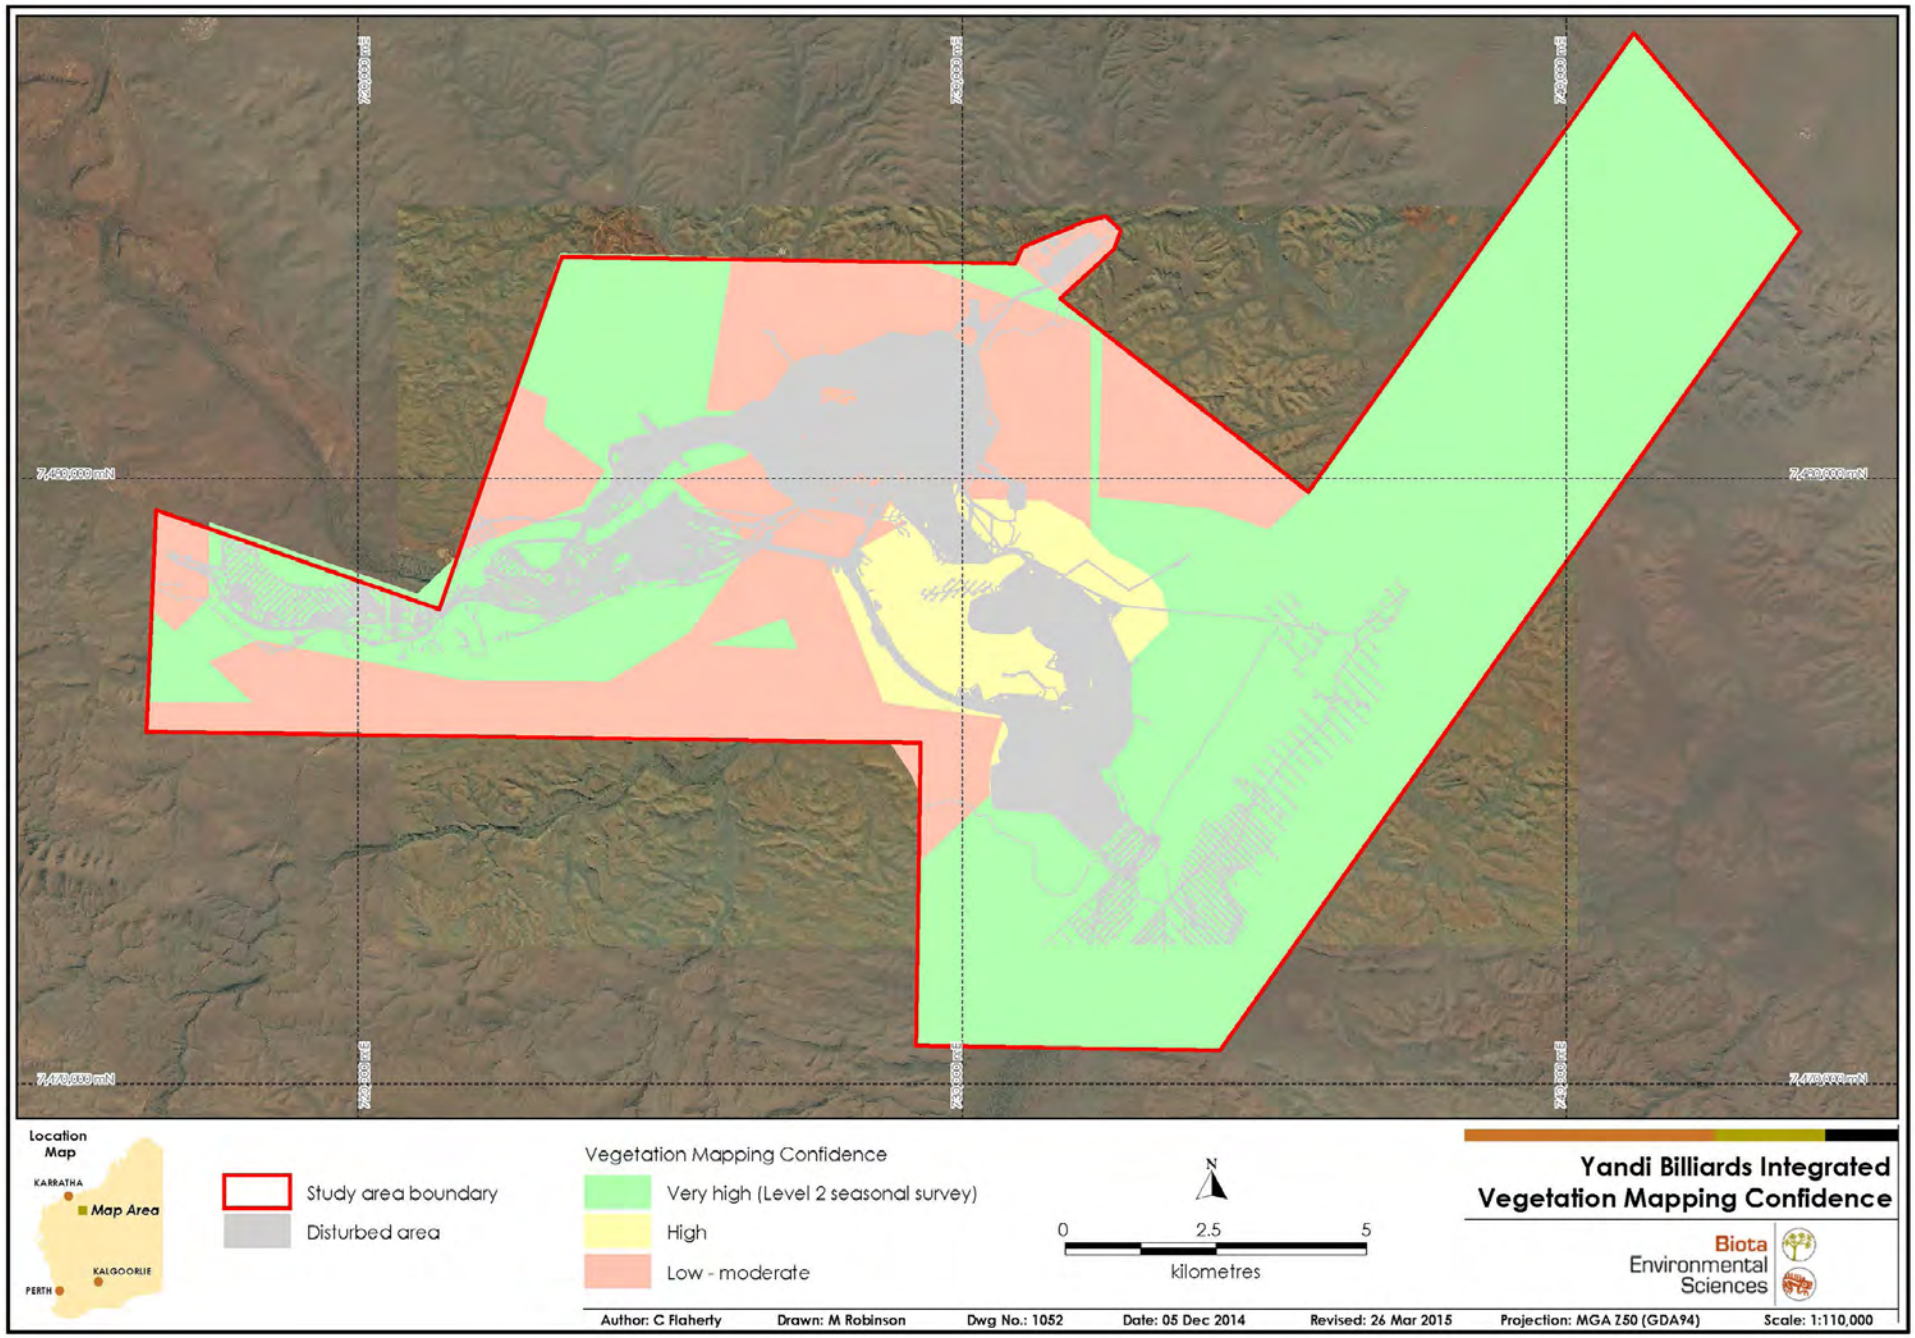

Figure 4.1: Broad indication of the level of confidence in the accuracy of the vegetation mapping presented in this report.

4.3 Vegetation Condition

Vegetation condition mapping for the study area is presented in Appendix 6. The vegetation condition ranking was based on the weed density, human impact, feral animals and livestock activities, and the perceived structural integrity of the vegetation as a whole. Appendix 2 presents the vegetation condition scale from Trudgen (1988) that was used to determine the vegetation condition rankings.

A total of 2,770 ha (approximately 14%) of the study area was mapped as Disturbed, which is equivalent to a Completely Degraded vegetation condition (Trudgen 1988). These areas comprised, mine pits, haul roads, exploration tracks and drill pads, as well as buildings and infrastructure associated with the existing approved Yandi mines (see Figure 4.1 and Appendix 4). The extents of these areas were largely based on Rio Tinto's December 2013 disturbance footprint layer, however some additional areas identified as disturbed on aerial photography were also mapped as disturbed. At the time of the second phase of the PBS field survey (July 2014; Biota 2014a), additional drill lines were being cleared on the eastern side of Weeli Wolli Creek, south of the confluence with Marillana Creek. These new drill lines were not mapped as disturbed areas, as they were too recent to be visible on aerial photography or captured in the Rio Tinto December 2013 disturbance footprint layer. A total of 31 quadrats and one relevé have been cleared since they were first established in the study area (see Table 4.1).

Table 4.1: Sites in the study area that have been cleared.

Total	32	

The remaining 86% of the study area represents intact vegetation that ranged from Excellent to Very Poor condition (see Appendix 6). The main disturbance factors in the study area were weed invasion and disturbance from livestock (cattle) including grazing, tracks, trampled vegetation and scats. It was noted during some of the surveys (e.g. Biota 2004a, 2014a) that some areas of hills and slopes were burnt. Fire is a natural process in the Pilbara region and natural fire regimes are not considered as part of the overall assessment of vegetation condition.

Dense weed infestations and high cattle activity were generally restricted to the creeklines and floodplains of the study area (Sections 4.1.1 and 4.1.2). **Cenchrus ciliaris* (Buffel Grass; Plate 4.1) was the most prolific weed in these habitats, sometimes occurring together with **C. setiger* (Birdwood Grass). **Cenchrus* species were present as a continuous population along the edges of Weeli Wolli and Marillana Creeks and on some adjacent floodplains. Where the **Cenchrus* formed a closed tussock grassland, a low number of native species was recorded in the understorey. Given the aggressive, invasive nature of these grasses, it is probable that the

abundance of **Cenchrus* species will increase over time in areas of suitable habitat, and these weed populations may also spread to surrounding areas. Dispersal may be aided by factors such as flowing water, cattle activity, and clearing for tracks and other infrastructure; all of which are already present in the study area.

Several other weed species were found in the creeklines of the study area, but these were usually present as scattered individuals only (see Section 5.6 for more information on the weeds in the study area). While most creekline and floodplain vegetation types were rated as being in Very Good to Good condition, some parts of vegetation types C4 and F2 were rated as Very Poor due to the high weed cover (greater than 70% cover) and evidence of extensive grazing and trampling by cattle (Plate 4.2).

Plate 4.1: **Cenchrus ciliaris*, the most prolific weed species in the study area.

Plate 4.2: Creekline vegetation in the study area with a dense **Cenchrus ciliaris* understorey grazed by cattle.

The hills, ridges and breakaways of the study area (Section 4.1.3) were mostly in Excellent condition and free from any form of disturbance. However, some vegetation types (H7, H9 and H10) contained occasional individuals of **Cenchrus ciliaris,* which had dispersed from nearby creekline or floodplain areas; these resulted in scaling down of the condition rating to Very Good or Good.

The plains of the study area (Section 4.1.4) also contained some weed species, which again did not usually occur as dense populations. Occasionally a very open tussock grassland of **Cenchrus ciliaris* was present, usually on plains adjacent to creeklines or floodplains. Evidence of cattle was also occasionally noted on the plains. The condition of the majority of the vegetation of the plains therefore ranged from Good to Excellent. Vegetation type P3 was generally in Very Good condition except for some parts that were rated as Poor due to a higher level of weed invasion.

4.4 Results of Floristic Clustering Analysis

There was a reasonable correspondence between the floristic groups identified through the PRIMER analyses and the vegetation types described for the study area, although these were not exact. This is as expected, given that floristic composition of vegetation varies along a continuum, while the classification of sample sites into vegetation types is an attempt to impose a framework of distinct groups incorporating vegetation structure.

The floristic analyses based on only the perennial species resulted in the closest match to the described vegetation sub-associations, as would be expected given that the latter were defined primarily on the abundance of the dominant species, which tended to be perennials. Figure 1 in Appendix 8 shows the similarity of sites from the study area based on the percent cover of perennial species only.

In the analysis of the total dataset, the sites from the current study area clustered with other sites from the broader locality on the basis of their floristic composition (see Figure 2 in Appendix 8). This was true whether all species or only perennial species were considered, and whether percent foliar cover or only presence / absence data were used, although the actual site clusters frequently changed (compare Figures 2 and 3 in Appendix 8).

Overall, sites from the current study area were most similar to sites from the nearby Koodaideri and Southern Flank/Jinidi-Mindi areas, and least similar to the more distant sites from West Angelas and the Bellbird to Juna Downs area (Figure 3 in Appendix 8). The degree of geographic patterning evident is relatively high, when it is considered that the dataset spans only a 100 km radius around the current study area. Similar fine-scale geographic patterns have been observed elsewhere in the Pilbara (M. Maier, Biota, pers. obs.).

As expected, the underlying landform was strongly linked to floristic composition (Figure 4 in Appendix 8). Sites located on stony hills (vegetation codes with an "H" prefix) tended to cluster separately on the basis of their floristic composition from sites in major creeks (vegetation codes with a "C" prefix; see Appendix 3). Sites on stony plains (vegetation codes with a "P" prefix) and in minor drainages and on floodplains (vegetation codes with an "F" prefix) were more variable floristically, being distributed between these two broad groupings (Figure 4 in Appendix 8). This is as expected, given that the topographic position of the plains landform is intermediate between the hills and drainages; and that water availability, which strongly influences the species present, declines markedly along this gradient.

Figure 5 in Appendix 8 shows the NMDS plot based on percent foliar cover of perennial species only for the entire dataset. This shows again the clear patterning evident for some vegetation types, particularly C1-C5, H1-H3 and P5-P6, although sites in these vegetation types were frequently spread across more than one floristic group.

At a nominal 30% level of similarity, several floristic groups contained sites only from the current study area when the percent foliar cover data of perennial species were considered (groups z, at, az, bc, bd and be; see Table 1 in Appendix 8). However, only one such group was evident when presence/absence data were considered (group h; Table 1 in Appendix 8), and this group contained an entirely different site. Different groupings were again evident when annual and perennial species were considered together (Table 1 in Appendix 8). This means that there were no floristic groups at the 30% level containing only sites from the study area that were supported by all of the analyses, and thus none of the floristic groups are considered likely to be restricted to the study area.

4.5 Vegetation of Conservation Significance

4.5.1 Threatened Ecological Communities and Priority Ecological Communities

Threatened Ecological Communities (TECs) are described by the Department of Parks and Wildlife as "biological (flora or fauna) assemblages occurring in a particular habitat, which are under threat of modification or destruction from various processes" (DEC 2010a). TECs listed by the Department of Parks and Wildlife are significant at the State level and are protected as Environmentally Sensitive Areas under the WA *Environmental Protection Act 1986*.

Two TECs are listed for the Pilbara bioregion: the '*Themeda* grasslands on cracking clays (Hamersley Station, Pilbara)' and the 'Ethel Gorge aquifer stygobiont community' (Department of Parks and Wildlife 2014a). Twenty-three of the 69 TECs listed in Western Australia are also nationally recognised and listed under the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (the EPBC Act). These do not include either of the two TECs listed for the Pilbara bioregion. The Ethel Gorge stygobiont TEC is approximately 77 km southeast of the study area, while the nearest area of the *Themeda* grasslands TEC is approximately 140 km northwest. Neither TEC is therefore relevant to the study area.

Priority Ecological Communities (PECs) include possible TECs that do not meet survey criteria or are not adequately defined (DEC 2010a). These are added to the Department of Parks and Wildlife's PEC list under Priorities 1 (highest priority), 2 and 3. Ecological Communities that are: 1) adequately known; 2) are rare but not threatened, or meet criteria for Near Threatened; or 3) have been recently removed from the threatened list, are placed in Priority 4. Conservation dependent ecological communities are placed in Priority 5.

Thirty PECs are listed for the Pilbara bioregion (Department of Parks and Wildlife 2014b). The nearest PECs to the study area are the Priority 1 'Weeli Wolli Spring community', located approximately 7 km to the south; and two sand dunes supporting the Priority 3 'Vegetation of sand dunes of the Hamersley Range/Fortescue Valley' PEC, one located approximately 5 km to the east and the other 5 km to the northwest of the study area. In addition, the Priority 1 'Fortescue Marsh (Marsh Land System)' PEC occurs in the broader locality; the marsh itself is located approximately 27 km north of the study area, and is surrounded by fringing vegetation. None of these mapped occurrences of PECs would be directly impacted by the proposed development.

None of the vegetation units defined for the study area represent TECs listed under either the Commonwealth EPBC Act or the WA *Environmental Protection Act 1986,* nor do they represent PECs listed by the Department of Parks and Wildlife.

4.5.2 Other Communities of Local Conservation Significance

The then Department of Conservation and Land Management listed TECs and also compiled a list of other "ecosystems at risk" as part of the biodiversity audit of each IBRA subregion (May and McKenzie 2003). When the PEC listing process was subsequently established, the ecosystems at risk in each subregion that were considered to be of the highest conservation significance were then listed under this process.

One ecosystem at risk identified for the Hamersley and Fortescue Plains subregions of the Pilbara bioregion (see Kendrick 2003a, 2003b) is relevant to the study area:

- 'All major ephemeral water courses' in the Hamersley subregion were listed as an ecosystem at risk by Kendrick (2003a). These water courses were described as supporting "*Eucalyptus* forests with a shrubby understorey", which were considered to be under threat of degradation from weed invasion and grazing and trampling by feral herbivores (Kendrick 2003a).

This ecosystem at risk was not subsequently identified as a PEC by the Department of Parks and Wildlife, however significant drainages are widely recognised as being of importance to the functioning of the local ecosystem. Groundwater drawdown could also potentially impact such vegetation if it includes phreatophytic flora, which are species that are primarily or totally reliant on groundwater to meet their physiological water requirements. It is generally accepted that the common Pilbara riparian species *Melaleuca argentea* and *Eucalyptus camaldulensis* are phreatophytic (Thorburn et al. 1993, O'Grady et al. 2005). *Melaleuca argentea,* in particular, occurs only where there is water permanently at or near the ground surface (within 5 m; Ecosystems Research Group 2012). In contrast, *Eucalyptus camaldulensis* appears to utilise surface water when available, with greater proportions of groundwater used in drier months of the year (see for example Halpern Glick Maunsell 2000b). It should be noted that discharge of dewatering water may also promote the growth or recruitment of phreatophytic species.

Five vegetation types comprising a total of 2,313 ha (11.9%) of the study area have been mapped as riparian vegetation associated with Marillana Creek and Weeli Wolli Creek, which are two of the major ephemeral creek systems for the locality. These creek systems are at risk of degradation from a variety of factors, including development, groundwater drawdown, frequent fires, grazing and weed invasion. Four of the five riparian vegetation units have been identified as being of local conservation significance (Table 4.2).

Two of the riparian vegetation types (C1 and C4) comprised woodlands associated with Marillana Creek and Weeli Wolli Creek. With regards to the two woodland vegetation types:

- Vegetation type C1 was in Good condition; although several weed species were recorded, there were no dense infestations that could have an impact on native flora diversity. This vegetation also supported both *Melaleuca argentea* and *Eucalyptus camaldulensis*, two species that could be affected by groundwater drawdown (and also potentially discharge) from the adjacent mining operations. Similar vegetation to unit C1 is widespread in major creek systems through the Pilbara, including the Robe River, Hardey River, Caves Creek/Duck Creek and Marillana Creek/Weeli Wolli Creek systems. This vegetation is therefore considered significant at a local, rather than regional, scale.
- While vegetation type C4 also occurred in the major creeklines of the study area (mainly on the broad floodplains of Weeli Wolli and Marillana Creek), it has been extensively degraded by the invasion of **Cenchrus ciliaris* (often together with **C. setiger*) in the understorey and the condition was rated as Good to Very Poor. This vegetation has therefore already been substantially impacted by the processes threatening riparian vegetation, and is not considered to be of particular conservation significance.

Three other vegetation types (C2, C3 and C5) comprised riparian vegetation along these same major creek systems, but featured only scattered trees of *Eucalyptus victrix*. These vegetation types did not typically support the phreatophytic species present in C1, but were in Good to Very Good condition, with **Cenchrus* spp. generally present only as scattered individuals rather than a continuous understorey. Similar vegetation assemblages are widespread in major creek systems through the Pilbara including tributaries of the Beasley River, and in the Caves Creek/Duck Creek, Hardey River and Marillana Creek/Weeli Wolli Creek systems. These vegetation types are thus again considered significant at a local, rather than regional, scale.

Table 4.2: Riparian vegetation types in the study area.

Vegetation Code	Vegetation Description	Area (ha)	Percentage of the Study Area
Woodlands of *Eucalyptus camaldulensis, E. victrix* or *Melaleuca argentea*			
C1: EcEvMaMgAc (local significance)	*Eucalyptus camaldulensis* subsp. *refulgens, E. victrix* woodland over *Melaleuca argentea, M. glomerata, Acacia coriacea* subsp. *pendens* low open woodland	318.1	1.6%
C4: EvAciAprAThCEc (degraded by Buffel Grass invasion)	*Eucalyptus victrix* open woodland over *Acacia citrinoviridis, A. pruinocarpa, Atalaya hemiglauca* low woodland over **Cenchrus ciliaris* tussock grassland	1,395.5	7.2%
Scattered trees of *Eucalyptus victrix*			
C2: EvChAtuGwTErCYpERItTHt (local significance)	*Eucalyptus victrix, Corymbia hamersleyana* scattered low trees over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* subsp. *hispidula* tall shrubland over *Tephrosia rosea* low shrubland over *Cymbopogon ambiguus*, *C. procerus, Eriachne tenuiculmis, Themeda triandra* very open tussock grassland	191.8	1.0%
C3: EvAciAcMgCEc (local significance)	*Eucalyptus victrix* scattered trees over *Acacia citrinoviridis, A. coriacea* subsp. *pendens, Melaleuca glomerata* tall open shrubland over **Cenchrus ciliaris* scattered tussock grasses	381.6	2.0%
C5: EvAbAaAmERItTHt (local significance)	*Eucalyptus victrix* scattered low trees over *Acacia bivenosa, A. ancistrocarpa, A. maitlandii* tall open shrubland over *Eriachne tenuiculmis, Themeda triandra* very open tussock grassland	26.0	0.1%
	Total	2,313 ha	11.9%

4.5.3 Other Conservation Values

All of the habitats in the study area are widespread in the locality, and none of the vegetation types appear to be restricted in distribution on the basis of their floristic composition (see Section 4.4).

The remaining vegetation types in the study area are therefore considered to be of low conservation significance, being representative of the vegetation occurring in similar habitats throughout the local area. This is not meant to imply that the vegetation in the study area is of no conservation value, as all intact native vegetation is inherently valuable (DEWHA 2010).

This page intentionally blank.

5.0 Flora of the Study Area

5.1 Overview

A total of 548 native vascular flora taxa from 173 genera and 53 families were recorded from the study area, based on all survey effort to date. This includes one Threatened species (discussed in Section 5.4) and five Priority flora species (discussed in Section 5.4.2). A total of 36 introduced flora species were also recorded (see Section 5.6). A list of all species recorded in the study area, and in each individual survey area, is provided in Appendix 5.

Table 5.1 presents the total number of species in various taxonomic groups for each survey area. These totals represent flora recorded from each individual survey conducted previously in the current study area. Where only a portion of the survey area overlapped the current study area, only the relevant subset of the total species recorded is presented. Species lists were reviewed and taxa have been updated to reflect current taxonomy as necessary.

Table 5.1: Total number of vascular plant families, genera and species recorded in the study area.

5.2 Dominant Families and Genera

The dominant families and genera (native taxa only) recorded from the study area are presented in Table 5.10. These are typical of the most well represented families and genera in the Pilbara bioregion.

Table 5.2: Dominant plant families and genera in the study area.

Family	No. of Native Taxa	Genus	No. of Native Taxa
Fabaceae	114	*Acacia*	51
Poaceae	90	*Senna*	24
Malvaceae	59	*Sida*	16
Asteraceae	28	*Euphorbia*	15
Amaranthaceae	24	*Ptilotus*	14

5.3 Species Richness – Regional Context

Species richness tends to vary on a logarithmic scale with the size of the survey area. However, the array of habitats (and therefore vegetation types) present also has a large influence on the number and type of species recorded, as different habitats provide a greater variety of ecological niches that can be occupied by a greater number of different species. The shape of the survey area may also influence the number of species recorded, with long linear survey areas tending to intersect a greater variety of habitats and, depending on the length, sometimes different biogeographic regions.

Figure 5.1 plots the number of vascular flora species against the area surveyed for the overall Yandi integration study area, as well as the main component survey areas at Yandi[8]. Five other flora and vegetation surveys in the Pilbara region are also plotted to provide a comparison: Western Turner Syncline (Biota 2013), Koodaideri Mining Lease (Biota 2012c), Koodaideri Northern Extension Area (Biota 2012d), Koodaideri Southern Infrastructure Corridor (Biota 2012e) and Southern Flank to Jinidi Rail Corridor (Biota 2012b).

When compared to the other survey areas, the total number of native flora in the individual component survey areas within Yandi are in the range expected for areas of similar size in this locality (this includes the Yandi PBS survey area of Biota 2014a). The species richness of the overall Yandi integration study area is slightly higher, but still within the range expected for a survey area of that size; this is probably due to the larger number of habitats and high level of survey effort in this area.

8 Species richness from Biota (2002, 2004b) and Halpern Glick Maunsell (2000a) not shown, as only a small portion of these survey areas overlaps the current study area.

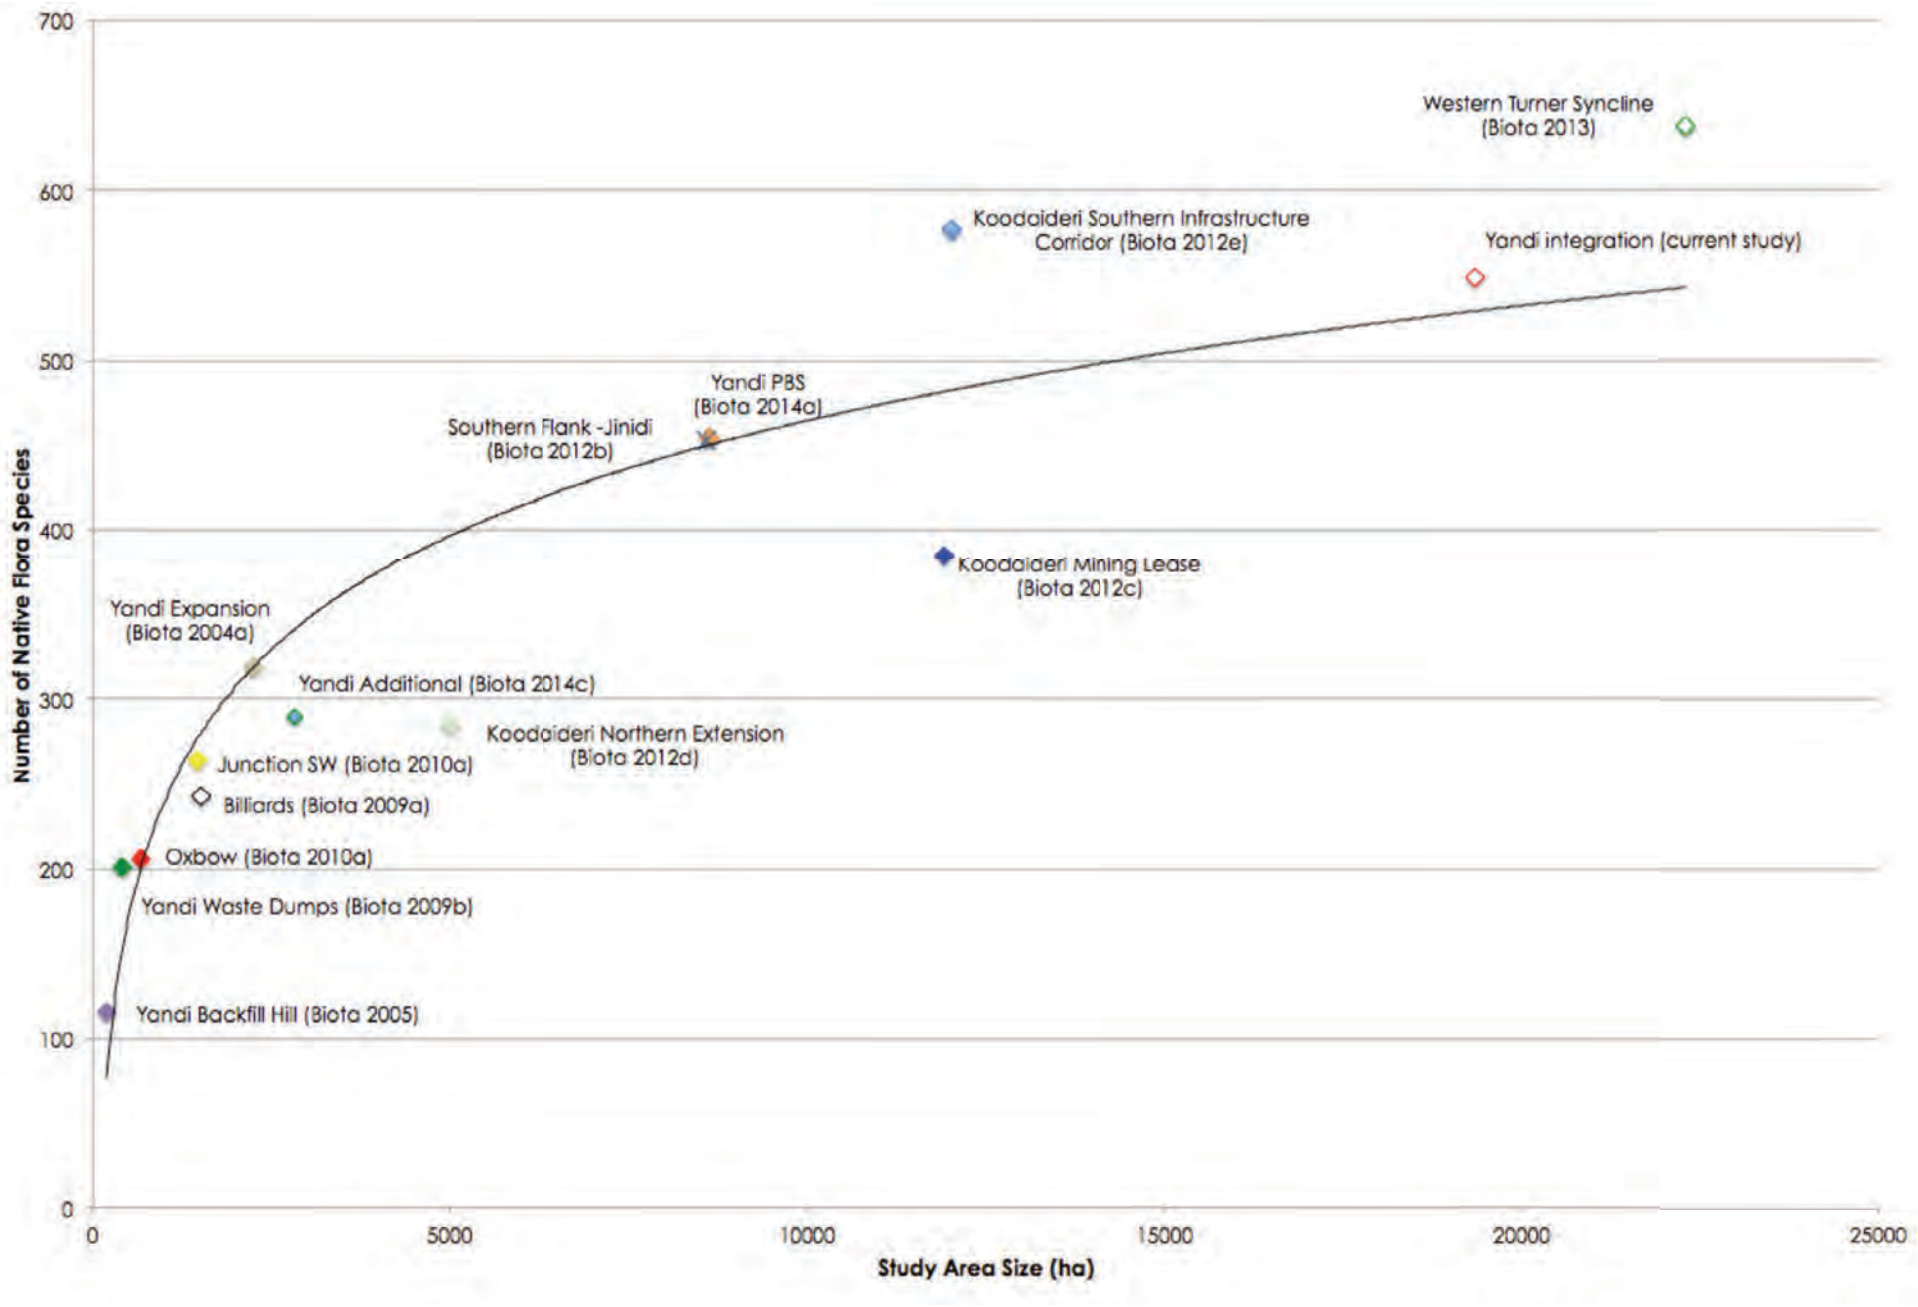

Figure 5.1: The number of native taxa recorded from the different surveys completed in the Yandi study area compared to other surveys in the locality.

Table 5.3: Threatened and Priority flora species occurring in the study area.

5.4 Flora of Conservation Significance

A combined total of six species of conservation significance were recorded from the study area (Table 5.3). These comprise one Threatened species, *Lepidium catapycnon* (see Section 5.4.1), and five species of Priority flora (see Section 5.4.2).

In addition, three vascular flora taxa are potentially of some conservation interest. These species are discussed briefly in Section 5.4.3.

5.4.1 Threatened Flora

Three Threatened flora species (*Aluta quadrata, Lepidium catapycnon* and *Thryptomene wittweri*) are known from the Pilbara bioregion. *Lepidium catapycnon* and *Thryptomene wittweri* are listed as Threatened flora under the Commonwealth EPBC Act as well as the WA *Wildlife Conservation Act 1950*. *Aluta quadrata* has only recently been listed in WA (State of Western Australia 2012) and is currently only recognised as Threatened under the *Wildlife Conservation Act 1950.*

It should be noted that *Lepidium catapycnon* has been proposed to be removed from the State Threatened flora listing for a number of years, due to the relatively large number of populations that have been identified. The Department of Parks and Wildlife has apparently recently nominated this species to the WA Threatened Species Scientific Committee for delisting, however the results of this nomination are not yet known (J. Naaykens, Rio Tinto, pers. comm. 2015).

With regards to these three Threatened species:

- *Thryptomene wittweri* would not occur in the study area as no suitable habitat is present (mountains greater than 1,000 m elevation).
- *Aluta quadrata* is restricted to the southern flanks of the range of hills around Paraburdoo and, given its localised distribution, would not occur in the study area.
- *Lepidium catapycnon* (Hamersley Lepidium) has been recorded from the study area.

Lepidium catapycnon (Hamersley Lepidium) is a woody perennial herb to low shrub, which typically occurs in hummock grasslands on skeletal soils on the slopes of low to moderate-sized stony hills (Plate 5.1), occasionally extending onto the surrounding stony plains. It is frequently recorded in association with the Newman land system. This relatively short-lived species is often recorded from areas that have been recently disturbed, apparently persisting for only a few years.

Lepidium catapycnon was recorded from 81 locations in the study area, forming 11 separate populations[9] (Table 5.4). Over 4,211 individuals have been found in the study area to date (the number of individuals was not supplied for some records, and these are not included in the total). Locations are displayed on the vegetation mapping in Appendix 4.

All *Lepidium catapycnon* populations were located on the hills and slopes of the study area. Most populations (all except Populations 5 and 8) were associated with vegetation type H1, which typically occurred on a rocky, shale-covered surface (Plate 5.1). Populations 5 and 8 were located in vegetation types H6 and H2 respectively. Two of the records of *L. catapycnon* made from Population 5 were from an area that had been disturbed, and several records from Populations 3 were from hillslopes that were recently burnt (within 2-3 years; Plate 5.2). As noted previously, both fire and ground disturbance appear to promote recruitment in this species. While both adult and juvenile plants were noted in Populations 3 and 4, a higher proportion of juvenile plants were noted in Population 3 than in Population 4, where the fire age was estimated at 4-5 years (Biota 2014a). Two of the older records of *L. catapycnon* were revisited during a later survey but were not able to be found (see Table 5.4). It is possible that these populations have senesced after a period of years where no recruitment had occurred.

9 Plants more than 500 m from a known population were considered to be a new population (as per DEC 2010b).

Plate 5.1: A mature *Lepidium catapycnon* plant (left) and its preferred habitat of stony hillslopes with a shale surface (right).

Plate 5.2: Location of *Lepidium catapycnon* recorded by Biota (2010a, 2014b) at the base of the powerline tower (left), and a recently burnt hillslope within the *L. catapycnon* Population 3 (right).

Lepidium catapycnon occurs over a broad range through the Pilbara, extending from northwest of Tom Price across to Newman (Department of Parks and Wildlife 2014c). Over 30 populations are known, including one population in the conservation estate of the Karijini National Park, and some of these populations number in the hundreds to over a thousand individuals (M. Maier, Biota, pers. obs.). The 11 populations recorded in the study area are located within the known range of the species. The populations within the study area would therefore not be considered to be of regional significance, and would be unlikely to be of local significance.

Based on the vegetation mapped for the study area, considerable additional suitable habitat for *Lepidium catapycnon* occurs in the study area, not all of which has been searched. It is therefore possible that this species occurs at other locations within the study area. All hills and slopes of the study area (vegetation types H1-H11; totalling 9,074.6 ha) could potentially comprise suitable habitat for *L. catapycnon*, especially areas that have been burnt recently or have rocky ironstone shale slopes. However, most populations were recorded in vegetation type H1 and this vegetation type (2,840.3 ha) remains the most prospective unit for this species. Given the nature of the Channel Iron Deposits, the majority of the Yandi development would likely occur in the valleys and drainage areas rather than on the hilltops and slopes.

Table 5.4: All records of the Threatened species, *Lepidium catapycnon*, located in the study area.

† Population not found in 2014 during the PBS survey.

5.4.2 Priority Flora

The previous surveys have recorded five Priority flora species from the study area. These are described briefly below:

- *Rostellularia adscendens* var. *latifolia* (Priority 3)
  This herb to low shrub with purple-violet flowers (Plate 5.3) occurs in a broad range of habitats, but is most frequently recorded in drainage areas and low-lying areas on plains (Department of Parks and Wildlife 2014c). Two populations of this species totalling 13 individuals were recorded in the study area (Table 5.5). Population 1 was recorded approximately 60 m north of Marillana Creek, but this location has since been cleared for the JSW mine. Population 2 occurred on the floodplain of a major tributary of Marillana Creek (vegetation type F1).

  Table 5.5: All records of *Rostellularia adscendens* var. *latifolia* (Priority 3) in the study area.

Population	Source	Date	Easting (mE)	Northing (mN)	No. of Individuals
Population 1	Rio Tinto rare flora survey	10-Mar-02	724687	7479780	2
Population 2	Biota (2014b)	01-Mar-12	718797	7478505	10
		02-Mar-12	718790	7478459	1

  This taxon has a broad distribution across the Pilbara (over 400 km, extending from the Brockman locality to the Oakover River), with five populations known from Karijini National Park (Department of Parks and Wildlife 2014c). Several records of *Rostellularia adscendens* var. *latifolia* were made during a recent survey on a floodplain of Marillana Creek to the north of the YOX development, just outside the study area (Biota 2014e). Given that there are several records in the Yandi locality and that the study area lies within the broad range of this species, these populations are not considered to be either regionally or locally significant.

  It is possible that additional populations occur in the study area. The most prospective vegetation for this species would be vegetation type F1 (418.4 ha) and vegetation type F2 (314.6 ha).

- *Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3)
  This spreading shrub (Plate 5.4) grows to 0.5 m tall and produces yellow flowers in August. It typically occurs on steep slopes with red skeletal soils and exposed rock, often in gorges and gullies. Two populations of this species were recorded in the study area (Table 5.6). Population 1 was recorded from the bank of Marillana Creek, in between the YJC and JSW developments. This location has since been cleared for a haul road. The two other records were made south of the proposed PBS development from a rocky ridgeline (vegetation type H5). The first record, of three individuals, was located near the southern boundary of the study area. The second record, of two individuals, was made approximately 10 m outside the study area boundary. At both of these locations, the plants were growing out of the side of a free face at the top of a steep, shale-covered hillslope.

Table 5.6: All records of *Sida* sp. Barlee Range (S. van Leeuwen 1642) in the study area.

Population	Source	Date	Easting (mE)	Northing (mN)	No. of Individuals
Population 1	Biota (2004a)	02-Sep-04	731037	7478616	Not supplied
Population 2	Biota (2014a)	09-Jul-14	733697	7470558	3
		09-Jul-14	733720	7470548	2¥

¥ NB. 10 m south of the study area boundary.

Sida sp. Barlee Range (S. van Leeuwen 1642) is known from a number of locations throughout the Hamersley Range, extending over a range of approximately 250 km from Brockman to 36 km southeast at Coondiner Creek (Department of Parks and Wildlife 2014c). Numerous additional locations have been recorded approximately 30 km northwest at Koodaideri (Biota 2012a). The hills of the study area would contain considerable areas of suitable habitat and the low number of records of this species from the study area is likely a reflection of survey effort rather than an actual indication of this species' distribution. The individuals recorded from the study area would be unlikely to be considered regionally or locally significant.

The preferred habitat for *Sida* sp. Barlee Range (S. van Leeuwen 1642) comprises exposed rock in gullies and gorges, and vegetation type H5 (27.6 ha) and vegetation type H9 (13.8 ha) are therefore considered to represent the most prospective vegetation types to support further populations of this species in the study area.

Plate 5.3: *Rostellularia adscendens* var. *latifolia* (photo not from study area).

Plate 5.4: *Sida* sp. Barlee Range (S. van Leeuwen 1642) growing out of a rocky free face in the study area.

- *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) (Priority 3)
  This tussock grass (Plate 5.5) grows to 1.8 m tall and is typically associated with red clay pans where it may form dense grasslands, however there are occasional records of small populations or isolated individuals from creeks and floodplains. It differs from the more common and widespread *Themeda triandra* by its larger size, sturdier culms and pale bluish colouring (*T. triandra* has yellowish colouring). One record of this species has been made in the study area (Table 5.8) from vegetation type P2, approximately 160 m north of Marillana Creek in between the YJC and JSW developments.

Table 5.7: All records of *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) in the study area.

Population	Source	Date	Easting (mE)	Northing (mN)	No. of Individuals
Population 1	Biota (2004a)	02-Sep-04	731034	7479113	Not supplied

Themeda sp. Hamersley Station (M.E. Trudgen 11431) has a broad distribution over the Pilbara region. It has been recorded near Karratha and as far south as West Angelas, with dense grasslands occurring on the plains of Hamersley Station. Records have also been made in the Millstream-Chichester and Karijini National Parks (Department of Parks and Wildlife 2014c). The study area is located within the known range of this species. While only one record has been made in the study area, several populations are known from Koodaideri (Biota 2012e), which is situated to the north of Yandi. This record of *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) from the study area is therefore unlikely to be regionally or locally significant.

It is possible that additional isolated individuals of this species may occur in the study area. Floodplains such as vegetation units F1 (414.8 ha) and F2 (314.6 ha) or plains adjacent to Marillana and Weeli Wolli Creek would provide the most prospective habitats for this species.

- *Goodenia nuda* (Priority 4)

This erect to ascending, slender herb (Plate 5.6) grows to 50 cm tall, with yellow flowers and narrow, pale green glaucous leaves (Department of Parks and Wildlife 2014c). This species is typically found growing near creeklines and in wet areas. A total of 154 individuals from 11 separate populations were recorded from the study area (Table 5.8). *Goodenia nuda* was recorded in the east of the study area from Mulga woodlands (vegetation type P6; Populations 7, 8, 10 and 11) and plains (vegetation types P2 and P3; Population 9 and six individuals from population 7) located adjacent to Weeli Wolli and Marillana creeks. Two records were made in the JSW area; two records north of the JSW development in a tributary of Marillana Creek (vegetation types C2 and F1; Population 2) and the other record on a floodplain south of Marillana Creek (vegetation type F1; Population 1). The remaining records (Populations 3, 4, 5 and 6) were from the YOX area from a floodplain along a tributary of Marillana Creek (vegetation type F1).

Table 5.8: All records of *Goodenia nuda* in the study area.

Population	Source	Date	Easting (mE)	Northing (mN)	Number of Individuals
Population 1	Biota (2010a)	01-Aug-08	725105	7479657	Unknown

Population 11	Biota (2014a)	16-Mar-14	734807	7474388	5

Goodenia nuda has a broad distribution; most records occur over a range of approximately 500 km through the Pilbara bioregion, from Mardie Station on the coast to the eastern section of the Fortescue Valley (Department of Parks and Wildlife 2014c). Populations are known from Karijini and Millstream-Chichester National Parks. There is also an outlying record from the Canning Stock Route in the Gascoyne bioregion (Department of Parks and Wildlife 2014c).

Given the known range and the number of populations that occur in the study area, the records of *Goodenia nuda* are not considered to be regionally or locally significant.

It is possible that additional populations of this species occur in the study area. A large number of individuals are already known from the study area and this species is a small, often inconspicuous, herb. It would particularly be expected to occur on floodplains such as vegetation types F1 (414.8 ha) and F2 (314.6 ha). While F1 is the most prospective vegetation type for this species, it could also be found on the banks of creeklines or on plains.

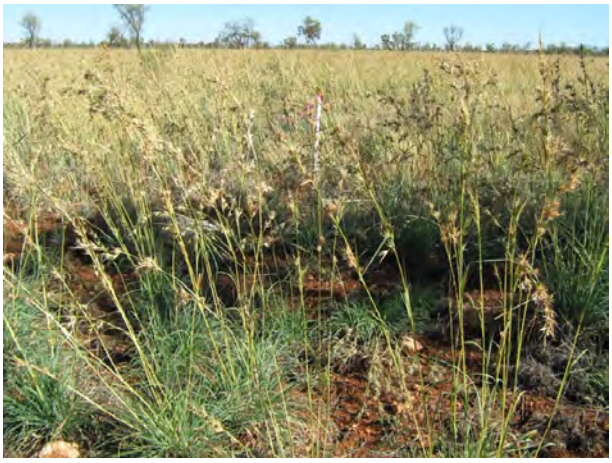

Plate 5.5: *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) (photo not from the study area).

Plate 5.6: *Goodenia nuda* inflorescence (photo not from the study area).

- *Rhynchosia bungarensis* (Priority 4)

This compact, prostrate creeper to low shrub (Plate 5.7) grows to 50 cm in height and has very resinous trifoliate leaves (Department of Parks and Wildlife 2014c). It has been recorded growing in pebbly, shingly coarse sand amongst boulders, in flowlines, on floodplains and in rocky gullies. One population was recorded in the study area, however the number of individuals was not provided (Table 5.9). The first location was in a small remnant of vegetation type P5 adjacent to the YJC development. The second location in the YJC development has since been cleared for a haul road.

Table 5.9: All records of *Rhynchosia bungarensis* in the study area.

Population	Source	Date	Easting (mE)	Northing (mN)	Number of Individuals
Population 1	Hamersley Iron (2003c)	Not supplied	728416	7480090	Unknown
		Not supplied	728557	7480244	Unknown

Rhynchosia bungarensis is known from a number of locations and has a broad distribution across the Pilbara. Populations are known from Karijini, Millstream-Chichester, Barlee Range and Cape Range National Parks. The population recorded in the study area is on the eastern edge of this species range. Several populations (together totalling 1,000+ individuals) have also been recorded from Koodaideri, which is situated to the north of Yandi (Biota 2012a). The population of *Rhynchosia bungarensis* in the study area is therefore not considered to be regionally or locally significant.

It is possible that additional populations occur in the study area, with the most prospective habitats for this species being the rocky beds of moderate-sized creeklines supporting vegetation types C2 (191.8 ha), C4 (1,395.5 ha) and C5 (26.0 ha) and gorges supporting vegetation types such as H9 (13.8 ha).

Plate 5.7: *Rhynchosia bungarensis* (photo not from the study area).

Although no records are known, one additional Priority flora species may potentially occur in the study area:

- *Stylidium weeliwolli* (Priority 2)
  This annual herb grows to 25 cm tall and produces pink flowers between August and September. This species has a relatively broad range through the Pilbara and Gascoyne bioregions, extending over more than 330 km, but is only infrequently recorded. This is probably partly due to its small and delicate stature, and also a reflection of the habitats in which it occurs (on floodplains, in seasonally damp or wet areas including root mats of *Melaleuca*, and in seepages around granite rocks). In the Pilbara, this species occurs mainly along major watercourses.

  There are two records of *Stylidium weeliwolli* from the Yandi locality: from a tributary of Marillana Creek (approximately 1.3 km from the western end of the study area), and from the vicinity of Weeli Wolli Springs in Weeli Wolli Creek (the closest record is approximately 9 km upstream of the study area). As these records are in close proximity and are located upstream in the respective creek systems, it is considered possible that this species occurs in the study area, with the most prospective habitat being the wetter parts of Marillana Creek and Weeli Wolli Creek (vegetation type C1). The small size and annual nature of this herb makes it difficult to locate, and further survey effort (systematic searches through prospective habitat) under optimal conditions would be required to determine whether this species does in fact occur.

5.4.3 Other Flora of Conservation Significance

Three flora taxa of interest were recorded from the study area. These are described briefly below:

- *Eulalia* sp. (Three Rivers Station, B. Forsyth AQ6789133)
  This currently undescribed species of *Eulalia* (Plate 5.8) was recorded from four locations within the study area (Biota 2014a, 2014c) including two records from a plain (vegetation type P2), one record from a floodplain (vegetation type F1) and one record from a minor creekline (vegetation type F4). Dr. Ken Tinley first collected this species in 2008 on Three Rivers Homestead (approximately 290 km south of Yandi) and the phrase name *Eulalia* sp. (Three Rivers Station) was applied (Bryan Simon, Queensland Herbarium, pers. comm. 2012). *Eulalia* sp. (Three Rivers Station) differs from the common *Eulalia* species occurring in the Pilbara (*E. aurea*) by its broader leaves, elongated rhizomes and the inflorescences remaining closed at maturity (Simon and Alfonso 2012). Currently, the phrase name is not recognised on FloraBase or Australia's Virtual Herbarium, however a formal description of *Eulalia* sp. (Three Rivers Station) is being progressed by Rachel Butler (Biota) and Mr. Malcolm Trudgen (M.E. Trudgen and Associates).

  This species has a broad range extending over approximately 380 km from the Pilbara to the Gascoyne bioregion, and it has been recorded from other surveys in the locality including at West Angelas (Biota 2014f) and Koodaideri (Biota 2012a). It is likely that this taxon has been under-collected given its similarity to *Eulalia aurea*. The populations in the study area are therefore unlikely to be considered either regionally or locally significant.

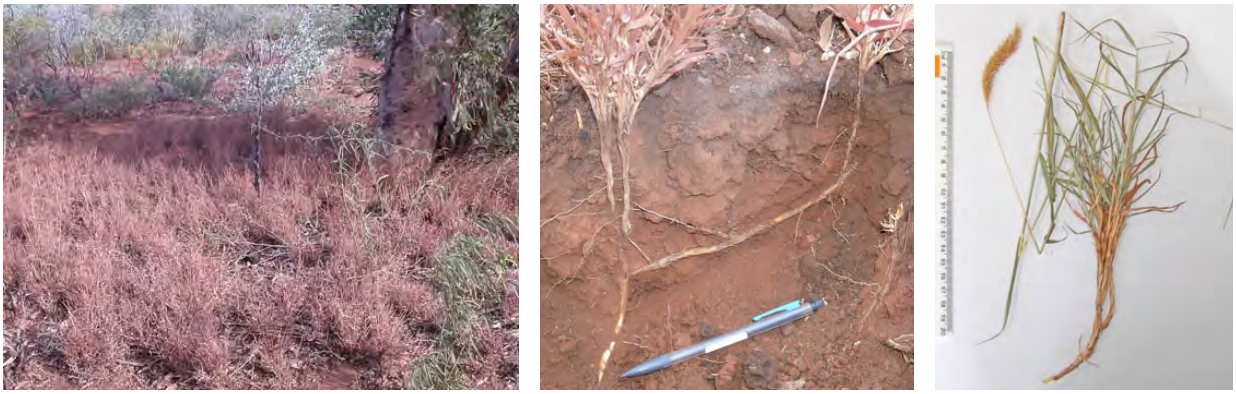

Plate 5.8: *Eulalia* sp. (Three Rivers Station, B. Forsyth AQ6789133): growth form, underground rhizome and pressed specimen.

- *Glycine* sp. aff. *arenaria*
  This creeper with apparent affinities to *Glycine arenaria* was collected from a single site in Marillana Creek (vegetation type C1), in between the YJC and the JSW developments (Biota 2014b). This taxon was identified by Malcolm Trudgen (M.E. Trudgen and Associates), who described it as uncommon in the Pilbara. To date, no specimens of *G. arenaria* have been vouchered from outside the Northern Kimberley. The voucher specimen collected by Biota was submitted to the WA Herbarium for lodgement in February 2013, but is believed to be still awaiting incorporation to the collection. This record may be regionally significant, however this cannot be determined until the taxonomy of this specimen is resolved.
- *Goodenia nuda/triodiophila*
  Two collections that could not be confidently identified as being either *Goodenia triodiophila* or the Priority 4 species *Goodenia nuda* (see Section 5.4.2) were recorded from a floodplain along a tributary of Marillana Creek near the YOX development (vegetation type F1). The two specimens collected represented a population of 33 individuals. Both of these collections were determined as unresolved by Malcolm Trudgen and have been submitted to the WA Herbarium for lodgement. The difficulty in identifying these specimens is most likely due to the poor quality of the material and even if they do represent the Priority 4 *Goodenia nuda*, they are unlikely to be locally or regionally significant records (see Section 5.4.2).

5.5 Poorly Collected, Variable or Incompletely Resolved Taxa

Some apparent range extensions were recorded, which are considered likely to represent poorly collected taxa (*Euphorbia australis* var. *australis, Glycine* sp. aff. *arenaria, Heliotropium glabellum Peripleura hispidula* var. *hispidula* and *Sida* sp. A. Kimberley Flora (P.A. Fryxell &L.A. Craven 3900); see Appendix 7). In addition, some variable taxa that were distinguished with informal names in previous reporting are referred to in this document as single entities but with the suffix “sens. lat.”, meaning ‘in the broad sense’ (see Appendix 7). Two taxa (*Portulaca oleracea/intraterranea* and *Sorghum plumosum* var. *plumosum*) recorded from the study area have not been conclusively resolved due to a lack of taxonomic framework (see Appendix 7). None of these taxa are currently considered to be of conservation significance.

5.6 Introduced Flora Species (Weeds)

A total of 36 introduced flora species have been recorded from the study area to date. This includes the 22 species recorded from the component vegetation and flora surveys (see Section 3.1) and an additional 14 species that were recorded during other surveys (i.e. records from Rio Tinto’s database of introduced flora).

Table 5.10 presents the total number of locations from which each weed was recorded. These locations are mapped in Appendix 6. Weeds were most densely distributed around areas of development and disturbance, and also along creeklines and floodplains in the study area. These records are indicative only, as the entire area was not searched, thus resulting in an

underestimation of the actual weed presence in the area. It is noteworthy that some of these locations have subsequently been cleared. Descriptions of each weed species and co-ordinates for each weed record are provided in the individual survey reports.

None of the weeds recorded are listed as Weeds of National Significance (Thorp and Lynch 2000)[10]. However, **Argemone ochroleuca* (Mexican Poppy) is listed under the WA *Biosecurity and Agriculture Management Act 2007* (the BAM Act) as a declared pest for the whole of WA in category C3 (management).

The Department of Parks and Wildlife currently applies an alternative ranking system to weed species within each management region, called the Weed Prioritisation Process (Department of Parks and Wildlife 2013). None of the weed species recorded in the study area are ranked as Very High or High management priorities for the Pilbara region. However, it should be noted that for some species (e.g. **Cenchrus* spp.), this is a result of their low feasibility of control, rather than a reflection of their perceived invasiveness.

Ricinus communis* is listed as an 'Alert' species, meaning that while it is known from the Pilbara region it does not occur on land managed by the Department of Parks and Wildlife (Department of Parks and Wildlife 2013). While the management priority of **Acetosa vesicaria* is ranked by the Department of Parks and Wildlife (2013) as Medium, most other species recorded in the study area are ranked as Low or Negligible. It is noted that further assessment is required to rank **Chloris virgata.* Several species that are uncommon or not known from the Pilbara (Catharanthus roseus, Lactuca serriola, *Sonchus asper, *Lotus sp., *Oxalis corniculata, *Cenchrus clandestinus, *Paspalum dilatatum* and **Typha orientalis*) had no ranking.

[10] For the current listing of Weeds of National Significance, go to http://www.weeds.org.au/WoNS/

6.0 Key Findings and Discussion

6.1 Survey Effort

A large proportion (63%) of the Yandi Integration study area has been surveyed for vegetation and flora values at a detailed level. An additional 15% of the study area has been subject to historical vegetation and flora surveys, however the flora data associated with these surveys were not provided in the relevant reports and could therefore not be used as part of this study. The broad level at which these vegetation types were described, coupled with the absence of any flora data to verify the units, prevented the integration of this vegetation mapping with the more recent surveys. Consequently, this mapping is not discussed in detail or presented in this report. These areas, together with the 8% of the study area that remains unsurveyed, were mapped as a desktop exercise using aerial photography and information extrapolated from adjacent mapping. The resulting vegetation mapping should be viewed as indicative only (refer to Figure 4.1) and would need to be ground-truthed and validated with flora sampling sites.

A total of 209 quadrats and 35 relevés have been sampled in the study area to date. All vegetation types were sampled by at least one flora site, and all but four vegetation types (H8, H9, H10 and H11) were sampled by two or more flora sites. Quadrats were more numerous around the newer development areas (YJC, YSW and YOX) and the proposed PBS deposit.

Seasonal sampling of quadrats is a requirement for a Level 2 flora and vegetation survey as per EPA (2004). It has been acknowledged that a 'High' level of satisfaction can be reached from resampling a proportion of quadrats (approximately 25–50%) if the initial survey was completed under appropriate seasonal conditions (EPA and DEC 2012, p. 123). Seasonally sampled quadrats were completed for the Billiards/PBS, JSW and YOX survey areas, however no quadrats were resampled for the Yandi Expansion survey, located in the centre of the study area near the existing YJC. A subset of 83 (40%) of the total number of quadrats were seasonally sampled. The proportion of quadrats resampled was higher for the more recent surveys (e.g. approximately 56% of quadrats were resampled within the PBS survey area). Further discussion of the proposed PBS development is provided in Section 6.4.

6.2 Vegetation of Conservation Significance

A total of 30 vegetation types have been described for the study area, none of which represent TECs or PECs. This is considered to be within the range expected for a study area of this size in this locality, taking into account the habitats present and the scale at which the vegetation mapping was completed. None of the vegetation types are considered to be restricted to the study area.

Four riparian vegetation types (C1, C2, C3 and C5) are considered to be of local conservation significance: these were all associated with Marillana Creek and Weeli Wolli Creek, which are major ephemeral water courses for the locality. Vegetation type C1 comprised a woodland of riparian Eucalypts with scattered stands of *Melaleuca argentea*. Although creeklines are susceptible to weed invasion and disturbance from grazing herbivores, this vegetation type was in Good condition, with only scattered weeds and limited disturbance from cattle. Due to the presence of two phreatophytic tree species (*Eucalyptus camaldulensis* and *Melaleuca argentea*) as dominant species, vegetation type C1 would be most susceptible to changes in groundwater depth causes by dewatering and discharge associated with below water table mining. Vegetation types C2, C3 and C5 were dominated by only scattered trees of *Eucalyptus victrix,* but were similarly in Good to Very Good condition. Similar vegetation assemblages are widespread throughout the Pilbara in several major creek systems, and these vegetation types would therefore be of significance at the local, rather than regional, scale.

A total of 2,770 ha (approximately 14%) of the study area was mapped as Disturbed. The vegetation in the remaining sections of the study area was ranked between Excellent and Very Poor condition. The main disturbance factor noted was invasion by weeds. Most weed species occurred as

scattered individuals, however **Cenchrus ciliaris* (sometimes together with **C. setiger*) formed dense populations causing degradation in some creeklines and floodplains. Cattle were present in the study area but were generally restricted to creekline and floodplain habitat. Some damage caused by grazing and trampling was noted, and this was more prevalent in the vegetation that was extensively invaded by **Cenchrus* spp.

Two vegetation types associated with Weeli Wolli Creek and Marillana Creek were degraded by these disturbances, comprising vegetation types C4 (rated Good to Very Poor) and F2 (rated Poor to Very Poor). All other vegetation types in the study area have inherent value as relatively intact and good quality examples of native vegetation, but are not considered to have any elevated conservation value beyond this.

6.3 Flora of Conservation Significance

A total of 548 native flora species have been recorded from the study area. This total is in the range expected for a study area of this size in this locality.

One Threatened flora species, *Lepidium catapycnon* (Hamersley Lepidium), has been recorded. This species was recorded from 81 locations on the hills and slopes of the study area (vegetation types H1, H2 and H6), comprising a total of 4,211 individuals in nine separate populations. All hills and slopes of the study area could provide potential suitable habitat for further populations of this species, however as most populations occurred in vegetation type H1 (2,840.3 ha), this is considered the most prospective habitat for this species. The two other Threatened species listed for the Pilbara (*Aluta quadrata* and *Thryptomene wittweri*) would not occur in the study area due to a lack of suitable habitat and their relatively restricted distributions in the Pilbara (south-facing gullies near Paraburdoo, and the crests and upper slopes of a mountain in Karijini National park, respectively).

Five Priority flora species have been recorded from the study area:

- *Rostellularia adscendens* var. *latifolia* (Priority 3) was recorded from three locations on a floodplain (vegetation type F1), comprising two populations with a total of 13 individuals. One of these populations (of two individuals) has since been cleared.
- *Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3) was recorded from three locations, comprising two populations with a total of five individuals. One population was recorded from the bank of Marillana Creek, which has now been cleared (the number of individuals in this population was not recorded). The remaining population was recorded from a rocky ridgeline (vegetation type H5).
- *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) (Priority 3) was recorded from one location on a plain adjacent to Marillana Creek (vegetation type P2); the number of individuals was not recorded.
- *Goodenia nuda* (Priority 4) was recorded from 21 locations from floodplains (vegetation type F1), creeklines (vegetation type C2) and plains (vegetation type P6, P2 and P3). A total of 154 individuals were recorded from 11 separate populations.
- *Rhynchosia bungarensis* (Priority 4) was recorded from two locations forming one population in vegetation type P5; the number of individuals was not recorded. One of these locations has since been cleared.

One other Priority species, *Stylidium weeliwolli* (Priority 2), could potentially occur in the study area. This delicate ephemeral herb could potentially occur in vegetation type C1 along Marillana Creek and Weeli Wolli Creek, although it has not been recorded to date. This species typically occurs in permanent or seasonally wet areas, but would only be recorded under optimal conditions. There are two records of this species from the Yandi locality, with the closest being 1.3 km upstream of the study area.

The remainder of the species recorded for the study area are considered to be typical for this part of the Pilbara region. The flora of the study area is therefore representative of the locality.

A total of 36 weed species were recorded in the study area. None of the weeds recorded are listed as Weeds of National Significance (Thorp and Lynch 2000). However, **Argemone ochroleuca* (Mexican Poppy) is listed under the BAM Act as a declared pest for the whole of WA in category C3 (management). **Cenchrus ciliaris* (often together with **C. setiger*) was the most prolific weed in the study area and formed dense infestations in some floodplains and creeklines.

6.4 Proposed PBS Development

A Level 2 vegetation and flora survey has been completed in the Billiards area for the proposed PBS development (see Figure 2.1; details of this survey are provided in Biota (2014a)). These vegetation and flora data form part of a wider dataset, which has been compiled from several vegetation and flora surveys that have been completed in the Yandi integration study area. The main findings of the PBS survey can be placed into a better context when viewed as part of the overall Yandi study area.

In general, the vegetation and flora values found within the PBS survey area are consistent with the wider dataset for the Yandi integration study area. Most vegetation types and vascular flora species recorded in the PBS area have also been recorded in the other survey areas at Yandi (see Sections 4.1 and 5.1). The species richness of the PBS survey area is within the range expected for a survey area of this size in the locality, and is comparable to the other survey areas within the Yandi study area (see Section 5.3).

The two Priority flora that occur in the PBS survey area, *Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3) and *Goodenia nuda* (Priority 4), have both been recorded from other locations in the Yandi integration study area. The populations in the area would not be expected to represent regionally or locally significant populations (see Section 5.4.2).

Four populations of the Threatened species, *Lepidium catapycnon,* are currently known to occur in the PBS survey area (Populations 1 to 4), two of which are located in proposed preliminary waste dump locations (Biota 2014a). No *L. catapycnon* individuals are currently located within the proposed PBS pit. An additional five *L. catapycnon* populations occur outside the proposed PBS development area, with nine populations in total occurring in the Yandi integration study area. The number of individuals within the PBS development area is relatively low compared to the wider Yandi area (a total of 1,097 individuals occur in the PBS development area, compared with 3,085 individuals outside the PBS development area in the wider Yandi integration study area). There are also a large number of records of this species from the broader locality and some of the populations comprise hundreds to over a thousand individuals (see Section 5.4).

This page intentionally blank.

7.0 Glossary and Acronyms

*	Used prior to a species name to denote a weed species.
Alluvial	Loose, unconsolidated (not cemented together into a solid rock) soil or sediments, which have been eroded, reshaped by water in some form, and redeposited in a non-marine setting.
Anabranching	An anabranching river consists of multiple channels separated by vegetated (sometimes semi-permanent) alluvial islands.
Annual (plant)	A plant that lives for only one year.
BAM Act	The WA *Biosecurity and Agriculture Management Act 2007.*
Conservation Significant	A plant that is recognised to be rare, unusual, new or poorly sampled; may have a formally assigned conservation ranking (see Appendix 1 for more on the WA conservation framework).
Culm	The stem of a grass or sedge.
EPA	Environmental Protection Authority of Western Australia.
EPBC Act	The Commonwealth *Environment Protection and Biodiversity Conservation Act 1999.*
Ephemeral	A plant that lives a very short time; less than one year, usually less than six months.
Floodout	An area of land, usually adjacent to a river or major drainage system, that receives water during periods of overbank flow associated with normal or extreme flood events. Can be situated at the end of the drainage line.
Flora keys	Botanical publications containing a series of questions regarding the characteristics of plants, aiding in the identification of different taxa.
Foot Traverse	Consists of walking through an area to confirm or note vegetation boundaries or to search for flora (usually sampling a narrow corridor/cross section of vegetation).
Free face	A vertical or near vertical landform element situated part way up a slope but not comprising the entire slope.
GIS	Geographic Information System.
GPS	Global Positioning System.
PEC	Priority Ecological Community (see Appendix 1 for more on the WA conservation framework).
Perennial	A plant that lives for more than two growing seasons.
Phreatophytic	A species that is primarily or totally reliant on groundwater to meet its physiological water requirements.
Priority flora	Flora species listed by the Department of Parks and Wildlife as requiring additional information to properly evaluate their conservation significance; see Appendix 1 for more on the WA conservation framework.
sens. lat.	Abbreviation of *sensu lato* (Latin), meaning “in the broad sense”.
sp. (plural: spp.)	Abbreviation of “species”.
Stratum (plural: strata)	A horizontal level of vegetation defined by growth form (and sometimes height); e.g. low trees, tall trees, tussock grasses, hummock grasses.
subsp.	Abbreviation of “subspecies”.
Taxon (plural: taxa)	A taxonomic entity, typically at species level or below.
TEC	Threatened Ecological Community (see Appendix 1 for more on the WA conservation framework).

Threatened flora	Flora species protected by legislation, either listed under the Commonwealth EPBC Act or the WA *Wildlife Conservation Act 1950* (species formerly known as Declared Rare Flora); see Appendix 1 for more on the WA conservation framework.
var.	Abbreviation of “variety”.

Appendix 1

Framework for Conservation Significance Ranking of Communities and Species in WA

A. Definitions, Categories and Criteria for Threatened and Priority Ecological Communities

1. General Definitions

Ecological Community
A naturally occurring biological assemblage that occurs in a particular type of habitat.

Note: The scale at which ecological communities are defined will often depend on the level of detail in the information source, therefore no particular scale is specified.

A threatened ecological community (TEC) is one which is found to fit into one of the following categories; "presumed totally destroyed", "critically endangered", "endangered" or "vulnerable".

Possible threatened ecological communities that do not meet survey criteria are added to DPaW's Priority Ecological Community Lists under Priorities 1, 2 and 3. Ecological Communities that are adequately known, are rare but not threatened, or meet criteria for Near Threatened, or that have been recently removed from the threatened list, are placed in Priority 4. These ecological communities require regular monitoring. Conservation Dependent ecological communities are placed in Priority 5.

An assemblage is a defined group of biological entities.

Habitat is defined as the areas in which an organism and/or assemblage of organisms lives. It includes the abiotic factors (e.g. substrate and topography), and the biotic factors.

Occurrence: a discrete example of an ecological community, separated from other examples of the same community by more than 20 metres of a different ecological community, an artificial surface or a totally destroyed community.

By ensuring that every discrete occurrence is recognised and recorded future changes in status can be readily monitored.

Adequately Surveyed is defined as follows:
"An ecological community that has been searched for thoroughly in most likely habitats, by relevant experts."

Community structure is defined as follows:
"The spatial organisation, construction and arrangement of the biological elements comprising a biological assemblage" (e.g. *Eucalyptus salmonophloia* woodland over scattered small shrubs over dense herbs; structure in a faunal assemblage could refer to trophic structure, e.g. dominance by feeders on detritus as distinct from feeders on live plants).

Definitions of Modification and Destruction of an ecological community:

Modification: "changes to some or all of ecological processes (including abiotic processes such as hydrology), species composition and community structure as a direct or indirect result of human activities. The level of damage involved could be ameliorated naturally or by human intervention."

Destruction: "modification such that reestablishment of ecological processes, species composition and community structure within the range of variability exhibited by the original community is unlikely within the foreseeable future even with positive human intervention."

Note: Modification and destruction are difficult concepts to quantify, and their application will be determined by scientific judgement. Examples of modification and total destruction are cited below:

Modification of ecological processes: The hydrology of Toolibin Lake has been altered by clearing of the catchment such that death of some of the original flora has occurred due to dependence on fresh water. The system may be bought back to a semblance of the original state by redirecting saline runoff and pumping waters of the rising underground watertable away to restore the hydrological balance. Total destruction of downstream lakes has occurred due to hydrology being altered to the point that few of the original flora or fauna species are able to tolerate the level of salinity and/or water logging.

Modification of structure: The understorey of a plant community may be altered by weed invasion due to nutrient enrichment by addition of fertiliser. Should the additional nutrients be removed from the system the balance may be restored, and the original plant species better able to compete. Total destruction may occur if additional nutrients continue to be added to the system causing the understorey to be completely replaced by weed species, and death of overstorey species due to inability to tolerate high nutrient levels.

Modification of species composition: Pollution may cause alteration of the invertebrate species present in a freshwater lake. Removal of pollutants may allow the return of the original inhabitant species. Addition of

residual highly toxic substances may cause permanent changes to water quality, and total destruction of the community.

Threatening processes are defined as follows:
"Any process or activity that threatens to destroy or significantly modify the ecological community and/or affect the continuing evolutionary processes within any ecological community."

Examples of some of the continuing threatening processes in Western Australia include: general pollution; competition, predation and change induced in ecological communities as a result of introduced animals; competition and displacement of native plants by introduced species; hydrological changes; inappropriate fire regimes; diseases resulting from introduced micro-organisms; direct human exploitation and disturbance of ecological communities.

Restoration is defined as returning an ecological community to its pre-disturbance or natural state in terms of abiotic conditions, community structure and species composition.

Rehabilitation is defined as the re-establishment of ecological attributes in a damaged ecological community although the community will remain modified.

2. Definitions and Criteria for Presumed Totally Destroyed, Critically Endangered, Endangered and Vulnerable Ecological Communities

ECOLOGICAL COMMUNITIES

Presumed Totally Destroyed (PD)
An ecological community that has been adequately searched for but for which no representative occurrences have been located. The community has been found to be totally destroyed or so extensively modified throughout its range that no occurrence of it is likely to recover its species composition and/or structure in the foreseeable future.

An ecological community will be listed as presumed totally destroyed if there are no recent records of the community being extant and either of the following applies (A or B):

A) Records within the last 50 years have not been confirmed despite thorough searches of known or likely habitats or

B) All occurrences recorded within the last 50 years have since been destroyed

Critically Endangered (CR)
An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or that was originally of limited distribution and is facing severe modification or destruction throughout its range in the immediate future, or is already severely degraded throughout its range but capable of being substantially restored or rehabilitated.

An ecological community will be listed as Critically Endangered when it has been adequately surveyed and is found to be facing an extremely high risk of total destruction in the immediate future. This will be determined on the basis of the best available information, by it meeting any one or more of the following criteria (A, B or C):

A) The estimated geographic range, and/or total area occupied, and/or number of discrete occurrences since European settlement have been reduced by at least 90% and either or both of the following apply (i or ii):

   i) geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is imminent (within approximately 10 years);

   ii) modification throughout its range is continuing such that in the immediate future (within approximately 10 years) the community is unlikely to be capable of being substantially rehabilitated.

B) Current distribution is limited, and one or more of the following apply (i, ii or iii):

   i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the immediate future (within approximately 10 years);

   ii) there are very few occurrences, each of which is small and/or isolated and extremely vulnerable to known threatening processes;

   iii) there may be many occurrences but total area is very small and each occurrence is small and/or isolated and extremely vulnerable to known threatening processes.

C) The ecological community exists only as highly modified occurrences that may be capable of being rehabilitated if such work begins in the immediate future (within approximately 10 years).

Endangered (EN)
An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or was originally of limited distribution and is in danger of significant modification throughout its range or severe modification or destruction over most of its range in the near future.

An ecological community will be listed as Endangered when it has been adequately surveyed and is not Critically Endangered but is facing a very high risk of total destruction in the near future. This will be determined on the basis of the best available information by it meeting any one or more of the following criteria (A, B, or C):

A) The geographic range, and/or total area occupied, and/or number of discrete occurrences have been reduced by at least 70% since European settlement and either or both of the following apply (i or ii):

   i) the estimated geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is likely in the short term future (within approximately 20 years);

   ii) modification throughout its range is continuing such that in the short term future (within approximately 20 years) the community is unlikely to be capable of being substantially restored or rehabilitated.

B) Current distribution is limited, and one or more of the following apply (i, ii or iii):

   i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the short term future (within approximately 20 years);

   ii) there are few occurrences, each of which is small and/or isolated and all or most occurrences are very vulnerable to known threatening processes;

   iii) there may be many occurrences but total area is small and all or most occurrences are small and/or isolated and very vulnerable to known threatening processes.

C) The ecological community exists only as very modified occurrences that may be capable of being substantially restored or rehabilitated if such work begins in the short-term future (within approximately 20 years).

Vulnerable (VU)
An ecological community that has been adequately surveyed and is found to be declining and/or has declined in distribution and/or condition and whose ultimate security has not yet been assured and/or a community that is still widespread but is believed likely to move into a category of higher threat in the near future if threatening processes continue or begin operating throughout its range.

An ecological community will be listed as Vulnerable when it has been adequately surveyed and is not Critically Endangered or Endangered but is facing a high risk of total destruction or significant modification in the medium to long-term future. This will be determined on the basis of the best available information by it meeting any one or more of the following criteria (A, B or C):

A) The ecological community exists largely as modified occurrences that are likely to be capable of being substantially restored or rehabilitated.

B) The ecological community may already be modified and would be vulnerable to threatening processes, is restricted in area and/or range and/or is only found at a few locations.

C) The ecological community may be still widespread but is believed likely to move into a category of higher threat in the medium to long term future because of existing or impending threatening processes.

3. Definitions and Criteria for Priority Ecological Communities

PRIORITY ECOLOGICAL COMMUNITY LIST
Possible threatened ecological communities that do not meet survey criteria or that are not adequately defined are added to the Priority Ecological Community Lists under Priorities 1, 2 and 3. These three categories are ranked in order of priority for survey and/or definition of the community, and evaluation of conservation status, so that consideration can be given to their declaration as threatened ecological communities. Ecological Communities that are adequately known, and are rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list, are placed in Priority 4. These ecological communities require regular monitoring. Conservation Dependent ecological communities are placed in Priority 5.

Priority One: Poorly-known ecological communities
Ecological communities with apparently few, small occurrences, all or most not actively managed for conservation (e.g. within agricultural or pastoral lands, urban areas, active mineral leases) and for which current threats exist. Communities may be included if they are comparatively well-known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under immediate threat from known threatening processes across their range.

Priority Two: Poorly-known ecological communities
Communities that are known from few small occurrences, all or most of which are actively managed for conservation (e.g. within national parks, conservation parks, nature reserves, State forest, unallocated Crown land, water reserves, etc.) and not under imminent threat of destruction or degradation. Communities may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under threat from known threatening processes.

Priority Three: Poorly known ecological communities

(i) Communities that are known from several to many occurrences, a significant number or area of which are not under threat of habitat destruction or degradation or:

(ii) communities known from a few widespread occurrences, which are either large or within significant remaining areas of habitat in which other occurrences may occur, much of it not under imminent threat, or;

(iii) communities made up of large, and/or widespread occurrences, that may or not be represented in the reserve system, but are under threat of modification across much of their range from processes such as grazing by domestic and/or feral stock, and inappropriate fire regimes.

Communities may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and/or are not well defined, and known threatening processes exist that could affect them.

Priority Four: Ecological communities that are adequately known, rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list. These communities require regular monitoring.

(a) Rare. Ecological communities known from few occurrences that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These communities are usually represented on conservation lands.

(b) Near Threatened. Ecological communities that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable.

(c) Ecological communities that have been removed from the list of threatened communities during the past five years.

Priority Five: Conservation Dependent ecological communities
Ecological communities that are not threatened but are subject to a specific conservation program, the cessation of which would result in the community becoming threatened within five years.

Department of Parks and Wildlife

CONSERVATION CODES

for Western Australian Flora and Fauna

T: **Threatened species -** Specially protected under the *Wildlife Conservation Act 1950,* listed under Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice for Threatened Fauna and Wildlife Conservation (Rare Flora) Notice for Threatened Flora (which may also be referred to as Declared Rare Flora).

Species* which have been adequately searched for and are deemed to be in the wild either rare, in danger of extinction, or otherwise in need of special protection, and have been gazetted as such.

X: **Presumed extinct species -** Specially protected under the *Wildlife Conservation Act 1950,* listed under Schedule 2 of the Wildlife Conservation (Specially Protected Fauna) Notice for Presumed Extinct Fauna and Wildlife Conservation (Rare Flora) Notice for Presumed Extinct Flora (which may also be referred to as Declared Rare Flora).

Species* which have been adequately searched for and there is no reasonable doubt that the last individual has died, and have been gazetted as such.

IA: **Migratory birds protected under an international agreement -** Specially protected under the *Wildlife Conservation Act 1950,* listed under Schedule 3 of the Wildlife Conservation (Specially Protected Fauna) Notice.

Birds that are subject to an agreement between governments of Australia and Japan, China and The Republic of Korea relating to the protection of migratory birds and birds in danger of extinction.

S: **Other specially protected fauna -** Specially protected under the *Wildlife Conservation Act 1950,* listed under Schedule 4 of the Wildlife Conservation (Specially Protected Fauna) Notice.

Threatened Fauna and Flora are further recognised by the Department according to their level of threat using IUCN Red List criteria. For example Carnaby's Cockatoo *Calyptorynchus latirostris* is specially protected under the *Wildlife Conservation Act 1950* as a threatened species with a ranking of endangered.

Ranking:

CR: Critically Endangered - considered to be facing an extremely high risk of extinction in the wild.

EN: Endangered – considered to be facing a very high risk of extinction in the wild.

VU: Vulnerable - considered to be facing a high risk of extinction in the wild.

A list of the current rankings can be downloaded from the Listing of species and ecological communities webpage http://dpaw.wa.gov.au/plants-and-animals/threatened-species-and-communities/84-listing-of-species-and-ecological-communities .

Species that have not yet been adequately surveyed to be listed under Schedule 1 or 2 are added to the Priority Flora and Priority Fauna Lists under Priorities 1, 2 or 3. These three categories are ranked in order of priority for survey and evaluation of conservation status so that consideration can be given to their declaration as threatened flora or fauna. Species that are adequately known, are rare but not threatened, or meet criteria for Near Threatened, or that have been recently removed from the threatened list for other than taxonomic reasons, are placed in Priority 4. These species require regular monitoring. Conservation Dependent species are placed in Priority 5.

1: Priority One: Poorly-known species

Species that are known from one or a few collections or sight records (generally less than five), all on lands not managed for conservation, e.g. agricultural or pastoral lands, urban areas, Shire, rail reserves and Main Roads WA road, gravel and soil reserves, and active mineral leases and under threat of habitat destruction or degradation. Species may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under immediate threat from known threatening processes.

2: Priority Two: Poorly-known species

Species that are known from one or a few collections or sight records, some of which are on lands not under imminent threat of habitat destruction or degradation, e.g. national parks, conservation parks, nature reserves, State forest, unallocated Crown land, water reserves, etc. Species may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under threat from known threatening processes.

3: Priority Three: Poorly-known species

Species that are known from collections or sight records from several localities not under imminent threat, or from few but widespread localities with either large population size or significant remaining areas of apparently suitable habitat, much of it not under imminent threat. Species may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and known threatening processes exist that could affect them.

4: Priority Four: Rare, Near Threatened and other species in need of monitoring

(a) Rare. Species that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These species are usually represented on conservation lands.
(b) Near Threatened. Species that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable.
(c) Species that have been removed from the list of threatened species during the past five years for reasons other than taxonomy.

5: Priority Five: Conservation Dependent species

Species that are not threatened but are subject to a specific conservation program, the cessation of which would result in the species becoming threatened within five years.

*Species includes all taxa (plural of taxon - a classificatory group of any taxonomic rank, e.g. a family, genus, species or any infraspecific category i.e. subspecies, variety or forma).

Appendix 2

Vegetation Structural Classes and Condition Scale

Vegetation Structural Classes*

Stratum	Canopy Cover (%)				
	70-100%	30-70%	10-30%	2-10%	<2%
Trees over 30 m	Tall closed forest	Tall open forest	Tall woodland	Tall open woodland	Scattered tall trees
Trees 10-30 m	Closed forest	Open forest	Woodland	Open woodland	Scattered trees
Trees under 10 m	Low closed forest	Low open forest	Low woodland	Low open woodland	Scattered low trees
Shrubs over 2 m	Tall closed scrub	Tall open scrub	Tall shrubland	Tall open shrubland	Scattered tall shrubs
Shrubs 1-2 m	Closed heath	Open heath	Shrubland	Open shrubland	Scattered shrubs
Shrubs under 1 m	Low closed heath	Low open heath	Low shrubland	Low open shrubland	Scattered low shrubs
Hummock grasses	Closed hummock grassland	Hummock grassland	Open hummock grassland	Very open hummock grassland	Scattered hummock grasses
Grasses, Sedges, Herbs	Closed tussock grassland / bunch grassland / sedgeland / herbland	Tussock grassland / bunch grassland / sedgeland / herbland	Open tussock grassland / bunch grassland / sedgeland / herbland	Very open tussock grassland / bunch grassland / sedgeland / herbland	Scattered tussock grasses / bunch grasses / sedges / herbs

* Based on Muir (1977), and Aplin's (1979) modification of the vegetation classification system of Specht (1970):

- Aplin T.E.H. (1979). The Flora. Chapter 3 In O'Brien, B.J. (ed.) (1979). *Environment and Science*. University of Western Australia Press;
- Muir B.G. (1977). Biological Survey of the Western Australian Wheatbelt. Part II: Vegetation and habitat of Bendering Reserve. *Records of the Western Australian Museum*, Suppl. No. 3;
- Specht R.L. (1970). Vegetation. In: *The Australian Environment*. 4th edn (Ed. G.W. Leeper). Melbourne.

Vegetation Condition Scale*

E = Excellent (=Pristine of BushForever) Pristine or nearly so; no obvious signs of damage caused by the activities of European man.
VG = Very Good (= Excellent of BushForever) Some relatively slight signs of damage caused by the activities of European man. For example, some signs of damage to tree trunks caused by repeated fire, the presence of some relatively non-aggressive weeds such as **Sonchus oleraceus* or **Citrullus* spp., or occasional vehicle tracks.
G = Good (= Very Good of BushForever) More obvious signs of damage caused by the activities of European man, including some obvious impact on the vegetation structure such as that caused by low levels of grazing or by selective logging. Weeds as above, possibly plus some more aggressive ones such as **Cenchrus* spp.
P = Poor (= Good of BushForever) Still retains basic vegetation structure or ability to regenerate to it after very obvious impacts of activities of European man, such as grazing, partial clearing (chaining) or frequent fires. Weeds as above, probably plus some more aggressive ones such as **Cenchrus* spp.
VP = Very Poor (= Degraded of BushForever) Severely impacted by grazing, very frequent fires, clearing or a combination of these activities. Scope for some regeneration but not to a state approaching good condition without intensive management. Usually with a number of weed species including very aggressive species such as **Prosopis* spp.
D = Completely Degraded (= Completely Degraded of BushForever) Areas that are completely or almost completely without native species in the structure of their vegetation; i.e. areas that are cleared or 'parkland cleared' with their flora comprising weed or crop species with isolated native trees or shrubs.

* Based on Trudgen M.E. (1988). A Report on the Flora and Vegetation of the Port Kennedy Area. Unpublished report prepared for Bowman Bishaw and Associates, West Perth.

Appendix 3

Summary of Vegetation Types Recorded in the Study Area

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
Vegetation of Major Creeklines and Tributaries						
C1: EcEvMaMgAc	*Eucalyptus camaldulensis* subsp. *refulgens, E. victrix* woodland over *Melaleuca argentea*¥, *M. glomerata, Acacia coriacea* subsp. *pendens* low open woodland ¥ *M. argentea* was not continuous through this vegetation type but rather occurred as scattered stands.	318.1	Scoured creekbeds and channels in the wetter parts of Marillana and Weeli Wolli Creeks; throughout the study area, except in the northeast.	9 quadrats: OXB06^, YAQ22, YEX16, YEX21, YEX39, YBI23, YBI30S^, YSW08, YVI06.	Very Good to Good.	
C2: EvChAtuGwTErCYpERItTHt	*Eucalyptus victrix,* (*Corymbia hamersleyana*¥) scattered low trees over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* tall shrubland over *Tephrosia rosea* var. Fortescue Creeks (M.I.H. Brooker 2186) low shrubland over *Cymbopogon ambiguus, C. procerus, Eriachne tenuiculmis, Themeda triandra* very open tussock grassland ¥ *C. hamersleyana* was a dominant species in tributaries but not in the main channels of Marillana Creek.	191.8	Creekbeds of Marillana Creek, (south of the YJC mine) and major tributaries of Marillana and Weeli Wolli Creeks throughout the study area.	6 quadrats: BIL02^, BIL31^, OXB16^, YEX25, YSW01 (cleared), YVI09.	Very Good to Good.	
C3: EvAciAcMgCEc	*Eucalyptus victrix* scattered trees over *Acacia citrinoviridis, A. coriacea* subsp. *pendens, Melaleuca glomerata* tall open shrubland over **Cenchrus ciliaris* scattered tussock grasses	381.6	Anabranching creekbeds found along the main channel of Weeli Wolli Creek and some channels in the eastern parts of Marillana Creek. Also occurred in two major tributaries of Marillana Creek.	4 quadrats: BIL30^, YEX28, YBI01^, YSW04. 2 relevés: YEX-K, YBI-RRWB.	Very Good.	

11 ^ denotes that the quadrat has been seasonally sampled. See Table 3.2 for the study that each site code (BIL, YEX, etc.) relates to.

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
C4: EvAciAprAThCEc	*Eucalyptus victrix* open woodland over *Acacia citrinoviridis, A. pruinocarpa, Atalaya hemiglauca* low woodland over **Cenchrus ciliaris* tussock grassland	1,395.5	Creek banks and floodplains of the major channels of Marillana and Weeli Wolli Creeks throughout the study area. Also occurred in two tributaries of Weeli Wolli Creek near the proposed PBS development.	13 quadrats: HAD09^, H050^, H051 (cleared), YAQ12^, YAQ13, YAQ21, YBI02, YBI03, YBI04, YBI08^, YEX02^, YEX17, YEX29. 5 relevés: YAQ-CSRA, YBI-RBMK, YBI-RPHB, YBI-RPHA, YEX-M.	Good to Very Poor.	
C5: EvAbAaAmERltTHt	*Eucalyptus victrix* scattered low trees over *Acacia bivenosa, A. ancistrocarpa, A. maitlandii* tall open shrubland over *Eriachne tenuiculmis, Themeda triandra* very open tussock grassland	26.0	Several major tributaries feeding into Marillana Creek around the JSW and YJC mines.	2 quadrats: YVI15, YSW19S^.	Very Good.	
Vegetation of Minor Creeklines, Floodplains and Valleys						
F1: ChAtuGwTp	*Corymbia hamersleyana* scattered low trees to low open woodland over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* tall open shrubland over *Triodia pungens* hummock grassland	414.8	Floodplains and minor creeklines throughout the study area.	13 quadrats: BIL16^, OXB04^, YAQ03, YAQ05, YAQ20, YBI20^, YBI25, YBI35S^, YSW05, YSW18S^, YVI11, YVI12, YVI13. 3 relevés: BIL-RCFC, BILRSWA, YBIRBME.	Very Good to Good.	

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
F2: AprAciCEc	*Acacia pruinocarpa, A. citrinoviridis* tall open shrubland over **Cenchrus ciliaris* tussock grassland	314.6	Floodplains and some minor tributaries of Weeli Wolli Creek.	4 quadrats: BIL23^, BIL24^, YAQ30^, YEX38^. 4 relevés: YAQ-CSRC, YAQ-CSRD, YBI-RBMF, YBIRBMH.	Poor to Very Poor.	
F3: ElChAtuAaAbGwTspp	*Eucalyptus leucophloia, Corymbia hamersleyana* low open woodland over *Acacia tumida* var. *pilbarensis*, *A. ancistrocarpa, A. bivenosa, Grevillea wickhamii* tall open scrub over mixed *Triodia* hummock grassland	260.8	Minor creeklines flowing between low hills. Mainly distributed around the JSW and YJC mines.	7 quadrats: BIL35^, BIL36^, YEX07 (cleared), YEX08^, YEX11 (cleared), YEX26, YEX34 (cleared). 2 relevés: YAQ-RPLA, YEX-G.	Good.	
F4: ChAtuAaPcAtenBONeARh PAmTp	*Corymbia hamersleyana* scattered low trees over *Acacia tumida* var. *pilbarensis* tall open shrubland over *A. ancistrocarpa, Petalostylis cassioides, A. tenuissima* open shrubland over *Bonamia erecta* very open herbland over *Aristida holathera* var. *holathera, Paraneurachne muelleri* very open tussock grassland and *Triodia pungens* very open hummock grassland.	41.7	Occurred north of the proposed PBS development on the west side of Weeli Wolli Creek, on a floodout that was located on a plain and fed by minor creeklines flowing through low hills to the east.	3 quadrats: BIL11^, BIL14, BIL46^.	Very Good.	

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
F5: ChAciAaAiSENsppTp	*Corymbia hamersleyana* scattered low trees over *Acacia citrinoviridis, A. ancistrocarpa, A. inaequilatera* tall open shrubland over *Senna* spp. open shrubland over *Triodia pungens* open hummock grassland.	31.4	Occurred near the proposed PBS development, east of Weeli Wolli Creek in a small area of floodplains and floodouts.	2 quadrats: BIL21^, BIL47.	Good.	
Vegetation of Hills, Ridges, Gorges and Breakaways						
H1: ElHcAiGwTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Hakea chordophylla, Acacia inaequilatera, Grevillea wickhamii* tall open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland	2,840.3	Widespread throughout the study area on elevated hill crests and some rocky hill slopes.	38 quadrats: BIL05, BIL17, BIL19, BIL20, BIL28, BIL34, BIL37, BIL43, OXB01^, OXB05^, OXB10^, OXB11^, YAQ01, YAQ07, YAQ09, YAQ10, YAQ11, YAQ14, YAQ25, YAQ27, YBI18, YBI31S^, YBI33S^, YEX01^, YEX06^, YEX10 (cleared), YEX13 (cleared), YEX18 (cleared), YEX24 (cleared), YEX30, YEX35, YEX36 (cleared), YEX37, YSW03, YSW13, YSW15, YVI07, YVI14. 1 relevé: YVI-RMMA.	Excellent.	

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
H2: ElAiTwTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Acacia inaequilatera* scattered tall shrubs over *Triodia wiseana*, (*T.* sp. Shovelanna Hill (S. van Leeuwen 3835)) open hummock grassland	5,841.6	Widespread throughout the study area on rolling stony hills and slopes.	25 quadrats: BIL03, BIL15^, BIL26, BIL27, BIL29, BIL39^, BIL40, BIL44, HDA16, HDA24^, OXB02^, YAQ02, YAQ04, YAQ06, YAQ08, YAQ15, YAQ18, YAQ19, YBI05^, YBI32S^, YBI36^, YSW06^, YSW17S^, YVI01, YVI02. 1 relevé: BIL-RCFA.	Excellent.	
H3: ElGwAarTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Grevillea wickhamii* tall open shrubland over *Acacia arida* shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) open hummock grassland	210.4	Slopes and crests of a range of low stony hills northeast of the proposed PBS development.	2 quadrats: BIL01^, BIL06^. 1 relevé: BIL-RPCA.	Excellent.	
H4: ChAarTspsTw	*Corymbia hamersleyana* scattered low trees over *Acacia arida* open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), *T. wiseana* hummock grassland	74.3	Crests of two low stony hills northeast of the proposed PBS development.	2 quadrats: BIL04^, YBI24^.	Excellent.	

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
H5: ElCfERlmTHspp	*Eucalyptus leucophloia* subsp. *leucophloia, Corymbia ferriticola* scattered low trees over *Eremophila latrobei* subsp. *filiformis, Senna* spp. scattered shrubs over *Cymbopogon ambiguus, Eriachne mucronata, Themeda* sp. Mt Barricade (M.E. Trudgen 2471), *T. triandra* open tussock grassland	27.6	Found throughout the study area on narrow ridgelines with free face and breakaway slopes.	4 relevés: BIL-RCFB, BIL-RCFD, YEX-F, YEX-J.	Very Good.	
H6: ElAbTw	*Eucalyptus leucophloia* scattered low trees over *Acacia bivenosa* open shrubland over *Triodia wiseana* hummock grassland	7.4	Slopes and crests of some hills near the JSW and YOX mines.	2 quadrats: OXB13^, YSW20S^.	Excellent.	
H7: ElAprTwTp	*Eucalyptus leucophloia* scattered low trees over *Acacia pruinocarpa* tall open shrubland over *Triodia wiseana, T. pungens* open hummock grassland	32.9	Low stony hills, mainly fringing Marillana Creek near the YOX and JSW mines.	4 quadrats: YSW09, YSW16, YVI05 (cleared), YVI16.	Very Good	

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
H8: AmoTspsTw	*Acacia monticola* tall shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), *T. wiseana* closed hummock grassland	1.2	Recorded from a single area along a breakaway on a hillslope, near Marillana Creek. It has since been dissected by drill lines associated with the JSW mine.	1 quadrat: YSW14.	Excellent.	H9: ChGOrANlAtuGwTHtCYa	*Corymbia hamersleyana* scattered low trees over *Gossypium robinsonii, Androcalva luteiflora, Acacia tumida* var. *pilbarensis*, *Grevillea wickhamii* shrubland over *Themeda triandra, Cymbopogon ambiguus* open tussock grassland	13.8	Recorded in a single gorge southwest of the YOX mine. Also mapped from two other similar-sized gorges (one near the Yandi camp and the other south of the Oxbow deposit), however these areas have not been ground-truthed.	1 quadrat: OXB03.	Very Good.	
H10: AiERfTp	*Acacia inaequilatera* scattered tall shrubs over *Eremophila fraseri* subsp. *fraseri* scattered shrubs over *Triodia pungens* very open hummock grassland	25.0	Located on a single hill adjacent to Marillana Creek, north of the JSE mine.	1 quadrat: YAQ17.	Good.	

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
H11: GpERfTp	*Grevillea pyramidalis* subsp. *leucadendron, Eremophila fraseri* tall open shrubland over *Triodia pungens* hummock grassland	0.1	Recorded from a single area of low stony hill on the northern side of Marillana Creek, near the JSW mine. The extent of this vegetation has been reduced through clearing for the mine.	1 quadrat: YSW02 (cleared).	Excellent.	Vegetation of Stony Plains						
P1: ElEgAprAbAaAdTwTpTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia pruinocarpa* scattered tall shrubs over *A. bivenosa, A. ancistrocarpa, A. dictyophleba* shrubland over *Triodia wiseana, T. pungens*, *T.* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland	395.9	Undulating colluvial plains throughout the study area.	11 quadrats: BIL38^, BIL39, OXB03^, OXB09^, YEX05 (cleared), YSW07, YSW11, YSW12, YVI04 (cleared), YVI08, YVI10. 1 relevé: YSW-RBMA.	Excellent to Very Good.	
P2: ChAprAiAsclApaTp	*Corymbia hamersleyana, Acacia pruinocarpa* scattered low trees over *A. inaequilatera, A. sclerosperma* subsp. *sclerosperma, A. pachyacra* tall open shrubland over *Triodia pungens* hummock grassland	1,065.3	Occurred broadly over plains in the eastern half of the study area, fringing the floodplain on the southern side of Marillana Creek and on both sides of Weeli Wolli Creek.	14 quadrats: BIL07^, BIL08, BIL09, BIL10^, YAQ16^, YAQ24, YAQ29, YBI10^, YBI26, YEX14 (cleared), YEX19, YEX20, YEX23, YEX27. 2 relevés: YBI-RBMC, YBI-RBMD.	Good.	

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
P3: AprAciAiAsclTlo	*Acacia pruinocarpa* low open woodland over *A. citrinoviridis, A. inaequilatera, A. sclerosperma* subsp. *sclerosperma* open shrubland over *Triodia longiceps* hummock grassland	177.9	Occurred along either side of Weeli Wolli Creek, fringing the floodplains along the central section of the creek.	3 quadrats: HDA14 (cleared), YBI11^, YBI17^. 1 relevé: YBI-RBMJ.	Very Good (some small areas Poor).	
P4: AprAsyAiTw	*Acacia pruinocarpa* low open woodland over *A. synchronicia, A. inaequilatera* scattered tall shrubs over *Triodia wiseana* open hummock grassland	352.1	Occurred in the southern half of the study area along Weeli Wolli Creek, where it fringed the floodplains on both sides of the creek.	6 quadrats: HDA07 (cleared), HDA15 (cleared), YBI19 (cleared), YEX03 (cleared), YEX04^, YEX32 (cleared). 1 relevé: YAQ-CSRB	Excellent to Good.	
P5: ElEgAbAaTb	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia bivenosa, A. ancistrocarpa* open shrubland over *Triodia basedowii* open hummock grassland	1547.2	Occurred broadly over the stony plains of the Billiards area along either side of Weeli Wolli Creek, and also in small areas around the JSW and YJC mines.	18 quadrats: BIL18, BIL33^, HDA12 (cleared), YAQ23^, YBI06^, YBI07^, YBI09^, YBI14, YBI16, YBI21, YBI22, YBI27^, YBI28, YBI29, YBI34S^, YEX15, YEX33 (cleared), WW30. 4 relevés: YBI-RBMA, YBIRBMB, YBI-RROA, YEX-N.	Excellent to Good.	

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
P6: AapERfoERl/g	*Acacia aptaneura* low open forest over *Eremophila forrestii* subsp. *forrestii* open shrubland over *E. lanceolata* low open shrubland over mixed very open grassland	144.1	Occurred only in the Billiards area, mainly in narrow stands adjacent to the floodplains along Weeli Wolli Creek; several small patches of this vegetation also occurred on plains and hill crests.	8 quadrats: BIL32^, HDA08^, HDA13, YBI12^, YBI13, YBI15^, YEX09 (cleared), YEX12 (cleared). 2 relevés: BIL-RSPA, YBI-RBMI.	Good.	
P7: ERf/g	*Eremophila fraseri* subsp. *fraseri* open shrubland over mixed very open grassland	35.6	Occurred on three small areas of plain with a calcrete substrate near the proposed PBS development.	2 quadrats: BIL25^, BIL48. 1 relevé: YBI-RBMG.	Good.	
P8: EgAiTs	*Eucalyptus gamophylla* scattered low mallees over *Acacia inaequilatera* scattered tall shrubs over *Triodia schinzii* hummock grassland	32.4	Gently sloping pediment slopes and colluvial plains at the base of a range of low hills north of the proposed PBS development.	2 quadrats: BIL22^, BIL42^.	Excellent.	

Vegetation Code	Vegetation Description	Area (ha)	Distribution	Flora Sampling Sites[11]	Vegetation Condition	Photograph
P9: ChEgAiAaAprPcTb	*Corymbia hamersleyana* scattered low trees over *Eucalyptus gamophylla* scattered low mallees over *Acacia inaequilatera, A. ancistrocarpa, A. pruinocarpa* tall open shrubland over *Petalostylis cassioides* open shrubland over *Triodia basedowii* open hummock grassland	380.1	Occurred broadly over the plains on the western side of Weeli Wolli Creek, north of Marillana Creek.	6 quadrats: BIL12^, BIL13, BIL41^, BIL45^, YEX31 (cleared), YEX33 (cleared).	Very Good.	

Appendix 4

Vegetation Mapping and Locations of Conservation Significant Flora

Vegetation of Yandi Billiards Integrated

Vegetation of Major Creeklines and Tributaries

C1: EcEvMaMgAc	*Eucalyptus camaldulensis* subsp. *refulgens, E. victrix* woodland over *Melaleuca argentea, M. glomerata, Acacia coriacea* subsp. *pendens* low open woodland
C2: EvChAtuGwTErCYp-ERItTHt	*Eucalyptus victrix,* (*Corymbia hamersleyana*) scattered low trees over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* tall shrubland over *Tephrosia rosea* var. Fortescue Creeks (M.I.H. Brooker 2186) low shrubland over *Cymbopogon mbiguous, C. procerus, Eriachne tenuiculmis, Themeda triandra* very open tussock grassland
C3: EvAciAcMgCEc	*Eucalyptus victrix* scattered trees over *Acacia citrinoviridis, A. coriacea* subsp. *pendens, Melaleuca glomerata* tall open shrubland over **Cenchrus ciliaris* scattered tussock grasses
C4: EvAciAprAThCEc	*Eucalyptus victrix* open woodland over *Acacia citrinoviridis, A. pruinocarpa, Atalaya hemiglauca* low woodland over **Cenchrus ciliaris* tussock grassland
C5: EvAbAaAmERItTHt	*Eucalyptus victrix* scattered low trees over *Acacia bivenosa, A. ancistrocarpa, A. maitlandii* tall open shrubland over *Eriachne tenuiculmis, Themeda triandra* very open tussock grassland

Vegetation of Minor Creeklines, Floodplains and Valleys

F1: ChAtuGwTp	*Corymbia hamersleyana* scattered low trees to low open woodland over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* tall open shrubland over *Triodia pungens* hummock grassland
F2: AprAciCEc	*Acacia pruinocarpa, A. citrinoviridis* tall open shrubland over **Cenchrus ciliaris* tussock grassland
F3: ElChAtuAaAbGwTspp	*Eucalyptus leucophloia, Corymbia hamersleyana* low open woodland over *Acacia tumida* var. *pilbarensis*, *A. ancistrocarpa, A. bivenosa, Grevillea wickhamii* tall open scrub over mixed *Triodia* hummock grassland
F4: ChAtuAaPcAtenBONe-ARhPAmTp	*Corymbia hamersleyana* scattered low trees over *Acacia tumida* var. *pilbarensis* tall open shrubland over *A. ancistrocarpa, Petalostylis cassioides, A. tenuissima* open shrubland over *Bonamia erecta* very open herbland over *Aristida holathera* var. *holathera, Paraneurachne muelleri* very open tussock grassland and *Triodia pungens* very open hummock grassland
F5: ChAciAaAiSENsppTp	*Corymbia hamersleyana* scattered low trees over *Acacia citrinoviridis, A. ancistrocarpa, A. inaequilatera* tall open shrubland over *Senna* spp. open shrubland over *Triodia pungens* open hummock grassland

Appendix 5

Vascular Flora Species Recorded in the Study Area

Species (Ordered by Family)	Biota 2014a	Biota 2014b	Biota 2014c	Biota 2011	Biota 2010 (JSW)	Biota 2010 (YOX)	Biota 2009a	Biota 2009b	Biota 2005	Biota 2004a	Biota 2004b	Biota 2002	HGM 2000	Rio Tinto Database
Family: Acanthaceae														
Dicladanthera forrestii	X	X	X		X		X	X		X		X		
Dipteracanthus australasicus subsp. *australasicus*	X	X			X			X		X	X	X		
Rostellularia adscendens var. *clementii*		X			X					X				
Rostellularia adscendens var. *latifolia* (Priority 3)		X												
Family: Aizoaceae														
Trianthema glossostigmum	X		X				X	X		X				
Trianthema pilosum	X						X	X		X				
Zaleya galericulata subsp. *galericulata*	X		X											
Family: Amaranthaceae														
Achyranthes aspera	X	X	X		X					X	X	X		
**Aerva javanica*	X		X				X							X
Alternanthera angustifolia	X													
Alternanthera denticulata	X													
Alternanthera nana	X	X			X	X	X	X		X	X			
Alternanthera nodiflora	X									X				
**Alternanthera pungens*														X
Amaranthus cuspidifolius	X	X			X	X		X						
Amaranthus undulatus	X	X	X		X	X	X			X		X		
Gomphrena affinis subsp. *pilbarensis*	X													
Gomphrena cunninghamii	X	X	X		X	X	X	X	X	X	X	X		
Gomphrena kanisii							X							
Ptilotus aervoides	X	X			X		X			X	X			
Ptilotus astrolasius	X	X	X		X	X	X	X	X	X	X			
Ptilotus auriculifolius	X	X	X		X	X	X		X	X				
Ptilotus calostachyus	X	X	X	X	X	X	X	X	X	X				
Ptilotus clementii	X	X	X		X	X		X		X	X			
Ptilotus fusiformis	X	X	X		X	X				X				
Ptilotus gaudichaudii subsp. *gaudichaudii*	X						X			X	X			
Ptilotus helipteroides	X		X				X	X		X	X			
Ptilotus incanus									X					
Ptilotus nobilis subsp. *nobilis*	X	X	X	X	X	X	X	X		X	X			
Ptilotus obovatus var. *obovatus*	X	X	X	X	X	X	X	X	X	X	X	X		
Ptilotus polystachyus	X	X	X		X		X	X		X	X			
Ptilotus roei	X									X				

Species (Ordered by Family)	Biota 2014a	Biota 2014b	Biota 2014c	Biota 2011	Biota 2010 (JSW)	Biota 2010 (YOX)	Biota 2009a	Biota 2009b	Biota 2005	Biota 2004a	Biota 2004b	Biota 2002	HGM 2000	Rio Tinto Database
Ptilotus rotundifolius	X	X	X		X	X	X	X	X	X	X			
Family: Apocynaceae														
**Catharanthus roseus*														X
Cynanchum floribundum		X				X								
Rhyncharrhena linearis	X	X	X		X			X						
Sarcostemma viminale subsp. *australe*										X				
Tylophora flexuosa	X													
Family: Araliaceae														
Astrotricha hamptonii		X				X								
Trachymene oleracea subsp. *oleracea*	X	X	X		X	X	X	X		X				
Family: Asteraceae														
**Bidens bipinnata*	X	X	X		X	X	X			X	X			X
Blumea tenella	X						X							
Calotis hispidula		X				X								
Calotis plumulifera	X									X				
Centipeda minima subsp. *macrocephala*	X	X	X							X	X			
Chrysocephalum apiculatum	X	X	X		X	X		X	X	X				
Chrysocephalum gilesii	X									X				
Chrysocephalum pterochaetum	X						X							
**Conyza bonariensis*		X			X			X		X				X
**Flaveria trinervia*	X	X	X		X	X				X	X			X
Helichrysum luteoalbum	X		X							X				
Ixiochlamys cuneifolia	X		X							X				
**Lactuca serriola*														X
Olearia fluvialis		X	X		X	X				X				
Peripleura arida	X						X			X				
Peripleura hispidula var. *hispidula*	X		X											
Peripleura obovata		X			X					X				
Peripleura virgata		X			X	X								
Pluchea dentex	X	X	X		X			X		X				
Pluchea dunlopii	X	X			X		X	X		X				
Pluchea ferdinandi-muelleri	X	X			X		X			X				
Pluchea rubelliflora	X	X	X	X	X	X	X	X		X		X		
Pluchea tetranthera		X			X	X				X				
Pterocaulon sphacelatum	X	X	X		X		X				X	X	X	

Species (Ordered by Family)	Biota 2014a	Biota 2014b	Biota 2014c	Biota 2011	Biota 2010 (JSW)	Biota 2010 (YOX)	Biota 2009a	Biota 2009b	Biota 2005	Biota 2004a	Biota 2004b	Biota 2002	HGM 2000	Rio Tinto Database
Pterocaulon sphaeranthoides								X	X					
Rhodanthe citrina					X									
Rhodanthe floribunda	X									X				
Rhodanthe margarethae		X				X		X		X				
**Sigesbeckia orientalis*	X	X				X					X			X
**Sonchus asper*														X
**Sonchus oleraceus*	X	X	X					X		X	X			X
Streptoglossa bubakii	X	X	X		X		X			X	X			
Streptoglossa decurrens	X	X	X			X	X	X		X	X			
Streptoglossa odora	X										X			
**Tridax procumbens*														X
Vittadinia dissecta var. *hirta*							X							
Family: Boraginaceae														
Heliotropium chrysocarpum	X	X	X			X		X						
Heliotropium cunninghamii	X	X	X		X	X	X			X	X			
Heliotropium glabellum	X		X											
Heliotropium heteranthum	X													
Heliotropium inexplicitum	X	X	X		X		X			X	X			
Heliotropium pachyphyllum	X	X	X		X	X	X	X		X	X			
Heliotropium aff. *pachyphyllum*			X											
Heliotropium tanythrix	X													
Heliotropium tenuifolium	X	X	X	X	X	X		X		X				
Heliotropium sp. (*tenuifolium/cunninghamii*; sterile)		X												
Trichodesma zeylanicum var. zeylanicum	X	X	X		X	X	X		X	X	X	X		
Family: Brassicaceae														
Lepidium catapycnon (Threatened)	X	X				X		X						
Lepidium muelleri-ferdinandii		X			X			X		X				
Lepidium oxytrichum	X									X				
Lepidium pedicellosum	X													
Lepidium phlebopetalum	X	X			X		X	X		X				
Lepidium pholidogynum	X										X			
Lepidium platypetalum										X				
**Sisymbrium irio*										X				
**Sisymbrium orientale*	X	X	X			X		X						X

Species (Ordered by Family)	Biota 2014a	Biota 2014b	Biota 2014c	Biota 2011	Biota 2010 (JSW)	Biota 2010 (YOX)	Biota 2009a	Biota 2009b	Biota 2005	Biota 2004a	Biota 2004b	Biota 2002	HGM 2000	Rio Tinto Database
Family: Campanulaceae														
Lobelia arnhemiaca	X	X	X					X	X	X				
Wahlenbergia tumidifructa	X	X	X		X					X				
Family: Capparaceae														
Capparis lasiantha	X								X					
Capparis spinosa var. *nummularia*	X		X				X			X		X		
Family: Caryophyllaceae														
Polycarpaea corymbosa var. *corymbosa*	X	X	X		X	X	X	X		X				
Polycarpaea holtzei	X	X	X		X	X	X	X		X	X			
Polycarpaea longiflora	X	X	X		X	X	X	X	X	X		X		
Family: Celastraceae														
Stackhousia intermedia			X											
Family: Chenopodiaceae														
Dysphania cristata	X										X			
Dysphania kalpari	X							X		X	X			
Dysphania melanocarpa forma *melanocarpa*	X						X			X	X	X		
Dysphania plantaginella	X		X				X							
Dysphania rhadinostachya (sterile; subsp. not determined)	X	X	X		X	X	X	X						
Dysphania rhadinostachya subsp. *inflata*	X													
Dysphania rhadinostachya subsp. *rhadinostachya*	X		X				X			X	X			
Dysphania sp. (sterile; insufficient material for further determination)	X	X												
Enchylaena tomentosa var. *tomentosa*	X		X				X	X		X	X	X		
Maireana planifolia	X	X			X		X	X		X	X			
Maireana planifolia x *villosa*	X									X	X			
Maireana villosa	X	X	X				X			X	X			
Rhagodia eremaea	X		X					X	X	X	X	X		
Salsola australis	X	X	X			X		X		X	X			
Sclerolaena cornishiana	X	X	X		X		X	X		X	X	X		
Sclerolaena costata		X			X									
Sclerolaena eriacantha	X									X				
Family: Cleomaceae														
Cleome viscosa	X	X	X	X	X	X	X	X	X	X	X	X		

Species (Ordered by Family)	Biota 2014a	Biota 2014b	Biota 2014c	Biota 2011	Biota 2010 (JSW)	Biota 2010 (YOX)	Biota 2009a	Biota 2009b	Biota 2005	Biota 2004a	Biota 2004b	Biota 2002	HGM 2000	Rio Tinto Database
Family: Convolvulaceae														
Bonamia erecta	X	X	X		X	X	X	X	X	X			X	
Bonamia pannosa	X								X	X				
Bonamia sp. Dampier (A.A. Mitchell PRP 217)	X	X	X		X	X	X	X	X	X	X			
Convolvulus clementii	X						X			X	X			
Duperreya commixta	X	X	X			X	X	X	X	X		X		
Evolvulus alsinoides (sterile; var. not determined)	X							X						
Evolvulus alsinoides var. *decumbens*	X	X	X		X	X				X		X		
Evolvulus alsinoides var. *villosicalyx*	X	X	X		X	X	X	X		X	X			
Ipomoea muelleri	X	X	X		X	X	X	X		X				
Ipomoea polymorpha	X													
Operculina aequisepala	X													
Polymeria ambigua	X	X	X		X	X	X	X		X	X			
Family: Cucurbitaceae														
**Citrullus colocynthis*		X				X								X
**Citrullus lanatus*														X
**Citrullus* aff. *lanatus*		X												
Cucumis melo	X		X				X							X
Cucumis variabilis	X	X	X		X	X	X	X	X	X	X			
Family: Cyperaceae														
Bulbostylis barbata	X	X	X		X	X	X	X		X	X			
Bulbostylis turbinata	X	X				X				X	X			
Cyperus cunninghamii subsp. *cunninghamii*	X													
Cyperus difformis	X									X				
Cyperus iria	X									X				
Cyperus ixiocarpus	X		X											
Cyperus squarrosus	X													
Cyperus vaginatus	X	X	X	X	X	X		X						
Eleocharis atropurpurea	X													
Eleocharis geniculata										X				
Fimbristylis dichotoma	X	X	X		X	X	X			X	X			
Fimbristylis microcarya	X													
Fimbristylis simulans	X	X	X		X	X	X			X	X			
Schoenoplectus subulatus	X									X				

Species (Ordered by Family)	Biota 2014a	Biota 2014b	Biota 2014c	Biota 2011	Biota 2010 (JSW)	Biota 2010 (YOX)	Biota 2009a	Biota 2009b	Biota 2005	Biota 2004a	Biota 2004b	Biota 2002	HGM 2000	Rio Tinto Database
Family: Droseraceae														
Drosera indica		X												
Family: Elatinaceae														
Bergia pedicellaris										X				
Bergia trimera					X					X				
Family: Euphorbiaceae														
Adriana tomentosa var. *tomentosa*							X							
Euphorbia australis (insufficient material for further determination)	X	X			X	X		X			X			
Euphorbia australis var. *australis*	X													
Euphorbia australis var. *erythrantha*	X	X	X		X		X			X	X			
Euphorbia australis var. *hispidula*	X	X								X				
Euphorbia australis var. *subtomentosa*	X	X	X		X	X	X	X	X	X	X	X		
Euphorbia biconvexa	X	X	X		X	X	X				X			
Euphorbia boophthona	X	X	X		X	X		X		X	X			
Euphorbia coghlanii	X		X						X					
Euphorbia drummondii	X													
**Euphorbia hirta*														X
Euphorbia tannensis subsp. *eremophila*	X	X	X		X	X	X			X	X			
Euphorbia trigonosperma	X	X	X				X			X				
Euphorbia vaccaria var. *vaccaria*			X							X				
Euphorbia sp. (*biconvexa/coghlanii/trigonosperma*; sterile)	X	X			X					X				
Euphorbia sp. (*coghlanii/trigonosperma*)	X	X	X		X	X				X		X		
Euphorbia sp. (insufficient material for further determination)	X	X			X	X	X							
**Ricinus communis*														X
Family: Fabaceae														
Acacia adoxa var. *adoxa*	X	X	X	X	X	X	X	X	X	X	X			
Acacia adsurgens	X		X				X			X				
Acacia ampliceps		X			X	X								
Acacia ancistrocarpa	X	X	X	X	X	X	X	X	X	X	X		X	
Acacia ancistrocarpa x *arida*	X													
Acacia ancistrocarpa x *trachycarpa*		X				X		X						
Acacia aneura								X						
Acacia aptaneura	X		X	X	X		X	X		X	X			

Species (Ordered by Family)	Biota 2014a	Biota 2014b	Biota 2014c	Biota 2011	Biota 2010 (JSW)	Biota 2010 (YOX)	Biota 2009a	Biota 2009b	Biota 2005	Biota 2004a	Biota 2004b	Biota 2002	HGM 2000	Rio Tinto Database
Acacia aptaneura x *ayersiana*	X													
Acacia aptaneura x *incurvaneura*	X									X	X			
Acacia aptaneura x *macraneura*	X									X				
Acacia aptaneura x (unknown hybrid)	X						X			X				
Acacia aff. *aptaneura*				X						X				
Acacia arida	X			X			X							
Acacia arida x *hilliana*	X						X							
Acacia ayersiana	X		X				X			X	X			
Acacia bivenosa	X	X	X	X	X	X	X	X	X	X	X			
Acacia bivenosa (wispy/weeping form)	X		X					X			X			
Acacia catenulata	X						X			X				
Acacia citrinoviridis	X	X	X	X	X		X	X	X	X	X	X		
Acacia colei var. *colei*										X				
Acacia coriacea subsp. *pendens*	X	X	X	X	X	X	X	X	X	X	X	X		
Acacia dictyophleba	X	X	X	X	X	X	X	X	X	X	X		X	
Acacia elachantha	X	X			X	X	X	X		X				
Acacia hamersleyensis								X						
Acacia hilliana	X	X	X	X	X	X	X	X	X	X	X			
Acacia inaequilatera	X	X	X	X	X	X	X	X	X	X	X		X	
Acacia kempeana	X													
Acacia ligulata			X											
Acacia maitlandii	X	X	X	X	X	X		X	X	X				
Acacia marramamba	X								X					
Acacia monticola	X	X	X	X	X	X		X						
Acacia pachyacra	X	X	X	X	X	X	X	X	X	X			X	
Acacia pruinocarpa		X	X	X	X	X	X	X	X	X	X		X	
Acacia pteraneura				X										
Acacia pyrifolia (var. not determined)	X			X				X	X	X				
Acacia pyrifolia var. *morrisonii*	X	X	X											
Acacia pyrifolia var. *pyrifolia*	X	X	X		X	X	X							
Acacia rhodophloia								X						
Acacia sclerosperma subsp. *sclerosperma*	X		X	X			X	X		X	X			
Acacia sclerosperma hybrid	X		X											
Acacia sericophylla	X									X				
Acacia sibirica	X						X	X		X				

Species (Ordered by Family)	Biota 2014a	Biota 2014b	Biota 2014c	Biota 2011	Biota 2010 (JSW)	Biota 2010 (YOX)	Biota 2009a	Biota 2009b	Biota 2005	Biota 2004a	Biota 2004b	Biota 2002	HGM 2000	Rio Tinto Database
Acacia spondylophylla	X			X			X							
Acacia synchronicia	X	X	X	X	X		X	X	X	X	X			
Acacia tenuissima	X	X	X		X		X	X	X					
Acacia tetragonophylla	X	X			X	X								
Acacia trudgeniana	X		X											
Acacia tumida var. *pilbarensis*	X	X	X	X	X	X	X	X	X	X	X			
Acacia wanyu				X										
Acacia sp. (insufficient material for further determination)		X			X									
Alysicarpus muelleri	X	X	X		X									
Crotalaria medicaginea var. *neglecta*	X	X	X		X	X	X	X		X	X			
Crotalaria novae-hollandiae subsp. *novae-hollandiae*	X		X						X	X				
Cullen lachnostachys	X													
Cullen leucanthum					X			X		X				
Cullen leucochaites	X	X	X		X		X	X	X	X				
Cullen martinii	X													
Dichrostachys spicata										X				
Glycine canescens	X	X	X		X	X	X			X	X	X		
Glycine sp. aff. *arenaria*		X												
Glycine tabacina		X												
Gompholobium oreophilum	X						X	X		X				
Indigofera colutea	X	X	X		X									
Indigofera georgei	X		X				X	X		X				
Indigofera linifolia	X		X								X			
Indigofera linnaei	X	X			X	X								
Indigofera monophylla	X	X	X	X	X	X	X	X	X	X	X	X		
Indigofera rugosa	X	X	X		X		X		X	X				
Isotropis atropurpurea	X	X	X		X	X		X		X				
**Lotus* sp.														X
Mirbelia viminalis		X			X									
Petalostylis cassioides	X						X							
Petalostylis labicheoides	X	X	X					X		X				
Rhynchosia minima	X	X	X		X	X	X	X	X	X	X	X		
Senna artemisioides subsp. ? *oligophylla* x *S. glaucifolia*		X

Appendix 7

Poorly Collected, Variable or Incompletely Resolved Taxa

Taxon	Reason	Specimen Lodged with WA Herbarium?
Poorly Collected Taxa		
Euphorbia australis var. *australis*	The current vouchered specimens of this taxon are predominantly from coastal locations, with only one vouchered record from the central Pilbara. Two specimens keying to *Euphorbia australis* var. *australis* were collected from the study area, both of which were confirmed by Andrew Perkins (taxonomist with the WA Herbarium).	Yes
Glycine sp. aff. *arenaria*	One specimen of a creeper with affinities to *G. arenaria* was collected. To date, no specimens of *G. arenaria* have been vouchered from outside the northern Kimberley (see Section 5.4.3).	Yes
Heliotropium glabellum	Five specimens keying to *Heliotropium glabellum* were collected from the study area. Although this species is widespread through the Kimberley, it is uncommon in the Pilbara, with only a few voucher records from the far east of the region.	Yes
Peripleura hispidula var. *hispidula*	A single specimen keying to *Peripleura hispidula* var. *hispidula* was collected from the study area, however this taxon had not previously been considered to occur in WA. Equivalent material has been recorded from other survey areas in the Pilbara, including near West Angelas (Biota 2014d), and has been confirmed as this taxon by Andrew Perkins (taxonomist with the WA Herbarium).	Yes
Sida sp. A Kimberley Flora (P.A. Fryxell & L.A. Craven 3900)	One specimen identified as this species was collected from the study area. This species occurs largely in the Kimberley, with one record known from the Pilbara (in the Bungaroo Valley near Pannawonica, approximately 300 km from the study area).	Yes
**Sisymbrium irio*	This weed species is known from much of the south west and central WA but there are currently no vouchered specimens from the Pilbara region. This species has been previously recorded in the region (Biota unpubl. data).	No; voucher specimen rejected.
Variable Taxa		
Abutilon lepidum	Three apparently undescribed entities in this species were identified by Malcolm Trudgen (M.E. Trudgen and Associates) amongst material from the study area, all of which are widespread and not believed to be of conservation significance: *Abutilon* aff. *lepidum* (1) (MET 15352), *A.* aff. *lepidum* (2) (MET 15970) and *A.* aff. *lepidum* (4). For the purpose of this report, they are recognised as one entity: *Abutilon lepidum* sens. lat.	Yes: *A.* aff. l*epidum* (4).
**Citrullus* aff. *lanatus*	One specimen collected from the study area was identified by Malcolm Trudgen (M.E. Trudgen and Associates) to represent a variation of **Citrullus lanatus.* The specimen was sterile and a juvenile with the cotyledons still present.	Yes
Eriachne mucronata	Two forms of *Eriachne mucronata* were present in the study area: the 'typical form' (culms with sparse erect hairs), and one designated as 'arid form' (which has white woolly hairs on the culms). Both forms are widespread in the Pilbara bioregion and commonly collected. Although not formally recognised, they have been treated as separate entities for this report since they are clearly distinguishable.	No
Gossypium australe	Two apparently undescribed forms of *Gossypium* were recorded from the study area: *G. australe* (Burrup Peninsula form) and *G. australe* (Whim Creek form). These entities are widespread in the Pilbara. For the purpose of this report they have been recognised as a single entity: *Gossypium australe*.	No
Heliotropium pachyphyllum	One specimen was collected from the study area that has characters intermediate between *H. pachyphyllum* and *H. ovalifolium*. This entity is designated *Heliotropium* aff. *pachyphyllum* in this report.	Yes

Taxon	Reason	Specimen Lodged with WA Herbarium?
Hibiscus coatesii	Considerable variation is observed within Pilbara specimens of this taxon. Two apparently undescribed entities were identified from the study area, both of which are widespread: *Hibiscus* aff. *coatesii* (MET 16,542) and *H.* aff. *coatesii* (site 664). For the purpose of this report, they are recognised as a single entity: *Hibiscus coatesii.*	Yes: *H.* aff. *coatesii* (site 664).
Hibiscus sturtii	Considerable variation is observed within the Pilbara specimens of this taxon. One apparently undescribed taxon, *Hibiscus* aff. sturtii (HD7-11), was identified from the study area. This entity is widespread and for the purpose of this report is recognised as *Hibiscus sturtii*.	No
Indigofera monophylla	Several forms of *Indigofera monophylla* were identified by Malcolm Trudgen (M.E. Trudgen and Associates) amongst the specimens from the study area. All forms are considered to be widespread in the Pilbara. For the purpose of this report, the different forms of *Indigofera monophylla* have not been distinguished and they are referred to as a single entity.	Yes: brown calyx form and small leaflet form.
Polymeria ambigua	One taxon that represents a variation of *P. ambigua* was recorded from the study area: *Polymeria* aff. *ambigua* (PAN 26B-20). For the purpose of the report, this entity is designated as *P. ambigua*.	Yes
Senna artemisioides subsp. *oligophylla* (thinly sericeous form MET 15,035)	This taxon is a form of *Senna artemisioides* subsp. *oligophylla* recognised by Malcolm Trudgen (M.E. Trudgen and Associates), which can be distinguished by the very appressed hairs on the leaflets. Although not formally recognised, this taxon has been included in this report because it appears distinctly different from *S. artemisioides* subsp. *oligophylla* and is easily recognised. It also occurred in the study area as a hybrid with *Senna artemisioides* subsp. *helmsii*.	No
Sida echinocarpa	One taxon that represents a variation of *Sida echinocarpa* was recorded from the study area*: Sida* aff. *echinocarpa* (MET 15,350). For the purpose of this report, this entity is designated as *S. echinocarpa.*	Yes
Sida fibulifera sens. lat.	*Sida fibulifera* is a recognised species complex. In past surveys, six apparently undescribed entities were identified from the study area: *Sida* aff. *fibulifera* (FMG 125-20), *S.* aff. *fibulifera* (HD12-39), *S.* aff. *fibulifera* (HD237-9), *S.* aff. *fibulifera* (oblong; MET 15 220), *S.* aff. *fibulifera* (site 1394) and *Sida* aff. *fibulifera* (prostrate A.A. Mitchell 3 572). None of these taxa are considered to be rare, and it is likely that more entities exist within this group. For the purpose of this report, all entities have been assigned to *Sida fibulifera* sens. lat.	No
Triodia basedowii	Following a discussion with Dr Matthew Barrett (Kings Park and Botanic Garden), all specimens of *Triodia lanigera* collected from the study area have been re-determined as *T. basedowii*. A relevant specialist taxonomist will be consulted for further confirmation.	No
Incompletely Resolved Taxa		
Goodenia nuda/triodiophila	Two collections of *Goodenia* could not be confidently distinguished between these two species (see Section 5.4.3).	Yes
Portulaca oleracea/Portulaca intraterranea	The taxonomy of "*Portulaca oleracea*" in the Pilbara is currently unresolved. It is not clear whether specimens from this region with weakly developed tubercles on the seeds belong to *Portulaca oleracea, P. intraterranea* and/or one or more undescribed taxa (S. Dillon, WA Herbarium, pers. comm. 2012). For the purposes of this report, all specimens have been allocated to "*Portulaca oleracea/P. intraterranea*", with the exception of a single specimen that was confirmed as *P. intraterranea* by Andrew Perkins (WA Herbarium taxonomist). The latter specimen was conspicuously different to the other specimens designated as "*Portulaca oleracea/intraterranea*", having seeds with very prominent elongated tubercles with star-shaped bases.	Yes

Taxon	Reason	Specimen Lodged with WA Herbarium?
Sorghum plumosum var. *plumosum*	One specimen collected from the study area that was identified as *Sorghum plumosum* var. *plumosum* by Malcolm Trudgen (M.E. Trudgen and Associates) was noted to have some unusual features for this species. The taxonomy of this genus is in need of review.	No. Specimen was of poor quality but was returned to Malcolm Trudgen for future reference.

1. Scope

1.1 Rio Tinto Operations

Rio Tinto's Iron Ore business in Western Australia includes several wholly owned subsidiaries and joint venture initiatives in the Pilbara region of north-west Western Australia. The Rio Tinto Iron Ore WA operations include assets owned by Hamersley Iron, Robe River Iron Associates and Hamersley Hope Management Services.

The operations include a network of open cut mines, shipping terminals and a connecting heavy freight rail network (Figure 1-1). Ore is generally mined, crushed and screened at source, and then transported by rail to port facilities where it is stockpiled, sorted and shipped to customers.

As part of these combined operations Rio Tinto is responsible for managing mines, infrastructure and supporting assets. Rio Tinto also undertakes exploration for new ore bodies, and extensions to existing orebodies; Greenfield and Brownfield expansions, and provides corporate and site services.

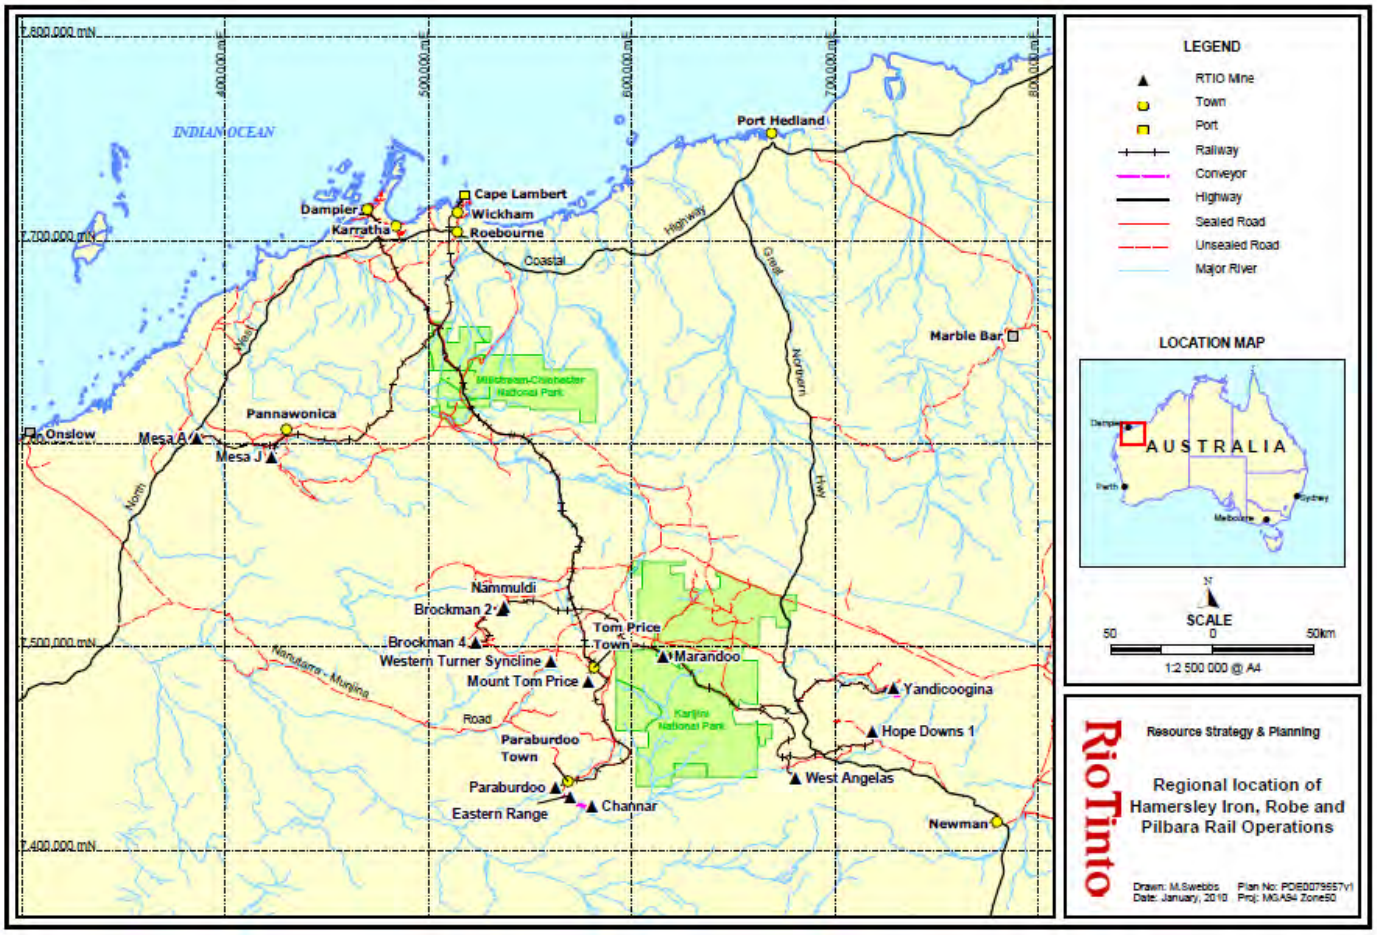

Figure 1-1 Rio Tinto Iron Ore Operations in WA

© 2014 Rio Tinto

1.2 EPBC Act

The *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) provides a legal framework to protect and manage nationally and internationally important flora, fauna, ecological communities and heritage places. These conservation assets are defined in the EPBC Act as matters of national environmental significance. The EPBC Act is administered by the Commonwealth Department of Department of the Environment (DoE).

Threatened fauna and flora listed under the EPBC Act are described as species of National Environmental Significance (**NES**), including the categories endangered, critically endangered, conservation dependant, vulnerable, extinct in the wild and extinct.

1.3 Management Plan Purpose

This Significant Species Management Plan (**SSMP**) provides the framework for Rio Tinto to minimise impacts to Pilbara populations of significant species from activities associated with its iron ore mining operations. The scope of the SSMP includes expansions to Rio Tinto's existing operations and new mining and infrastructure projects. The key elements of the management plan include:

- a summary of the broad aspects of Rio Tinto's operations with the potential to impact Pilbara populations of species of national environmental significance;
- a concise summary of the general distribution, ecology, conservation status and threatening processes for species of national environmental significance relevant to Rio Tinto's operations in the Pilbara;
- an updated consolidation of all readily available records of these species in the Pilbara region, and a comparison of this with database results for the species from the EPBC Act 1999 Protected Matters Search Tool;
- an overview of the broad scale management measures that Rio Tinto will use to minimise impacts to species of national environmental significance; and
- site specific management measures and local scale species information where species of national environmental significance are at elevated risk from Rio Tinto operations.

The purpose of the plan is to meet Commonwealth requirements and to communicate Rio Tinto's management measures for species of national environmental significance to relevant stakeholders. Where relevant this plan will operate in conjunction with any Rio Tinto site specific Environment Management Plans. The SSMP has been developed in accordance with relevant provisions of the EPBC Act and Western Australian *Environmental Protection Act 1986* (EP Act). The DoE and the WA Environmental Protection Authority (EPA) are the relevant federal and state administering authorities of these acts respectively.

1.4 Review schedule

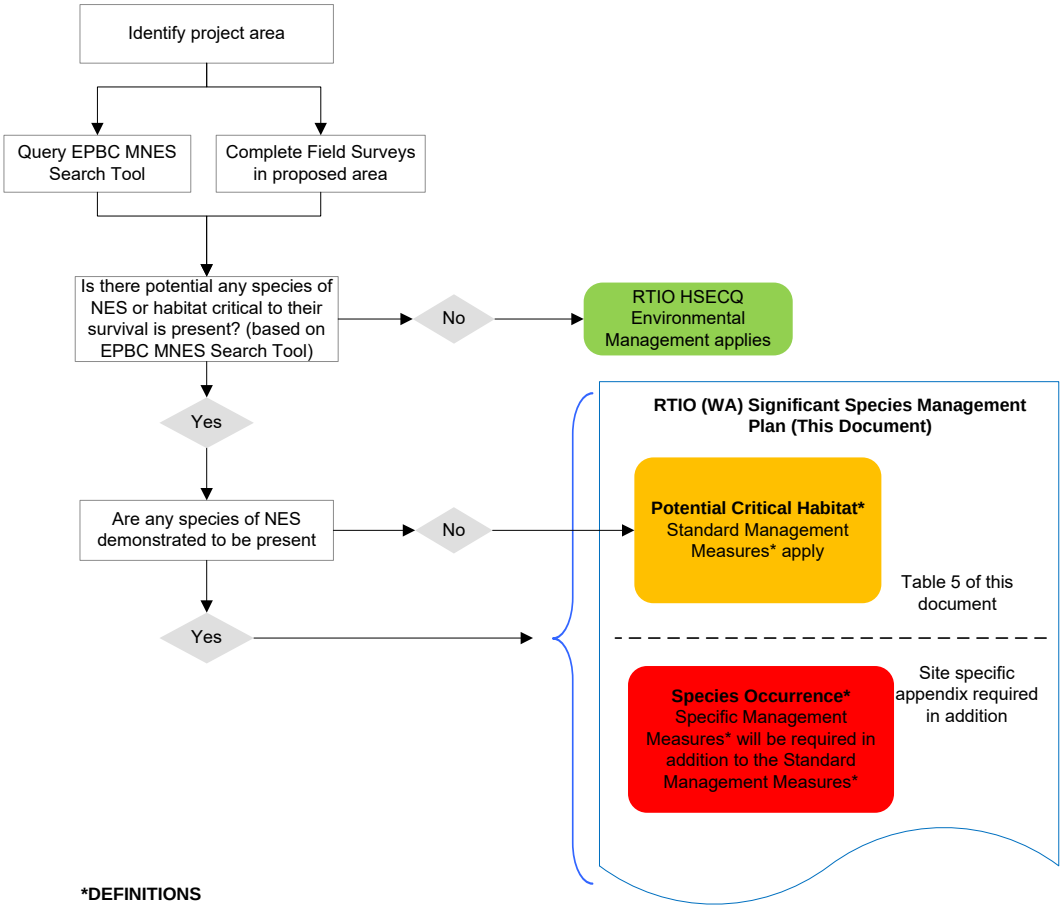
The plan will be reviewed and updated regularly in response to changing legislation, EPA and DoE policies, changes in the conservation status of MNES, changes in key threatening processes, and RIO TINTO's new and expanding operations. Regular revisions are a component of an adaptive management approach, and will provide for the incorporation of new scientific knowledge and management techniques as these become available.

Uncontrolled when printed **© 2014 Rio Tinto**

2. Application of the SSMP

The way in which the SSMP is applied will depend on the specific context of each new or expanded Rio Tinto project. The framework for implementing the SSMP is described in Figure 2-1, which demonstrates how different components of the plan are relevant for different situations.

This SSMP also sits within the broader context of current Rio Tinto environmental management policies, programs and procedures within an overall Health, Safety, Environment and Quality (HSEQ) Management System. This relationship is described in Figure 2-2.



***DEFINITIONS**

Potential Critical Habitat: Habitat critical to the survival of the species of NES, but species not proven to be present
Species Occurrence: species is proven to be present in the critical habitat

Standard Management Measures: RTIO (WA)'s standard management measures to minimise impact to species of NES in the RTIO (WA) Significant Species Management Plan
Specific Management Measures: Further management measures RTIO (WA) will undertake that are specific to individual species and individual projects in the RTIO (WA) Significant Species Management Plan

3. Rio Tinto Environmental Management

Rio Tinto aims to conduct its business in an efficient and environmentally responsible manner that is compatible with stakeholder expectations. Rio Tinto recognises that environmental responsibilities go beyond those required under statutory regulations. As part of their commitment, Rio Tinto has a Health, Safety, Environment and Quality (HSEQ) Policy endorsed by management that is the guiding document for driving environmental management, and provides context and direction for continuous improvement (Figure 2-2).

3.1 Environmental Management System

Rio Tinto operates under an Environmental Management System (EMS), contained within the Health, Safety, Environment, Communities and Quality (HSECQ) Management System. It provides a structured framework for developing an EMS based on an organisational policy and management objectives, which take into account legal requirements and information about significant environmental aspects. The Standard places emphasis on securing management commitment and appropriately allocating resources for the establishment of systems to reduce environmental risk. Key elements include assessing environmental risk and legal requirements (including requirements under state and federal acts), developing objectives and targets, training, operational control, corrective actions, audits and review.

The Rio Tinto EMS includes systems for managing environmental incidents which could include potential and actual impacts on species of national environmental significance. The EMS requires internal reporting, investigation, and review of incidents to determine if they require reporting to relevant authorities and any remedial actions. These processes allow Rio Tinto to minimise harm to the environment, and ensure all incidents are recorded, trends noted, and corrective actions determined.

The Rio Tinto EMS includes induction and training requirements. The induction program includes information on all aspects of environmental management including responsibilities, legal requirements and Rio Tinto's expectations. In particular the induction program includes information on the potential for mining activities to affect flora, fauna and habitat, fauna encounter procedures, and feral animal and weed control. The induction program is designed to ensure employees and contractors understand environmental risks and legal requirements associated with their roles.

The Rio Tinto EMS is audited on an annual basis and where auditing finds management actions are not effective, the audits may recommend changes to procedures and systems. Environmental performance and compliance with commitment and conditions is reported in Annual Environment Reports. The Department of Environment Regulation (DER) Audit Branch may undertake regular audits in conjunction with these reports. The EMS is reviewed annually to ensure its continuing suitability, adequacy and effectiveness.

Uncontrolled when printed **© 2014 Rio Tinto**

3.2 Approvals Request System

In addition to the EMS, Rio Tinto maintains an Approvals Request System for all ground disturbance activities. This is a coordination process, administered by a company Approvals Coordination Officer, which prior to the commencement of any work ensures:

- relevant biological surveys are complete;
- relevant heritage survey are complete; and
- appropriate government regulatory approvals are in place.

After these checks are made, an Approvals Permit is issued which may contain specific conditions based on results of surveys or approval requirements. The process minimises the risk of disturbing any protected areas and assists Rio Tinto in complying with legal and social requirements.

Uncontrolled when printed **© 2014 Rio Tinto**

4. Aspects and Impacts

Various aspects of Rio Tinto's activities have the potential to impact on species of national environmental significance. Rio Tinto's management objectives for species of national environmental significance are to:

- avoid areas of high sensitivity where practicable;
- minimise impacts by appropriate design and operation; and
- mitigate potential impacts through rehabilitation

Table 4-1 Aspects of Rio Tinto activities with the potential to impact on species of national environmental significance

Aspect	Potential Impacts	Type & Potential Duration of Impact*	Management Objective
Clearing & Disturbance	- Critical and/or peripheral habitat decreased, altered or fragmented - Populations decreased, altered or fragmented	Direct Medium term	Maintain the abundance, species diversity, geographic distribution and productivity of significant habitat or flora populations, by avoiding or minimising clearing, and utilising appropriate engineering and management of areas to be cleared
			Progressively restore habitat for flora and fauna, particularly areas of habitat for significant species/ populations, and develop self sustaining, non-polluting final landforms to support ecosystems
Spread of weed species	- Critical and/or peripheral habitat altered - Populations altered or displaced	Indirect Long term	Minimise the introduction and spread of weed species to significant flora and fauna habitat and populations
Increase in feral animals	- Direct Mortality - Increased competition	Indirect Long term	Minimise the effect of feral animals on native terrestrial fauna by controlling spread and mitigating impacts through management
Dust generation	- Critical and/or peripheral habitat altered - Populations decreased or altered	Indirect Short term	Protect significant fauna habitat and vegetation by controlling dust emissions
Direct MNES encounter	- Direct Mortality	Direct Short term	Protect native fauna by avoiding species / ecological communities with conservation significance wherever practicable; utilising engineering designs, management controls, education of site personnel and traffic management
Changes to hydrology and hydrogeology	- Critical and/or peripheral habitat decreased or altered - Populations decreased or altered	Cumulative Long term	Maintain the quantity and quality of water to protect existing and potential values, including ecosystem maintenance, flow paths and water quality.
Altered fire regimes	- Critical and/or peripheral habitat altered - Populations altered	Indirect Medium term	Protect significant habitat from fire where beneficial and minimise fire occurring from human activities

*Potential Duration of impact:
- Short term: impact limited to discrete phase of mining
- Medium: life of mine
- Long term: impact extends beyond closure

© 2014 Rio Tinto

5. Management measures

5.1 Standard management

Standard management measures for species of national environmental significance are described in Table 5-1. Rio Tinto will adopt these management measures at all operations where there is:

- Potential for species of national environmental significance to be present; or
- Potential for critical habitat of species of national environmental significance.

These standard management measures apply to the following species:

- Northern Quoll (*Dasyurus hallucatus*)
- Pilbara Leaf-Nosed Bat (*Rhinonicteris aurantia)*
- Pilbara Olive Python (*Liasis olivaceus barroni*)
- Hamersley Lepidium (*Lepidium catapycnon*)
- Greater Bilby (*Macrotis lagotis*)

Table 5-1 Management Measures for species of national environmental significance

Aspect	Action	Rio Tinto Accountability	References	Species applies to
Clearing & Disturbance	Baseline surveys (following EPA guidance statements) will be completed in all areas with planned mining developments and infrastructure.	- Environment Manager Approvals	- Approvals Request system	- Northern Quoll - Pilbara Olive Python - Pilbara Leaf-Nosed Bat - Greater Bilby - Hamersley Lepidium
	Location of species of NES and their habitats identified within and adjacent to Rio Tinto project boundaries will be recorded on the Rio Tinto GIS database.	- Environment Manager Approvals		
	Proposed clearing and disturbance will be assessed through the Rio Tinto Approvals Request System.	- Environment Manager Approvals - Site, Project, Study & Exploration Managers		
	The Rio Tinto Approvals Request System will ensure: - disturbance remains within approved boundaries - clearing is minimised to meet specific demands - planned clearing is adjusted where possible to avoid disturbance of significant areas - planned clearing meets legal obligations.	- Environment Managers Approvals, Operation & Expansions - Site, Project, Study & Exploration Managers		
	All areas to be cleared will be demarcated prior to disturbance.	- Site, Project, Study & Exploration Managers		

Uncontrolled when printed © 2014 Rio Tinto

	Completion criteria will be developed as part of the closure and rehabilitation plan to provide the basis for functioning habitat post mining.	- Water & Closure Manager	- Closure plans	
Spread of weed species	Weed management measures will be implemented in accordance with Rio Tinto's EMS Weed management Strategy and equipment hygiene procedures to ensure weeds are controlled and recorded and equipment is cleaned to minimise the spread of weeds.	- Environment Managers Operations & Expansions - Site, Project, Study & Exploration Managers	- Weed Management Strategy	- Northern Quoll - Pilbara Olive Python - Greater Bilby - Hamersley Lepidium
Increase in feral animals	Feral animal control will be undertaken by: • prohibiting feeding animals • prohibiting keeping pets • appropriate waste disposal for food scraps and other wastes as per the Rio Tinto EMS waste management guidelines • regular feral animal reduction programs	- Environment Managers Operations & Expansions - Site, Project, Study & Exploration Managers	- Wildlife Interaction Guidelines - Waste Management Treatment, Storage & Disposal Guidelines	- Northern Quoll - Pilbara Olive Python - Greater Bilby
Dust generation	Dust control measures (including road watering, water sprays and dust suppression systems) will be used to minimise dust from sites	- Environment Managers Operations & Expansions - Site, Project, Study & Exploration Managers	- Cleaner air management plan	- Hamersley Lepidium
Direct MNES encounter / sighting	A register of any MNES encountered on site will be developed and maintained. This will include GIS locations, and MNES status (alive/dead).	- Environment Managers Operations & Expansions - Site, Project, Study & Exploration Managers	- Wildlife Interaction Guidelines - Waste Management Treatment, Storage & Disposal Guidelines	- Northern Quoll - Pilbara Olive Python - Pilbara Leaf-Nosed Bat - Greater Bilby
	Native fauna encountered on site will be given the opportunity to move on if there is no threat to personnel safety in doing so.			
	Fauna (including injured fauna) encountered on site will be handled and transported in accordance with Rio Tinto's Wildlife interaction guidelines.			
	Feeding of native fauna, hunting, keeping of firearms or pets on site will be prohibited	- Site, Project, Study & Exploration Managers	- Rio Tinto induction program	- Northern Quoll - Pilbara Olive Python - Pilbara Leaf-Nosed Bat - Greater Bilby - Hamersley Lepidium
	Appropriate speed limits for mining equipment and light vehicles will be implemented, sign-posted and enforced, and communicated via education of site personnel			

Uncontrolled when printed **© 2014 Rio Tinto**

	Vehicles will remain on designated roads and will not be permitted off designated roads unless in the case of emergency. Location of any significant roost sites adjacent to the operations will be demarcated and access prohibited to all personnel.	- Site, Project, Study & Exploration Managers		- Pilbara Leaf-Nosed Bat
Changes to hydrology and hydrogeology	Taking water only from points licensed by the DoW and remaining within licence limits. Storing, handling and disposing of effluent in accordance with the environmental licence Adhering to site specific Groundwater, Surface Water and Drainage Management Plans where applicable Adhering to discharge conditions Installing appropriate hydrocarbon bunding and management practices at hydrocarbon use and storage facilities	- Environment Managers Operations & Expansions - Site, Project, Study & Exploration Managers	- Existing site management plans - Licences	- Northern Quoll - Pilbara Olive Python - Pilbara Leaf-Nosed Bat - Greater Bilby - Hamersley Lepidium
Altered Fire Regimes	Control fires caused by operations Minimise risk of fire from ignition sources	- Environment Managers Operations & Expansions - Site, Project, Study & Exploration Managers	- Emergency management procedures - Weed Management Plan - Hot work Standard	- Northern Quoll - Pilbara Olive Python - Pilbara Leaf-Nosed Bat - Greater Bilby - Hamersley Lepidium

5.2 Site specific management measures

In addition to the above measures, further specific measures may need to be undertaken at Rio Tinto operations in the event that there is confirmation of species of national environmental significance present.

Site specific measures will be matched to local scale environmental protection and threat mitigation requirements. These will be addressed in detail in the site specific addendums to this management plan. These further management measures will predominantly focus on minimisation of impact on potential critical habitat through appropriate design and construction.

Uncontrolled when printed © 2014 Rio Tinto

6. Contingency

Threatening processes are continually monitored and assessed by Rio Tinto, along with consultation with appropriate government agencies, including the Department of Parks and Wildlife (DPaW), OEPA and DoE. If the status of any species or threatening process changes, Rio Tinto will consult with the relevant agency and update the management plan where required.

7. Monitoring

Rio Tinto is committed to designing and implementing monitoring programs specific at its operations to meet all regulatory requirements. In special cases monitoring will be designed to enable an assessment of the effectiveness of flora and fauna management measures. An example of considerations to be addressed by Rio Tinto monitoring programs is shown below.

Table 7-1 Monitoring Requirements

Sources of monitoring requirements	- Ministerial conditions - Licence requirements - Referral requirements - Part IV assessment commitments - Rio Tinto requirements
Monitoring and Survey guidelines	- EPA guidance note 56 (Terrestrial Fauna Surveys for Environmental Impact Assessment in Western Australia) - EPA guidance note 51 (Terrestrial Flora and Vegetation Surveys for Environmental Impact Assessment in Western Australia) - EPA Technical Guide – Terrestrial Vertebrate Fauna Surveys for Environmental Impact Assessment - Significant Impact guidelines 1.1 Matters of National Environmental Significance - Species significant guidelines issued by DoE eg EPBC Act policy Referral guidelines for the Northern Quoll *Dasyurus hallucatus*
Purpose of monitoring	- Collection of baseline data - Knowledge gain - Measurement of impacts on matters of National Environmental Significance - Determination of trigger values to change practices on site - Determine effectiveness of management measures
Reporting of monitoring	- Present findings and trends in the Annual Environment Report - Identify and understand impacts and cumulative impacts - Identify trigger values and responses required for exceedance of trigger values - Trigger updates to management plan where required - Include justification for survey methodology - Include discussion on scientific reliability of surveys

© 2014 Rio Tinto

8. Significant Species descriptions

8.1 Northern Quoll (*Dasyurus hallucatus*)

Biology

The Northern Quoll is a medium-sized dasyurid marsupial, with adult weight ranging from 300 to 1,200 g. It is considered a partially arboreal and aggressive carnivore, preying on a varied diet of small invertebrates and vertebrates, including lizards, birds, snakes, small mammals and frogs (Oakwood 2000). It is also known to feed on fleshy fruit and carrion. The Northern Quoll is mostly nocturnal, although crepuscular (dusk and dawn) activity also occurs.

The Northern Quoll is short-lived, with both sexes maturing at approximately 11 months. Females reproduce only once each year and males typically undergo die-off after mating (Dickman and Braithwaite 1992, Oakwood 2000). The timing of breeding varies across the species range but typically occurs between July and September. In the Kimberley bioregion of Western Australia breeding has been recorded between July and August while in the Pilbara bioregion breeding has also been recorded in September (How et al. 2009), (Biota, 2009).

The home range size and density of Northern Quoll populations is poorly understood across the species range. In Savanna populations the home range of male Northern Quolls may extend over 100 hectares and encompass numerous female territories (Oakwood 2000). There is some suggestion that rocky habitats such as those commonly found in the Pilbara bioregion support denser populations of quolls (DoE 2014) and as such the size of home ranges may be smaller in these habitats.

Habitat preferences

A regional analysis completed by Biota (2009), found that the majority of Northern Quoll records from the Pilbara region came from land systems containing rocky hills, mesas, plateaux, drainages and granite tor fields. When dispersing, foraging or seeking mates, the species may also utilise other parts of the landscape and as a result occurs in a wide variety of habitats across its range (Hill & Ward 2010).

The species is known to occupy denning and shelter sites located amongst rock crevices, hollow logs, goanna burrows, termite mounds and human dwellings (Hill & Ward 2010). Many records from the Pilbara bioregion have come from mesa, plateaux and breakaway features abutting large creeks (Garth Humphreys, Biota Environmental Sciences, pers. obs.) and from boulder tors of the Abydos-Woodstock Plain (How et al. 1991), (Biota, 2009).

Distribution

The Northern Quoll's (*Dasyurus hallucatus*) distribution is discontinuous across northern Australia and is restricted to six main areas:

- Top end of the Northern Territory;
- North of Cape York;
- The Atherton-Cairns area,
- The Carnarvon Range-Bowen area of Queensland (Menkhorst 2001),
- The northwest Kimberley and
- The Pilbara region of Western Australia (Braithwaite and Griffiths 1994)

© 2014 Rio Tinto

The Northern Quoll also occurs on numerous islands off the Australian coast (Abbott and Burbidge 1995, Burbidge and McKenzie 1978; How et al. 2006).

In the Pilbara bioregion the Northern Quoll is widely distributed and has been recorded from all four subregions of the Pilbara bioregion. A total of 245 records of the Northern Quoll are known from locations across the extent of the bioregion (Figure 8.1-1). Population density varies across the region, with reliable populations occurring in several areas including the Robe River valley, rocky areas inland of Port Hedland and the Abydos-Woodstock plain. The species appears to occur at lower frequency across other parts of the Pilbara and density of populations appears to wane toward the southeast of the region. Population numbers and spatial extent also contracts and expands interannually, presumably in response to seasonal conditions, related abundance of prey species and fire regimes.

Threats

The National Recovery Plan for the Northern Quoll (Hill & Ward 2010) identifies a variety of threats to regional Northern Quoll populations throughout the species range. These threats include; Cane Toads, feral predators, inappropriate fire regimes, habitat degradation and destruction, weeds, disease, hunting and population isolation (Hill & Ward 2010).

The most significant threat to the Northern Quoll in Queensland, the Northern Territory and the Kimberley bioregion of Western Australia is the invasion of the Cane Toad *Bufo marinus*. The Cane Toad does not occur in the Pilbara bioregion and current modelling suggests it is not expected to become established in inland areas of the Pilbara (Urban et al. 2007, DoE 2014).

Specific threats to the Pilbara regional population of the Northern Quoll are thought to include:

- Predation by feral predators
- Inappropriate fire regimes
- Pastoralism
- Habitat clearing and modification

Conservation Status

Dasyurus hallucatus is specially protected under both State and Federal legislation. The species is listed as Schedule 1 (‘Endangered’) under the *Western Australian Wildlife Conservation Act 1950- 1979* and is also listed as ‘Endangered’ under both the Commonwealth *EPBC Act 1999* and the IUCN Red List.

Uncontrolled when printed **© 2014 Rio Tinto**

8.2 Pilbara Olive Python (*Liasis olivaceus barroni*)

Biology

The Pilbara Olive Python (*Liasis olivaceus barroni)* is an olive brown/pale fawn python growing to 2.5m. The diet includes birds, reptiles, and mammals as large as rock wallabies (Wilson and Swan 2008, Pearson 1993). Breeding commences in June - August, with males travelling distances of several kilometres in search of mates. Eggs are laid in October and juveniles hatch in summer, following which they disperse. Adults may occupy very large home ranges, up to approximately 450 ha in size (Pearson 2006).

Habitat preferences

Restricted to gorges and escarpments in the Pilbara and Gascoyne, this species shows a preference for rocky habitats near water, particularly where permanent or semi-permanent rock pools are present. Individuals may shelter in deep rock crevices.

Distribution

The olive python is endemic to Western Australia, occurring in a restricted region within the Pilbara and Gascoyne regions (Wilson and Swan 2008). It is distributed throughout most rocky areas of the Pilbara bioregion, including the Burrup Peninsula, throughout the Hamersley and Chichester Ranges, parts of the eastern Pilbara and Barlee Range Nature Reserve. Based on the Department of Parks and Wildlife's (**DPaW**) NatureMap database and Rio Tinto data, there are 48 records of this species spanning the majority of the bioregion (Figure 8.2-1). Known populations occur in association with rockpiles on the Burrup Peninsula, mesas of the Robe River valley and the Millstream spring system (Pearson 1993), though it appears to occur in lower density across suitable habitat in the majority of the bioregion.

Threats

Identified threatening processes for the Pilbara Olive Python include:

- predation of individual pythons by feral cats and foxes (particularly juveniles);
- predation of python prey species by foxes (competition); and
- habitat loss due to resources development (especially on Burrup Peninsula) (Pearson 2006).

Other impacts on the species include the loss of individuals due to road kills and deliberate killing of individuals due to misidentification as a venomous species (Pearson 2006).

Conservation Status

The species is listed as 'Vulnerable' under the Commonwealth Environment Protection and Biodiversity Conservation Act 1999. At State level, the Pilbara Olive Python is also listed under Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice 2010.

It should be noted that in 2003, a publication by the then Department of Conservation and Land Management (May and Mackenzie 2003) concluded that this species was not under threat at regional scale. Pearson (1993) also commented that a large proportion of the species' habitat in the Pilbara region was well represented in the conservation estate in Karijini National Park.

© 2014 Rio Tinto

8.3 Hamersley Lepidium (*Lepidium catapycnon*)

Biology

Hamersley Lepidium is a short lived perennial herb or shrub up to 40 cm high, with stems that zigzag. (Mattiske & Assoc., 1994; Brown et al., 1998). The leaves are small, linear, terete, and succulent (Hewson, 1981). White flowers occur as a dense head at the tips, and the life cycle is that of a pioneer ephemeral, with flowering from August to January (Hewson, 1981; Brown et al., 1998).

It should be noted that *Lepidium catapycnon* superficially resembles *L. platypetalum Hewson*; both have distinctive linear, more or less terete leaves, however *L. catapycnon* is defined by its characteristically zigzag shaped branches (Hewson, 1981).

Habitat preferences

Lepidium catapycnon is found in the following preferred habitats:

- stony hill slopes such as the uplands of the Hamersley Range plateau;
- skeletal soils;
- open woodland in usually hilly areas, more frequently on south facing slopes; and
- hill hummock grasslands

It tends to be displaced by maturing *Triodia sp*. (Spinifex), re-appearing after fires. It has also been found on road-verges and cuttings (Hewson, 1981).

In previous Rio Tinto vegetation surveys *Lepidium catapycnon* has often been found in association with *Eucalyptus sp*. over mixed *Acacia sp*. shrubland over *Triodia sp*. hummock grassland vegetation stands. The most common associated species are *Eucalyptus leucophloia*, *Eucalyptus xerothermica*, *Triodia wiseana*, *Triodia basedowii*, *Acacia bivenosa*, and *Acacia pruinocarpa*.

Distribution

Lepidium catapycnon is endemic to Western Australia and found in the Pilbara. Records are from around Newman, Wittenoom, Weeli Wolli creek and West Angelas.

DPaW's maintained database NatureMap indicates 44 records of *Lepidium catapycnon*. However, the Rio Tinto database lists 230 known recordings, with some stands containing approximately 1000 plants.

The species' extent of occurrence is approximately 10 280 km^2. There are insufficient data available to determine the area of occurrence although this species has now been recorded within Karijini National Park (Figure 8.3-1).

The distribution of this species is not known to overlap with any EPBC Act-listed threatened ecological community.

© 2014 Rio Tinto

Lepidium catapycnon is found on stony hill slopes such as the uplands of the Hamersley Range plateau (Figure 8.3-1)

Threats

Potential threats to the *L. catapycnon* include road works, as many populations are on or adjacent to frequently graded mining/exploration tracks (Brown et al., 1998), clearing, and invasion of the introduced Ruby Dock (*Acetosa vesicaria*), which may displace populations in some areas.

Conservation Status

Lepidium catapycnon is specially protected under both State and Federal legislation. The species is listed as 'Declared Rare Flora' under the *Western Australian Wildlife Conservation Act 1950* and is also listed as 'Vulnerable' under the Commonwealth EPBC Act 1999.

Uncontrolled when printed **© 2014 Rio Tinto**

8.4 Pilbara Leaf Nosed Bat (*Rhinonicteris aurantius)*

Biology

The Pilbara Leaf Nosed Bat (*Rhinonicteris aurantius)* is a moderate sized bat with short fur, relatively small ears and a fleshy noseleaf structure surrounding the nostrils. It has bright orange fur on the front of the body and the back appears darker because of brownish tips on the fur this also. Morphologically smaller than the northern form of this species, the nocturnal Pilbara Leaf-nosed Bat has a head and body length ranging from 40.8 – 47.4 mm, with an average of 42.7 mm (van Dyck and Strahan 2008).

Rhinonicteris aurantia are opportunistic in their diet, with prey primarily consisting of moths, beetles and termites, but supplemented with other insects (Churchill 2008).

Mating occurs in July, with females giving birth to solitary young in late December or early January. Young grow rapidly until weaning in February, with females becoming sexually mature in their first year at about seven months, although males do not mature until their second year.

Habitat preferences

The local distribution of the Pilbara Leaf-nosed Bat is mostly strongly influenced by the suitability of roost caves (hot and with a high humidity level) rather than habitat type. Many deeper caves that provide a suitable microclimate arise in Brockman Iron Formation ranges (Armstrong 2000, 2001), and there is a general association of the species records with this geology type (Figure 8.2-1). Foraging habitat appears to be diverse and not a restricting factor.

In the Pilbara, core roost sites are thought to be restricted to caves where at least semi-permanent water is nearby (Armstrong 2000, 2001, Churchill 2008). While they typically occur in caves, significant roosts have also become established in man-made structures such as abandoned mines in the Pilbara region (Churchill 1991, Dr Norm McKenzie, DPaW, unpubl. data). This includes confirmed roosts in the northern Pilbara at Lalla Rookh, Klondyke Queen (Armstrong 2010) and Bamboo Creek amongst others (DoE 2014).

Distribution

The Pilbara form of *Rhinonicteris aurantia* is found across the Pilbara bioregion and also just inside the Gascoyne bioregion at Barlee Range Nature Reserve.

Historically, individual R. aurantia have been recorded from a range of locations across the Pilbara since 1925. The Department of Environment and Conservation's Pilbara Biological Survey found *Rhinonicteris aurantia* to be more common than previously supposed, with numerous records from three of the four Pilbara sub-regions (McKenzie and Bullen 2009). The exception was the Fortescue subregion, which lacks suitable roost caves. Colonies of the species are scattered throughout the landscape in the Pilbara, and permanent roosts are known from abandoned mines and exploration adits in the eastern Pilbara, throughout the Hamersley Range and from sandstone formations south of the Hamersley Range. These colonies represent central points of population density, with individuals foraging out at distances of tens of kilometres. Pilbara colonies

© 2014 Rio Tinto

contain relatively small numbers of individuals, ranging from a few individuals to a few hundred, with 30 being a typical Pilbara roost size.

Threats

DoE (2014) lists nine threats to the conservation status of the Pilbara Leaf-nosed Bat:

- Heat and water loss: the species is known for its poor ability to maintain body temperature and water. Consequently, where roosts are disturbed the risk and/or rate of mortality may increase;
- Mine collapse: resulting in direct mortality;
- Flooding: resulting in destruction of roost sites and possibly direct mortality;
- Natural predators: direct mortality resulting from predators such as the Ghost Bat *Macroderma gigas*;
- Mine development: may result in the destruction of roost sites;
- Blasting in adjacent workings: resulting in abandoning of roost sites by bats;
- Human entry of roosts: resulting in animals abandoning the site;
- Roadkills: direct mortality resulting from increased vehicle activity; and
- Site rehabilitation.

Conservation status

Rhinonicteris aurantius is listed as Schedule 1 ('Vulnerable') under the Western Australian *Wildlife Conservation Act 1950 - 1979* and is also listed as 'Vulnerable' under the Commonwealth *Environmental Protection and Biodiversity Conservation Act 1999*. It is currently listed as 'Least Concern' under the IUCN Red List, however it should be noted that this listing includes the both the Kimberley and Northern Territory populations.

8.	Figures	16
9.	EPBC Decision Notice 2011/5815 for Yandicoogina Junction South West and Oxbow Iron Ore Mine	21

Document Owner:	**Environment Manager, Approvals**
Document Revision:	September 2014

1. Purpose

This plan is a site specific addendum to the Rio Tinto (WA) Significant Species Management Plan (**SSMP**), to manage potential impacts to species of National Environmental Significance (**NES**) protected under the *Environment Protection and Biodiversity Conservation Act 1999* (**EPBC Act**). This document must be read as an addendum to the Rio Tinto (WA) SSMP.

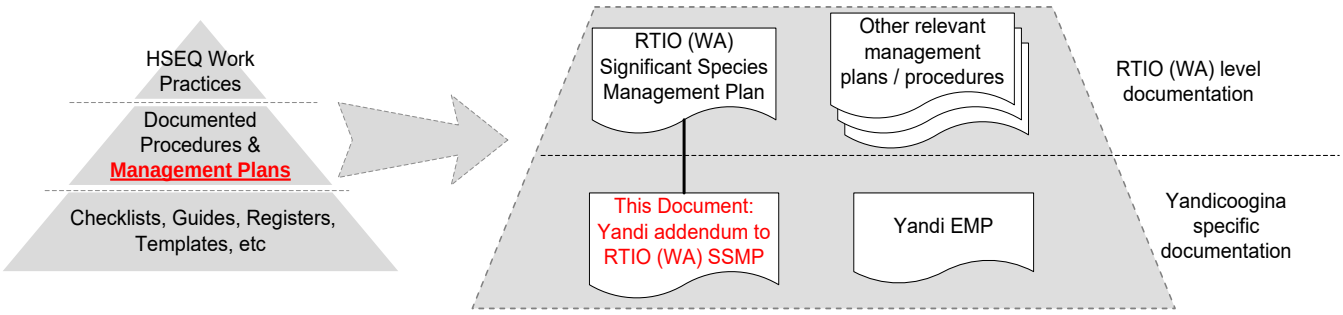

Figure 1-1 Relationship of Significant Species Management documents

Four species of NES occur, or have potential to occur in the vicinity of the Pocket and Billiard South Proposal:

- Pilbara Olive Python (*Liasis olivaceus barroni*) – known to occur
- Hamersley Lepidium (*Lepidium catapycnon*) – known to occur
- Northern Quoll (*Dasyurus hallucatus*) – potentially occurs
- Pilbara Leaf Nosed Bat (*Rhinonicteris aurantius*) – potentially occurs

The Proposal is unlikely to cause significant impacts to populations of these species, although it is possible impact to individuals of some species may occur.

2. Site context

The Yandicoogina operation is located approximately 90 km north-west of Newman in the eastern Pilbara region of Western Australia. Yandicoogina comprises a number of existing open-cut iron ore operations (and associated railway and infrastructure): Junction Central (approved in 1996) and Junction South east (JSE) (approved in 2005), and the more recent Junction South west (JSW) and Oxbow deposits (approved in 2012).

© 2014 Rio Tinto

An additional operation, the Pocket and Billiard South Project (the **Proposal**), will augment and ultimately replace the existing Yandicoogina operations as ore is eventually depleted from the existing mine pits. The Proposal requires clearing of up to 2,800 ha of native vegetation within a broader Yandicoogina Operations Development Envelope, and as the majority of the deposit occurs below the water table, dewatering of an additional ~30 GL/annum will be required to enable mining of the PBS deposit. Surplus water discharge in excess of operational requirements will be discharged to an ephemeral watercourse (Marillana Creek), which intersects Weeli Wolli Creek approximately 2 km downstream. Options for alternate surplus water management options are currently being investigated.

The Proposal has been determined to require assessment at a Public Environmental Review level under the Western Australian *Environmental Protection Act 1986*.

The Yandicoogina Mine area is within the Fortescue Botanical District of the Eremaean Botanical Province, as defined by Beard (1975), and is located near the boundary of the Hamersley and Fortescue sub-regions of the Pilbara Biogeographic Region as defined by the Interim Biogeographic Regionalisation for Australia (Environment Australia 2000). The majority of the Proposal area is typical of the Hamersley sub-region where the major creek systems (Marillana, Yandicoogina and Weeli Wolli Creek) form part of the Fortescue sub-region (Biota 2004a).

3. Potential Impacts on species of NES

Potential short term impacts of the Proposal that may affect individuals of species of NES, if present in the Proposal area include:

- Direct loss of habitat and fragmentation due to clearing;
- Alteration of surface hydrological regimes;
- Injury or mortality of fauna struck by vehicles;
- Spatial and temporal increase in suitable foraging habitat due to dewatering discharge.

Potential long term impacts that may affect individuals of species of NES, if present in the Proposal area include:

- Direct loss of habitat due to clearing and altered landforms;
- Alteration of surface hydrological regimes due to altered landforms;
- Indirect habitat disturbance by introduction of weed and pest species;
- Degradation of riparian habitat along the section of Weeli Wolli Creek within and adjacent to The PBS Mine pit due to mining and dewatering;
- Potential impacts on water dependent communities as a result of closure and creek system return from perennial to ephemeral regime
- Alteration of aquifer properties and groundwater chemistry resulting from post mining landform.

© 2014 Rio Tinto

Potential cumulative impacts to flora and fauna of NES by the Proposal and surrounding mining projects include:

- Direct loss of habitat due to clearing and altered landforms;
- Alteration of surface hydrological regimes due to altered landforms;
- Direct habitat disturbance on the Weeli Wolli creek system by release of surplus dewater by Yandicoogina, BHPBIO Yandicoogina and Hope Downs 1 operations
- Altered hydrology of the Fortescue Marsh, if combined dewatering discharge should ever inadvertently reach the marsh. Modelling studies indicate that potential discharges into Weeli Wolli Creek from mining project in the upper catchment are projected to cease ~23 km south of the southern edge of the Fortescue Marsh.

4. Site specific management objectives

Management objectives to minimise the potential impact of the Proposal on NES species are detailed in Table 5-1, and the following items are identified:

- Management measures/commitments that will ensure the Proposal achieves these objectives, comprising:
    - standard management measures for NES species as detailed in Table 5-1 of the SSMP;
    - site specific management measures for NES species as detailed in Table 6-1;
    - other relevant environmental management commitments that are part of the proposal being assessed under Part IV of the *Environmental Protection Act 1986* (WA) (**EP Act**) by the Environmental Protection Authority (**EPA**);
- Expected or known requirements under State legislation that will ensure specified management measures/commitments are implemented.

Table 5-1 Yandicoogina Management Objectives for species of national environmental significance and mechanisms to achieve

Aspect	Rio Tinto overarching objective	PBS objective	Management measures/commitments	State legislative requirements to implement management measures/commitments [1]
Clearing and disturbance	Maintain the abundance, species diversity, geographic distribution and productivity of significant habitat or flora populations, by avoiding or minimising clearing, and utilising appropriate engineering and management of areas to be cleared.	• Overarching Rio Tinto objective.	• Standard management measures (SSMP Table 5-1); • Additional site specific management measures (Table 6-1). Additional management measures for JSW & Oxbow: • EPBC Decision Notice 2011/5815 (Refer to Section 9)	The Ministerial Statement (**MS**) authorising the Proposal under Part IV of the *Environmental Protection Act 1986* (WA) (**EP Act**) is expected to maintain or impose Revised Conditions to MS914 that; • Limit the area of clearing to 2800ha within the Project Area; • Limit the extent of clearing of any vegetation or habitat considered significant by State government agencies; • Require implementation of the Proposal as assessed by the EPA, including management commitments associated with this objective.

Aspect	Rio Tinto overarching objective	PBS objective	Management measures/commitments	State legislative requirements to implement management measures/commitments [1]
	Progressively restore habitat for flora and fauna, particularly areas of habitat for significant species/populations, and develop self-sustaining, non-polluting final landforms to support ecosystems.	• Overarching Rio Tinto objective.	• Standard management measures (SSMP Table 5-1); • A Closure Plan for the Proposal has been developed, in accordance with the Rio Tinto Closure Standard and the Guidelines for Preparing Mine Closure Plans (DMP/EPA 2011). The Closure Plan specifies closure objectives that are aligned with this overarching objective, and management measures to achieve closure objectives. Additional management measures for JSW & Oxbow: • EPBC Decision Notice 2011/5815 (Refer to Section 9)	The MS authorising the Proposal under Part IV of the EP Act is expected to maintain or impose Revised Conditions to MS914 that; • Require EPA approval of a Closure Plan that meets the requirements of the Guidelines for Preparing Mine Closure Plans (DMP/EPA 2011); • Require progressive implementation of the Closure Plan (including rehabilitation) during the operational stage of the Proposal; • Require ongoing review and update of the Closure Plan, with periodic review by State government agencies during the operational stage of the Proposal; • Require approval by State government agencies of a final Closure Plan prior to closure of the operation.
Spread of weed species	Minimise the introduction and spread of weed species to significant flora and fauna habitat and populations.	• Overarching Rio Tinto objective.	• Standard management measures (SSMP Table 5-1); • A site specific Weed Action Plan has been developed and will be implemented, in accordance with the requirements of the RTIO (WA) Weed Management Strategy. Additional management measures for JSW & Oxbow: • EPBC Decision Notice 2011/5815 (Refer to Section 9)	The MS authorising the Proposal under Part IV of the EP Act is expected maintain or impose Revised Conditions to MS914 that require weed management and monitoring to ensure no increase in diversity or abundance of weed species due to Proposal implementation.
Increase in feral animals	Minimise the impact of feral animals by controlling their spread and mitigate impacts through feral animal management.	• Overarching Rio Tinto objective.	• Standard management measures (SSMP Table 5-1); • Management measures (aligned with standard SSMP management measures) are part of the Proposal being assessed under Part IV of the EP Act. Additional management measures for JSW & Oxbow: • EPBC Decision Notice 2011/5815 (Refer to Section 9)	The MS authorising the Proposal under Part IV of the EP Act is expected to maintain or impose Revised Conditions to MS914 that require implementation of the Proposal as assessed by the EPA, including management commitments associated with this objective.

Page 7

Aspect	Rio Tinto overarching objective	PBS objective	Management measures/commitments	State legislative requirements to implement management measures/commitments [1]
Dust generation	Protect significant fauna habitat and vegetation by controlling dust emissions.	• Overarching Rio Tinto objective.	• Standard management measures (SSMP Table 5-1); • Management measures (aligned with standard SSMP management measures) are part of the Proposal being assessed under Part IV of the EP Act. Additional management measures for JSW & Oxbow: • EPBC Decision Notice 2011/5815 (Refer to Section 9)	The MS authorising the Proposal under Part IV of the EP Act is expected to maintain or impose Revised Conditions to MS914 that require implementation of the Proposal as assessed by the EPA, including management commitments associated with this objective. The Licence to operate the Primary Crusher under Part V of the EP Act will impose conditions as deemed necessary by the Department of Environment Regulation (**DER**) to control/manage dust emissions.
Direct MNES encounter	Protect native fauna by avoiding species / ecological communities with conservation significance wherever practicable; utilising engineering designs, management controls, education of site personnel and traffic management.	• Overarching Rio Tinto objective.	• Standard management measures (SSMP Table 5-1); • Additional site specific management measures (Table 6-1); • Management measures (aligned with standard SSMP management measures) are part of the Proposal being assessed under Part IV of the EP Act. Additional management measures for JSW & Oxbow: • EPBC Decision Notice 2011/5815 (Refer to Section 9)	The MS authorising the Proposal under Part IV of the EP Act is expected maintain or impose Revised Conditions to MS914 that require implementation of the Proposal as assessed by the EPA, including management commitments associated with this objective.

Page 8

Aspect	Rio Tinto overarching objective	PBS objective	Management measures/commitments	State legislative requirements to implement management measures/commitments [1]
Changes to hydrology and hydrogeology	Maintain the quantity and quality of water to protect existing and potential values, including ecosystem maintenance, flow paths and water quality.	• Overarching Rio Tinto objective; • Pit voids do not cause significant adverse impacts on the regional groundwater resource, or environmental values of the PBS area.	• Standard management measures (SSMP Table 5-1); • A Closure Plan for the Proposal has been developed, in accordance with internal Rio Tinto Closure practices and the Guidelines for Preparing Mine Closure Plans (DMP/EPA 2011). The Closure Plan specifies closure objectives that are aligned with this overarching objective, and management measures to achieve closure objectives. • A specific closure objective in relation to pit voids is specified (refer objective column), and measures to achieve are detailed in the Closure Plan. The PBS pit void is proposed to be left with a number of pit lakes, with investigations to date indicating the lake should not cause significant environmental impacts. Additional management measures for JSW & Oxbow: • EPBC Decision Notice 2011/5815 (Refer to Section 9)	The MS authorising the Proposal under Part IV of the EP Act is expected to maintain or impose Revised Conditions to MS914 that: • Require EPA approval of a Closure Plan that meets the requirements of the Guidelines for Preparing Mine Closure Plans (DMP/EPA 2011); • Require progressive implementation of the Closure Plan (including rehabilitation) during the operational stage of the Proposal; • Require ongoing review and update of the Closure Plan, with periodic review by State government agencies during the operational stage of the Proposal; • Require approval by State government agencies of a final Closure Plan prior to closure of the operation.
Altered fire regimes	Protect significant habitat from fire where beneficial, and minimise fire occurring from human activities.	• Overarching Rio Tinto objective.	Standard management measures (SSMP Table 5-1); Management measures (aligned with standard SSMP management measures) are part of the Proposal being assessed under Part IV of the EP Act. Additional management measures for JSW & Oxbow: EPBC Decision Notice 2011/5815 (Refer to Section 9)	The MS authorising the Proposal under Part IV of the EP Act is expected to maintain or impose Revised Conditions to MS914 that require implementation of the Proposal as assessed by the EPA, including management commitments associated with this objective.

[1] *To be periodically updated to align with conditions of State legislative approvals for the Proposal*

5. Site-specific management measures

In addition to the standard management measures in Table 5-1 of the SSMP, further specific measures apply at Yandicoogina (for the existing JSW and Oxbow Project and the PBS Proposal) (Table 6-1) where there is confirmation of species of NES present.

These further management measures apply to the following species:

- Pilbara Olive Python (*Liasis olivaceus barroni*) – known to occur
- Hamersley Lepidium (*Lepidium catapycnon*) – known to occur
- Northern Quoll (*Dasyurus hallucatus*) – potentially occurs
- Pilbara Leaf-nosed Bat (*Rhinonicteris aurantius*) – potentially occurs

© 2014 Rio Tinto

Table 6-1 Management Measures at Yandicoogina for species of NES

All management measures as listed in Table 5-1 of this document (RTIO (WA) Significant Species management plan

All management measures as listed in the Yandicoogina Iron Ore Operations Environmental Management Program 2013 (EMP):
• Surface Water Discharge Monitoring and Management Plan
• Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan
• Weed Monitoring Plan
• Yandicoogina Life of Mine Closure Plan
• Yandicoogina Threatened Species Offset Plan
• Yandicoogina Significant Species Management Plan
• Guidelines:
  ○ EMP 01 – Dust Management Guideline (E2)
  ○ EMP 02 – Acid Rock Drainage Management Guideline (E3)
  ○ EMP 03 – Greenhouse Gas Management Guideline (E4)
  ○ EMP 04 – Hazardous Materials Management Guideline (E5)
  ○ EMP 05 – Noise Management Guideline (E6)
  ○ EMP 06 – Non-Mineral Waste Management Guideline (E7)
  ○ EMP 07 – Mineral Waste Management Guideline (E8)
  ○ EMP 08 – Aboriginal Heritage Management Guideline (E9)
  ○ EMP 09 – Waste Water and Effluent Management Guideline
  ○ EMP 10 – Subterranean Fauna Management Guideline
  ○ EMP 11 – Significant Species Management Guideline
  ○ EMP 12 – Non Threatened Native Fauna Management Guideline
  ○ EMP 13 – Fire Management Guideline

Uncontrolled when printed

Additional Management Measures:				
Aspect	**Action**	**RTIO (WA) Accountability**	**References**	**Species applies to**
Clearing & Disturbance	Ensure any sightings or potential records of NES species encountered by the workforce during clearing operations are reported to site Environmental Advisors and recorded in a register. Site environmental inductions & educational posters utilised to raise awareness of NES species and specify protocols for reporting sightings.	All employees and contractors		- Northern Quoll - Pilbara Olive Python - Hamersley Lepidium
	Obtain botanical confirmation of any reported and previously undocumented populations of Hamersley Lepidium within the operations area. Map extent of population and carry out adaptive review of existing management and design for Yandi operations.	Environment Managers Operations & Expansions		- Hamersley Lepidium
	Targeted surveys will be undertaken to identify any significant species, habitat or communities for any new projects/expansions - investigate ways to minimise or avoid the clearing of significant species if identified - riparian vegetation will be managed as per the Vegetation and Groundwater Dependent Ecosystems Monitoring and Management plan.	Environment Managers Operations & Expansions		- Northern Quoll - Pilbara Olive Python - Pilbara Leaf-nosed Bat - Hamersley Lepidium
Direct MNES encounter	Follow the Yandicoogina Pilbara Olive Python relocation protocol for any individuals encountered within the Yandi operational area. This should comprise measures for safe capture of individuals, temporary storage and suitable habitat release areas outside of the Yandi operations.	Environment Managers, Operations & Expansions	RTIO Wildlife interaction guidelines	- Pilbara Olive Python
	Native animals encountered onsite will be given the opportunity to move on if there is no threat to personnel safety in doing so. All animal strikes by vehicles will be recorded and documented.	All employees and contractors		- Northern Quoll - Pilbara Olive Python

Page 12
© 2014 Rio Tinto

6. Surveys & Monitoring

Based on detailed knowledge of the occurrence of NES species and potential core habitat in the PBS area, and the implementation of standard and additional site specific management measures (SSMP Table 5-1; Table 6-1 herein), the PBS Proposal will not result in significant impact on population or species of NES, or potential 'core' habitat for NES species, at a local or regional scale.

Therefore, in addition to regular monitoring requirements at Yandicoogina within the broader Development Envelope (including the monitoring conditions of EPBC 2011/5815 for JSW and Oxbow), monitoring will comprise recording of any future sightings of species of NES in the both the PBS Proposal area and surrounds and recording the extent of potential core habitat cleared during Proposal implementation. These additional monitoring actions are described in table 7-1.

© 2014 Rio Tinto
Uncontrolled when printed

Table 7-1 Monitoring at Yandicoogina for species of NES

Refer to Yandicoogina Expansion Northern Quoll Position Paper (Biota, 2010)
Refer to Yandicoogina Targeted Northern Quoll Survey (Biota, 2014b)
Refer to Yandicoogina Iron Ore Operations Environmental Management Program 2013 (EMP) (RTIO 2013)
Refer to Yandicoogina Junction South West and Oxbow Iron Ore Project EPBC Decision Notice 2011/5815

Additional Monitoring Measures:

Species Targeted	Design / Guidelines	Purpose	Reporting & Review
Northern Quoll	Presence monitoring for the Northern Quoll comprising the use of automatic infrared cameras deployed in suitable habitat for the species at Yandi.	To identify whether this species does use the Yandicoogina area as habitat, whether any populations exist in the general area, and when this species is present at Yandi during the life of the operations. If camera records indicate a potential increase in the local population, then consideration may be given to a targeted survey.	- Annual Environmental Report - Review of monitoring results after 5 years to interpret, recommend and assess future requirements - Review habitat for changes in vegetation condition
Hamersley Lepidium	Monitoring of dust levels for known populations adjacent to operational areas. This will be complemented by systematic monitoring of the populations of Hamersley Lepidium at selected sites. Local populations outside of the influence of the operations will also be similarly monitored to distinguish project effects from regional stochastic change.	To collect data on any change in Hamersley Lepidium population density or condition in relation to measured dust levels. These data will inform both site management procedures and future assessment of ecological risk for Hamersley Lepidium in relation to dust deposition.	- Annual Environmental Report - Review of monitoring results after 5 years to interpret, recommend and assess future requirements
Pilbara Olive Python	Maintain a site register of number of individuals relocated under the relocation protocol during the life of the operation.	To collect data on total number of python records within the Yandi operations over time.	- Annual Environmental Report - Review of monitoring results after 5 years to interpret, recommend and assess future requirements - Review habitat for changes in vegetation condition
Riparian Vegetation	Tree health monitoring program	Continue existing tree health monitoring program	- Annual Environmental Report - Ongoing review of monitoring results to interpret, recommend and assess future requirements

9. EPBC Decision Notice 2011/5815 for Yandicoogina Junction South West and Oxbow Iron Ore Mine

Australian Government

Department of Sustainability, Environment, Water, Population and Communities

Approval

Yandicoogina Junction South West and Oxbow Iron Ore Project, WA (EPBC 2011/5815)

This decision is made under sections 130(1) and 133 of the *Environment Protection and Biodiversity Conservation Act 1999*.

Proposed action

person to whom the approval is granted	Hamersley Iron Pty Ltd
proponent's ACN (if applicable)	ACN 004558276
proposed action	To develop new mine pits and supporting infrastructure, at Yandicoogina, central Pilbara region of WA, as described in the referral received by the department on 20 January 2011. [See EPBC Act referral 2011/5815].

Approval decision

Controlling Provision	Decision
Listed threatened species and communities (sections 18 & 18A)	Approve

conditions of approval

This approval is subject to the conditions specified below.

expiry date of approval

This approval has effect until 30 September 2025

Decision-maker

name and position	James Tregurtha Assistant Secretary South-Eastern Australia Environment Assessment Branch
signature	
date of decision	20 NOVEMBER 2012

Conditions attached to the approval

1) To protect habitat for the **Northern Quoll** and **Pilbara Olive Python disturbance** of vegetation must:

   a) not exceed a total of 2,200 hectares and must only occur within the **development footprint**; and

   b) not exceed 40 hectares within the floodplain and riparian vegetation zone associated with **Marillana Creek** located within the **development footprint**.

2) The person taking the action must establish and maintain an **EPBC Act listed threatened species** Register on a publicly available website. The Register must record any sightings of **EPBC Act listed threatened species**, alive or dead, in the **project area** no less than every three months during **construction**, and no less than every 12 months during **operation**. The web address of the register must be provided to the **department** within 30 days of establishment.

3) The person taking the action must develop a staff environmental induction to be undertaken by all staff, including contractors, prior to the **commencement** of their duties and annually thereafter. The induction material must include, but not necessarily be limited to:

   a) clear colour images and simple descriptions of the ecology and diagnostic features of **EPBC Act listed threatened species** and their habitat;

   b) protocols for reporting sightings, including vehicle strike (including GPS coordinates), of **EPBC Act listed threatened species** within seven days to the officer in charge of implementing the **EPBC Act listed threatened species** Register described in condition 2);

   c) reference to the penalties imposed for causing intentional harm to **EPBC Act listed threatened species**; and

   d) legal and on site environmental responsibilities.

4) The person taking the action must display the information required in condition 3) a) on signs or posters around staff amenities, construction camps and material/equipment depots, and on laminated cards for all staff vehicles. The signs, posters and laminated cards must also state that the **Pilbara Olive Python** is slow moving and highly susceptible to road strike.

5) In the event one or more **Northern Quoll** and/or **Pilbara Olive Python** individuals are detected within the **development footprint**, the person taking the action must limit vehicle speeds outside the **active pit areas**, excluding automated haulage machines, to 40 km per hour on all roads within the **development footprint** between dusk and dawn until no **Northern Quolls** and/or **Pilbara Olive Python** individuals are sighted for a continuous period of four weeks;

6) The person taking the action must ensure that all vehicles, machinery, and equipment remain within the **development footprint**, and must prevent off road driving, unless in case of an emergency;

7) The person taking the action must ensure that all vehicles, machinery and equipment are prevented from accessing known locations of the **Hamersley Lepidium**, as seen in Annexure 1 during **construction** and **operation**.

8) The person taking the action must implement measures to prevent the spread or establishment of feral animal species populations within the **project area** in a manner that is sympathetic with the conservation of **EPBC Act listed threatened species**. Measures must include, but not necessarily be limited to:

a) appropriate waste management associated with staff amenities, **construction** camps and material/equipment depots;

b) a control program which is consistent with current national guidelines for pest control; and

c) annual monitoring, reporting and evaluation of the measures.

9) The person taking the action must implement measures to prevent the spread or establishment of invasive weeds within the **project area** in a manner that is sympathetic with the conservation of **EPBC Act listed threatened species**. Measures must include, but not necessarily be limited to:

a) baseline surveys and Geographical Information System mapping of target weed species, as determined by a **suitably qualified expert**;

b) a targeted control program;

c) weed hygiene measures for vehicles and mining equipment and machinery; and

d) annual monitoring, reporting and evaluation of the measures identified in conditions 9) a) to c).

10) The person taking the action must implement measures to prevent and/or control the spread of fires caused by any component of **construction** and **operation**.

11) In the event the person taking the action becomes aware of new information regarding the presence of any **EPBC Act listed threatened species** within the **development footprint**, that information must be reported to the **Minister** within seven business days of becoming aware of the new information.

12) The person taking the action must implement measures to minimise potential impacts from **dewatering** and discharge of surplus water on habitat for the **Northern Quoll** and **Pilbara Olive Python** along **Marillana Creek** and **Weeli Wolli Creek**, both in the dewatering and surplus water discharge impact areas. Measures must include, but not necessarily be limited to:

a) baseline data surveys to be undertaken prior to **dewatering** and the discharge of surplus water, for **Northern Quoll** and **Pilbara Olive Python** habitat, including vegetation abundance, health, foliage cover and diversity;

b) appropriate monitoring (including annual surveys) to detect changes, occurring as a result of the action, to **Northern Quoll** and **Pilbara Olive Python** habitat, including vegetation abundance, health, foliage cover and diversity;

c) thresholds appropriate for the changes determined for condition 12) b) that establish when the action is resulting in degradation of habitat taking into consideration climatic variability, seasonal variation and discharge volumes from other relevant mines;

d) contingency measures to be implemented, should the thresholds indentified in condition 12) c) be exceeded as a result of the action, for addressing current and future exceedances and remediation of habitat degraded by dewatering and discharge activities;

e) protocols for reporting to the **Minister** within seven days if the thresholds developed for condition 12) c) are exceeded, within 30 days for contingency measures implemented and within 6 months on the success the contingency measures.

13) The person taking the action must rehabilitate all potentially suitable habitat for **EPBC Act listed threatened species** that is **disturbed** during **construction** and **operation**. The rehabilitation must be developed in consultation with a **suitably qualified expert** and must include, but not necessarily be limited to:

a) baseline data of the characteristics of the pre-mining ecosystems within the **development footprint**;

b) use of plant species of local provenance that are compatible with land system units that provide suitable habitat for **EPBC Act listed threatened species**; and

c) monitoring and evaluation annually for three years or until establishment.

14) To compensate for the residual impacts of the action and for the better protection and long-term conservation of the **Northern Quoll** and **Pilbara Olive Python**, a Threatened Species Offset Plan (TSOP) must be submitted to the **Minister** for approval. The TSOP must include, but not necessarily be limited to:

a) a contribution of no less than $3,000,000 (GST exclusive) to fund, extend or expand a land management program within the Pilbara bioregion for a period of no less than five years;

b) details of measures to control and/or manage, for the benefit of the **Northern Quoll** and **Pilbara Olive Python**:

i) introduced predators;

ii) feral herbivores;

iii) wild fires; and

iv) invasive weeds.

c) for each threat identified in condition 14) b), the TSOP must define:

i) how the control/management measures are expected to benefit the **Northern Quoll** and **Pilbara Olive Python**;

ii) details of the location and area of land to be managed which must be mapped and provided to the **department** in a **shapefile(s)**;

iii) details of methodology, timing, frequency and intensity (effort) of management measures;

iv) responsibility for management measures;

v) details of how the management actions identified for condition 14) b) will be undertaken in a manner that is sympathetic with the conservation of other relevant threatened species listed under the **EPBC Act** known to occur in the area identified under 14) c) ii);

d) details of a monitoring program, including but not necessarily limited to:

i) methodology, timing, frequency, scope and survey effort for/of monitoring;

ii) baseline surveys of the area to be managed;

iii) monitoring during and post land management actions to determine the effectiveness of land management actions;

iv) performance indicators, which will determine the effectiveness of the land management program; and

v) measures to make the results of the monitoring made publically available.

The TSOP must be submitted to the **Minister** for approval by 31 December 2013. Should the TSOP be approved then the approved TSOP must be implemented.

15) Documentary evidence must be submitted to the **department** showing that payments of the total amount required in condition 14) a) have been made to the person(s) responsible for implementation of the land management program within 18 months of the date of approval of the TSOP.

16) Annually on 30 April, after **commencement** of the action, a report must be submitted to the **Minister** detailing how condition 14) is, or has been, met including:

    a) whether the timeframes for undertaking the management actions identified in condition 14) c) and d) have been met; and

    b) whether the performance indicators required for condition 14) c) have been met.

17) Within 10 days after the **commencement** of the action, the person taking the action must advise the **Department** in writing of the actual date of **commencement**.

18) The person taking the action must maintain accurate records substantiating all activities associated with or relevant to the conditions of approval, including measures taken to implement the plans required by this approval, and make them available upon request to the **department**. Such records may be subject to audit by the **department** or an independent auditor in accordance with section 458 of the **EPBC Act**, or used to verify compliance with the conditions of approval. Summaries of audits will be posted on the **department's** website. The results of audits may also be publicised through the general media.

19) Annually on 30 April, after **commencement** of the action, the person taking the action must publish a report on their website addressing compliance with each of the conditions of this approval, including implementation of any management plans as specified in the conditions. Documentary evidence providing proof of the date of publication and non-compliance with any of the conditions of this approval must be provided to the **department** at the same time as the compliance report is published.

20) Upon the direction of the **Minister**, the person taking the action must ensure that an independent audit of compliance with the conditions of approval is conducted and a report submitted to the **Minister**. The independent auditor must be approved by the **Minister** prior to the commencement of the audit. Audit criteria must be agreed to by the **Minister** and the audit report must address the criteria to the satisfaction of the **Minister**.

21) If the person taking the action wishes to carry out any activity otherwise than in accordance with the plan(s) as specified in the conditions, the person taking the action must submit to the **department** for the **Minister's** written approval a revised version of that plan(s). The varied activity shall not commence until the **Minister** has approved the varied plan(s) in writing. The **Minister** will not approve a varied plan(s) unless the revised plan(s) would result in an equivalent or improved environmental outcome over time. If the **Minister** approves the revised plan(s), that plan(s) must be implemented in place of the plan(s) originally approved.

22) If the **Minister** believes that it is necessary or convenient for the better protection of listed threatened species and communities to do so, the **Minister** may request that the person taking the action make specified revisions to the plan(s) specified in the conditions and submit the revised plan(s) for the **Minister's** written approval. The person taking the action must comply with any such request. The revised approved plan(s) must be implemented. Unless the **Minister** has approved the revised plan(s), then the person taking the action must continue to implement the plan(s) originally approved, as specified in the conditions.

23) If, at any time after five (5) years from the date of this approval, the person taking the action has not **substantially commenced** the action, then the person taking the action must not **substantially commence** the action without the written agreement of the **Minister**.

24) Unless otherwise agreed to in writing by the **Minister**, the person taking the action must publish all plan(s) referred to in these conditions of approval on their website. Each plan must be published on the website within 1 month of being approved.

Definitions

Active pit areas means the area identified as 'JSW & Oxbow Conceptual Mine Pits' in Annexure 3.

Commencement of the action (except in the sense of **substantial commencement**) means the **commencement** of **construction**.

Construction means clearance of vegetation, the erection of any onsite temporary structures and the use of heavy duty equipment for the purpose of breaking the ground for buildings or infrastructure within the **development footprint** excluding works associated with the **existing mining operation**.

Department means the Australian Government Department administering the *Environment Protection and Biodiversity Conservation Act 1999.*

Development footprint means the area identified as "JSW & Oxbow proposed mining and infrastructure" in Annexure 1 excluding the areas associated with the **existing mining operation**.

De-watering means the removal of water by pumping, drainage, or evaporation.

Diagnostic features mean physical features or distinguishing characteristics which may aid in species identification

Disturb or **disturbance** of vegetation means the cutting down, felling, thinning, logging, removing, killing, destroying, poisoning, ringbarking, uprooting or burning of native vegetation, this also includes any activities associated with earth moving.

EPBC Act Listed threatened species means the **Northern Quoll**, the **Pilbara Olive Python** and the **Hamersley Lepidium**.

Existing mining operation means the area identified as "disturbed or cleared – associated with MS417, 523 & 695" in Annexure 1.

Hamersley Lepidium means *Lepidium catapycnon.*

Marillana Creek means the creek line identified as "Marillana Creek" in Annexure 2.

Minister means the Minister administering the *Environment Protection and Biodiversity Conservation Act 1999* and includes a delegate of the Minister.

Northern Quoll means *Dasyurus hallucatus.*

Operation includes any activities associated with the extraction and transportation of iron ore.

Pilbara Olive Python means *Liasis olivaceus barroni*

Population means 'population of a species' as per the Significant Impact Guidelines 1.1 – Matters of National Environmental Significance.

Project area means the area identified as "Overall project area" in Annexure 1.

Shapefiles means an ESRI ArcGIS Shapefile, containing '.shp', '.shx.' and '.dbf' files and other files. Shapefiles must include appropriate metadata capturing attributes including but not limited to the EPBC reference number of the approved action and details of the EPBC protected matters present within the offset, covenant or legal protection details, including type and identification. The **department** prefers **shapefiles** using the Geocentric Datum of Australia (GDA) 94.

Substantially commence means the erection of any permanent infrastructure, excluding signage and fences, associated with the action.

Suitably qualified expert means a suitably qualified botanist, ecologist, or environmental scientist with demonstrated expertise in the survey, management and, if need be, translocation in the relevant **EPBC Act Listed threatened species**.

Weeli Wolli Creek means the creek line identified as "Weeli Wolli Creek" in Annexure 2.

EXECUTIVE SUMMARY

Rio Tinto is seeking environmental approval for mining of Pocket and Billiards South (PBS) Pit at the Yandicoogina mine site. For closure of the pit, backfilling above the water table with waste from the Billiards North is proposed to prevent any groundwater closure issues. However, in the event that Billiards North pit development does not proceed, RTIO has asked RPS to complete water balance modeling of PBS water levels under a scenario where no pit backfill occurs.

A GoldSim model simulating water conditions post mine closure has been created for PBS pit. The purpose of the model is to estimate the following:

- Variations in pit pond water levels with time.
- Range of likely salt concentrations within the pit pond.
- Frequency of pit pond overtopping the pit void.

The hydrogeological parameters within the GoldSim model were the same as those adopted in a previous study, when they were calibrated such that GoldSim replicated groundwater conditions at PBS predicted by Rio Tinto's regional groundwater model.

The GoldSim model was used to perform a Monte Carlo analysis to estimate potential ranges of pit water levels and pit water salinities, using 1,000 iterations of the model. RTIO wishes to use the statistics to report likely pit water conditions to environmental assessors.

The GoldSim Monte Carlo analysis of the water balance predicts the following:

- Pit water levels varies in response to the magnitude and frequency of creek overflow events.
- The mean pit water level is typically RL467m.
- The pit is likely to overtop on average 1.5 times every 100 years.
- Salinity is highly variable with time, and responds to pit water levels and creek overflow events.
- The mean pit water salinity is 3,000mg/L at the end of the 1,000 year model run.
- Models with more frequent pit overtopping events generally have much lower pit salinities (salinity as low as 200mg/L).
- Models with few pit overtopping events show a trend of increasing pit salinity (salinity up to 13,000mg/L).
- The high pit salinity model runs only require a large creek overtopping event to reduce the overall pit salinity.

1. BACKGROUND

1.1 General

The Yandicoogina Mine Site (Yandi) is an iron ore mine operated by Rio Tinto Iron Ore (RTIO) and located 90km north of Newman. RTIO are mining a Channel Iron Deposit (CID), which has formed in the Tertiary sediment infilling a historic river valley. The mine currently consists of several separate pits that follow the meandering path of this historic river.

Pocket and Billiards South (PBS) Pit is one of the deposits that is being developed by RTIO at Yandi (refer Figure 1). As part of the pit closure and rehabilitation studies, RTIO has asked RPS to prepare a GoldSim water balance and salt balance model of the PBS pit to predict the outcomes of a potential pit closure scenario.

GoldSim is a Monte Carlo simulation software, that allows for users to create customised models based on built-in functions within the software. The software is well suited for water balance projects, and because the calculations are only set once, and then run through every time-step, it is computationally more efficient than MS Excel, in this instance, where the formulas are defined every time step.

1.2 Context

Rio Tinto is seeking environmental approval for mining of Pocket and Billiards South (PBS) Pit at the Yandicoogina mine site. For closure of the pit, backfilling above the water table with waste from the Billiards North is proposed to reduce environmental closure issues related to groundwater. However, in the event that Billiards North pit development does not proceed, RTIO has asked RPS to complete water and salt balance modeling of PBS water levels under a scenario where the pit is not backfilled. The pit does contain a “pillar” of waste in the central part of the pit to an elevation of RL465m. A plan of the PBS pit, showing the footprint of the open-pit closure landform is shown in Figure 2.

A GoldSim model simulating groundwater conditions post mine closure has been created for PBS pit. The purpose of this model is to estimate the following:

- Long-term (recovered) pit water levels.
- Frequency and volume of water overtopping pit.
- Pit pond water salinity concentration with time.

The purpose of this report is to:

- Document the assumptions that have been made in the model, including using the GoldSim model to generate synthetic rainfall patterns and approximate groundwater conditions.
- Summarise the formulas and logic within the model.
- Present the results from the model.
- Discuss the results from the model.

2. CONCEPTUAL MODEL OVERVIEW AND HIGH LEVEL ASSUMPTIONS

2.1 Conceptual Model

Groundwater flows through the PBS pit have been modelled using GoldSim. An overview of the conceptual model is shown in Figure 3. Conceptually, the PBS pit is modelled as a single "bucket" for which the groundwater and surface water flows in and out of the bucket are balanced with changes in storage volume of the bucket at each time step. The GoldSim model predicts the water level in the bucket at each time step using the defined stage/storage relationship for the pit, and the sum of all groundwater and surface water inflows and outflows.

The water balance for the pit can be summarised by the following list of inflows and losses:

- Water inflows:
  - Direct rainfall
  - External catchment runoff
  - Weeli Wolli Creek overflow into pit
  - Creek seepage
  - Groundwater inflow
- Water losses:
  - Evaporation
  - Pit overflow
  - Groundwater outflow.

A constant estimated salinity was assigned to each of the water inputs to the pit, and a salt mass balance model was used for the pit to estimate the mass of salt within the pit, and therefore the salinity concentration of ponded water within the pit at each time step (assuming full water mixing). The pond water salinity concentration at each time step was applied to each water loss component from the pit to complete the salt balance model.

Note that in the conceptual model there is no groundwater flow in/out of the pit to the surrounding low permeability basement rocks (i.e. all groundwater flow through CID aquifer only).

Previously, RPS completed a GoldSim water balance exercise for all six pits at Yandi, and used groundwater level recovery predictions from a short-term RTIO developed regional Modflow groundwater flow model for the Yandicoogina Mine Site as the boundary conditions for the model. For the current project, constant groundwater levels immediately upstream and downstream of the pit were assumed for the full duration of the model, and hydrogeological parameters adopted for the PBS pit in the Six Pit Model were again adopted.

Weeli Wolli Creek crosses the CID formation to the south west of PBS pit and flows adjacent to the north west side of the pit. When the GoldSim model dictates that the creek is flowing, a hydraulic gradient is formed between the creek bed and the pit water level which causes seepage into the pit. The hydraulic gradient is used in Darcy's Law to estimate the rate of seepage from the creek. The conditions which dictate that Weeli Wolli Creek is flowing are discussed later in Section 3 of this document.

The model approximates water levels over a 1,000 year period on a daily timestep, such that all calculations are updated every day. The model is run for a number of iterations (100) to allow a Monte Carlo analysis of results from the model.

2.2 High Level Assumptions

2.2.1 Horizontal Groundwater Flow

The groundwater flow calculations within the model are based on Darcy's Law for flow caused by differential groundwater levels. Darcy's Law is as follows:

$$= \frac{K * A * H}{L}$$

Where:

- Q = groundwater flow (m^3/d).
- K = hydraulic conductivity (m/d).
- A = cross sectional area for flow (m^2).
- H = pressure differential, in this case elevation difference (m).
- L = length over which the change in head is occurring (m).

In the GoldSim model, the hydraulic conductivity has been assumed to have a value of 10m/d in the CID, and 5m/d in the alluvial aquifer.

A multiplier is applied to the hydraulic conductivity values used within the model to vary the value about the mean, with the multiplier selected from a normal distribution (discussed further below in Section 3, with baseline distribution factor values listed in Section 4). The purpose of the multiplier is to account for potential sensitivities in the model due to variations in the conductivity values being used. This multiplier is calculated separately for each hydraulic linkage to the pit, and is only changed after each iteration of the model is complete (i.e. it is constant throughout each iteration for each hydraulic linkage).

The water level differential for the calculations is the elevation difference between water levels on either side of the hydraulic link (i.e. the pit water level and the external groundwater level, or creek bed level for seepage calculations).

For the connection between the external groundwater in the CID either side of PBS pit, the assumed area of flow is a semi-circle circumference where the diameter is the average width of the pit (assumed to be half the top width of the pit) multiplied by the depth of water in the pit.

Where creek seepage into the pit is calculated, the effective flow area is assumed to be the difference between the height of the pre-mining water table at the pit edge and the base pit water level, multiplied by a semi-circle circumference where the diameter is the average (half) width of the pit (although the driving head is assumed to be the difference between the creek level and the pit water level).

2.2.2 General

Logic has been programmed into the GoldSim PBS pit model to produce a stochastic rainfall record for use in model predictions. The generation of this rainfall record has been based on statistics derived by RTIO from historic climate records at the Flat Rocks gauging station. The climate events have been applied to the whole site.

The GoldSim model assumes that the rainfall distribution fits a Gumbel (Extreme Value Distribution) probability distribution. However, the magnitude of large rainfall events produced by the Gumbel distribution (as defined by statistics derived from historic rainfall data) are too small compared with the assumed IFD data for Yandi (provided by RTIO). A random multiplier (between 0 and 4) was introduced into the model to ensure that large rainfall events (and therefore hydrological responses caused by large rainfall events) would occur at a reasonable frequency. The random multiplier fit a probability distribution that ensured that the annual average rainfall was not altered by modifying the magnitude of large rainfall events.

The calculation of stream flow durations for Weeli Wolli Creek was completed by RTIO through the use of a RORB model to provide tables of the stream flow duration that would occur for rainfall events of standard duration and recurrence interval. Similarly, RTIO also completed 2-D flood modeling of Weeli Wolli Creek and the proposed pit closure landform to estimate the volume of water that may overtop from Weeli Wolli Creek into the pit following different rainfall events of standard duration and frequency. These tables are “looked up” within the GoldSim water balance whenever a rainfall event occurs. This calculation is a limitation to the model approach, which is discussed in further detail in Section 2.3.

The model uses a constant groundwater elevation outside either end of the pit as the groundwater boundary conditions for the model calculations.

2.3 Model Limitations

The largest limitation in the model approach is that all rainfall events occur over a 1-day period in the model, regardless of rainfall duration. In addition to this, modeled hydrological responses from the rainfall event are modeled as occurring over the same 1-day period as the rainfall event. These hydrological responses include catchment runoff to the cells, seepage input from the creeks and overflow from Weeli Wolli Creek. The impact of this limitation is that modeled ponding levels will generally be higher due to the rainfall response occurring immediately, rather than being spread out over a longer time period. Given that the same volume of water reports to the pit (but in a shorter period of time), the impact of this limitation on long-term results is likely to be negligible.

A further limitation is that all lookup tables only extend to a maximum return period of 100 years. If a rainfall event occurs within the model which is greater than the 100-year event, the model assigns the event with a 100-year return period for the purpose of using the hydrological response look-up tables, whereas larger hydraulic responses may actually occur.

3. MODEL STRUCTURE

The GoldSim model is run on a daily time step, to ensure the synthetic rainfall generation can be based on the statistics derived from daily rainfall records.

When the model simulates rainfall events, these are calculated at the start of each day, with the rainfall event held constant until the following day. This means that only one rainfall event can occur on any single day within the model, and that the entire rainfall event occurs over a single day (i.e. even though the rainfall simulation model may produce a storm with a duration of 72 hours for ARI definition purposes, the model assumes that the impact of that rainfall event occurs over the day that the event occurs at three times the rate and not spread out over three days). Consequently, if the model is run with a time step length longer than 1 day, the results will under-estimate rainfall.

Some data inputs that are used globally throughout the model are defined within the model run settings rather than as a data input element with the model. These include:

- Mean hydraulic conductivity of the CID aquifer (10m/d).
- Mean hydraulic conductivity of the alluvial aquifer (5m/d).
- Salinity of rainwater (0.005kg/m^3).
- Salinity of river seepage (0.05kg/m^3).
- Salinity of groundwater (0.5kg/m^3).

The majority of the GoldSim model logic has remained unchanged from previous model reports, but is documented below for completeness.

3.1 Climate

The following sub-containers (in Goldsim) have been setup within the Climate container and are discussed below. The climate data and logic is largely unchanged from the previous modelling by RPS (apart from the extreme rainfall probability distribution), but repeated below for completeness:

- Rainfall Probability
- Rainfall Volume
- Rainfall Duration
- ARI
- Evaporation.

3.1.1 Rainfall Probability

The Rainfall Probability sub-container calculates what the probability of rainfall is for each day in the model. The logic behind this calculation is based on the formulas that were contained in the original Rio Tinto Excel based water balance, but transposed into GoldSim.

Each month, the number of rain-days per month is randomly chosen within a truncated normal probability distribution defined by the mean, standard deviation and minimum (always set to zero) and maximum number of rain days as defined in Table 4.3.

The probability of rainfall is used to determine if the rainfall event is classed as a “Storm” (probability greater than 0.6) or “Rain” (probability less than 0.6) event when determining the rainfall volume.

3.1.2 Rainfall Volume

The Rainfall Volume sub-container is used to determine the depth of rainfall that will fall on each day of the model run. The calculations performed in this container are based on the outcome of the Rainfall Probability outcome discussed above. Where the probability of rainfall is equal to zero, the depth of rainfall on that day will be equal to zero.

A rainfall event is classified as either a “Storm” (Rainfall Probability > 0.6) or as “Rain” (Rainfall Probability < 0.6). Based on this outcome, relevant Storm or Rain lookup tables for each month are used to determine the rainfall depth that would occur for the given rainfall probability.

The lookup table that relates probability to rainfall depth was generated in Excel assuming a normal distribution for Rain events, and a Gumbel distribution for Storm events. Monthly values for rainfall median and standard deviation were provided by RTIO to define the Rain normal probability distribution and Storm Gumbel probability distribution. For Storm events, the rainfall depth that is returned by the model is multiplied by a random number generated by GoldSim to increase the rainfall depth in extreme events. The random number was sampled from the a cumulative probability distribution defined as follows:

- Probability = 0, Value = 0
- Probability = 0.1, Value = 0.8
- Probability = 0.95, Value = 1.2
- Probability =1, Value = 4.

The daily evaporation rate is subtracted from the calculated rainfall depth prior to use in the model. The calculation of Daily Evaporation is described below.

3.1.3 Rainfall Duration

The duration of an individual rainfall event was generated by RTIO based on observed data extracted from the Flat Rocks rainfall gauge (~22 km west of the Yandi mine). A linear function was fitted to simplify the relationship between rainfall and duration of the Flat Rocks data and this relationship was applied in the rainfall duration simulator to randomly generate the duration of each rainfall event. The rainfall duration (regardless of classification as a “Storm” or “Rain” event) is calculated based on the formula:

$$Storm\ Duration = ABS(A * Daily\ Rainfall + C)$$

The formula is applied only if the Daily Rainfall is greater than 0, the coefficient A is set at 0.1294 and the coefficient C is a randomly selected number from a uniform probability distribution bounded by values of -7.5069 and 15.4931 (as provided by RTIO).

3.1.4 ARI

The annual recurrence interval (ARI) for the stochastically generated rainfall event is calculated within the model. The ARI is calculated based on a lookup table of event duration vs. rainfall volume (as discussed above). The model uses the resultant ARI value within lookup table calculations for runoff coefficients and creek flow durations based on each rainfall’s event duration and ARI.

3.1.5 Evaporation

The evaporation rate is sampled each day from a truncated normal distribution that is defined by distribution parameters which are set for each month of the year (standard deviation, mean, minimum value and maximum value). The values of the factors used to define the evaporation are displayed in Table 4.4.

3.2 Creek Flows

The model calculates the creek discharge volume and duration of creek flow for each of the creeks that impact the model (Weeli Wolli Creek). The logic behind the calculation of discharges through the creeks is similar for each of the creeks, with lookup tables used to determine the flow volume and duration for a given rainfall event (defined by duration and ARI).

3.3 PBS Pit Data

The PBS pit is represented by a sub-container that calculates the water balance and groundwater and surface water inputs and losses to the pit based on the results of the Climate and Creek Flow containers (discussed above).

Within the PBS pit sub-container, the following main components are found.

3.3.1 Pit Water Reservoir Element

The pit water reservoir element calculates the stored volume of water within the pit at each time-step by determining the change in volume over the time step through subtracting the sum of water losses out of the pit from the sum of water additions to the pit. The water losses and gains are quantified in the other sub-containers within the PBS pit container. The pit dimensions and starting conditions are defined.

3.3.2 Pit Characteristics

The following list of pit characteristics which are defined are as follows:

- Stage versus Surface Area relationship.
- Stage versus Volume relationship.
- Initial volume of water held in the pit.
- Ex-pit groundwater elevation time series.
- Distance to creek.
- Creek elevation.
- Creek contact length.
- Distance to external groundwater boundary condition.
- Pit backfill elevation.
- Pit surface water catchment area.
- Pit evapotranspiration (ET) rate.
- Pit overflow elevation.

3.3.3 Runoff Generation

The volume of surface water run-off to the pit is calculated from the surface water catchment area around the pit, and the direct rainfall on the pit area. The runoff coefficient used for the pit runoff is dependent on the ARI of the rainfall event. Typically for larger catchments in the Yandi area, on average less than 5% of the annual rainfall runs off to creeks/rivers as measurable flow (Upper Fortescue River near Newman 4.8%, Marillana Creek at Flat Rocks 2.2%). Given that the pit catchments are smaller and relatively steep compared to a major creek or river system, the annual runoff coefficient would be expected to be greater than 5%. The runoff coefficients adopted in this model result in an average annual volume of runoff from the pit catchments to the pit of around 10% to 15% of the annual rainfall in the model, which RPS feels is a reasonable estimation.

3.3.4 Groundwater

The groundwater calculations in the GoldSim water balance model provide an analytical estimate of groundwater flow conditions in the PBS pit area. This simplification means that the model can be run assuming a range of input conditions in a time frame consistent with the overall project requirements.

As discussed, RTIO developed a regional groundwater model and the results of the regional model were used to check that the GoldSim model replicates expected groundwater flow conditions in previous modeling excercises. This process was not repeated for this project, as a regional groundwater model was not completed for this closure option.

As mentioned in Section 2, to account for potential sensitivities in the GoldSim model due to variations in the permeability of aquifers, a multiplier factor is used to vary the hydraulic

conductivity around the mean value. The mean, standard deviation (sigma), minimum and maximum values for the normal distribution of the multiplier factor are defined, and used to determine the multiplier factor (refer Section 4 for baseline values). Note that the GoldSim model chooses the multiplier factor at the beginning of each model iteration, and this remains constant for the full iteration.

Creek seepage into the pit is predicted within the pit sub-container (in GoldSim). The predictions are dependent on the location of the surrounding creeks, the contact lengths between the creek channel and the pit, and if the contact is with an alluvial aquifer or directly with the CID aquifer.

The data that was used for this calculation was based on measurements from mapping and input from RTIO Hydrogeology to the original regional groundwater flow model. One of the key parameters that was introduced to the GoldSim model to ensure consistency with the Modflow regional model predictions was a Seepage Reduction Factor. This factor was previously adjusted to achieve GoldSim prediction results similar to the Modflow predictions, with the same factor adopted for this project.

3.3.5 Pit Evaporation

The evaporative losses from any ponded water within the pit are calculated within the model. The calculation applies the evaporation rate to the pit pond's surface area.

3.3.6 Pit Pond Overflow

Logic was incorporated within the model to allow ponded water above a set depth (i.e. pit overflow point of 487.5mRL) to overflow out of the pit. The model does not simulate water levels in Weeli Wolli Creek, and therefore assumes that water from PBS pit above RL487.5 can discharge to Weeli Wolli Creek.

4. INPUT DATA

The model parameters that define the model are listed in the tables below for completeness. The model parameters listed generated the solution discussed in the results section of this report (Section 5).

4.1 Pit Data Inputs

The pit characteristics data is summarised in Table 4.1.

The Stage/Surface Area/Volume relationship was determined based on the PBS pit closure geometry profile provided to RPS by RTIO. The PBS pit closure geometry file contained a "pillar" of backfill within the pit, which reduced the relative pit volume at each stage level used within the GoldSim model. These relationships are an input to the model in the form of a lookup table, and aren't reproduced in this report. The volume/area data was determined for every 0.1m elevation increment within each cell.

Table 4.1: Summary of Inputs Defining PBS Pit

Pit	PBS
Pit base level (mRL)	419.9
Initial water level (mRL)	645
Backfill elevation (mRL)	N/A
Top of pit (mRL)	487.5
Pit width (m)	500
Upstream groundwater elevation (mRL)	500
Downstream groundwater elevation (mRL)	465
Distance to groundwater boundary conditions (m)	3000
Distance to Weeli Wolli Creek (m)	500
Weeli Wolli Creek elevation (mRL)	525
Alluvium contact length (m)	2750
Pit Catchment Area (km^2)	47

4.2 Climate Inputs

The following inputs are contained within the Climate sub-container in GoldSim to define the Rainfall Probability.

Table 4.2: Summary of Inputs Defining Rainfall Probability

	Max Month Rain Days	Std Dev Rain Days	Mean Rain Days
January	21	5.2	10.2
February	18	4.6	11.8
March	22	5.1	8.6
April	11	3.4	4.8
May	4	1.6	1.7
June	8	2.4	2.5
July	8	2.8	2.6
August	4	1.3	1.2

	Max Month Rain Days	Std Dev Rain Days	Mean Rain Days
September	3	1.2	0.8
October	10	3.1	2.3
November	9	3.1	4.4
December	14	4.3	6.7

The Rainfall Volume is calculated based on using the probability calculated from the Rainfall Probability container within a probability distribution. The probability distribution for the Rainfall Volume calculation is based on the parameters shown in Table 4.3. For events classed as "Rain", a normal probability distribution is used. For events classed as "Storm", a Gumbel distribution is used.

Table 4.3: Summary of Inputs Defining Rainfall Volume

	Rainfall Median	Storm Rain Vol Std Dev	Rain Vol Std Dev
January	2.3mm	22.2mm	2.5mm
February	3.6mm	14.1mm	2.8mm
March	2.8mm	16.1mm	2.9mm
April	2.2mm	8.2mm	2.5mm
May	1.4mm	7.5mm	2.5mm
June	1.8mm	5.5mm	2.6mm
July	1.2mm	14.7mm	2.0mm
August	1.8mm	4.1mm	2.4mm
September	2mm	15.1mm	3.2mm
October	0.8mm	6.4mm	2.1mm
November	1.4mm	7.0mm	2.4mm
December	2.2mm	32.0mm	2.6mm

For Storm events, the rainfall depth that is returned by the model is multiplied by a random number generated by GoldSim to increase the rainfall depth in extreme events. The random number was sampled from a cumulative probability distribution defined as follows:

- Probability = 0, Value = 0
- Probability = 0.1, Value = 0.8
- Probability = 0.95, Value = 1.2
- Probability =1, Value = 4.

The evaporation rates are calculated using the coefficients in Table 4.4. These parameters are used to define the truncated normal distribution from which the evaporation rates are selected for each of the daily time steps.

Table 4.4: Summary of Inputs Defining Evaporation Probability Distribution

	Evaporation Mean	Evaporation Std Dev	Evaporation Minimum	Evaporation Maximum
January	5.1mm	3.1mm	0.6mm	14.9mm

4.3 Runoff Coefficients

The data in Table 4.7 has been used to define the run-off to the PBS Pit.

4.4 Groundwater Parameters

The baseline hydraulic conductivity for the CID is set as 10m/d and the hydraulic conductivity for the alluvium is set as 5m/d.

For each iteration of the model, the hydraulic conductivity is modified around the mean values provided above by a multiplier factor that is based on a truncated normal distribution defined by the following base parameters:

- Multiplier Mean = 0
- Multiplier Sigma = 0.067
- Multiplier Min = -0.2
- Multiplier Max = 0.2.

Table 4.7: Summary of Inputs Defining Runoff to Each Pit

	JSE
Runoff Coef. (<1yr ARI)	0.42
Runoff Coef. (1yr ARI)	0.47
Runoff Coef. (2yr ARI)	0.51

	JSE
Runoff Coef. (5yr ARI)	0.56
Runoff Coef. (10yr ARI)	0.60
Runoff Coef. (20yr ARI)	0.64
Runoff Coef. (50yr ARI)	0.70
Runoff Coef. (100yr ARI)	0.74
Runoff Coef. Reduction Factor	0.25

4.5 Creek Flow Data

RTIO provided creek flow durations for each standard rainfall event (defined by rainfall duration and annual recurrence interval) for Weeli Wolli Creek. The data provided is summarised in Table 4.8.

Table 4.8: Weeli Wolli Creek Flow Duration Lookup Table (Hours)

	<1yr ARI	1yr ARI	2yr ARI	5yr ARI	10yr ARI	20yr ARI	50yr ARI	100yr ARI

5. RESULTS

The GoldSim model was run for 100 model iterations over a 1,000 year period to produce the results that are discussed below.

5.1 Pit Water Levels

The GoldSim model has been started with an initial pit water level of RL465m, to match the elevation of the assumed downstream recovered groundwater elevation. Following an initial drop in the median pit water level across the model runs, the median pit water level varies between RL471m and RL466m. Within any individual model run, the pit pond water level could range between RL453m and RL487.5m (pit overflow level). A probability time series plot of the pit pond water level is shown in Figure 4.

On any individual model run, the pit pond water levels appear to respond to events that cause Weeli Wolli Creek to overtop into the pit. In between these periodic large water input pulses, pit pond water levels decline due to the evaporation from the pit pond surface area and groundwater discharge to the downstream end of the pit. An example of a typical time series of the pit pond water level for an individual model run is shown in Figure 5.

As an indicator of the processes that are driving the pit water levels, the main median inflow and outflow volumes from the pit over the 1,000 year model run were determined, as shown in Table 5.1. The table indicates that evaporation is the dominant process on the water balance, followed by local runoff and Weeli Wolli Creek overflow into the pit.

Table 5.1: Median Pit Water Balance - Summary

Pit Inputs		Pit Outputs	
Net groundwater from U/S	1.2GL/yr	Net groundwater from D/S	0.1GL/yr
Local runoff	2.9GL/yr	Evaporation	6.0GL/yr
Weeli Wolli Creek overflow	2.1GL/yr	Pit Overflow	0.4GL/yr
Weeli Wolli Creek seepage	0.3GL/yr		

A median across the 100 model iterations of 820 total creek overtop events per 1,000 year model run were recorded (above 1,000m^3 overtop volume). Given overflow events occur from some 2-year ARI rainfall events, this number appears reasonable. A statistical time series of the total cumulative Weeli Wolli Creek overflow events predicted by the model is shown in Figure 6.

Typically, between 4 and 14 overflow events of greater than 70GL (nominal definition of 100 year creek overflow event) occur within a single model iteration, which appears reasonable. A time series plot of Weeli Wolli Creek overflow volumes is shown in Figure 7.

5.2 Pit Overtopping Frequency

Pit overtopping frequency is largely driven by the frequency of large magnitude Weeli Wolli Creek overtopping events into the pit. The storage volume within the pit between the starting water level (RL465m) and the pit overflow level (RL487.5m) is approximately 80GL, which is a similar magnitude to a single 100-year creek overflow event (refer above). Hence, the pit would be expected to overtop more frequently than once every 100 years.

The GoldSim model predicts pit overtopping to occur at a frequency of approximately 1.5 events per 100 years, with model iterations ranging between 5 and 20 overtopping events across the 1,000 year model duration.

5.3 Pit Salinity

The salinity of pit pond water in PBS started with an assumed initial concentration of 500mg/L (equivalent to that assumed from groundwater seepage into the pit). With time, the median salinity

in the pit increases at a relatively steady rate to approximately 3,000mg/L by around year 900, but remains steady thereafter. A time series probability plot of pit salinity is shown in Figure 8.

The peak salinity concentration across the iterations at the end of the model is about 11,000mg/L, while other model iterations have salinity concentrations as low as 200mg/L. Inspection of individual model iterations indicates that the salinity concentration is dependent on the timing of overflow events from the pit, with the model run that returns the high salinity concentration only having 1 overflow event in the 1,000 year model run.

The salinity concentration in the ponded pit water with time from a typical model run is shown in Figure 9.

6. SUMMARY

A GoldSim model has been created to simulate pit water volumes within the PBS pit for a pit closure strategy that allows some stream flow events from the adjacent Weeli Wolli Creek to overtop the mine closure structures and discharge to the pit. The GoldSim model that was created simulated groundwater levels and salinity concentrations in the PBS pit over a 1,000 year period. The model was used to perform a Monte Carlo analysis of the pit water levels, with 100 iterations of the model run to produce statistical results for the water level and salinity concentration predictions within the pit.

The key results from the modelling exercise were as follows:

- Pit water levels vary in response to the magnitude and frequency of creek overflow events.
- The mean pit water level is typically RL467m.
- The pit is likely to overtop on average 1.5 times every 100 years.
- Salinity is highly variable with time, and responds to pit water levels and creek overflow events.
- The mean pit water salinity is 3,000mg/L at the end of the 1,000 year model run.
- Models with more frequent pit overtopping events generally have much lower pit salinities (salinity as low as 200mg/L).
- Models with few pit overtopping events show a trend of increasing pit salinity (salinity up to 13,000mg/L).
- The high pit salinity model runs only require a large creek overtopping event to reduce the overall pit salinity.

1 Context and Scope

1.1 Yandicoogina Project

Hamersley Iron – Yandi Pty Limited (the **Proponent**) manages and operates the Yandicoogina Iron Ore Project (**Yandicoogina project**). The Yandicoogina project is approved under the *Environmental Protection Act 1986* (**EP Act**) by the Minister for the Environment via Ministerial Statement (**MS**) 914.

The Yandicoogina project is located in the central Pilbara region of Western Australia, approximately 90 km east of Newman and is approximately 40 km South of Fortescue Marsh. Mineralisation occurs in an extensive Channel Iron Deposit (**CID**) located along a palaeochannel adjacent to, and in some areas intersecting, the downstream reaches of Marillana and Weeli Wolli Creek. The ore resource is predominantly below water table (**BWT**) and deposits, currently approved by MS 914, include:

- Junction Central (JC);
- Junction South East (JSE);
- Junction South West (JSW); and
- Oxbow.

In addition to the deposits currently approved, the Pocket and Billiard South (**PBS**) deposit is a proposed future deposit and is currently undergoing assessment under Part IV of the EP Act. The PBS deposit was referred under the EP Act in July 2014.

The spatial configuration of the PBS deposits within the context of the current approved mining operation is shown in Figure 1-1. The PBS deposits are contained within ML274SA established under the *Iron Ore (Yandicoogina) Agreement Act 1996*. The Yandicoogina camp is located in L021123.

1.2 Key Regulatory Requirements

The Proponent has obtained the following key regulatory environmental approvals for the Yandicoogina deposits:

- MS 417 on 25 May 1996 with subsequent modifications approved via MS 523 on 1 October 1999 (JC deposit).
- MS 695 on 22 October 2005 (JSE deposit).
- MS 914 (as revised proposal) on 18 October 2012 (JSW and Oxbow deposits).
- *Environmental Protection and Biodiversity Conservation Act* 1999 (**EPBC Act**) Decision Notice 2011/5815 on 20 November 2012 (JSW and Oxbow deposits).

The implementation conditions of MS 914 supersede those of MS 417, 523 and 695 in accordance with section 45B of the EP Act. As a consequence, MS 914 provides the current regulatory framework under the EP Act for environmental management across the entire Yandicoogina project (available at www.epa.gov.org).

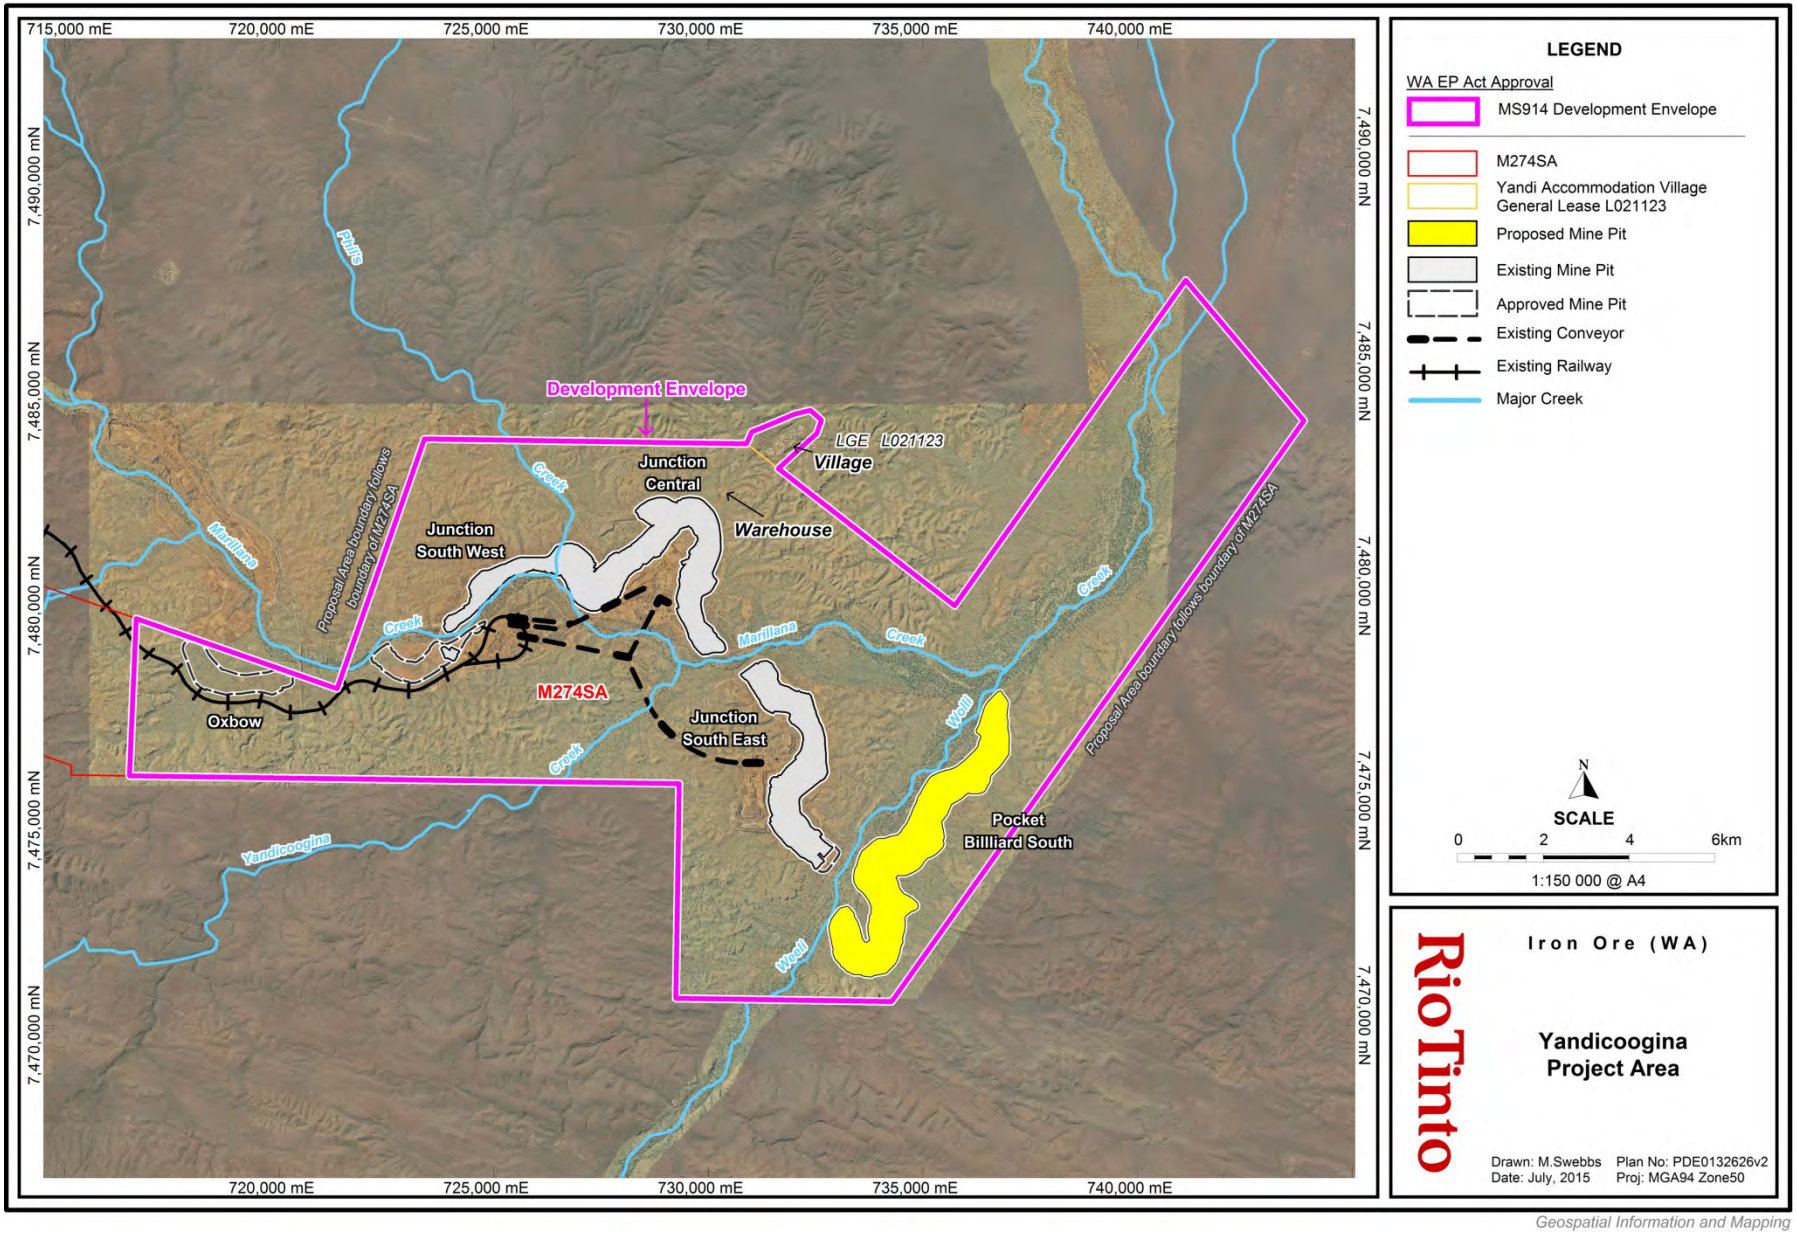

Figure 1-1: Yandicoogina Project Area

1.3 Environmental Factors

During assessment of the Yandicoogina Project, the Environmental Protection Authority (**EPA**) (EPA Bulletin 1148, August 2012) identified the following as key environmental factors which required conditioning in MS 914 via conditions 6 and 7:

(a) Vegetation, flora and fauna

(b) Groundwater and surface water.

This Monitoring and Management Plan (**MMP**) specifically addresses the requirements of Conditions 6 and 7 of MS 914, including the development of an Environmental Values Statement (**EVS**) and a comprehensive monitoring program for surface water and groundwater dependent ecosystems with associated management strategies.

In accordance with conditions 6-7 and 7-6, the MMP was implemented prior to commencing groundwater abstraction from or excavation below the water table at JSW and Oxbow and will continue to be implemented until advised otherwise by the CEO of EPA. In accordance with condition 7-7, the MMP has been reviewed and revised within the required 5 year interval, and to include the Pocket and Billiard South deposit. The MMP will continue to be reviewed and updated in future years as part of an ongoing adaptive management approach.

1.4 Environmental Objectives

The Proponent will ensure that dewatering required to implement the Yandicoogina project, and any contingency measures implemented, will not result in long term impacts to the environmental values identified in the Environmental Values Statement (**EVS**).

This approach is aligned with the EPA's broader environmental objectives for environmental factors vegetation, flora, groundwater and surface water, which are to:

- Maintain the quantity and quality of water so that existing and potential environmental values, including ecosystem maintenance, are protected.
- Maintain the abundance, diversity, geographic distribution and productivity of flora at species and ecosystem levels through the avoidance or management of adverse impacts and improvement in knowledge.
- Protect Declared Rare and Priority Flora, consistent with provisions of the *Wildlife Conservation Act 1950*

1.4.1 Environmental Values Statement

Condition 6-2 of MS 914 mandates the development of an EVS for the Weeli Wolli Creek System that defines the key environmental values of the Weeli Wolli Creek System, to the satisfaction of the CEO of the OEPA in consultation with the Department of Parks and Wildlife.

The key values of the Weeli Wolli Creek system are presented in Appendix 1 and are summarised as follows:

- **Value 1 – Fortescue Marsh:** The Yandicoogina Development Envelope is intersected by major ephemeral creek systems that ultimately drain into the Fortescue Marsh Priority Ecological Community and form part of its catchment.

- **Value 2 – Vegetation and Flora:** The vegetation communities and fauna habitats of the Yandicoogina Development Envelope are relatively widespread and well represented regionally. This includes local riparian vegetation communities and groundwater dependant ecosystems commonly associated with large ephemeral creek systems of the Pilbara region.

  One community, identified locally as the C1A riparian community, broadly comprises a Eucalypt woodland containing a co-dominant *Melaleuca argentea* component and is considered to have local conservation significance due to its groundwater dependency, associated mesic habitat values, somewhat restricted distribution, and association with a major creekline in the area. This community is similar but of different structure and reduced significance in relation to the vegetation community of Weeli Wolli Spring (significant *Melaleuca argentea* woodlands).

  The Yandicoogina Development Envelope also includes individuals of Declared Rare Flora (**DRF**) *Lepidium catapycnon*.

- **Value 3 – Stygofauna:** The Yandicoogina Development Envelope contains a number of stygofauna species known only from the Marillana-Weeli Wolli Catchment.

Note: Riparian habitat provides a corridor for the movement of microbats and other fauna. In the wider catchment, the Weeli Wolli Spring Priority Ecological Community (upstream from the Yandicoogina project area) is known to support microbat species.

The Yandicoogina Development Envelope contains potential habitat for the Pilbara olive python and northern quoll.

Heritage and social values are recognised and are addressed by the *Heritage of Western Australia Act 1990.*

1.4.2 Site Specific Trigger Values

Condition 6-4 of MS 914 requires the Proponent to ensure that the water quality of any surplus water discharged into the environment does not impact on the environmental values of the Weeli Wolli Creek System.

Local conditions vary naturally between river systems as influenced by geology, hydrology, ecosystem process and historical land uses. For this reason site specific trigger values (**SSTVs**) are preferable to the default guideline values contained in the ANZECC/ARMCANZ (2000) *Australian Water Quality Guidelines*, as depicted in the preferred hierarchy for deriving trigger values shown in Figure 2-1, and in line with the requirements of Condition 6-4 (3).

Rio Tinto has collected baseline (or reference) water quality data from the Yandicoogina groundwater and creek systems which have been used to develop SSTVs for the analytes shown in Appendix 2 and are based on an ecosystem hazard analysis (WRM 2015a), consistent with the ANZECC/ARMCANZ (2000) *Australian Water Quality Guidelines*.

2 Implementation of the Monitoring and Management Plan

This MMP addresses related environmental factors (and relevant environmental objectives), which were determined by the EPA as being relevant to the appropriate management of surface water and groundwater dependent ecosystems. In addition, it identifies the environmental criteria that the Proponent will use to monitor performance of the measures proposed to address the requirements of Conditions 6 and 7 of MS 914. Finally, it defines the management actions that the Proponent will take in response to monitoring results.

2.1 Environmental Criteria

Three levels of environmental criteria have been developed for this MMP. Level 1 and 2 criteria trigger investigative works and early management actions, whilst level 3 defines threshold criteria to measure compliance and ensure the environmental objectives are not compromised. In circumstances where three criteria levels are not appropriate only one or two levels of criteria are used.

Triggers

- **Level 1:** Conservative, early warning criteria to provide early feedback on potential impacts.
- **Level 2:** Causal investigations to be undertaken to ensure the event or issue is understood. Increased monitoring focus. Determine whether the event is the effect of mining activities or caused by changes in the natural environment. Remedial actions to be identified and may be taken where necessary. No significant or irreversible impacts are foreseen.

Threshold

- **Level 3:** Criteria framed to measure achievement of the environmental objective. Highest level of investigation with advisory notification of event or issue to regulatory agencies and other appropriate stakeholders including the relevant Traditional Owners. Activate appropriate intervention / contingency measures.

2.2 Monitoring and Management Actions

The purpose of monitoring is to inform, through the environmental criteria, if the environmental objective is being achieved and to identify when appropriate management actions need to be implemented.

Table 2-1 and Table 2-2 address the monitoring and management actions required for surface water and groundwater dependent ecosystems respectively. Figure 2-2 and Figure 2-4 depict the monitoring locations.

Monitoring results and management actions will be included in the annual Compliance Assessment Report, in accordance with the approved compliance assessment plan (MS 914, condition 4).

Table 2-1: Monitoring to Evaluate Environmental Performance against Trigger and Threshold Criteria and associated Management Actions for Surface Water

Environmental Objective	Ministerial Statement Condition	Monitoring Aspect	Monitoring Parameter	Monitoring Frequency	Trigger				Threshold	
					Level 1 Criteria	Level 1 Management Actions	Level 2 Criteria	Level 2 Management Actions	Level 3 Criteria	Level 3 Management Actions
To maintain the quantity and quality of water so that existing and potential environmental values, including ecosystem maintenance are protected.										
Preserve the environmental values of the Weeli Wolli creek system as identified in the EVS: Stygofauna & Ensure water discharged to the environment meets specified water quality requirements	6-1 6-6(1) 6-6(2) 6-6(3) 6-6(4) 6-4	Establish baseline surface water quality which supports subterranean habitat for Stygofauna. **Action Complete** Assess time series changes in surface water quality	**Surface water quality parameters (based on hazard analysis – Section 7; Appendix 2):** Alkalinity (as $CaCO_3$) Ba B Ca CO_3 EC Hardness Fe $N\text{-}NO_3$ pH P-total SO_4 TDS TSS U V **Surface water quality monitoring locations:** Compliance sites ▪ MAR 2-6 (Lower Marillana Creek below DO9) ▪ DPW0012 (Weeli Wolli Creek below DO6) **Upstream reference sites:** ▪ BHP discharge outlet ▪ MAR 1-1 (entering from BHP discharge outlet Yandi upstream) ▪ DPW0011 (entering from RTIO HD1 upstream) ▪ Operating discharge outlets (will vary over time – refer to DER licence) Extent of surface water discharge ▪ WW4-8 (Lower Weeli Wolli Creek)	Quarterly (subject to flow during monitoring schedule)	**Toxicant:** Rolling median concentration of any analyte recorded at MAR 2-6 or DPW0012 is above the hardness modified SSTV OR a single value is above the 95%ile of baseline or ANZECC/ ARMCANZ (2000) default 80% species protection level. **Stressor:** Rolling median concentration of any analyte recorded at MAR 2-6 or DPW0012 is above the hardness modified SSTV (refer to Appendix 2)	Investigate potential cause of water quality change Review water quality at the discharge points, compare to baseline and reference sites, review discharge volumes Determine environmental conditions in lead up to monitoring event; review rainfall and flood events Re-sample to validate results.	**Toxicant:** Rolling median concentration is statistically higher (refer figure 2-1) than the SSTV and resampling confirms the value still exceeds the SSTV local baseline and reference sites. **Stressor:** Rolling median concentration is statistically higher (figure 2-1) than the SSTV and resampling confirms the value still exceeds the SSTV local baseline and reference sites.	Investigate potential contamination sources other than dewatering discharge. If other sources are identified as a result of the Proponent's Yandicoogina operations then remove / eliminate source from the most likely pathway and resample. Review groundwater monitoring data from production borefield and investigate potential source from geology of orebody being dewatered. If investigations warrant, increase frequency of monitoring at selected downstream and reference sites to determine geographic extent of SSTV exceedance. Increase suite of parameters to include: Al, Cu, Mn, Se and SiO_2 until level 2 criteria are no longer met Seek expert advice on potential risk to the environment, and assess bioavailability of toxicants if warranted. Investigate possible remedial actions, for example, modification of discharge regime. Investigate field ecological monitoring at potential impact sites in comparison to baseline and reference sites	**Toxicant & Stressor:** Investigation indicates there is potential for detrimental long term impacts to the values identified in the EVS as a result of operations:	Implement the management options identified in the investigations stage to remediate the impacts If warranted, instigate additional field surveys and/or ecotoxicity studies to determine level of impact, if any, on aquatic biota. Consult with relevant stakeholders. Instigate external reporting. If field ecological monitoring or ecotoxicity studies indicate exceedance has no acute or chronic effect on biota, revise SSTVs in consultation with stakeholders and experts.

Environmental Objective	Ministerial Statement Condition	Monitoring Aspect	Monitoring Parameter	Monitoring Frequency	Trigger				Threshold	
					Level 1 Criteria	Level 1 Management Actions	Level 2 Criteria	Level 2 Management Actions	Level 3 Criteria	Level 3 Management Actions
Preserve the environmental values of the Weeli Wolli creek system as identified in the EVS: Stygofauna	6-1	Assess time series changes in subterranean habitat quantity.	Water availability in alluvium ▪ Dewatering discharge outlets volume (kL) ▪ Site based weather station rainfall (mm) ▪ Groundwater levels from selected groundwater monitoring bores within alluvium (when accessible)	Quarterly	Groundwater levels outside predicted range for all sites	Determine if linked to specific events (e.g. rains, flood or change in discharge regimes from the Proponent's Yandicoogina operations or other mines in the catchment	Groundwater levels outside predicted range at all sites for successive quarterly monitoring events	Investigate and establish the potential cause of water level deviation from predicted natural range. If the Proponent's operations are identified as a potential cause of detrimental water level change then operations will identify options for modifying water levels to maintain sufficient groundwater habitat. Context results with critical correlative environmental parameters including: ▪ monthly rainfall ▪ proximal groundwater levels ▪ flood events; ▪ monthly discharge volumes ▪ Additional groundwater quality parameters as per GWOS ▪ Stygofauna assemblages (opportunistic)	Groundwater levels outside predicted range at all sites for successive monitoring events with no reversible trend, and investigation indicates there is potential for detrimental long term impacts to Stygofauna as a result of operations	Implement the management options identified in the investigations stage to remediate groundwater habitat impacts Consult with relevant stakeholders
Prevent discharge from water flow or pooling further than 17km downstream from the Marillana and Weeli Wolli Creek System Confluence Discharge extent to prevent permanent connection to Fortescue Marsh (EVS 3)	6-3 6-6(2) 6-6(4) 7(2)	Monitor the extent of the discharge footprint in the Weeli Wolli Creek. "Discharge footprint" is defined as the saturated creek bed once steady state conditions are established. Respond to the extent of the wetting front in Weeli Wolli Creek if a trigger exceedance or potential for trigger exceedance is identified	Distance of persistent water flow (the discharge footprint) extends from the Marillana Creek and Weeli Wolli Creek, into Weeli Wolli Creek (Zone 3) System confluence where discharge footprint is defined as saturated creek bed once steady state conditions are established.	Monthly	Water flow occurs >15km from the Marillana Creek and Weeli Wolli Creek System confluence.	Investigate and establish the potential cause of persistent water flow or pooling. Compare against critical correlative environmental parameters: ▪ Monthly rainfall ▪ Groundwater levels ▪ Flood events ▪ Monthly discharge from the Proponent's operations. ▪ Change in discharge regime of other mines in the catchment) Identify potential actions to reduce the extent of the discharge footprint within Weeli Wolli	N/A	N/A	Water flow occurs ≥17km from the Marillana Creek and Weeli Wolli Creek System confluence, and investigation indicates it is attributable to the Proponent's operations:	Consult with relevant stakeholders (OEPA, DoW and DER) Evaluate extent of impact to the values (as per the EVS). If appropriate, modify discharge regime to meet management objective.

Environmental Objective	Ministerial Statement Condition	Monitoring Aspect	Monitoring Parameter	Monitoring Frequency	Trigger				Threshold	
					Level 1 Criteria	Level 1 Management Actions	Level 2 Criteria	Level 2 Management Actions	Level 3 Criteria	Level 3 Management Actions
						Creek.				
Maintain major creekline flood flows and minimise erosion in the creeklines.	6-6(2) 6-6(5) 7-5(5)	Erosion and sedimentation assessment	Visual assessment of erosion and photographic record at operational discharge outlets 2, 3, 5, 6, 8 and 9	Biannually (post wet season and dry season)	Erosion visually identified at discharge outlets (severity rating ≥ medium) Erosion and/or sedimentation visually identified in major creek channels (severity rating ≥ medium)	Review results of total suspended solids monitoring from discharge outlets and surface water sites Mar 1-1, Mar 2-6, DPWW0011, DPWW0012 and WW4-8 (refer to Figure 2-2) Compare against critical correlative environmental parameters: ▪ Monthly rainfall ▪ Flood events ▪ Monthly discharge volumes	Erosion assessed to be a result of surplus water discharge	Assess whether erosion is continuing or accelerating through comparison over multiple inspections Assess extent of erosion downstream of discharge outlet/s Investigate possible remediation actions, for example modification of discharge regime. If warranted, seek expert advice on probable causes and environmental risk of changes observed.	Erosion is confirmed to be a result of discharge, extends beyond the immediate proximity of the discharge outlet and is assessed to be continuing/ worsening	Consult with relevant stakeholders. Instigate external reporting. Implement any dewatering discharge improvements which were identified in the investigation. Undertake rehabilitation works as required and as permitted.

Environmental Objective	Ministerial Statement Condition	Monitoring Aspect	Monitoring Parameter	Monitoring Frequency	Trigger				Threshold	
					Level 1 Criteria	Level 1 Management Actions	Level 2 Criteria	Level 2 Management Actions	Level 3 Criteria	Level 3 Management Actions
Maintain the abundance, diversity, geographic distribution and productivity of flora at species and ecosystem levels through the avoidance or management of adverse impacts and improvement in knowledge										
Prevent clearing or loss of vegetation or GDEs outside Zones 1, 2, 2a, 3*, 3a*, 4 and 5 resulting from dewatering discharge	7-2 7-5 (1-3;7)	Establish baseline riparian vegetation condition outside Zones 1, 2, 2a, 3: (3a & 3b), 4 and 5. **Action complete** Monitor riparian vegetation condition downstream of the zone 3 northern boundary	Canopy foliage cover as an indicator of tree health Site: Pug's Bore	Quarterly On detection of any clearing or loss	Water flow occurs ≥17km from the Marillana Creek and Weeli Wolli Creek System confluence	Quantify extent of discharge beyond 17km Confirm the cause of water flow ≥17km from the confluence, comparing the following correlative factors with assumptions used in predictive modelling: ▪ Monthly rainfall ▪ Groundwater levels ▪ Flood events ▪ Discharge from the Proponent's operations ▪ Discharge from other mining operations, including BHP Yandi and Hope Downs 1. Review the results of canopy foliage cover monitoring	Canopy foliage cover declines by ≥25% from baseline AND Investigation indicates persistent water flow occurring ≥17km from the Marillana Creek and Weeli Wolli Creek System confluence is attributable to the Proponent's operations	Review remotely sensed vegetation spectral data and vegetation monitoring (transect survey) data Review regional and reference sites to context decline with seasonal trends If investigations indicate it is warranted, initiate more frequent qualitative assessment of local riparian vegetation in impacted areas. Investigate possible remedial actions, for example, modification of discharge regime	Investigation confirms ≥25% foliage cover decline from baseline, in excess of declines in reference areas, is representative of riparian vegetation condition trends downstream from the zone 3 northern boundary, and is attributable to the proponent's dewatering discharge extending beyond the zone 3 boundary	Consult with relevant stakeholders Modify discharge regime to correct the exceedance in consultation with relevant stakeholders Evaluate if clearing or loss has occurred in the effected zone for a period of 12 months following corrective actions
			Riparian vegetation monitoring transects to determine species present (includes introduced taxa) Sites: WW25, WW30 and WW31	Biannually (post wet season and dry season)	Persistent water flow occurs ≥17km from the Marillana Creek and Weeli Wolli Creek System confluence	Confirm the cause of water flow ≥17km from the confluence, comparing the following correlative factors with assumptions used in predictive modelling: ▪ Monthly rainfall ▪ Groundwater levels ▪ Flood events ▪ Discharge from the Proponent's operations ▪ Discharge from other mining operations, including BHP Yandi and Hope Downs 1 Review the results of vegetation transects monitoring	Species richness of common native perennial riparian understorey and groundcover species at potential impact sites declines ≥ 20% from baseline, in excess of declines in reference areas AND Investigation indicates persistent water flow occurring ≥17km from the Marillana Creek and Weeli Wolli Creek System confluence is attributable to the Proponent's operations	Quantify extent of discharge beyond 17km. Review remotely sensed vegetation spectral data and vegetation monitoring (transect survey) data If investigations indicate it is warranted, initiate more frequent qualitative assessment of local riparian vegetation in impacted areas Investigate possible remedial actions, for example, modification of discharge regime	Investigation confirms ≥ 20% decline from baseline of species richness of common native perennial riparian understory and groundcover species at potential impact sites, in excess of declines in reference areas, is representative of riparian vegetation condition trends downstream from the zone 3 northern boundary, and is attributable to the proponent's dewatering discharge extending beyond the zone 3 boundary	Consult with relevant stakeholders. Modify discharge regime to correct the exceedance in consultation with relevant stakeholders Evaluate if clearing or loss has occurred in the effected zone for a period of 12 months following corrective actions

Environmental Objective	Ministerial Statement Condition	Monitoring Aspect	Monitoring Parameter	Monitoring Frequency	Trigger				Threshold	
					Level 1 Criteria	Level 1 Management Actions	Level 2 Criteria	Level 2 Management Actions	Level 3 Criteria	Level 3 Management Actions
Prevent clearing or loss of vegetation or GDEs outside Zones 1, 2, 2a, 3*, 3a*, 4 and 5 resulting from groundwater abstraction	7-1 7-5(1-3; 7)	Establish baseline riparian vegetation condition outside Zones 1, 2, 2a, 3: (3a & 3b), 4 and 5. **Action complete** Monitor riparian vegetation condition in Weeli Wolli Creek upstream from the southern boundary of zone 3a	Canopy foliage cover as an indicator of tree health Weeli Wolli Creek: Y10, Y11, Y12	Quarterly On detection of any clearing or loss	N/A	N/A	Canopy foliage cover declines by ≥25% from baseline, in excess of declines in reference areas	Review water availability, including surface water flows and groundwater levels to assess the likelihood of drawdown impacting riparian vegetation Review remotely sensed vegetation spectral data and vegetation monitoring transect data Identify potential remedial actions	Investigation indicates canopy foliage cover which has declined ≥25% from baseline, in excess of declines in reference areas is attributable to drawdown	Confirm cause of drawdown and implement remedial actions as required. Evaluate if clearing of loss has occurred in the effected zone for a period of 12 months following corrective actions. Notify relevant stakeholders
Maintain the abundance, diversity, geographical distribution and productivity of vegetation communities in the project area by avoiding or managing adverse impacts	7-5(4) 6-6(5)	Define limits of acceptable disturbance within the riparian zone. **Action complete** Respond to any disturbance (irreversible loss) exceeding defined limits of acceptable disturbance	Clearing requests Clearing permits Survey of cleared area & reconciliation with permit	Q1 2013 Ongoing If trigger values exceeded	Clearing request made for riparian vegetation community	Check area request against defined limits of acceptable disturbance for riparian vegetation	Clearing approved and works completed	Validate that approved disturbance is contained within approved boundaries Report total land clearing figures within the riparian zone in the annual Compliance Assessment Report	Disturbance occurs outside approved Approval Request permit area	Notify relevant stakeholders. If warranted, rehabilitate disturbed area outside approved clearing area.

Environmental Objective	Ministerial Statement Condition	Monitoring Aspect	Monitoring Parameter	Monitoring Frequency	Trigger				Threshold	
					Level 1 Criteria	Level 1 Management Actions	Level 2 Criteria	Level 2 Management Actions	Level 3 Criteria	Level 3 Management Actions
Prevent irreversible impact to riparian vegetation or GDEs within zones 1, 2, 2a, 3*, 3a*, 4 and 5 resulting from groundwater abstraction or discharge AND Maintain the abundance, diversity, geographical distribution and productivity of vegetation communities in the project area by avoiding or managing adverse impacts	7-3 7-5(1-3; 7) 7-5(4) 6-6(5)	Establish baseline riparian vegetation condition within zones 1, 2, 2a, 3: (3a & 3b), 4 and 5. **Action complete** Monitor riparian vegetation condition within all zones along Marillana and Weeli Wolli Creek	Canopy foliage cover as an indicator of tree health All Zones (Refer to Figure 2-3 and Figure 2-4)	Quarterly	±25% decrease in mean foliage cover relative to baseline at any individual DCP site within the riparian management zones	Identify the riparian community present at the DCP monitoring site. Context decline in foliage cover with reference and regional tree health results, taking into account the distribution of different riparian vegetation communities Review other environmental factors (such as climate, storm damage, fire and insect activity) Review groundwater abstraction and discharge operations/ volumes, and identify potential remedial actions Review remotely sensed vegetation spectral data If investigations indicate it is warranted, initiate more frequent qualitative assessment of local riparian vegetation in impacted areas	Within 2 or more zones, monitoring results exceed all of the following: 40% decrease in mean foliage cover from baseline at all DCP sites in excess of declines in reference areas 25% decline from baseline in species richness of common, native perennial riparian understory groundcover species at all vegetation transects, in excess of declines in reference areas 80% groundcover of weed species not recorded within the project area during baseline monitoring	Initiate additional monitoring as required to assess riparian vegetation condition in all appropriate zones against irreversible impact threshold criteria. Review regional and reference sites to context decline with seasonal trends If necessary, implement feasible remedial actions	Within 4 or more zones all of the following are exceeded: 30% death of mature trees (Diameter Breast Height >20 cm) in excess of mature tree deaths recorded at non-impact or reference sites 25% decline from baseline in species richness of common, native perennial riparian understory groundcover species, in excess of declines in reference areas Absence of recruitment of key local riparian tree species when compared to reference and non-impact sites 80% groundcover of weed species not recorded within the project area during baseline monitoring	Notify and consult with relevant stakeholders. Review operation and efficiency of dewatering and surplus water management system. Implement additional remedial actions on advice from relevant stakeholders. Instigate external reporting.
			Riparian vegetation monitoring transects to determine species present (includes introduced taxa) All Zones (Refer to Figure 2-3 and Figure 2-4)	Biannually (post wet season and dry season)	20% decline (from baseline) of species richness of common native perennial riparian understory and groundcover species at any potential impact site/s, in excess of declines in reference areas	Conduct visual qualitative inspection of local riparian vegetation, including the C1A community Review other environmental factors such as climate, fire, insect activity Review exposure of impacted sites to i) changed creek flow conditions; or ii) extent and duration of inundation with dewatering discharge Context change with reference and regional site results to ascertain if existing weed populations or populations of other native species are expanding where the number of common native species has declined. If investigations indicate it is necessary, manage weeds at the level appropriate to the weed risk and priority identified for each species (in accordance with the Invasive Plant Prioritisation Process, DEC 2011) Investigate other possible remedial actions, for example, modification of discharge regime				

Whilst establishing trigger and threshold* criteria, it was noted that due to the complexity of riparian woodland communities, there is insufficient scientific knowledge to use a singular pre-existing criterion, or establish a new criterion to define an irreversible impact, based on a singular monitoring technique. Individual monitoring techniques provide insight into how individual aspects of riparian vegetation respond to environmental conditions, and should be used collectively to assess the overall condition of the community. As such, the above criteria have been adopted as a threshold for irreversible impact to riparian vegetation

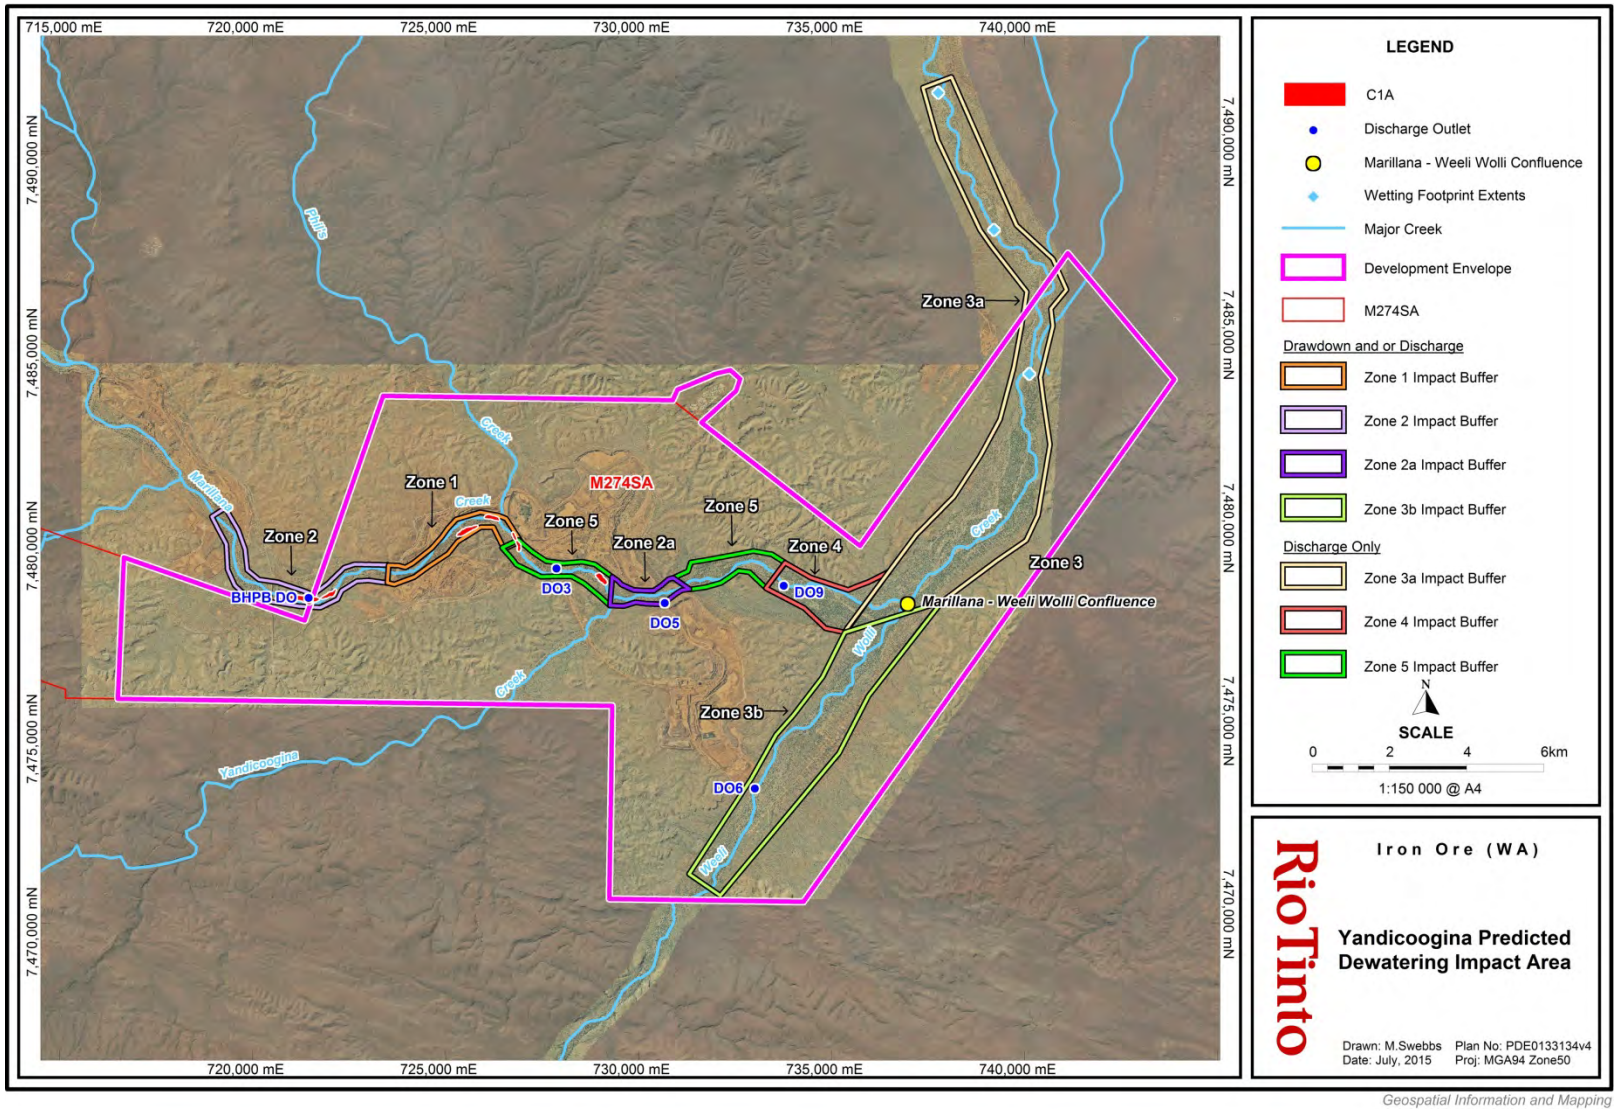

Figure 2-3: Yandicoogina Predicted Dewatering Impact Area

Note: the Proponent identified five riparian management zones where indirect impacts on environmental values may occur as a result of dewatering and discharge activities. Further details on the zones are available in the Report and Recommendations of the Environmental Protection Authority Report for Yandicoogina Iron Ore Project (EPA 2012). Zone 3 & 3a from (EPA2012) has been updated to Zone 3a and 3b to reflect predicted impact areas for the inclusion of the Pocket and Billiard South Project.

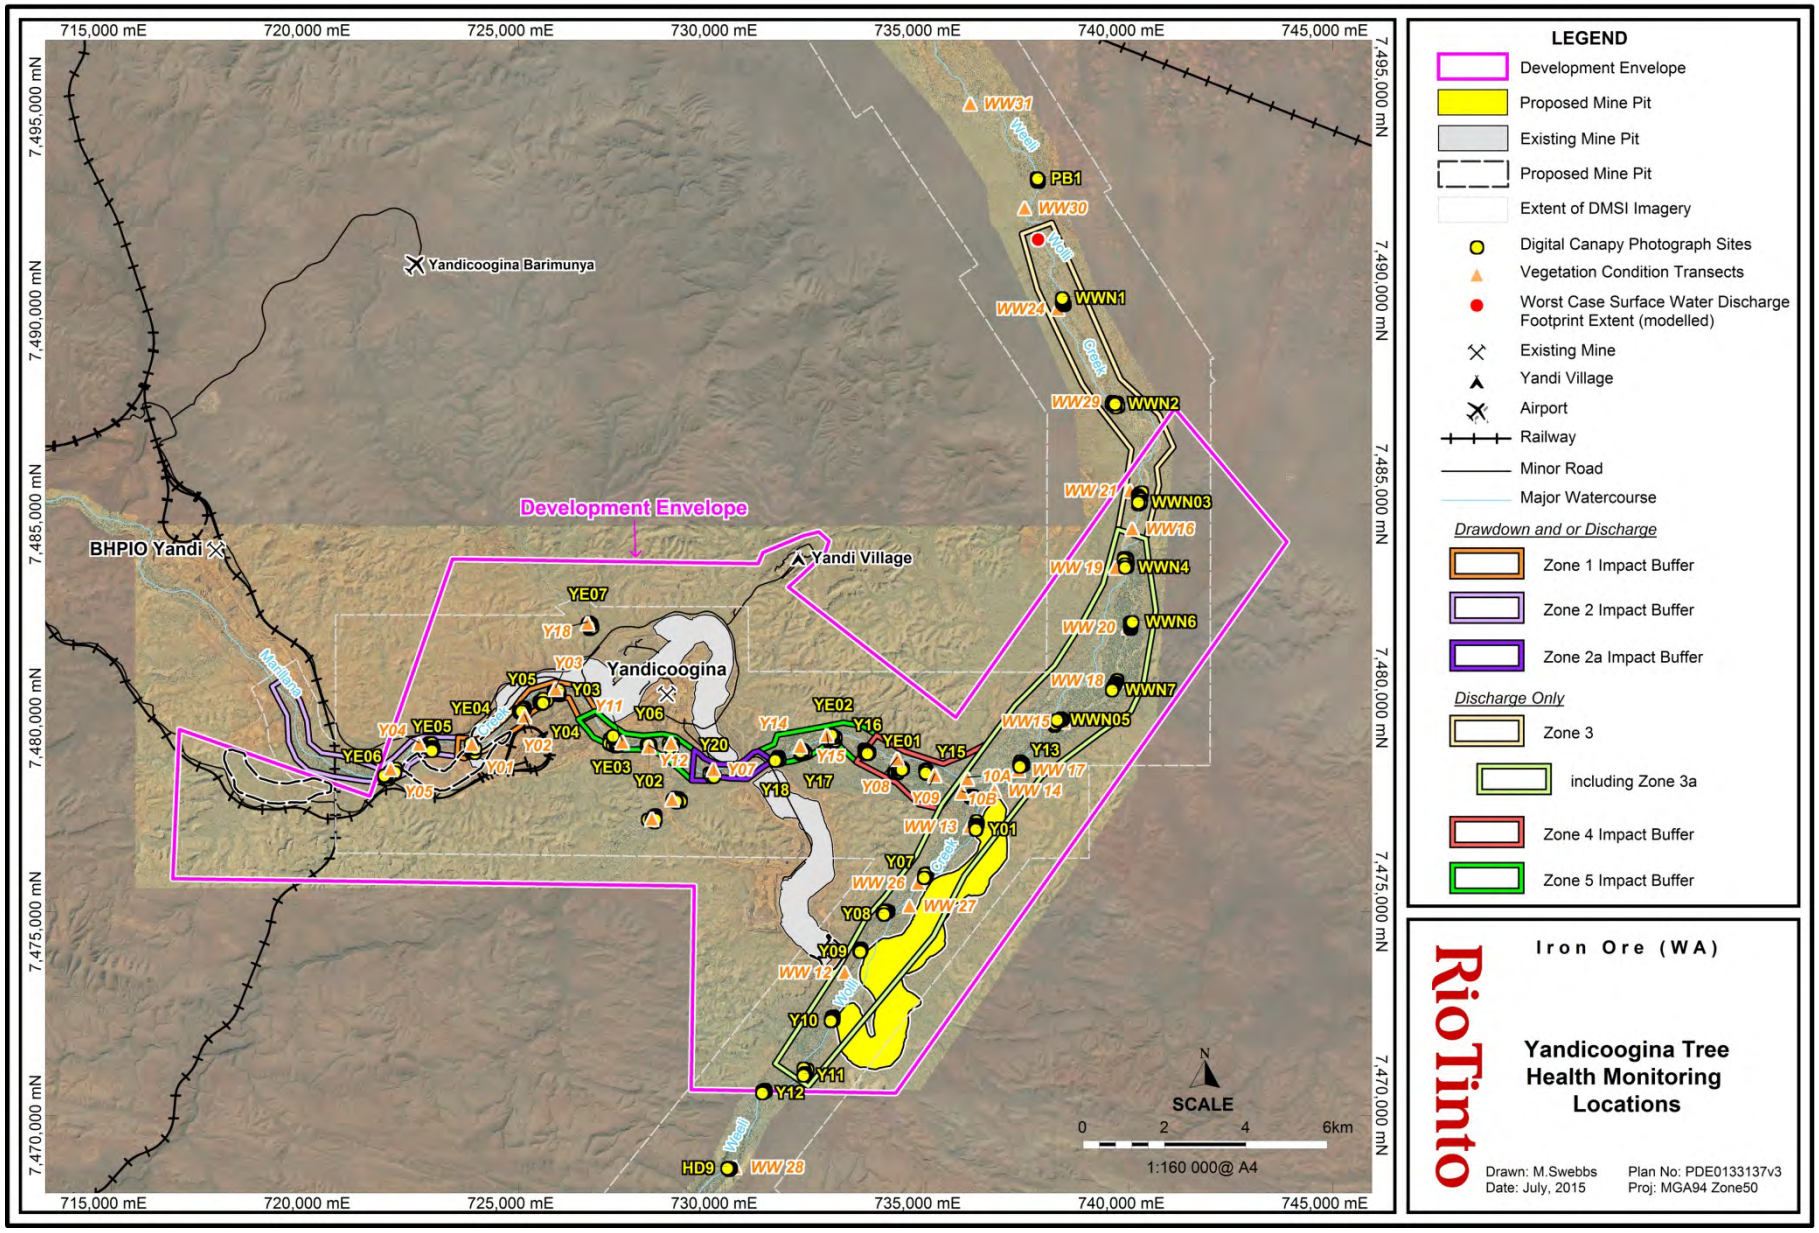

Figure 2-4: Yandicoogina Tree Health Monitoring Locations

3 Monitoring and Management Plan Review

This MMP will be reviewed as required throughout the duration of the Yandicoogina project at intervals not exceeding 5 years to the approval of the CEO of the EPA. In addition, review and revision of the plan will occur as appropriate in response to environmental incident resolutions, audit findings, monitoring results, continuous improvement and changes in regulatory and corporate requirements.

4 Stakeholder Consultation

The MMP and EVS was originally developed in consultation with the Department of Parks and Wildlife (**Parks and Wildlife**), Department of Water (**DoW**) and the Office of the EPA (**OEPA**) during 2012, post assessment of the Yandicoogina project and based on the conditions set out in MS914.

This update will be finalised in consultation with Parks and Wildlife, the Department of Environmental Regulation (**DER**) and the OEPA and will be ongoing as part of an adaptive management process and to support the development of the Pocket and Billiard South deposits.

The Proponent will continue consultation with relevant stakeholders during environmental assessment processes and through the implementation of the Yandicoogina project. These stakeholder groups include the Traditional Owner group represented by the Gumala Aboriginal Corporation and Marillana pastoral station operators.

5 Definitions

Baseline water quality levels: Water quality as defined by the inputs from upstream Mining operations which discharge surplus water into the Marillana and Weeli Wolli Creek systems (including at the western margin of the tenement: BHPBIO Yandi, and including the southern margin of the project area within Weeli Wolli creek: BHPBIO Jinidi operations and HMS Hope Downs 1 operation), and measured at locations depicted in Figure 2-2.

Irreversible impacts: an impact resulting in a permanent loss of environmental value(s); or where intensive, and/or un-proven management intervention, potentially over a long timeframe, would be required to restore the environmental value(s).

Life-of-Mine: Includes the time period from the start of construction until the end of active operations for the Yandicoogina JC, JSE, JSW deposits, Oxbow deposits and PBS deposit.

Long Term Impacts: an impact to an environmental value(s) over several decades which is not irreversible.

Major creekline flood flows: is defined as the 50yr ARI.

Project Area (Development Envelope): Encompasses the Yandicoogina project footprint within ML248SA as delineated in Figure 1-1.

17 km discharge: The discharge footprint is defined as the saturated creek bed once steady state conditions are established. The 17 km limit is defined based on the modelled discharge extent from the Yandicoogina project during *dry conditions*; at a dewatering rate of 53 GL/a; and as of October 2012 approved licence limits of other operations within the catchment (BHPBIO Yandi, Hope Downs 1) (Refer to Figure 2-2 and Figure 2-3).

7 Appendices

Appendix 1: Yandicoogina - High Level Values Statement

Weeli Wolli Creek Catchment - October 2015

High Level Values	Description
Fortescue Marsh	The Fortescue Marsh is the largest ephemeral wetland in the Pilbara region and is listed on the Directory of Important Wetlands of Australia as a wetland of national significance. The diverse ecosystem includes endemic flora, fauna and supports a rich diversity of restricted aquatic and terrestrial invertebrates. The Fortescue Marsh is classified as a Priority Ecological Community (PEC). Marillana and Weeli Wolli Creeks are ephemeral watercourses supported by a combination of groundwater flows and surface run off. This system ultimately drains into Fortescue Marsh, approximately 40 km downstream of Yandicoogina.
Flora and vegetation	A number of populations of the DRF (Declared Rare Flora) *Lepidium catapycnon* occur within the Yandicoogina Development Envelope. The species is listed as a DRF under the Wildlife Conservation Act and as Vulnerable under the EPBC Act. Five broad riparian woodland vegetation communities exist along the Weeli Wolli and Marillana creekline areas within the Yandicoogina Development Envelope. One community (C1A - open riparian Eucalypt woodland containing a mature and co-dominant *Melaleuca argentea* component) is considered to have local conservation significance due to its groundwater dependency, associated values, somewhat restricted distribution, and association with a major creekline in the area. This community is similar but of different structure and reduced significance to the vegetation community of Weeli Wolli Spring (significant *Melaleuca argentea* woodlands).
Stygofauna	A number of subterranean fauna species are known only from the Marillana-Weeli Wolli Catchment. The riparian woodland and ephemeral nature of the Weeli Wolli and Marillana Creeks, together with the underlying CID aquifer provide habitat for a range of fauna, including terrestrial, avian, aquatic and subterranean. Assemblages include aquatic fauna (micro and macroinvertebrates and fish), stygofauna, and animals of the hyporheic zone. The Development Envelope does not contain any permanent pools as refuge for aquatic fauna, and as a result there is no elevated conservation significance for aquatic fauna in the Development Envelope.
Other Recognised Values	
Fauna	In the wider catchment, the Weeli Wolli Spring (upstream from the Development Envelope) is known to support a significant microbat species assemblage, which includes the most northerly population of the Chocolate Wattle Bat (*Chalinobolus morio*). This bat species has been recorded in the south-west corner of the Development Envelope. The Pilbara Olive Python (*Liasis olivaceus barroni*) has been recorded within Weeli Wolli Creek within the southern area of the Development Envelope, and the Development Envelope may contain habitat for the Northern Quoll (*Dasyurus hallucatus*). The Weeli Wolli Creek catchment also contains records of listed migratory birds and Priority species.
Heritage and social	Aboriginal culture is spiritually and physically connected to the landscape through Jukurppa (Dreaming) stories, ceremony, and physical places such as ethnographic and archaeological heritage sites. Weeli Wolli Creek is an important ephemeral water source, food source, camping and meeting place and has been visited by the Traditional Owners of the area for many thousands of years. Significant ethnographic and archaeological heritage sites are also associated with the Marillana and Weeli Wolli water courses. Heritage and social values are recognised and are addressed by the *Heritage of Western Australia Act 1990.* Weeli Wolli Creek is also a significant tourism destination in the region.

Appendix 2: SSTVs for Yandicoogina operations (WRM2015a)

Analyte	SSTV MAR2-6	SSTV WW3-5	Comment	Frequency
Aluminium (Al)	0.055	0.055	Not elevated in surface water, but elevated in groundwater.	Only if potential source for significant enrichment identified (*e.g*. from regular monitoring of dewatering bores)
Alkalinity-total (as $CaCO_3$)	300	310	Elevated downstream of discharge outlet(s). Important to monitor hardness as it ameliorates toxicity of many metals. Alkalinity buffers waters against large fluctuations in pH. Increasing levels are also often associated with NMD. Readily analysed with water hardness.	**Quarterly**
Barium (Ba)	0.054	0.02	Elevated in surface water downstream of discharge outlet(s). Naturally elevated in surface water at some reference sites.	**Quarterly**
Boron (B)	0.37	0.37	Elevated in surface water downstream of discharge outlet(s). Naturally elevated in surface water at some reference sites.	**Quarterly**
Calcium (Ca)	53	57	Elevated in surface water downstream of discharge outlet(s). No ANZECC TV, but is important as it can have an ameliorating effect on metal toxicity. May be indicative of carbonate precipitate and bed armouring.	**Quarterly**
Carbonate (CO_3)	1	1	Elevated in surface water downstream of discharge outlet. No ANZECC TV, but is important as it can have an ameliorating effect on metal toxicity. May be indicative of carbonate precipitate and bed armouring.	**Quarterly**
Copper (Cu)	0.0014	0.0014	Not elevated in surface water. Occasional exceedances in groundwater may be sampling artefact. Requires further investigation.	Only if potential source for significant enrichment identified (*e.g*. from regular monitoring of dewatering bores)
Electrical Conductivity µS/cm (EC)	1010	880	Elevated in surface water downstream of discharge outlet(s). EC can be used as a surrogate for monitoring some major ions (*i.e*. K, Na, Cl, HCO_3). Important indicator of potential osmotic stress in aquatic fauna.	**Quarterly**
Hardness (as mg/L $CaCO_3$)	344	370	Elevated in surface water downstream of discharge outlet(s). Is important to monitor hardness as it ameliorates toxicity of many metals and can be used to adjust SSTVs. Also an indicator of NMD. Readily analysed with alkalinity.	**Quarterly**
Iron (Fe)	0.3	0.3	ANZECC state the default TV for iron is interim only as there is insufficient data on its toxicity. Occasionally elevated in surface water and enriched in ground-water.	**Quarterly**
Manganese (Mn)	1.9	1.9	Not elevated in surface water but elevated in groundwater.	Only if potential source for significant enrichment identified (*e.g*. from regular monitoring of dewatering bores)

Nitrate (NO_3)	11	11	Elevated in surface water downstream of discharge outlet(s). SSTV is to protect against direct toxicity effects. The concentration of NO_3 can be calculated from N-NO_3 and *vice versa* (see N-NO_3 below). Will also be captured in monitoring N-NO_3.	**Quarterly**
Nitrate-nitrogen (N-NO_3)	2.5	2.5	Elevated in surface water downstream of discharge outlet(s). To compare against the TV for nitrate (NO_3) as a toxicant (see above), multiply nitrate-nitrogen (N-NO_3) by 4.43.	**Quarterly**
N_NOx (eutrophication TV)	1.16	0.16	ANZECC only provide a TV for N-NOx (0.03 mg/L), which is the sum of N-NO_3 and N-NO_2 and is designed to protect against eutrophication. In Yandi surface and groundwaters, N-NO_3 constitutes most of the nitrogen present.	**Quarterly**
pH	6 - 8.5	6 - 8.5	Current levels in surface and groundwater well within SSTVs. Must be measured in the field using regularly calibrated field meters. Will be captured as part of aquatic fauna monitoring, but should be regularly monitored if AMD or NMD is potentially an issue.	**Quarterly**
Phosphorus-total (P-total)	0.02	0.02	Occasionally elevated downstream of discharge outlet(s). SSTV designed to protect against eutrophication.	**Quarterly**
Selenium (Se-total)	0.011	0.011	Not currently elevated downstream of discharge outlet(s). No ANZECC TV, but is important to monitor as increasing levels are often associated with NMD (neutral mine drainage). Se can also bioaccumulate through aquatic food chains.	Only if potential source for significant enrichment identified (*e.g*. from regular monitoring of dewatering bores)
Silicon (SiO_2)	50	30	Not currently elevated in surface water or ground-water. No ANZECC TV. Can have ameliorating effect on toxicity of Al. Often enriched in groundwaters due to weathering of minerals.	Only if potential source for significant enrichment identified (*e.g*. from regular monitoring of dewatering bores)
Sulphate (SO_4)	60	56	Elevated in surface water downstream of discharge outlet(s). No ANZECC TV, but is important to monitor (as either SO_4 or S-SO_4), as increasing levels are often associated with AMD or NMD.	**Quarterly**
Temperature	28	28	Biannual aquatic ecosystem monitoring indicated significant increase in temperature over time in lower Marillana Creek. May become elevated above SSTV as mining progresses further below water table. Must be measured in the field with regularly calibrated meters.	**Quarterly**
Total Dissolved Solids (TDS)	560	500	Elevated in surface water downstream of discharge outlet(s). Important to monitor as provides an indication of change in total concentration of major ions (*e.g*. Ca, K, Mg, Na, Cl, HCO_3, SO_4).	**Quarterly**
Total Suspended Solids (TSS)	5	5	Elevated in surface water downstream of discharge outlet(s). Provides an indication of turbidity and sediment loads; constant very high levels can smother / bury aquatic biota. Natural TSS in creeklines can be highly	**Quarterly**

			variable depending on seasonal rainfall runoff.	
Uranium (U)	0.002	0.002	Elevated in surface water downstream of discharge outlet(s). No ANZECC default TV as there is insufficient data on its toxicity. Important to monitor if only to demonstrate no effect on aquatic biota.	**Quarterly**
Vanadium (V)	0.005	0.005	Elevated in surface water downstream of discharge outlet(s). No ANZECC default TV as there is insufficient data on its toxicity. Important to monitor if only to demonstrate no effect on aquatic biota.	**Quarterly**
