- Based on the mapping refinement, the present day distribution and areal extent of OPV in the study area is significantly reduced from 2.6 km^2 to 1.01 km^2 (260ha to 101ha), when compared to previous broader scale vegetation mapping.

- Following an assessment of the degree to which presently mapped OPV is likely to be a result of surplus-water related discharge augmentation, the amount of this vegetation now considered to represent pre-mining baseline and occur within tenure has been interpreted to be approximately 0.29 km^2 or 29 ha, which is less than half of the OPV mapped as currently present during the vegetation mapping refinement process (1.01 km^2 or 101 ha).

- Consequently, three vegetation units (C1A, C1AA, and C1B) are now considered to represent true and therefore obligate phreatophytic vegetation likely to have been present (in the study area) in a similar form within the pre-mining environment.

- These units all also represent vegetation which is somewhat augmented (through increased biomass, and increases in structural and compositional diversity) by mining related discharge and nearly all representations of relevance to ongoing development in the area are quite small

in their areal extent. However, despite this fact, and despite the other negative anthropogenic impacts (both mining and grazing related) on them, they are still perceived to possess high to moderate "development significance", and are all highly sensitive to hydrological changes. Consequently they should be afforded effective management measures where practicable.

- Only the C1A and C1B units are of key relevance to potential impacts of proposed development within the study area. These two units only represent a small portion of the study area (approximately 2% of the areal extent of the riparian communities) which includes stretches of approximately 20km within both the Marillana and Weeli Wolli Creek systems.

- The distribution of these two key units of significance is highly spatially restricted to the confines of the low flow channels within the study area. Consequently; assuming mining related discharge is maintained in these creek systems throughout the various phases of development, the potential impacts associated with drawdown appear unlikely to be realised within these very small and often disjunct communities.

7 APPENDICES

Appendix 1: Vegetation structure and condition scale used for vegetation description and mapping formulated within this study.

Vegetation Structure and Condition Scale

Vegetation Structural Classes*

Stratum	Canopy Cover (%)				
	70-100%	30-70%	10-30%	2-10%	<2%
Trees over 30 m	Tall closed forest	Tall open forest	Tall woodland	Tall open woodland	Scattered tall trees
Trees 10-30 m	Closed forest	Open forest	Woodland	Open woodland	Scattered trees
Trees under 10 m	Low closed forest	Low open forest	Low woodland	Low open woodland	Scattered low trees
Shrubs over 2 m	Tall closed scrub	Tall open scrub	Tall shrubland	Tall open shrubland	Scattered tall shrubs
Shrubs 1-2 m	Closed heath	Open heath	Shrubland	Open shrubland	Scattered shrubs
Shrubs under 1 m	Low closed heath	Low open heath	Low shrubland	Low open shrubland	Scattered low shrubs
Hummock grasses	Closed hummock grassland	Hummock grassland	Open hummock grassland	Very open hummock grassland	Scattered hummock grasses
Grasses, Sedges, Herbs	Closed tussock grassland / bunch grassland / sedgeland / herbland	Tussock grassland / bunch grassland / sedgeland / herbland	Open tussock grassland / bunch grassland / sedgeland / herbland	Very open tussock grassland / bunch grassland / sedgeland / herbland	Scattered tussock grasses / bunch grasses / sedges / herbs

* Based on Muir (1977), and Aplin's (1979) modification of the vegetation classification system of Specht (1970): Aplin T.E.H. (1979). The Flora. Chapter 3 In O'Brien, B.J. (ed.) (1979). *Environment and Science*. University of Western Australia Press; Muir B.G. (1977). Biological Survey of the Western Australian Wheatbelt. Part II: Vegetation and habitat of Bendering Reserve. *Records of the Western Australian Museum*, Suppl. No. 3; Specht R.L. (1970). Vegetation. In: *The Australian Environment*. 4th edn (Ed. G.W. Leeper). Melbourne.

Vegetation Condition Scale*

E = Excellent (=Pristine of BushForever)
Pristine or nearly so; no obvious signs of damage caused by the activities of European man.

VG = Very Good (= Excellent of BushForever)
Some relatively slight signs of damage caused by the activities of European man. For example, some signs of damage to tree trunks caused by repeated fire, the presence of some relatively non-aggressive weeds such as **Sonchus oleraceus* or **Cucumis* spp., or occasional vehicle tracks.

G = Good (= Very Good of BushForever)
More obvious signs of damage caused by the activities of European man, including some obvious impact on the vegetation structure such as that caused by low levels of grazing or by selective logging. Weeds as above, possibly plus some more aggressive ones such as **Cenchrus* spp.

P = Poor (= Good of BushForever)
Still retains basic vegetation structure or ability to regenerate to it after very obvious impacts of activities of European man, such as grazing, partial clearing (chaining) or frequent fires. Weeds as above, probably plus some more aggressive ones such as **Cenchrus* spp.

VP = Very Poor (= Degraded of BushForever)
Severely impacted by grazing, very frequent fires, clearing or a combination of these activities. Scope for some regeneration but not to a state approaching good condition without intensive management. Usually with a number of weed species including very aggressive species such as **Prosopis* spp.

D = Completely Degraded (= Completely Degraded of BushForever)
Areas that are completely or almost completely without native species in the structure of their vegetation; ie. areas that are cleared or 'parkland cleared' with their flora comprising weed or crop species with isolated native trees or shrubs.

* Based on Trudgen M.E. (1988). A Report on the Flora and Vegetation of the Port Kennedy Area. Unpublished report prepared for Bowman Bishaw and Associates, West Perth.

Biodiversity values of Weeli Wolli Spring: A priority ecological community

Stephen van Leeuwen. DEC Science Division, (08) 9405 5169; stephen.vanleeuwen@dec.wa.gov.au

Background

Weeli Wolli Creek in the central Hamersley Range supports a permanent series of pools which are fed by Weeli Wolli Spring. This arid zone wetland supports a unique community of plants and animals some of which are endemic to the Spring. Grazing by livestock, inappropriate fire regimes and alteration to surface water flows and groundwater levels as a result of mining pose a significant threat to this unique Pilbara community. Consequently the community has been listed as a Priority 1 Ecological Community.

The Spring, which has considerable spiritual and cultural significance to traditional owners of the Hamersley Range, is located at the base of a large banded ironstone ridge that intersects the Creek providing an impermeable barrier to the subsurface downstream flow of water. The subsequent surface expression of water at the spring varies from a trickle to a significant flow which is expressed as pools and billabongs on the surface for up to 10 km.

Ironstone barrier at Weeli Wolli Spring

The vegetation of the spring and surrounding creek channel is typical of most Pilbara drainage features that support permanent water.

It is dominated by a fringing forest or tall woodland of Silver paperbark (*Melaleuca argentea*) and River Red gum (*Eucalyptus camaldulensis*) over trees of Coolibah (*E. victrix*) and a dense shrub layer dominated by an assortment of wattles, in particular Pilbara Jam (*Acacia citrinoviridis*). The presence of permanent water and very moist sediment also provides suitable habitat for many sedges and herbs. The area is a haven for birds and other fauna including many bats and also supports a rich community of surface and subsurface aquatic invertebrates.

Findings

The biodiversity values of Weeli Wolli Spring are high. Among the 120+ native plant species known from Weeli Wolli, apart from the majestic Silver cajuputs there are several species of conservation interest including a trigger plant named after the Spring – *Stylidium weeliwolli*. Botanical values also include a hybrid zone between two native cotton (*Gossypium*) species which has attracted significant commercial interest from multinational companies in the quest for a biological control agent of the pink bollworm, a serious predator of commercial cotton throughout the world.

The diversity of habitats in close proximity to the Spring also provides a haven for birds with over 60 species recorded along the creek. The Spring is recognised as a focal point for Pilbara birds and is promoted by local and State tourism agencies. Similarly the diversity of habitat types and rough landscapes provide many opportunities for bats, with the Spring being the only known Pilbara and most northern locality for the Chocolate Bat (*Chalinolobus morio*). The Ghost bat (*Macroderma gigas*) a threatened species, has also been recorded foraging above pools downstream of the Spring.

Water Mite - *Australiurus* sp. P1

The most significant biological values of the spring and its creek system are associated with the aquatic invertebrates that inhabit the Spring, pools and the underground water body. Three species of water mite (*Wandesia* sp. P1 (nr *glareosa*), *Austraturus* P1, *Guineaxonopsis* sp. P1 (PSW)) are only known from Weeli Wolli Creek and one other locality in the Pilbara. Similarly two underground aquatic invertebrates, a water mite (*Arrenurus* sp. nov. 1 (PSS), and a oligochaete (*Ainudrilus* sp. WA26 (PSS)), are only know from Weeli Wolli while three other crustaceans (*Gomphodella* sp. 4 (PSS), *Maarka* n. sp. *'wolli'* ms, *Meridiescandona* sp. 3' (PSS)) are only known from Weeli Wolli and one other locality in the Pilbara.

Management Implications

DEC is currently working with industry and traditional owners to manage impacts on Weeli Wolli Creek and the Spring from water abstraction and discharge associated with the Hope Downs mine. The primary objectives of these efforts are to protect cultural values and maintain the biological assets of the area. To this end the State Government will establish a reserve at Weeli Wolli in 2015 to protect and manage the values of the spring and several kilometres of the downstream creek.

For additional information on the flora and fauna of the Pilbara please visit the Pilbara Biological Survey website at http://www.dec.wa.gov.au/science-and-research.

Silver Cajuput (*Melaleuca argentea*) in Weeli Wolli Creek

1.0 Summary

1.1 Introduction

Rio Tinto's Yandicoogina (Yandi) iron ore project is located approximately 90 km northwest of Newman, in the Pilbara region of Western Australia and is currently operated by Hamersley Iron Pty Ltd – Yandi Pty Ltd (Hamersley Iron).

Biota Environmental Sciences (Biota) was commissioned by Rio Tinto to undertake a review of terrestrial fauna information available for the Yandi development envelope, which covers a total of 19,351 ha. The development envelope includes or intersects sections of the following individual Rio Tinto terrestrial fauna study areas:

- Yandi Junction Central (JDM study area: 3,733 ha);
- Hope Downs Rail Corridor Extension (HDR study area; 3,977 ha);
- Junction South East (JSE study area: 2,245 ha);
- Junction South West (JSW study area: 1,707 ha);
- Yandi Oxbow (YOX study area: 724 ha);
- Yandi Billiards (BIL study area: 4,410 ha); and
- Pocket and Billiard South (PBS study area: 8,639 ha).

1.2 Methodology

The collated Yandi fauna data used in this report were sourced from 14 separate studies from 2004 to 2014, some of which comprised seasonal survey phases. These surveys used a combination of systematic sampling and other methodologies, all conducted in accordance with relevant Environmental Protection Authority (EPA) policy and the Commonwealth *Environment Protection and Biodiversity Conservation (EPBC) Act 1999* (EPA 2002, 2004, 2009, EPA and DEC 2010, DSEWPaC 2011).

The systematic sampling effort in the Yandi development envelope comprised 54 trapping sites, collectively representing 7,138 trap nights of systematic effort. Avifauna censuses were carried out at a total of 49 sites across the development envelope, and the census time from all phases of survey work totalled approximately 107 hours (6,410 minutes).

Bat sampling was conducted in areas deemed mostly likely to yield bat records. This effort therefore focused on rocky free-face landforms (particularly where caves or other potential roost site features were present in gorges) and along larger drainages (particularly where water was present). Bat sampling effort totalled 62 survey nights across 21 sites.

Additionally, searches were conducted at a minimum of 42 sites to target invertebrate groups with the potential to contain Short Range Endemic (SRE) species:

- Mygalomorphae (trapdoor spiders);
- Diplopoda (millipedes);
- Scorpiones (scorpions);
- Pulmonata (land snails); and
- Pseudoscorpiones (pseudoscorpions).

1.3 Faunal Habitats and Assemblages

Fauna habitats were determined considering locality and broad-scale factors such as regional surface geology, land systems and landforms. PRIMER analyses of faunal assemblage were conducted using rationalised and transformed faunal abundance data. For herpetofauna and ground mammals, seven faunal assemblage clusters were identified at the 30% similarity level. Only five fauna assemblage clusters were identified for avifauna.

Non-metric Multi-Dimensional Scaling (NMDS) of the herpetofauna dataset showed separation of clusters, indicating that fauna assemblages could be placed into groups that were fundamentally different to each other. The best relationship between the seven herpetofauna assemblages and the site habitat factors was provided by 'survey locality', with the herpetofauna composition recorded from the PBS survey being noticeably different to data obtained from the other localities. It appears that this is an artefact of greater sampling effort, resulting in greater recorded species richness and abundance at the PBS sites, rather than a real trend based on sampling location.

NMDS plots indicated that, on the whole, bird assemblages were not fundamentally different between sites. In contrast, the ground mammal assemblage were fundamentally different between sites, but these differences could not be attributed to locality, land systems, geology or landform factors.

1.4 Fauna

A total of 206 vertebrate fauna species were recorded from the development envelope during the combined surveys. This total comprised three amphibians, 69 reptiles, 103 avifauna species, 15 native ground mammals, 10 bats and six introduced mammals.

The recorded herpetofauna species comprised three frogs and 69 reptiles. The reptile species comprised six dragons (family Agamidae), 12 geckos (Gekkonidae, Diplodactylidae and Carphodactylidae), seven legless lizards (Pygopodidae), 27 skinks (Scincidae), eight monitors (Varanidae), two blind snakes (Typhlopidae), two pythons (Boidae) and six front-fanged snakes (Elapidae). The gecko *Diplodactylus conspicillatus* (n=77 individuals) and the skinks *Ctenotus duricola* (n=68) and *Ctenotus saxatilis* (n=59) were the most abundant herpetofauna species recorded in the development envelope.

Twenty-one ground mammals, comprising 15 native and six introduced species, were recorded from the development envelope. This total comprised six carnivorous marsupial species (Dasyuridae), three kangaroo species (Macropodidae), six rodent species (Muridae), one cat (Felidae), one canine (Canidae), two equine species (Equidae), one cattle species (Bovidae) and one camel species (Camelidae). The introduced mammals recorded in the development envelope comprised the house mouse (*Mus musculus*), feral cat (*Felis catus*), donkey (*Equus asinus*), horse (*Equus caballus*), European cattle (*Bos taurus*) and camel (*Camelus dromedarius*). The most abundant mammals in the development envelope were the introduced house mouse *Mus musculus* (n=45 individuals), the Common Rock Rat *Zyzomys argurus* (n=30), and the Sandy Inland Mouse *Pseudomys hermannsburgensis* (n=29).

A total of 103 avifauna species from 40 families were recorded from the development envelope, comprising 53 passerine and 50 non-passerine species. The most speciose families were the Meliphagidae (honeyeaters and chats) with 11 species recorded, and the Accipitridae (raptors) with seven species recorded. The most abundant species were the Zebra Finch *Taeniopygia guttata* (n=142 individuals) and Weebill *Smicrornis brevirostris* (n=107), both of which were recorded from the majority of survey sites.

Of the eight prospective SRE taxa recorded within the development envelope, four mygalomorph spider putative species are considered to be potential SREs, as they have known distributions not exceeding the accepted 10,000 km^2 threshold (Harvey 2002). These species comprise Idiopidae sp. I1, Idiopidae sp. I9, Nemesiidae sp. N42 and Nemesiidae sp. N44. None of these species are confined solely to the development envelope.

1.5 Threatened Fauna

Nine vertebrate species of elevated conservation significance were recorded from the development envelope (Figure 4.16). This included five Schedule species listed under the *Wildlife Conservation Act 1950,* four of which are also listed under the Commonwealth *EPBC Act 1999*:

- Pilbara Olive Python, *Liasis olivaceus barroni* (State: Schedule 1; Commonwealth: Vulnerable)
  One individual was recorded opportunistically swimming in Weeli Wolli Creek. This species is not commonly observed.
- Rainbow Bee-eater, *Merops ornatus* (State: Schedule 3; Commonwealth: Migratory)
  This species was recorded from 23 locations within the Yandi development envelope across all source surveys. It showed little preference for specific land systems, being represented in five different types.
- Fork-tailed Swift, *Apus pacificus* (State: Schedule 3; Commonwealth: Migratory)
  Nine individuals were recorded flying overhead at a single location. This species is expected to be a transient visitor only, and would not rely on any terrestrial habitats within the development envelope.
- Eastern Great Egret, *Ardea modesta* (State: Schedule 3; Commonwealth: Migratory)
  A single bird was observed flying in the vicinity of Weeli Wolli Creek. This single observation within the development envelope during multiple phases suggests that the Eastern Great Egret is either uncommon or is an irregular visitor to the development envelope.
- Peregrine Falcon, *Falco peregrinus* (State: Schedule 4)
  One individual was recorded within the development envelope. This record is likely to represent a transitory or foraging individual.

Four species listed as Priority 4 by the Department of Parks and Wildlife were also recorded from the development envelope:

- Western Pebble-mound Mouse *Pseudomys chapmani:* pebble-mounds were recorded at 22 locations within the development envelope (Figure 4.16).
- Australian Bustard *Ardeotis australis*: observed on 17 occasions from 11 locations within the development envelope.
- Star Finch *Neochmia ruficauda subclarescens*: a total of 13 records were noted at two locations within the development envelope during the combined surveys.
- Brush-tailed Mulgara *Dasycercus blythi:* burrows of this species were recorded within the development envelope, however no individuals were captured. The burrows were thought to be inactive, as no signs of fresh diggings, scats or tracks were noted.

1.6 Conclusions

The combined Yandi fauna surveys represent a comprehensive sampling effort with 54 systematic sampling sites being conducted across 10 studies spanning 11 years, many of which had seasonal sampling components. The full range of habitats present in the development envelope was sampled.

Species accumulation curves generated from the data demonstrated asymptotic patterns, indicating few additional species would be added with further sampling using the same techniques. Non-parametric estimates for the vertebrate assemblage predict that 85% of the fauna are likely to have been documented via the methods used during the surveys.

The combined fauna assemblage of 206 vertebrate species recorded from the Yandi development envelope is extensive, but is typical of that which would be realistically expected for an area of similar size in this locality, subjected to a similar samoling effort. Although the development envelope contains habitat and species of conservation value, the suite of species present is representative of the fauna commonly recorded within both the Pilbara bioregion and the Hamersley subregion.

This study has documented the existence of potential SRE fauna within the broader Yandi development envelope. Eight species were recorded from two broad taxonomic groups with the potential to include SREs (pseudoscorpions and mygalomorph spiders), and four putative species of mygalomorph spider were identified as potential SREs. All of these taxa are also known to occur outside of the development envelope and as a result, there is a reduced risk that disturbance inside the development envelope will adversely affect these species populations.

2.0 Introduction

2.1 Project Background

Hamersley Iron Yanid currently operates the Yandi iron ore mine as part of its Pilbara Iron operations. The Yandi mine is situated approximately 90 km northwest of Newman in the Pilbara region of Western Australia (Figure 2.1). Construction of the original Yandi mine, Junction Central (YJC), started in 1997 with the first shipment of ore occurring in 1999. An expansion to the existing mining operations was later proposed in 2005 in the form of Junction South East (JSE). A number of other sustaining operations have subsequently been approved and are progressing, including at the Junction South West (JSW) deposit and the proposed Oxbow deposits (YOX).

Rio Tinto plans to sustain their existing Yandi operations by opening a new pit to replace the exising operational pis as they are depleted. The proposed development includes a feasibility study for development of the Channel Iron Deposits (CIDs) at Pocket and Billiard South (PBS), located approximately 7 km east of the existing Yandi mine.

The combined extent of these components represents the overall Yandi integrated development envelope (hereafter referred to as the "development envelope"), as shown in Figure 2.1 and Figure 2.2. The development envelope covers a total of 19,351 ha, including or intersecting sections of the following individual Rio Tinto study areas:

- Yandi Junction Central (JDM study area: 3,733 ha);
- Hope Downs Rail Corridor Extension (HDR study area; 3,977 ha);
- Junction South East (JSE study area: 2,245 ha);
- Junction South West (JSW study area: 1,707 ha);
- Yandi Oxbow (YOX study area: 724 ha);
- Yandi Billiards (BIL study area: 4,410 ha); and
- Pocket and Billiard South (PBS study area: 8,639 ha).

The proposed PBS development will be formally assessed under the State *Environmental Protection Act 1986* (Biota 2014a). In order to assist with these environmental impact assessments (EIA), Biota was commissioned to integrate the above Yandi Billiard terrestrial fauna surveys into a broader reference framework for the wider Yandi development envelope of Ministerial Statement 914.

2.2 Purpose and Scope of this Report

This report has been prepared as a supporting document for EIA of the proposed PBS development. It consolidates all data from the individual studies completed for various components of the broader Yandi development envelope into a consistent format and provides a synthesised framework and integrated summary of the data from the individual studies.

By integrating the Yandi fauna surveys into a consolidated document, potential impacts of the PBS deposits development can be placed into appropriate context to support the forthcoming EIA. This provides a better-informed view of the terrestrial faunal values of the development envelope. Additionally, records of vertebrate species of conservation significance and potential SRE invertebrates are placed into better context than provided by individual supporting studies. Integration also allows habitat definition to be rationalised and better informed by the more robust faunal assemblage data set.

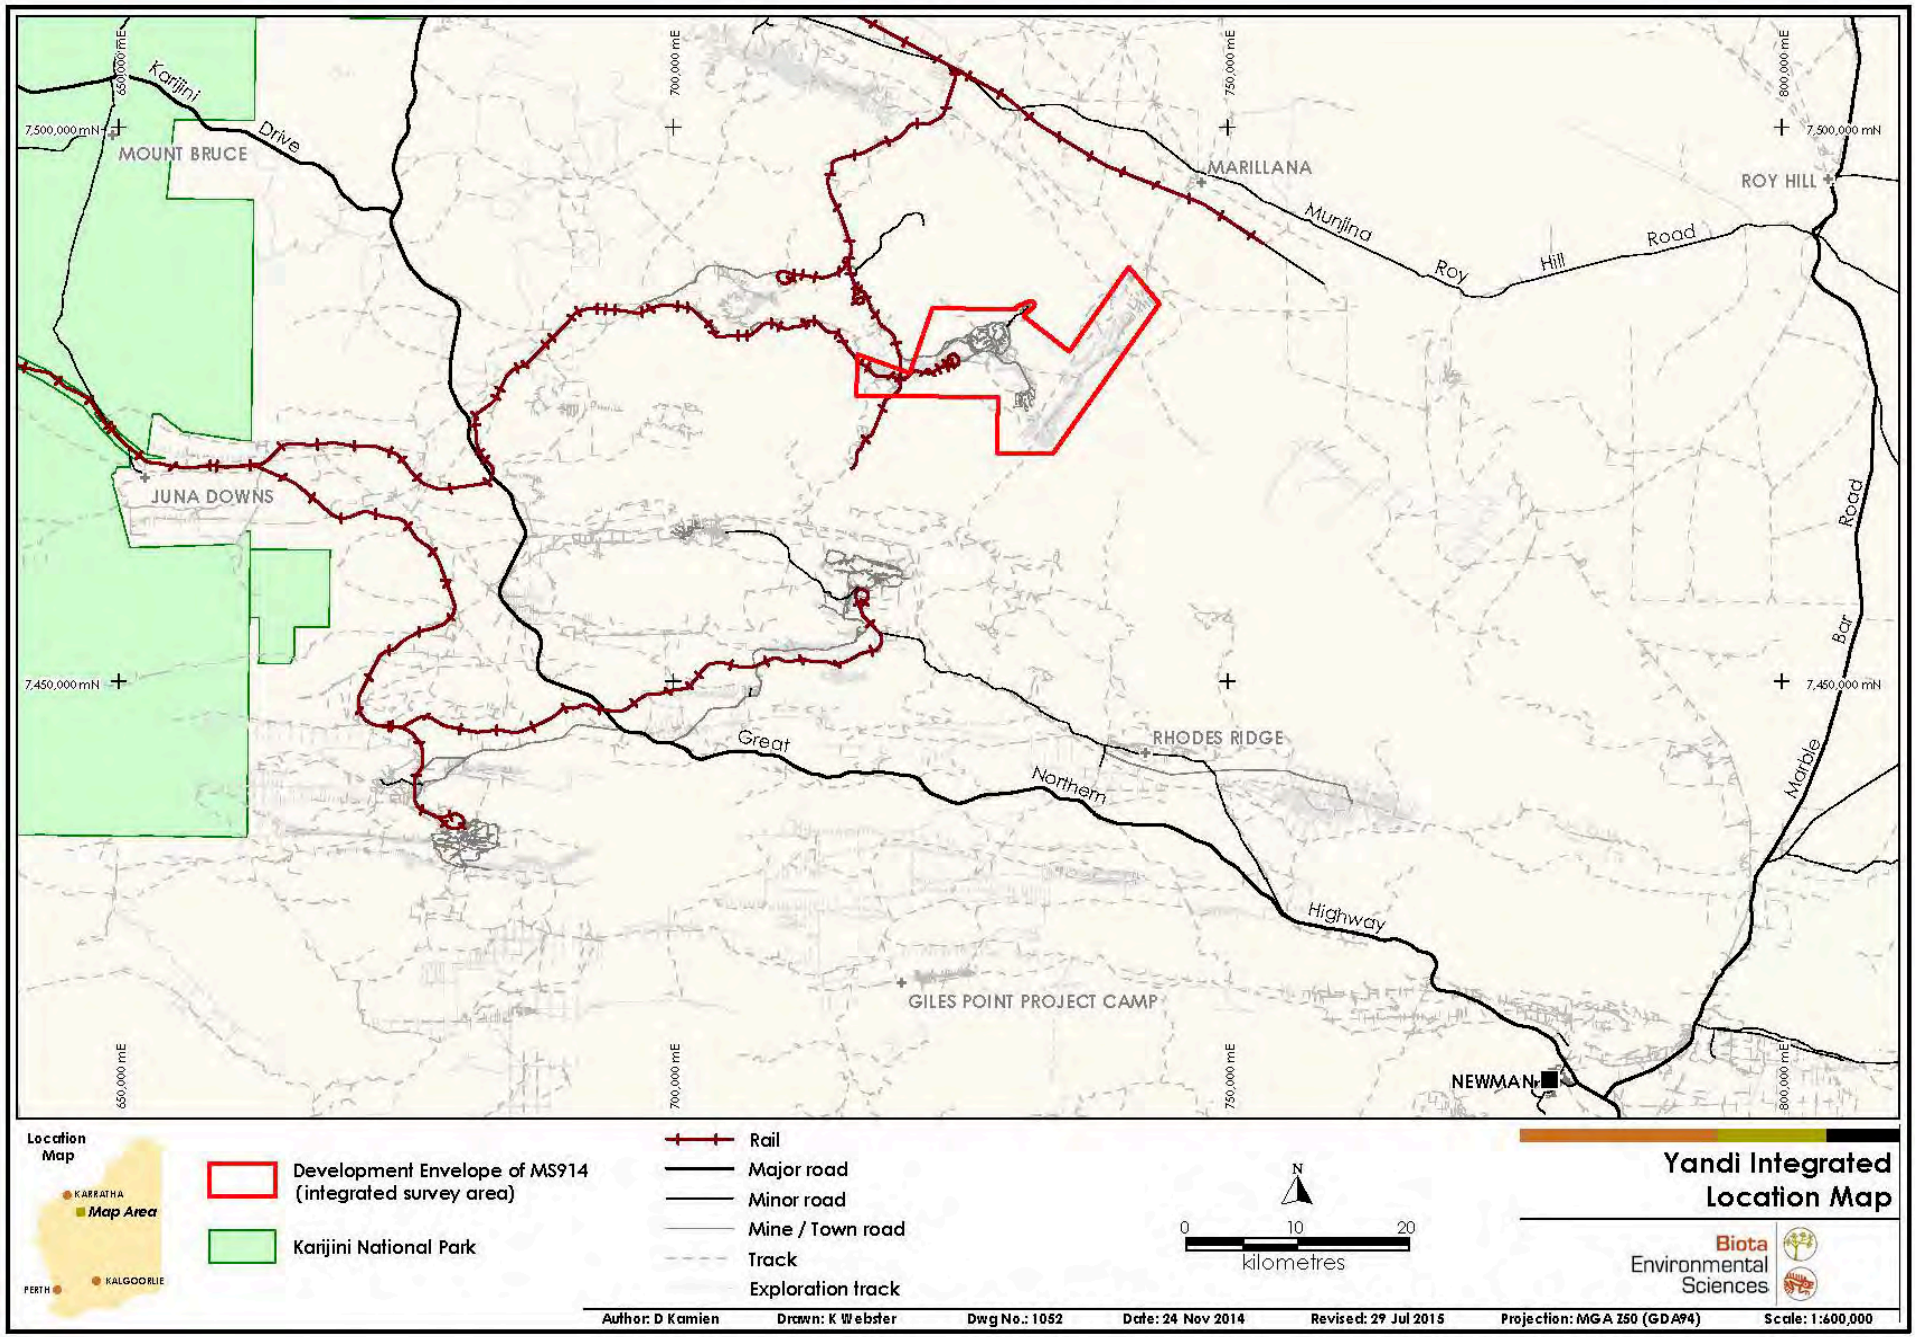

Figure 2.1: Location of the Yandi development envelope.

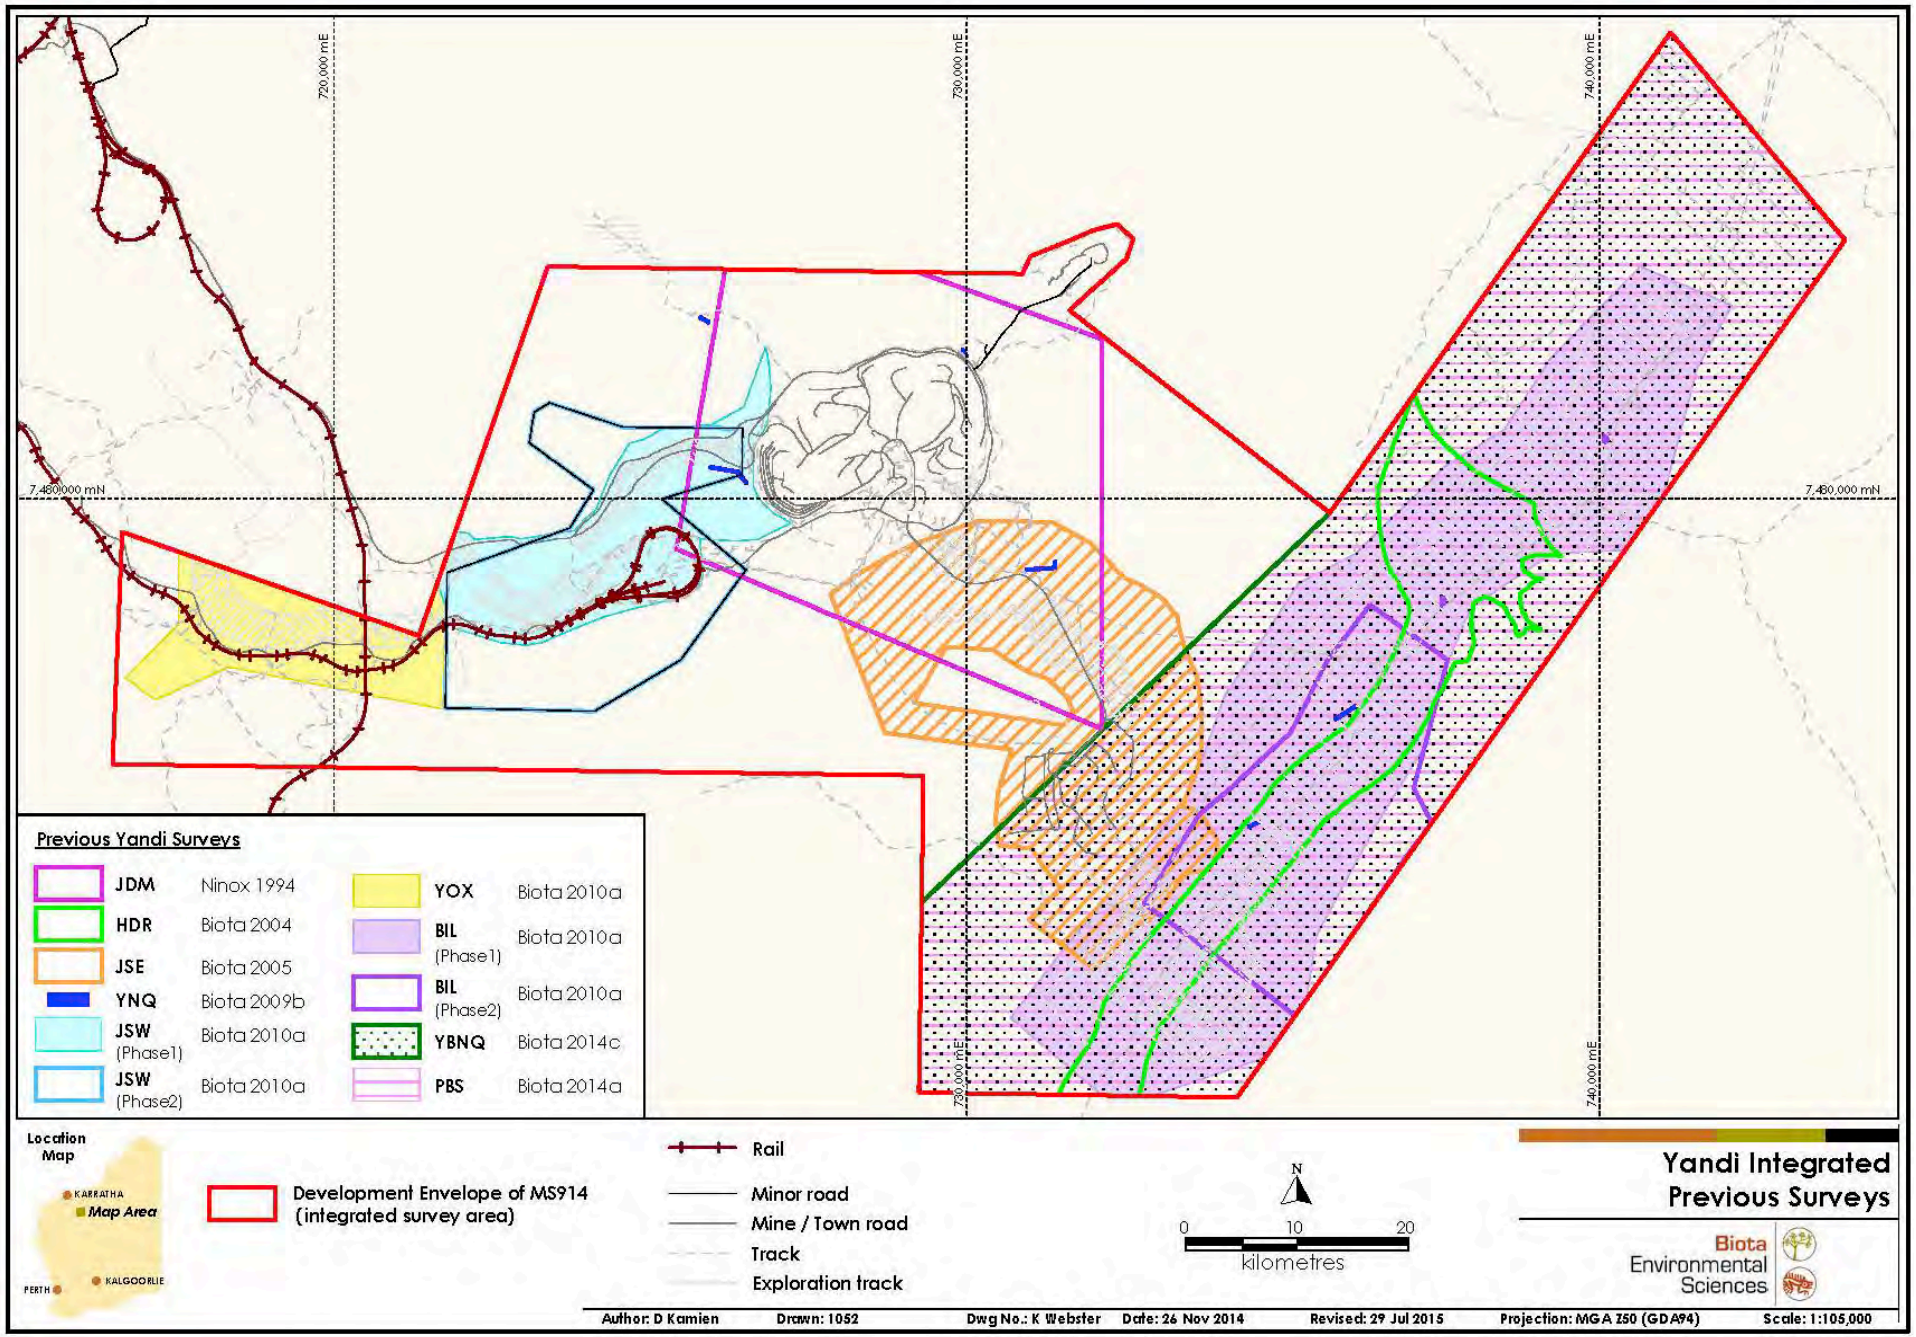

Figure 2.2: Spatial extent of individual studies covering the Yandi development envelope.

2.3 Fauna Background

2.3.1 Vertebrate Fauna

Although the primary purpose of this report is to consolidate all data from the individual studies completed for various components of the broader Yandi development envelope (see Section 2.2), it is important to note that certain species hold greater importance than others from an EIA perspective.

Fauna species listed as Threatened under the Commonwealth *EPBC Act 1999* constitute a Matter of National Environmental Significance (MNES). A significant impact to MNES species requires approval from the Australian Government Minister for the Environment. In cases where Threatened fauna are recorded, it is advisable to refer proposals to the Commonwealth Department of the Environment (DotE) to determine if the likely impacts are considered significant. Three threatened fauna species that are relevant at both State and Commonwealth levels are the Northern Quoll (*Dasyurus hallucatus*), Orange Leaf-nosed Bat (*Rhinonicteris aurantius*) and Pilbara Olive Python (*Liasis olivaceus barroni*).

2.3.1.1 Northern Quoll (*Dasyurus hallucatus*)

The Northern Quoll (Plate 2.1) is listed as Schedule 1 under the WA *Wildlife Conservation Act 1950* and Endangered under the Commonwealth *EPBC Act 1999*. It is a carnivorous dasyurid marsupial, which formerly occurred across much of northern Australia but is now considered to be restricted to six broad areas, including the Hamersley subregion in the Pilbara (DSEWPaC 2011).

The Northern Quoll favours rocky gorges, rocky free faces and hills, usually of high relief, and secondarily favours drainage lines (Biota 2009a, DSEWPaC 2011). Adjacent plains and vegetated areas provide habitats suitable for foraging and dispersal of young (van Dyck and Strahan 2008), but are considered to be of less importance for the species' conservation.

Plate 2.1: Northern Quoll, *Dasyurus hallucatus.*

2.3.1.2 Orange Leaf-nosed Bat (*Rhinonicteris aurantius*)

The Orange Leaf-nosed Bat (Plate 2.2) is listed as Schedule 1 under the WA *Wildlife Conservation Act 1950* and Vulnerable under the Commonwealth *EPBC Act 1999*. It is a relictual monotypic genus of the family Hipposideridae. An isolated population is found in the Pilbara region of Western Australia (van Dyck and Strahan 2008), although the species' wider distribution also includes the Kimberley region of Western Australia, the Northern Territory and north-western Queensland (Churchill 2008).

Occurrence of this species is influenced by the availability of suitable roost caves that offer high humidity and a stable temperature (Churchill et al. 2008). In the Pilbara, they are thought to be restricted to caves where semi-permanent or permanent water is nearby. Foraging typically occurs over open grasslands in gorges, low hills and on plains (Churchill et al. 2008).

Plate 2.2: Orange Leaf-nosed Bat, *Rhinonicteris aurantius*.

2.3.1.3 Pilbara Olive Python (*Liasis olivaceus barroni*)

The Pilbara Olive Python (Plate 2.3) is listed as Schedule 1 under the WA *Wildlife Conservation Act 1950* and Vulnerable under the Commonwealth *EPBC Act 1999*. It has a known distribution that approximately coincides with the Pilbara bioregion (Environment Australia 2000, Department of the Environment 2015). It occurs in rocky areas, showing a preference for gorges containing water in streams and rock pools (Wilson and Swan 2010).

Plate 2.3: Pilbara Olive Python, *Liasis olivaceus barroni.*

2.3.2 SRE Terrestrial Invertebrates

SRE invertebrates are groups of invertebrate fauna that display naturally small distributions (less than 10,000 km^2; Harvey 2002) These invertebrates often possess similar ecological and life-history characteristics, and are in part characterised by low fecundity, slow growth and poor dispersal capabilities (Harvey 2002). Examples exist from a range of groups including freshwater snails (Ponder and Colgan 2002) land snails (Johnson et al. 2004), and mygalomorph spiders (Main et al. 2000).

SRE invertebrates are often confined to disjunct 'refugial' habitats, having persisted from a time when moist conditions were more evenly distributed throughout the Australian landscape (Harvey 2002). Given their predisposition to restriction at small spatial scales, SRE fauna are more likely to experience population extinctions than more widely distributed taxa (Harvey 2002). As a result, the assessment of SRE taxa is therefore an important component of EIA (EPA 2009).

2.4 Threatened and Priority Ecological Communities

2.4.1 Threatened Ecological Communities

Threatened Ecological Communities (TECs) are defined by the Western Australian Department of Parks and Wildlife as naturally occurring biological assemblages, located in a particular habitat, which are under threat of modification or destruction from various processes.

No TECs occur within the development envelope. The nearest mapped TEC, the "Themeda grasslands on cracking clays (Hamersley Station, Pilbara)", is located approximately 30 km northeast of the development envelope. There is no suitable habitat for this TEC in the development envelope (Biota 2014b).

2.4.2 Priority Ecological Communities

Priority Ecological Communities (PECs) are vegetation and/or fauna communities that are recognised to be of significance, but do not meet the criteria for a TEC. The only PEC in the locality is the "Brockman Iron cracking clay communities of the Hamersley Range", which is known from approximately 30 km to the northeast of the development envelope (Biota 2014b). There is no suitable habitat (clay plains) for this PEC in the development envelope.

The Fortescue Marsh is located approximately 30 km northeast of the development envelope. The Fortescue Marsh is the largest ephemeral wetland in the Pilbara and is listed in the Directory of Important Wetlands in Australia (Environment Australia 2001). It is listed by the Department of Parks and Wildlife as a Priority 1 PEC.

3.0 Approach and Methods

3.1 Surveys and Timing

The collated Yandi fauna data used in this report were sourced from 10 separate studies, many involving two survey phases. A summary of the studies, survey timing and supporting reports is provided in Table 3.1. The spatial extents of the supporting surveys are shown in Figure 2.2.

Details on the individual survey teams and weather conditions are provided in the relevant supporting reports listed in Table 3.1. Aside from one targeted Northern Quoll survey, all components of the development envelope were surveyed at least once during warm conditions (March, September or October (Table 3.1). This timing was optimal from the survey adequacy perspective, particularly March sampling which occurred in months following summer rain. A summary of the survey methods used and combined sampling effort is provided in Section 3.2.

Table 3.1: Summary of Yandi surveys contributing to the collated data set.

Study (Reference)	Job Code	Survey Timing
Junction Deposit Mine and the Central Pilbara Transport Corridor (Ninox Wildlife Consulting 1994)	JDM	March 1994
Hope Downs Rail Corridor Extension - Hamersley Range (Biota 2004)	HDR	April 2003
Yandi Junction South East (Biota 2005)	JSE	August 2004
Yandicoogina Targeted Quoll Survey (Biota 2009b)	YNQ	October 2009
Yandi Junction South West (Biota 2010a)	JSW	Phase I: July 2008 Phase II: March 2010
Yandi Oxbow (Biota 2010a)	YOX	Phase I: July 2008 Phase II: March 2010
Yandi Billiards (Biota 2010a)	BIL	Phase I: July 2008 Phase II: March 2010
Yandi Billiards Targeted Quoll Survey (Biota 2014c)	YBNQ	August 2014
Pocket and Billiards South (Biota 2014a, 2014d)	PBS	Phase I: March 2014 (Biota 2014d) Phase II: September 2014 (Biota 2014a)
Yandi Oxbow E8 (Biota 2014e)	YOXE8	Phase I: September 2014

Other relevant reports that were reviewed but did not contribute additional data comprised:

- Yandicoogina Expansion Northern Quoll Position Paper (Biota 2010b);
- Yandi Billiards Terrestrial Fauna, Flora and Vegetation Desktop Assessment (Biota 2014f); and
- Yandi Billiards Interim Report on Conservation Significant Fauna (Biota 2014g).

3.2 Summary of Survey Methods

The fauna surveys completed at Yandi comprised a combination of systematic sampling and other methodologies (Sections 3.2.1 and 3.2.2). All sampling work was completed in accordance with relevant EPA and *EPBC Act 1999* policy, specifically:

- EPA Position Statement No. 3: "Terrestrial Biological Surveys as an Element of Biodiversity Protection" (EPA 2002);
- EPA Guidance Statement No. 56: "Terrestrial Fauna Surveys for Environmental Impact Assessment in Western Australia" (EPA 2004);
- EPA Guidance Statement No. 20: "Sampling of Short Range Endemic Invertebrate Fauna for Environmental Impact Assessment in Western Australia" (EPA 2009);

- Technical Guide - Terrestrial Vertebrate Fauna Surveys for Environmental Impact Assessment (EPA and DEC 2010); and
- *EPBC Act 1999* referral guidelines for the endangered northern quoll, *Dasyurus hallucatus* (DSEWPaC 2011).

3.2.1 Terrestrial Vertebrates

The systematic census component of the fauna surveys primarily comprised trapping transects. Each trap line was located within an identified landform and comprised:

- Pit lines: a single row of 10 pitfall traps arranged as alternating 20 litre buckets and 150 mm diameter x 600 mm high PVC tubes, spaced at approximately 10 m intervals and connected with a 90 m length of 300 mm high flywire fence (see Figure 3.1).
- Elliott lines: trapping transects consisting of a combination of medium and large Elliott box traps spaced at approximately 10 m to 15 m intervals (between 18 and 50 traps per line). Elliott traps were baited with a universal bait mixture of peanut butter and oats.
- Funnel lines: funnel traps placed in pairs at approximately 10 m intervals adjacent to a 100 m length of 300 mm high fly wire fence (see Figure 3.2).

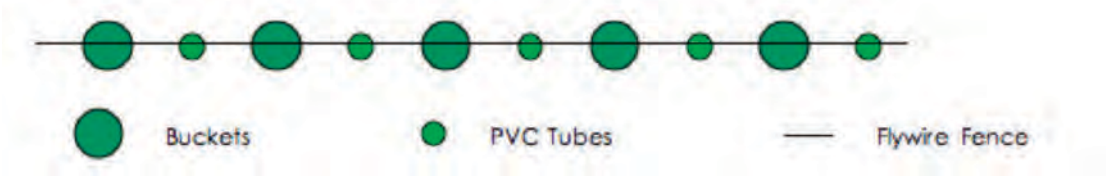

Figure 3.1: Layout of pit trapping transects.

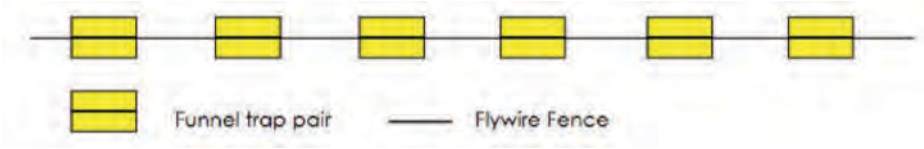

Figure 3.2: Layout of funnel trapping transects.

Pit trap lines sample the majority of the ground fauna with smaller body size, and were used in all accessible habitats across the development envelope. Funnel traps were used in selected locations where hard substrates made pit installation impractical, and were most effective at sampling snakes, legless lizards and geckos. Elliott traps were used primarily to target *Dasyurus hallucatus* (Northern Quoll) in areas prospective for this species (rocky gorges and breakaways).

3.2.1.1 Avifauna Sampling

Avifauna sampling during the surveys used a combination of techniques including:

- unbounded area searches (30-40 minutes duration) conducted at systematic trapping sites;
- unbounded area searches at opportunistic locations in habitats likely to support previously unrecorded species; and
- opportunistic observations of birds.

Individual censuses were confined to discrete landforms, typically corresponding to vegetation type at each trapping site. Censuses were usually conducted between 6:00 am and 11:00 am. Bird species were identified by sight or call.

3.2.1.2 Bat Sampling

Bat sampling was undertaken during the surveys using Anabat SD2 (Titley Scientific, NSW) and SM2 SongMeter (Wildlife Acoustics Inc, USA) echolocation call recorders, in addition to the direct capture method of harp traps. Sampling equipment was placed in locations considered likely to

provide records of a range of species, including at cave or rock shelter entrances, adjacent to standing water or in potential flyways through vegetation.

Echolocation calls were recorded continuously at all sites using either an LS-10 Professional PCM Recorder (Olympus, Japan) in conjunction with the Anabat SD2 unit, or using an SM2 SongMeter. COOL EDIT 2000 software (Syntrillium) was used to display continuous call sequences for identification. Calls were analysed using methods recommended by the Australasian Bat Society (2006) in conjunction with available reference data (Bullen and McKenzie 2002, McKenzie and Bullen 2003, 2009). Only sequences containing good quality search phase calls were considered for identification.

3.2.1.3 Non-Systematic Sampling of Vertebrate Fauna

Non-systematic fauna sampling was also undertaken to supplement trapping and investigate additional habitats and microhabitats identified during the course of the surveys. This included:

- searches of specific habitats, including plains, rocky gorge free faces and pools or streams, for Schedule and Priority listed fauna species;
- searching of microhabitats for reptile, frog and small mammal species not commonly recorded through trapping (e.g. by raking leaf litter and turning rocks and logs);
- opportunistic sightings;
- nocturnal work including road spotting and head-torching;
- identification of road kills and other animal remains found during the surveys;
- recording and identification of secondary trace signs (where possible) including tracks, scats and diggings; and
- the use of remote infrared cameras (Bushnell cameras) which are triggered by movement.

3.2.1.4 Nomenclature

Species nomenclature for herpetofauna and mammals follows the standards of the Western Australian Museum (WAM) fauna taxonomic checklist, in accordance with the requirements of the EPA and DEC (2010). Avifauna nomenclature used also meets this guidance and follows Christidis and Boles (2008).

3.2.2 Short Range Endemic Fauna

Sampling of the development envelope for SRE fauna involved both systematic (pit-trap transects) and non-systematic (targeted searching) sampling methods. Full details of terrestrial fauna sampling methods and sampling effort are provided in the source reports listed in Section 3.1, with a summary overview of the components relevant to SRE fauna provided below.

The relevant surveys targeted those invertebrate groups with the potential to contain SREs that were considered most likely to occur in the development envelope:

- Mygalomorphae (trapdoor spiders);
- Diplopoda (millipedes);
- Scorpiones (scorpions);
- Pseudoscorpiones (pseudoscorpions); and
- Pulmonata (land snails).

Pit traps were checked on a daily basis as part of the terrestrial vertebrate fauna surveys, during which time potential SRE fauna specimens were collected and curated in accordance with the procedures in Sections 3.2.2.1 to 3.2.2.5.

Targeted searching for potential SRE fauna was also conducted. These searches actively targeted microhabitats for invertebrate groups considered likely to support SRE taxa.

3.2.2.1 Mygalomorph Spiders

Mygalomorph spider burrows were located visually and were photographed prior to excavation. Holes were dug adjacent to each burrow, allowing the burrow to be followed down with forceps until the spider was located. One leg of each spider collected was removed and placed in 100% ethanol to provision for molecular studies, while the remainder of each spider was preserved in 70% ethanol for morphological studies.

3.2.2.2 Millipedes

Millipedes were located by raking through leaf litter and debris. All specimens collected were preserved in 70% ethanol.

3.2.2.3 Scorpions

Visual searches for scorpion burrows were conducted and scorpions were collected opportunistically while searching under rocks and raking through soil and leaf litter. Specimens were preserved in 70% ethanol.

3.2.2.4 Pseudoscorpions

Searches for pseudoscorpions were conducted by:

- searching on trees and beneath bark;
- searching under rocks;
- raking soil and leaf litter; and
- sieving soil and leaf litter.

Specimens were preserved in 70% ethanol.

3.2.2.5 Snails

Searches for land snails were conducted by:

- excavating leaf litter and soil around the base of spinifex (*Triodia* spp.) hummocks;
- searching under rocks and in rock crevices; and
- sieving soil and leaf litter.

Live free-sealing species were stored in calico bags for later preservation in ethanol for morphological analysis in Perth or lodgement with the WAM.

3.3 Sampling Effort

3.3.1 Systematic Trapping Sites

The systematic sampling effort conducted within the Yandi development envelope comprised 54 trapping sites as outlined in (Table 3.2) and depicted in Figure 3.3. Details of all systematic fauna sampling sites are provided in Appendix 1.

Table 3.2 Summary of Yandi survey systematic vertebrate trapping sites.

Study (Reference)	Job Code	Number and Types of Sites	Total Trap Nights	Site Code
Junction Deposit Mine and the Central Pilbara Transport Corridor (Ninox Wildlife Consulting 1994)	JDM	7 (7 pit/Elliott trap lines)	1,092	FS
Hope Downs Rail Corridor Extension Hamersley Range (Biota 2004)	HDR	4 (3 funnel and pit trap lines)	235	HDD HAC
Yandi Junction South East (Biota 2005)	JSE	0 (Desktop exercise and targeted invertebrate sampling only)	na	YEX

Study (Reference)	Job Code	Number and Types of Sites	Total Trap Nights	Site Code
Yandicoogina Targeted Quoll Survey (Biota 2009b)	YNQ	8 (8 Elliott trap lines)	1,186	YNQ
Yandicoogina Junction South West Fauna Survey (Biota 2010a)	JSW	5 (3 pit trap lines; 1 Elliott trap line; 1 funnel trap line	400	YAN
Yandicoogina Oxbow Fauna Survey (Biota 2010a)	YOX	6 (3 pit trap lines; 1 Elliott trap line, 1 funnel trap line)	693	OXB
Yandicoogina Expansion Billiard Deposit Fauna Survey (Biota 2010c)	BIL	8 (6 pit trap lines; 2 funnel traps lines)	600	BIL
Yandi Billiards Targeted Northern Quoll Survey (Biota 2014c)	YBNQ	5 (5 combination Elliott/cage trap lines)	862	YBQ,
Pocket Billiards South (Biota 2014d)	PBS	11 (5 pit trap lines; 4 funnel trap lines; 2 Elliott trap lines)	2,070	YBL

Sampling periods typically ranged from six to seven nights, and four surveys comprised multiple sampling phases (Section 3.1). The sampling collectively represented 7,138 trap nights of systematic effort in the Yandi development envelope (i.e. the number of traps multiplied by the number of nights that traps were active; see Table 3.2). Further details on individual site opening and closure dates and other specifics are provided in the respective source survey reports cited in Appendix 1.

The Pilbara bioregion is broadly mapped into land system units, which are defined on the basis of a combination of geomorphology, hydrology, soils and vegetation (van Vreeswyk et al. 2004). The distribution of survey sites within the land systems of the Yandi development envelope is shown in Figure 3.3.

The development envelope was spatially dominated by the Newman, McKay, Boolgeeda and River land systems (see Section 4.1). The majority of the systematic survey effort was expended in these units (Table 3.3). The majority of sampling was conducted on the Boolgeeda and River land systems due to their dominance in the individual areas surveyed (Figure 2.2), in combination with development envelope accessibility. All land systems except Rocklea (which comprised only 0.3% of the development envelope) were sampled during the combined surveys.

Table 3.3: Number of systematic trapping sites within land systems in the Yandi development envelope.

Land System	No. of Systematic Trapping Sites	Hectares within Development envelope	Proportion of Development envelope (%)
Newman	5	5,790	29.9
McKay	6	5,282	27.3
Boolgeeda	16	3,760	19.4
River	20	3,264	16.9
Robe	5	706	3.6
Urandy	2	496	2.6
Rocklea	0	53	0.3
Total	54	19,351	100.0

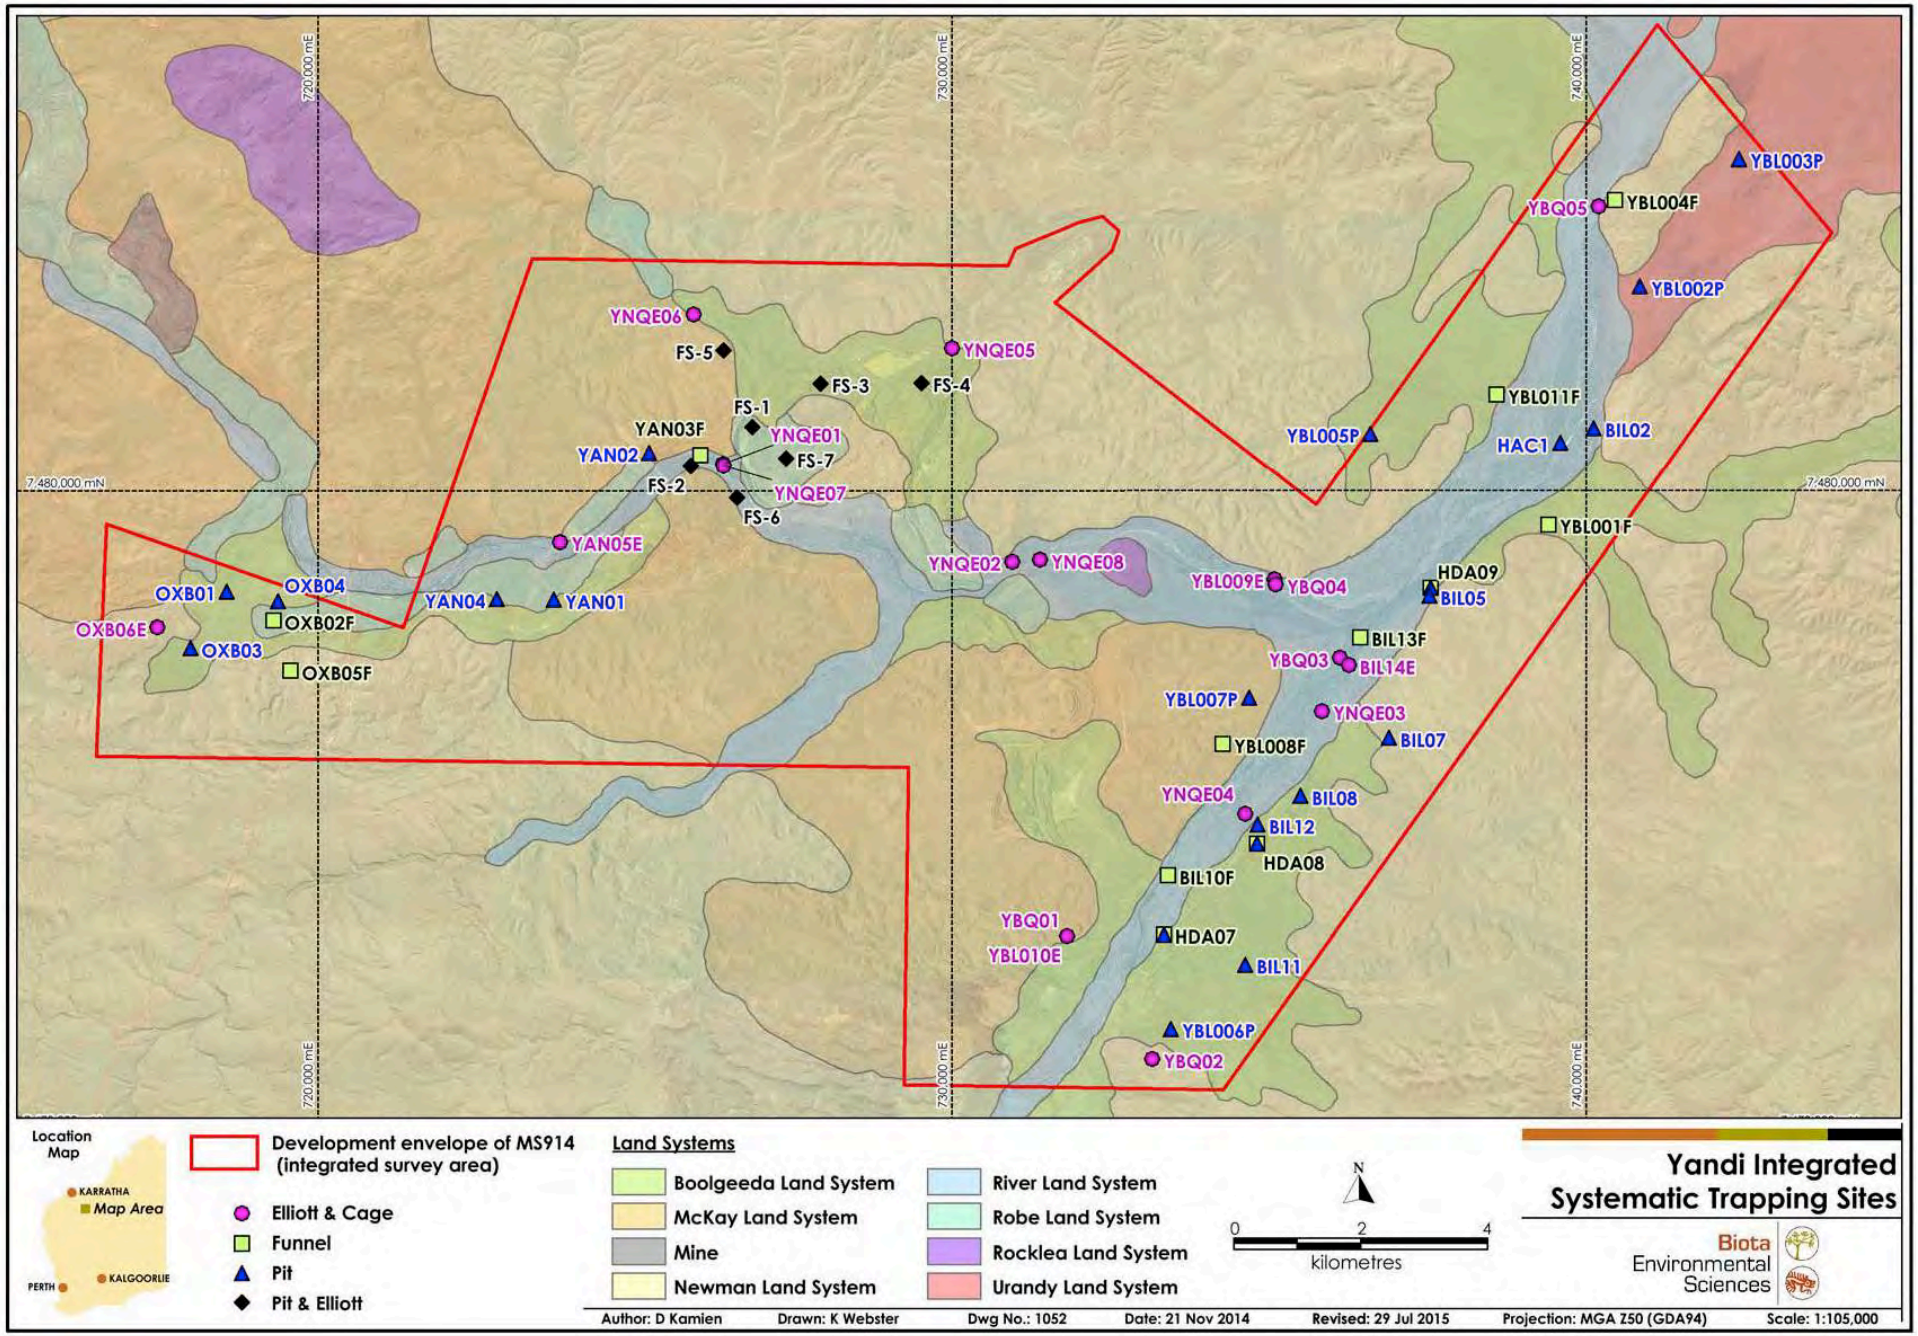

Figure 3.3: Systematic fauna trapping sites and land systems in the development envelope.

3.3.2 Avifauna Sampling

Systematic avifauna censuses were conducted at the majority of fauna trapping sites resulting in good spatial coverage across all components of the development envelope (Table 3.4 and Figure 3.3). A summary of avifauna survey effort is provided in Table 3.4.

Avifauna censuses were carried out at a total of 49 sites across the development envelope, and the census time from all phases of survey work totalled approximately 107 hours (6,410 minutes). Details of the avifauna censuses, including the exact times and dates censuses were carried out, can be found in the individual source reports listed in Table 3.4.

Table 3.4: Summary of Yandi avifauna census sites.

Study (Reference)	Job Code	Number of Sites	Total Census Time (mins)
Junction Deposit Mine and the Central Pilbara Transport Corridor (Ninox Wildlife Consulting 1994)	JDM	7	1,890
Hope Downs Rail Corridor Extension Hamersley Range (Biota 2004)	HDR	14	1,840

Yandi Billiards Targeted Northern Quoll (Biota 2014a, 2014c)	YBNQ	na	na
Pocket and Billiards South (Biota 2014a)	PBS	11	1,470

"na" indicates avifauna survey not conducted.

3.3.3 Non-systematic Sites

3.3.3.1 Bat Sites

Bat sampling was conducted in areas deemed mostly likely to yield bat records (Section 3.2.1.2). This effort was therefore focused in the rocky free-face landforms, particularly where caves or other potential roost site features were present in gorges, and along larger drainages, particularly where permanent water pools were present (Figure 3.4 and Appendix 1). Bat sampling effort totalled 62 survey nights across 21 sites as summarised in Table 3.5.

Table 3.5: Summary of Yandi bat survey sites.

Study (Reference)	Job Code	Number of Sites	Total Evenings Monitored
Junction Deposit Mine and the Central Pilbara Transport Corridor (Ninox Wildlife Consulting 1994)	JDM	opportunistic	na
Hope Downs Rail Corridor Extension Hamersley Range (Biota 2004)	HDR	4	16

Yandi Billiards Targeted Northern Quoll (Biota 2014a, 2014c)	YBNQ	6	18
Pocket and Billiards South (Biota 2014a)	PBS	8	18

"na" indicates bat survey not conducted.

3.3.3.2 Motion Camera Sites

Motion cameras were deployed during two studies within the development envelope (Table 3.6).

Table 3.6: Summary of Yandi motion camera sites.

Study (Reference)	Job Code	Number of Sites	Total Evenings Monitored
Yandi Billiards Targeted Northern Quoll Survey (Biota 2014c)	YBNQ	7	22
Pocket Billiards South (Biota 2014d)	PBS	5	17

3.3.4 Short Range Endemic Fauna Sampling

In addition to pit traps (Section 3.3.1), a minimum of 42 sites were non-systematically searched for potential SRE fauna. In many of the historical surveys, SRE searches were conducted opportunistically and the exact search effort was not recorded (Table 3.7). The spatial extent of recorded SRE searches is depicted in Figure 3.5.

Table 3.7: Summary of non-systematic SRE sampling effort within the Yandi development envelope.

Survey (Reference)	Job Code	Number of Search Sites	Search Effort (mins)
Junction Deposit Mine and the Central Pilbara Transport Corridor (Ninox Wildlife Consulting 1994)	JDM	na	na
Hope Downs Rail Corridor Extension Hamersley Range (Biota 2004)	HDR	Opportunistic	na
Yandi Junction South East (Biota 2005)	JSE	12	na
Yandicoogina Targeted Quoll Survey (Biota 2009b)	YNQ	na	na
Yandicoogina Expansion Billiard Deposit Fauna Survey (Biota 2010c)	BIL	Opportunistic	na
Yandicoogina Oxbow Fauna Survey (Biota 2010a)	YOX	Opportunistic	na
Yandicoogina Junction South West Fauna Survey (Biota 2010a)	JSW	Opportunistic	na
Yandi Billiards Targeted Northern Quoll (Biota 2014a, 2014c)	YBNQ	4	980
Pocket and Billiards South (Biota 2014a)	PBS	23	2,705
Yandi Oxbow E8 (Biota 2014e)	YOXE8	3	95

na - indicates SRE survey not conducted.

Opportunistic indicates that dedicated SRE survey sites were not established.

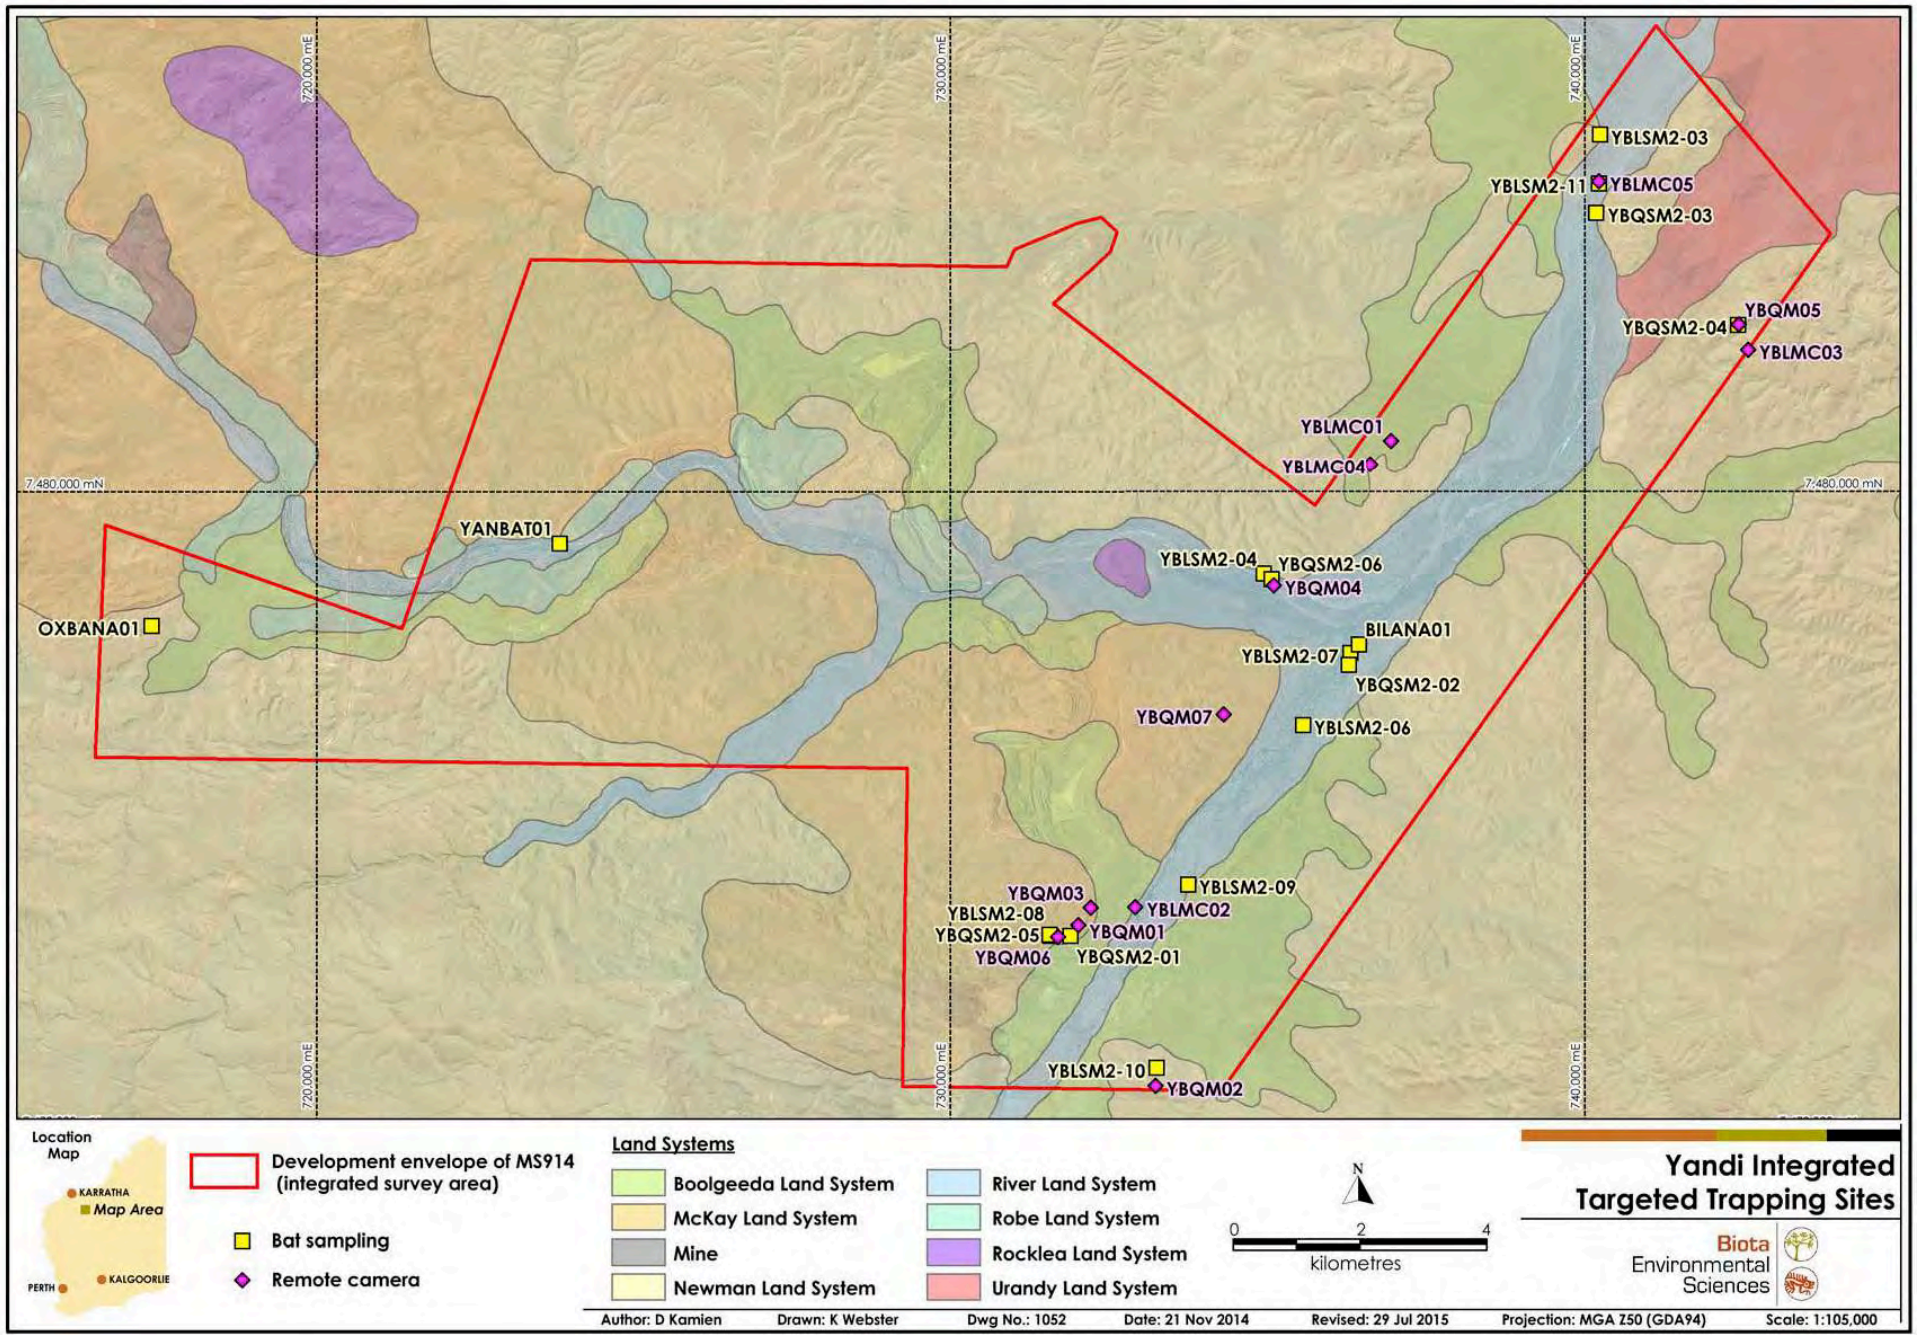

Figure 3.4: Non-systematic fauna sampling sites and land systems in the development envelope.

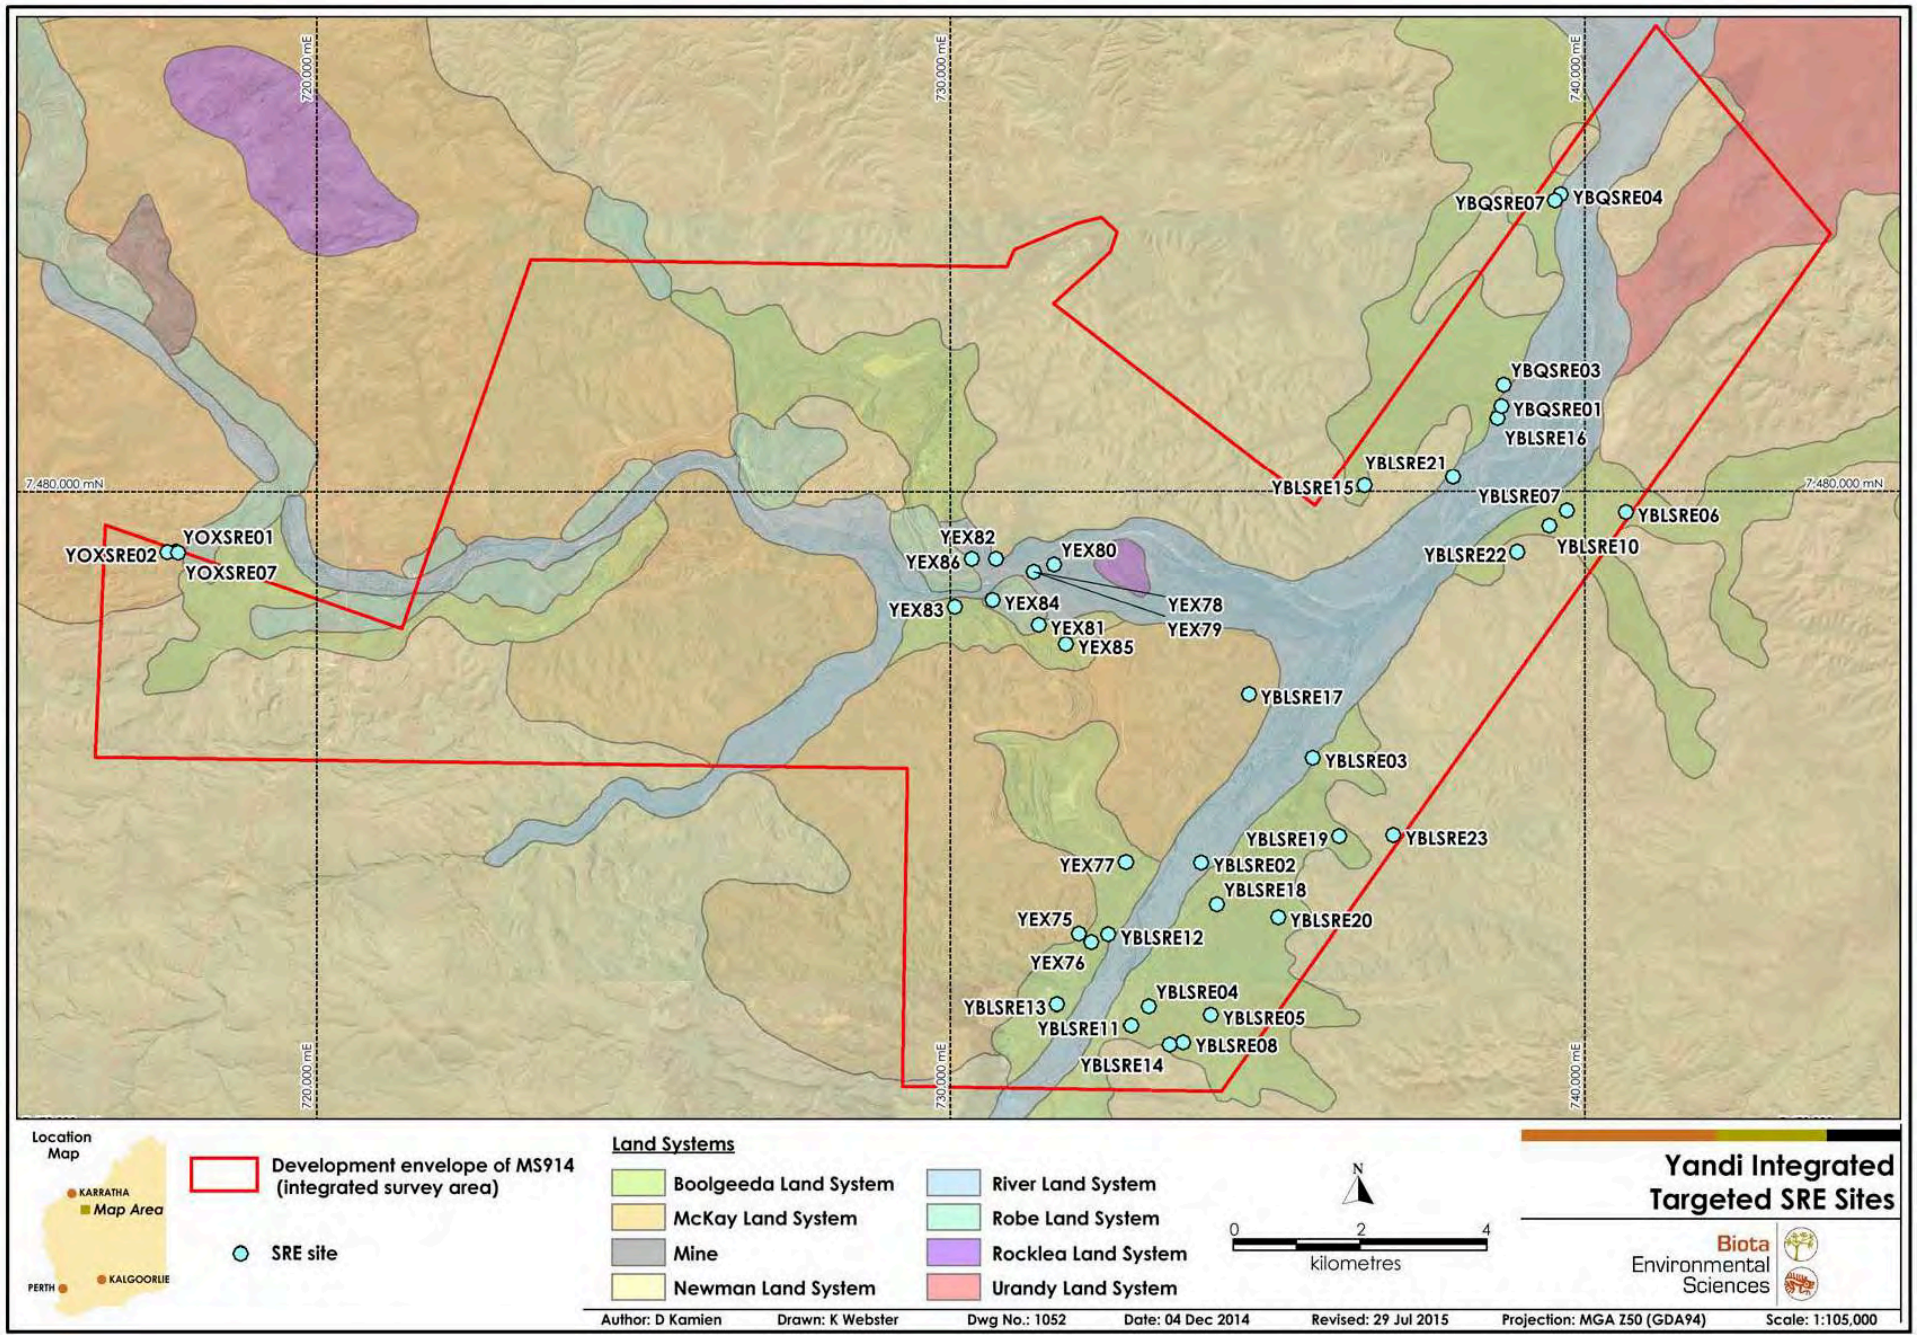

Figure 3.5: SRE fauna sampling sites and land systems in the development envelope.

3.4 Identification and Data Analysis

3.4.1 Vertebrate Assemblage and Habitat Analysis

The combined fauna data set was analysed using PRIMER v6.1 (Clarke and Gorley 2006). Excluding species accumulation curves, records were screened to remove data with the potential to bias the results. The following records were excluded from the analyses:

- opportunistic records that represented chance events and were not derived from equivalent sampling methods across sites;
- records from Elliott traps and Funnel traps for herpetofauna analysis, as these traps typically target specific mammal species;
- large body-size species that would not have been adequately sampled by the trapping sites (such as *Varanus panoptes and Pseudechis australis*), even when sightings occurred at systematic trap sites (i.e. not purely opportunistic records); and
- frog species, as they are prone to large abundance peaks following wet weather conditions, which can skew site resemblance analyses.

Bat records were also excluded from all data analysis including species accumulation analysis as these were determined by echolocation recordings, which cannot be used to calculate abundance.

The screened site by species matrix for each of the faunal groups was imported into PRIMER and square-root transformed to reduce the influence of high abundance species on the similarity analyses. A resemblance matrix was then constructed using the Bray-Curtis similarity index, which produces a similarity value for all pairs of sites based on species representation and transformed abundances. This was then used to generate a non-metric Multi-Dimensional Scaling (NMDS) plot to assist with visualising the groupings amongst the sites based on faunal composition. A 30% similarity level was used to inform assemblage groupings in correspondence with Similarity Profiles (SIMPROF) test results.

Habitat parameters for each site were imported into PRIMER, which comprised:

- surface geology (Thorne and Trendall 2001);
- land system (van Vreeswyk et al. 2004); and
- landform (as documented in the field by the survey zoologists; Section 4.1).

The NMDS plots were coded with various habitat factors to identify any relationships between them and the species assemblages. The consolidated outputs of this approach were then used to define habitats and matching faunal assemblages for the development envelope. Where appropriate, and where the data allowed, Similarity Percentages (SIMPER) analysis was also run in PRIMER to identify the individual faunal species that best characterised and typified each the assemblages.

3.4.2 Species Accumulation

Plots of species accumulation curves and trends in the resultant curves over time can be used to assess sampling adequacy. When a survey has sampled an adequate proportion of the faunal community, the curve should plateau and approach asymptote. PRIMER v6.1 was again used to calculate smoothed species accumulation curves based on 999 random permutations of the species data. Actual observed accumulation curves were also plotted (see Section 4.7).

Species accumulation curves alone cannot be reliably used to extrapolate predicted species richness for future biological sampling. In order to estimate asymptotic richness (i.e. extrapolation of species richness), asymptotic estimators were used (Clarke and Gorley 2006):

- Bootstrap estimator;
- Chao 1 richness estimator; and
- Jack-knife richness estimator.

3.4.3 Short Range Endemic Fauna

3.4.3.1 Morphological Identifications

Collected specimens were lodged at the WAM for taxonomic identification by the following specialists: Corey Whisson (land snails), Mieke Strong and Dr Mark Harvey (pseudoscorpions), and Julianne Waldock (araneomorph spiders). Tissue samples from mygalomorph spiders were lodged with Helix Molecular Solutions (Helix) for molecular analysis, with the remainder of each specimen being lodged with the WAM.

3.4.3.2 Genetic Analysis of Mygalomorph Spiders

Mygalomorph spiders are commonly recorded in the Pilbara bioregion, however very few of these have been resolved to the species level (source: Biota internal database). This report makes use of a broad genetic study into mygalomorph spiders to help infer putative species boundaries and better identify distributions.

Helix carried out the relevant molecular analysis. Sequence data derived from the WAM's collection was used to assign specimens collected from the Yandi development envelope to lineages based on Bayesian analysis of COX1 haplotypes. Previous assessments have been provided based on combining samples into species if they show less than 9.5% sequence divergence (Biota 2012a). This value was discussed with Dr Terrie Finston (Helix) and Dr Mark Harvey (WAM) as a suitably conservative threshold for identifying likely species.

3.4.3.3 Determining SRE Status

Table 3.8 details the criteria used to determine the SRE status of putative species for the purposes of this report.

Table 3.8: Criteria used to determine SRE status.

SRE Status	Defining Criteria
Known SRE	• Species, morphotype or genetic type has a documented range of <10,000 km^2. • Species, morphotype or genetic type is well collected with numerous specimens typed and habitat preference understood.
Potential SRE	• Species, morphotype or genetic type has a documented range of <10,000 km^2 but is poorly sampled. • Specimen may not be formally described or assigned to a morphotype / genetic type. • Short-range endemism may be common in genus or family. • May have been collected from restricted, refugial or isolated habitats.
Unlikely to be an SRE	• Species, morphotype or genetic type has a documented range of <10,000 km^2 but is poorly sampled. • Specimen may not be formally described or assigned to a morphotype / genetic type. • Short-range endemism is not common in genus or family. • Taxon was not collected from restricted, refugial or isolated habitats. • Few other individuals of the taxon collected, but records are separated by long distances (>100 km).
Not an SRE	• Specimen formally described or assigned to a morphotype / genetic type. • Species, morphotype or genetic type has a documented range of >10,000 km^2.
Undetermined	• Taxa where there is insufficient taxonomic framework available to provide any informed comment on the species-level distribution of the fauna or, therefore, the risk of small-scale spatial restrictions.

3.5 Study Team

Overarching fauna assessments of the Yandi development envelope were coordinated by Garth Humphreys and Roy Teale of Biota. Individual survey field team leaders comprised Roy Teale, Dan Kamien, Dr Phil Runham and Dr Stewart Ford (all of Biota). Consistent with regulatory guidelines (EPA and DEC 2010), the team members of the individual surveys are detailed in Table 3.9.

Analysis of bat call recordings was completed by Mr Bob Bullen (Bat Call WA). Paul Sawers, Ash Brown, Melissa Robinson and Kylie Webster (Biota) completed all Geographical Information System analyses and map preparation for the study.

Table 3.9: Details of the Yandi fauna assessment teams and their participation in the source field surveys.

3.6 Limitations

As this report collates data from source studies, the limitations that apply to each of those studies also apply here. The primary limitations comprise the following:

Vertebrate Fauna

- The habitats within each development envelope were not equally sampled, and sampling effort was not equal amongst the contributing surveys.
- Biases in individual sampling methods may influence richness estimates. For example, Elliott trapping is typically unreliable in sampling herpetofauna, and funnel traps are unreliable in sampling mammals.
- Not every section of the development envelope was ground-truthed or systematically sampled. Parts of the development envelope were inaccessible by vehicle, so installation and regular checking of fauna traps in these areas would not have been possible. Systematic fauna sampling was, however, completed in all habitats considered to represent the range of landforms and land units present in the development envelope (see Table 3.3).
- Targeted trapping of the Northern Quoll *Dasyurus hallucatus* before 2011 was not conducted in accordance with the *EPBC Act 1999* referral guidelines for this species ("EPBC Act policy statement 3.25" (DSEWPaC 2011)).
- Combined data were obtained from surveys undertaken in different seasonal conditions and by different survey teams. This may have confounded the SIMPER analyses results.

SRE Fauna

- Many groups containing SREs do not have a complete taxonomic framework, and there is insufficient taxonomic expertise for many potential SRE invertebrate groups.
- Many taxa are difficult to sample adequately (e.g. mygalomorph spiders are difficult to locate, and morphological identification requires male specimens, which can generally only be collected immediately after rainfall).
- Not all sections of the development envelope were equally ground-truthed or sampled for fauna, as parts of the development envelope were inaccessible. However, SRE fauna searches and sampling were conducted in habitats considered to be representative of the range of units present within the development envelope.
- The survey data presented here and related interpretations are based on reference information available at the time of completing this report. Other genetic sequencing of SRE fauna from the Pilbara bioregion is ongoing and comparisons with records beyond the development envelope have only been made based upon current data. Any significant changes to contextual information affecting the findings may be addressed through the supply of supplementary information or a future revision of this report.

4.0 Results

4.1 Fauna Habitats Framework

Several aspects of fauna habitats were examined in this study, including:

- regional geology;
- land systems; and
- landforms.

The geology of the development envelope was broadly typical of this area of the Pilbara bioregion (Thorne and Trendall 2001). The surface geology of the development envelope is dominated by both young alluvial formations (Qa) and ancient banded iron formations (PLHj) (Table 4.1).

Table 4.1: Surface geology units of the development envelope.

Geological Time Scale				Description	Area (ha)
Eon	Era	Period	Unit		
Phanerozoic	Cenozoic	Quaternary	Qa	Alluvium: unconsolidated silt, sand, and gravel in drainage channels and adjacent floodplains	4,225.8
			Qs	Eolian deposit: sand in sheets and longitudinal dunes.	1.3
			Qw	Alluvium and colluvium: red-brown sandy and clayey soil on low slopes and sheetwash areas.	826.0
		–	Czc	Colluvium: partly consolidated quartz and rock fragments in silt and sand matrix; old valley-fill deposits; locally derived.	3,443.7
			Czk	Calcrete: sheet carbonate, found along major drainage lines.	340.6
			Czp	Robe Pisolite: pisolitic limonite deposits developed along river channels.	808.2
			Czr	Hematite-goethite deposits on banded iron-formation and adjacent scree deposits.	8.5
Proterozoic	–	–	PLHb	Brockman Iron Formation: banded iron formation, chert, and pelite.	637.5
			PLHj	Weeli Wolli Formation: banded iron-formation (commonly jaspilitic), pelite, and numerous metadolerite sills.	9,059.6

The development envelope was dominated by four land systems (van Vreeswyk et al. 2004): Newman. McKay, Boolgeeda and River, which together accounted for 93.5% of the area (Table 4.2). The descriptions of these land systems therefore broadly characterise the habitats of the development envelope:

- Newman – rugged jaspilite plateaus, ridges and mountains supporting hard spinifex grasslands;
- McKay – hills, ridges, plateau remnants and breakaways of metasedimentary and sedimentary rocks supporting hard spinifex grasslands;
- Boolgeeda – stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands; and
- River – active flood plains and major rivers supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands.

The land systems of the development envelope are mapped in Figure 3.3, with their wider extent in the immediate locality also shown for context.

Table 4.2: Land systems occurring within the development envelope.

Land System	Extent in Development envelope	Proportion of Development envelope	Extent within Hamersley Subregion	Percent of Land System in the Subregion Occurring in the Development envelope
Newman	5,791 ha	29.9%	1,853,935 ha	0.31%
McKay	5,282 ha	27.3%	80,718 ha	6.54%
Boolgeeda	3,760 ha	19.4%	606,771 ha	0.62%
River	3,264 ha	16.9%	72,628 ha	4.49%
Robe	706 ha	3.6%	103,116 ha	0.68%
Urandy	496 ha	2.6%	42,024 ha	1.18%
Rocklea	53 ha	0.3%	711,645 ha	0.01%

Broad fauna landscape units were also documented for the development envelope, with common landform units and substrate types standardised across the various surveys (Section 3.4.1). Three broad landscapes were identified within the development envelope, with varying representation amongst the source development envelopes (Table 4.3).

Table 4.3: Broad fauna habitat landscape units and survey effort.

Landscape	Number of Survey Sites †								
	JDM	HDR	JSE	YNQ	JSW	YOX	BIL	YBNQ	PBS
Contemporary drainage systems of alluvial deposits with gently inclined slopes to flat land, below hills and raised plains.	2	2	na	6	2	–	5	3	1
Gently sloping lower slopes, stony plains and level alluvial plains.	4	2	na	2	2	4	3	–	6
Mountainous rugged terrain comprising ridges, plateaus, steep hills with free faces and stream channels.	1	–	na	–	1	2	1	2	4

† See Table 3.1 for explanation of job codes.

Within these landscapes, eight landforms were identified from the development envelope using Biota's fauna landscape approach (Biota 2013a), which adopts an amalgamation of landform patterns and specific landform elements that are considered to represent suitable habitats for species, and in particular, species of conservation significance. The identified landforms are comprise:

- major drainage lines (rivers) containing permanent water, with varying substrates including alluvium, clay loam, rock and sandy loams;
- minor ephemeral drainage lines (creeks);
- alluvial plains with clay loam substrate;
- plains with varying substrates including calcrete, loam and clay loams;
- pediment slopes covered with stony loams;
- hillslopes and hillcrests, mostly covered with stony loams or exposed rock;
- free faces with associated debris slope (gorges) on exposed rock; and
- breakaways adjacent to drainage lines.

A map depicting a broad overview of combined landforms is depicted in Figure 4.1). Sites surveyed within each landform are summarised in Table 4.4 with representative landforms provided in Plate 4.1 to Plate 4.8.

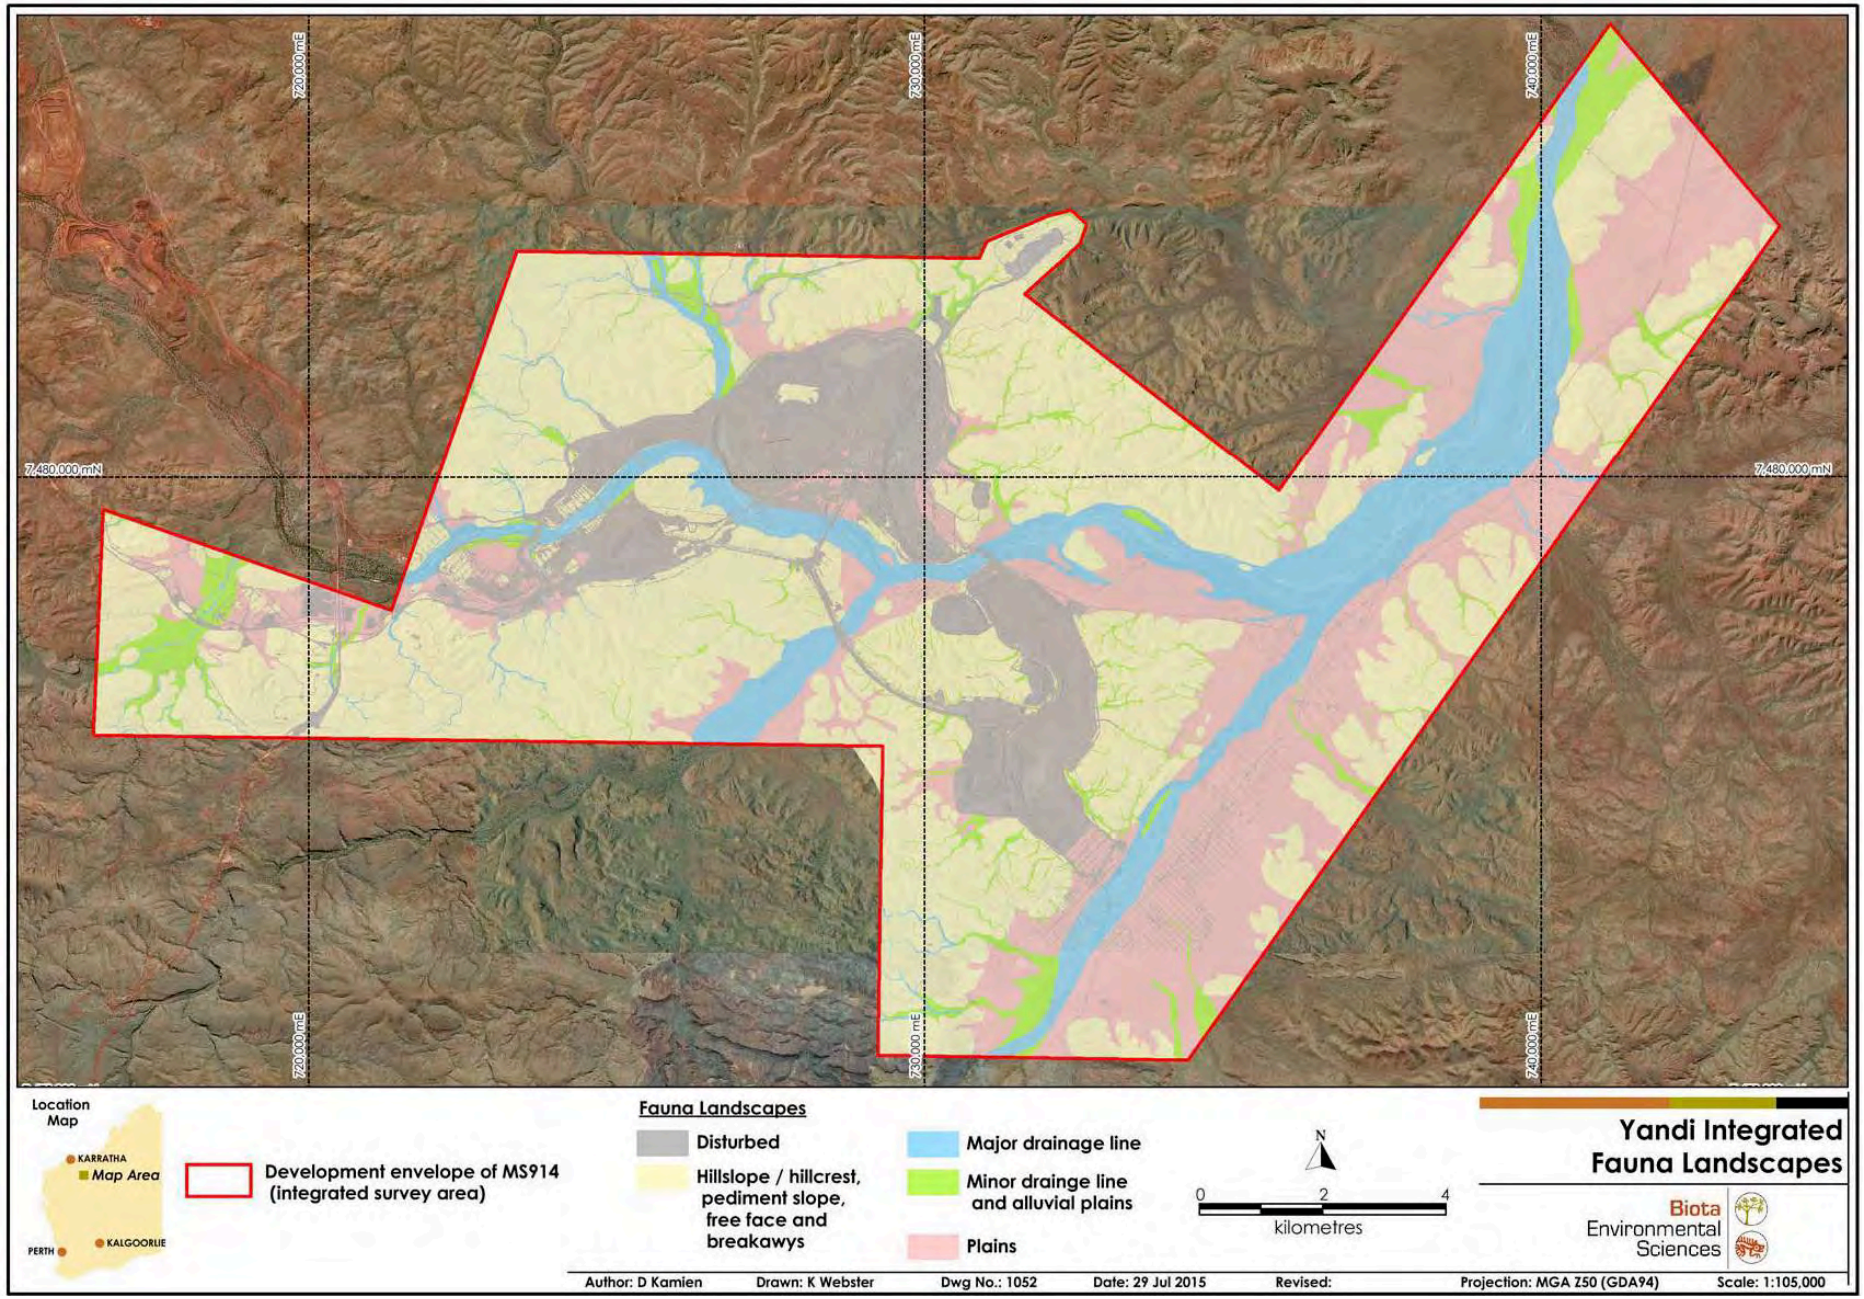

Figure 4.1: Map depicting broad landforms overview

Table 4.4: Landforms and systematic sampling sites within the development envelope.

Landform	No. of Sites	Survey Sites

4.2 Overview of the Fauna

A total of 206 vertebrate fauna species were recorded from the development envelope during the surveys, comprising three amphibians, 69 reptiles, 103 avifauna species, 15 native ground mammals, 10 bats and six introduced mammals (see Appendix 2). A summary of the number of species from each major vertebrate group recorded for each project component, and the development envelope as a whole, is provided in Table 4.5.

Table 4.5: Vertebrate fauna recorded in the Yandi integrated development envelope.

	Number of Species †									
Fauna Group	JDM	HDR	JSE	YNQ	JSW	YOX	BIL	YBNQ	PBS	Development envelope
Amphibians	2	1	na	1	0	0	2	0	3	3
Reptiles	27	16	na	5	8	8	8	1	59	69
Native non-volant mammals	6	3	na	2	2	3	3	5	14	15
Introduced mammals	4	0	na	1	2	0	2	1	3	6
Bats	3	na	na	na	5	4	3	10	9	10
Avifauna	71	64	na	na	42	24	44	3	93	103
"na" indicates taxon search not conducted									Total	206

† See Table 3.1 for explanation of job codes.

A desktop survey (Biota 2013b) indicated that there is the potential for 249 species to occur within the development envelope. The observed species richness of the development envelope comprises almost 83% of this total.

4.3 Herpetofauna

A total of 72 herpetofauna species were recorded from the development envelope comprising three frog species and 69 reptiles. Reptile species comprised six dragons (family Agamidae), 12 geckos (Gekkonidae, Diplodactylidae and Carphodactylidae), seven legless lizards (Pygopodidae), 27 skinks (Scincidae), eight monitors (Varanidae), two blind snakes (Typhlopidae), two pythons (Boidae) and six front-fanged snakes (Elapidae).

The gecko *Diplodactylus conspicillatus* (n=77 individuals) and the skinks *Ctenotus duricola* (n=68) and *Ctenotus saxatilis* (n=59) were the most abundant herpetofauna species recorded in the development envelope.

The Schedule 1 listed Pilbara Olive Python (*Liasis olivaceus barroni*) was recorded opportunistically during the PBS survey, observed swimming downstream in Weeli Wolli Creek during a nocturnal search at YBLNoct04 (zone 50, 740774 mE, 7481941 mN) (Biota 2014a). Several anecdotal sightings of this species have also been made at the existing Yandi operations.

4.3.1 The Assemblage

The SIMPROF test identified seven clusters of sites that were internally consistent based on the reptile species present (frogs were excluded; see Section 3.4.1). The resemblance matrix for the sites based on reptile composition was also used to generate NMDS plots, with sites coded by survey locality, land system, landform and geology (Figure 4.2, Figure 4.3, Figure 4.4 and Figure 4.5 respectively). For the majority of data, the NMDS plots showed separation of clusters, indicating that fauna assemblages could be placed into groups that were fundamentally different to each other.

The best relationship between the seven herpetofauna assemblages and the site habitat factors was provided by 'survey locality', where the herpetofauna composition recorded from the PBS survey was similar for each survey site, but noticeably different to data obtained in the other localities (Figure 4.2).

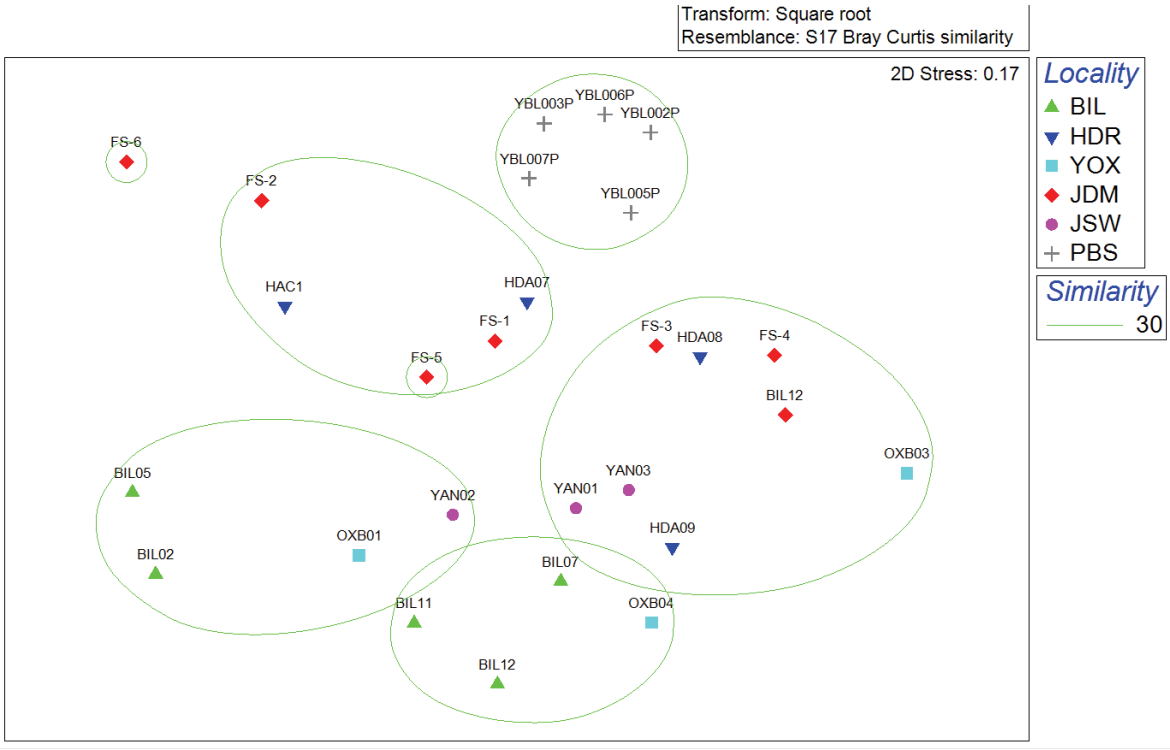

Figure 4.2: NMDS plot of Yandi survey sites based on herpetofauna composition and coded by survey locality.
See Table 3.1 for explanation of locality codes.

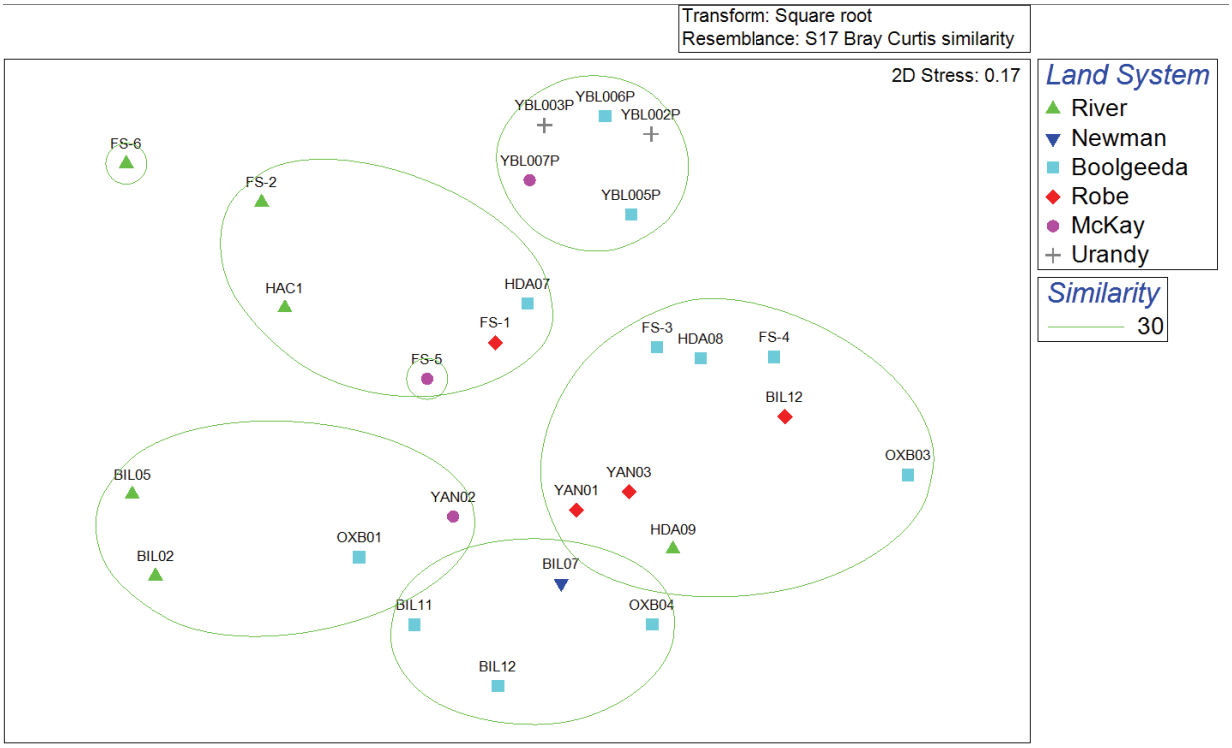

Figure 4.3: NMDS plot of Yandi survey sites based on herpetofauna composition and coded by land systems.

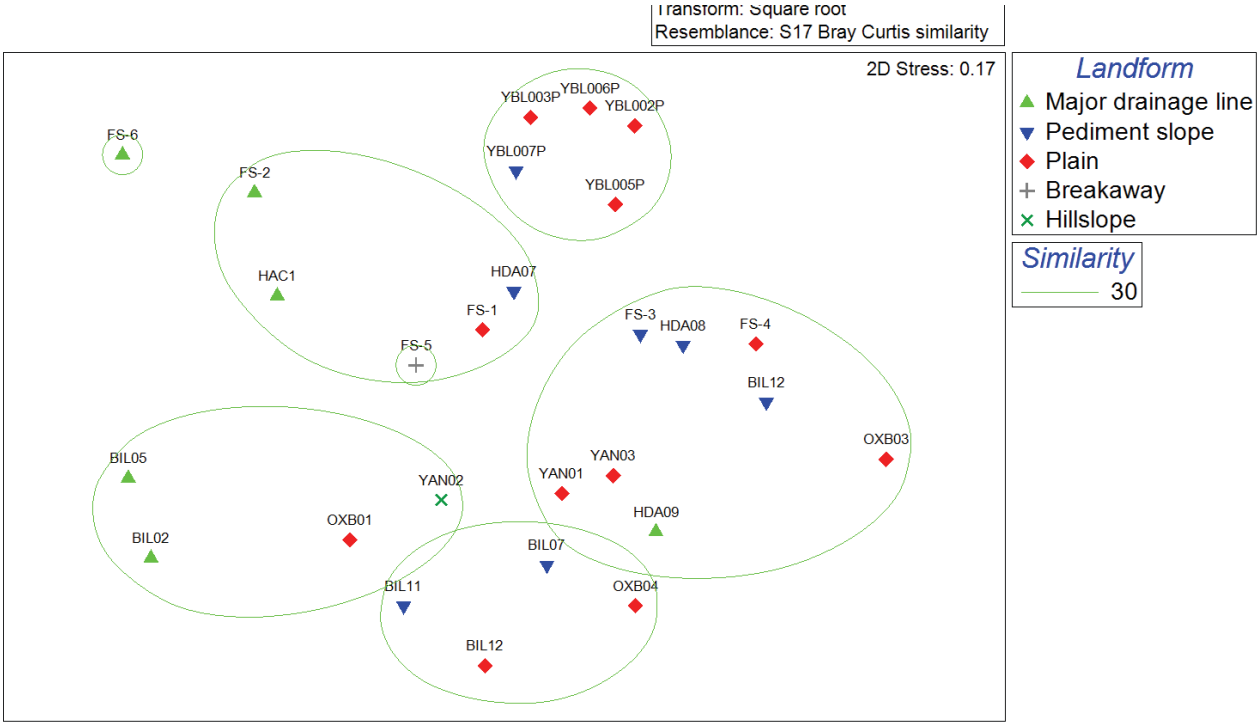

Figure 4.4: NMDS plot of Yandi survey sites based on herpetofauna composition and coded by landform.

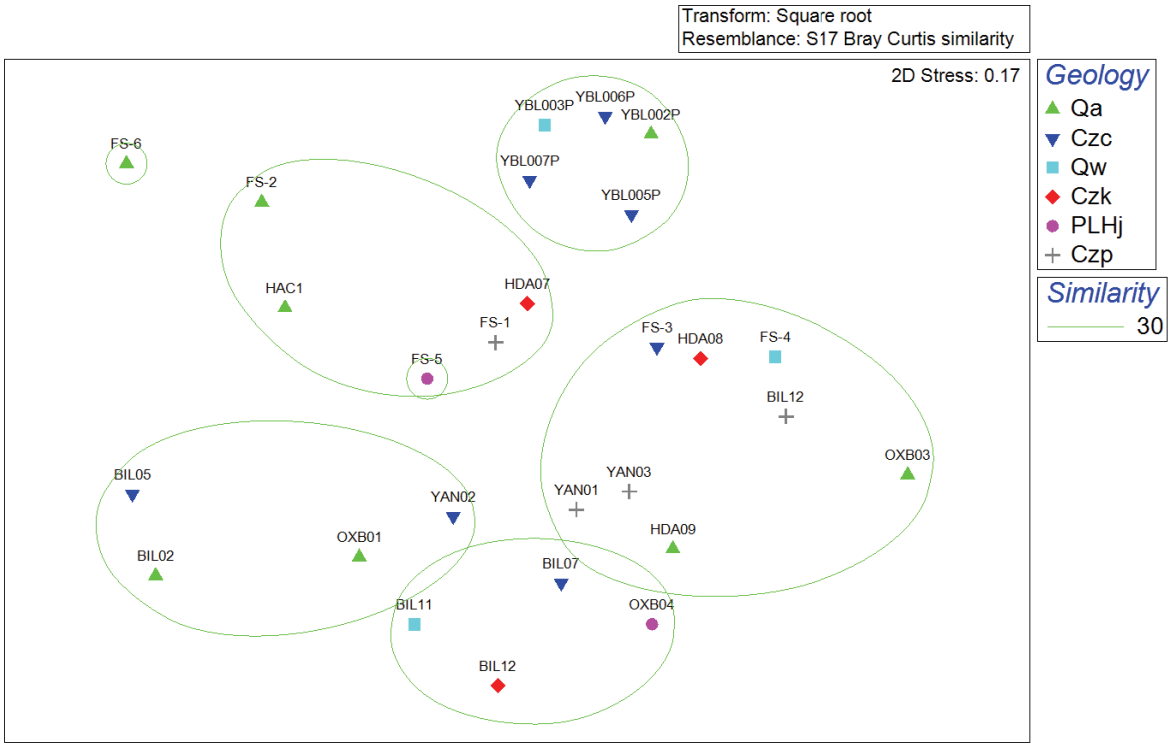

Figure 4.5: NMDS plot of Yandi survey sites based on herpetofauna composition and coded by geology.

A SIMPER analysis was used to identify the species that most strongly characterised each of the assemblages based on landform (Table 4.6). The species characterising each landform type are broadly consistent with the habitats in which they are typically recorded (Cogger 2014). Based on both survey results and previously documented habitat preferences, it is also apparent that certain species such as the dragon *Ctenophorus isolepis* and the skink *Ctenotus pantherinus* occur in a range of landforms and exhibit lower habitat specificity.

Table 4.6: Key herpetofauna species characterising each landform within the development envelope.

Landform †	Indicator Species ¥	Contribution to Group Similarity	Typical Habitats (Cogger 2014)
Major drainage line	*Amphibolurus longirostris*	65.1%	Watercourses.
	Varanus tristis	10.8%	Trees and rocky outcrops.
	Menetia greyii	10.8%	Woodland, shrubland, hummock grassland.
Alluvial plain	*Diplodactylus conspicillatus*	15.2%	Generalist.
	Ctenophorus isolepis	14.3%	Generalist often with hummock grassland.
	Ctenotus duricola	13.1%	Variety of habitats on stony soils.
	Ctenotus pantherinus	12.3%	Variety of habitats on stony soils. Hummock grassland, sandy areas.
Plain	*Ctenotus pantherinus*	52.2%	Hummock grassland, sandy areas.
	Ctenophorus isolepis	38.4%	Generalist, often with hummock grassland.
Pediment slope	*Ctenophorus caudicinctus*	27.2%	Rocky areas.
	Ctenotus pantherinus	25.8%	Hummock grassland, sandy areas.
	Lucasium stenodactylum	13.7%	Generalist
	Ctenotus duricola	12.3%	Variety of habitats on stony soils.
Hillslope	NA – less than two samples.	-	-
Breakaway	NA – less than two samples.	-	-

† Herpetofauna not analysed for free face, minor drainage line or hillcrest landforms due to incompatible trapping methods (see Section 3.4.1).

¥ Species with 10% or more contribution shown.

Although species' habitats are typically defined by the landform in which they most typically occur, it is evident that the habitats within the development envelope represent a continuum for many of the ground species. Landform type may therefore influence species occurrence, however additional variables will also have an influence on species distribution.

4.4 Ground Dwelling Mammals

Twenty-one ground mammals, comprising 15 native and six introduced species, were recorded from the development envelope. This total comprised six carnivorous marsupial species (Dasyuridae), three kangaroo species (Macropodidae), six rodent species (Muridae), one cat (Felidae), one canine (Canidae), two equine species (Equidae), one cattle species (Bovidae) and one camel species (Camelidae). The introduced mammals recorded in the development envelope comprised the house mouse (*Mus musculus*), feral cat (*Felis catus*), donkey (*Equus asinus*), horse (*Equus caballus*), European cattle (*Bos taurus*) and camel (*Camelus dromedarius*).

The most abundant mammals in the development envelope were the introduced house mouse *Mus musculus* (n=45 individuals from 14 sites), the Common Rock Rat *Zyzomys argurus* (n=30 individuals from seven sites) and the Sandy Inland Mouse *Pseudomys hermannsburgensis* (n=29 individuals from 16 sites).

The Priority 4 listed Western Pebble-mound Mouse *Pseudomys chapmani* and Brush-tailed Mulgara *Dasycercus blythi* were the only ground mammal species of conservation significance recorded from the development envelope. Twenty-eight Western Pebble-mound Mouse records were recorded from 22 locations within the development envelope. Three inactive Mulgara burrows were also recorded on an alluvial plain in the northeastern section of the development envelope.

4.4.1 The Assemblage

The SIMPROF test using ground mammal data identified multiple clusters of sites, which were internally consistent at 30% assemblage similarity. This is reflected in the NMDS plot, with many clusters encompassing single sites. This indicates that in most cases mammal assemblages were fundamentally different between individual sites (Figure 4.6). As a result, comparisons between assemblages recorded within different landforms, land systems and geology types were not conducted.

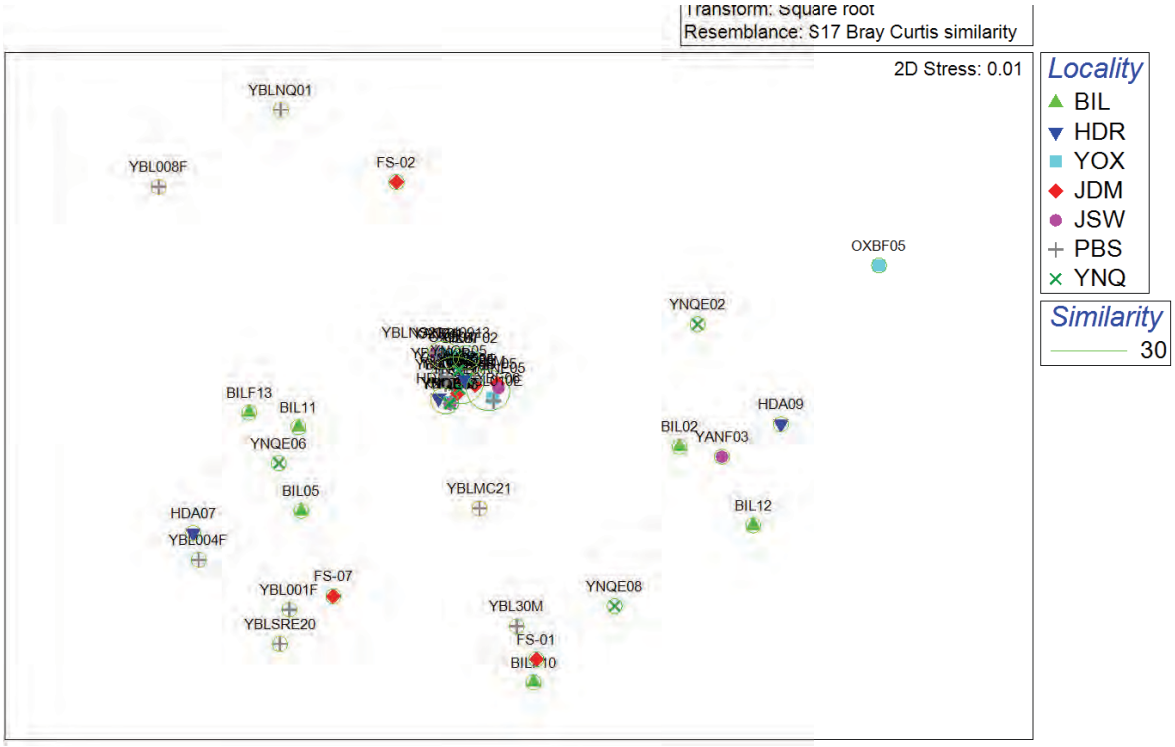

Figure 4.6: NMDS plot of Yandi survey sites based on ground mammal composition and coded by survey locality.

4.5 Bats

Ten bat species were recorded from the development envelope, comprising two species from the family Emballonuridae, three from the family Molossidae and five from the family Vespertilionidae. The most commonly encountered species were Finlayson's Cave Bat *Vespadelus finlaysoni* and Gould's Wattled Bat *Chalinolobus gouldii,* which were both recorded at all six of the survey localities where bat sampling was conducted. All 10 species were recorded from the YBNQ study area, while nine species were recorded from the PBS study area (Table 4.7).

Table 4.7: Occurrence of bat species at each locality within the development envelope.

FAMILY Species Name	Common Name	Locality †					
		JSW	YOX	BIL	JDM	YBNQ	PBS
EMBALLONURIDAE							
Saccolaimus flaviventris	Yellow-bellied Sheathtail Bat	✓		✓		✓	✓
Taphozous georgianus	Common Sheathtail Bat	✓	✓			✓	✓
MOLOSSIDAE							
Chaerephon jobensis	Northern Freetail Bat					✓	✓
Mormopterus beccarii	Beccari's Freetail Bat					✓	✓
Tadarida australis	White-striped Freetail Bat	✓				✓	
VESPERTILIONIDAE							
Chalinolobus gouldii	Gould's Wattled Bat	✓	✓	✓	✓	✓	✓
Chalinolobus morio	Chocolate Wattled Bat					✓	✓
Nyctophilus geoffroyi	Lesser Long-eared Bat					✓	✓
Scotorepens greyii	Little Broad-nosed Bat					✓	✓
Vespadelus finlaysoni	Inland Cave bat	✓	✓	✓	✓	✓	✓

† See Table 3.1 for explanation of locality codes.

4.6 Avifauna

A total of 103 avifauna species from 40 families were recorded from the development envelope. The total comprised 53 passerine and 50 non-passerine species. The most speciose families were the Meliphagidae (honeyeaters and chats) with 11 species recorded, and the Accipitridae (raptors) with seven species recorded. The most abundant bird species were the Zebra Finch *Taeniopygia guttata* (n=142 individuals) and the Weebill *Smicrornis brevirostris* (n=107), both of which were recorded from the majority of survey sites. The diversity of avifauna recorded in the development envelope was high and as a result, the two most abundant species stated above accounted for only 8% and 6% respectively of all avifauna recorded in the development envelope.

Six avifauna species of conservation significance were recorded during the surveys: the Rainbow Bee-eater *Merops ornatus* (Schedule 3, migratory), Fork-tailed Swift *Apus pacificus* (Schedule 3, migratory); Eastern Great Egret *Ardea modesta* (Schedule 3, Migratory); Peregrine Falcon *Falco peregrinus* (Schedule 4), Australian Bustard *Ardeotis australis* (Priority 4) and Star Finch (Western form) *Neochmia ruficauda subclarescens* (Priority 4; see Section 4.9 and Appendix 2).

4.6.1 The Assemblage

A SIMPROF test of avifauna data identified four clusters of sites at the 30% similarity level. However, an NMDS plot shows that the majority of sites group within a single large cluster (Figure 4.7). Apart from two outlier sites, the NMDS resulted in very little separation of the two remaining sites clusters, indicating that the avifauna assemblages at the majority of sites were not fundamentally different. The association of landform, land system and geology type with avifauna assemblage is depicted in Figure 4.8 to Figure 4.10.

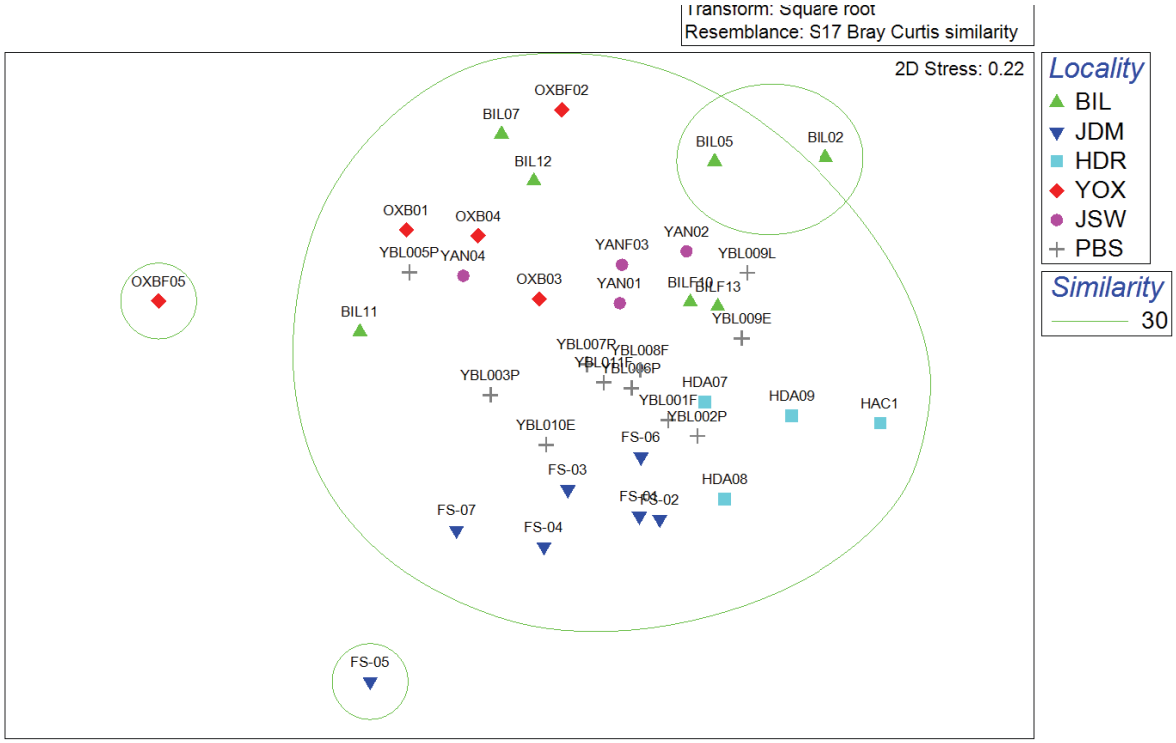

Figure 4.7: NMDS plot of Yandi survey sites based on avifauna composition and coded by survey locality. See Table 3.1 for explanation of locality codes.

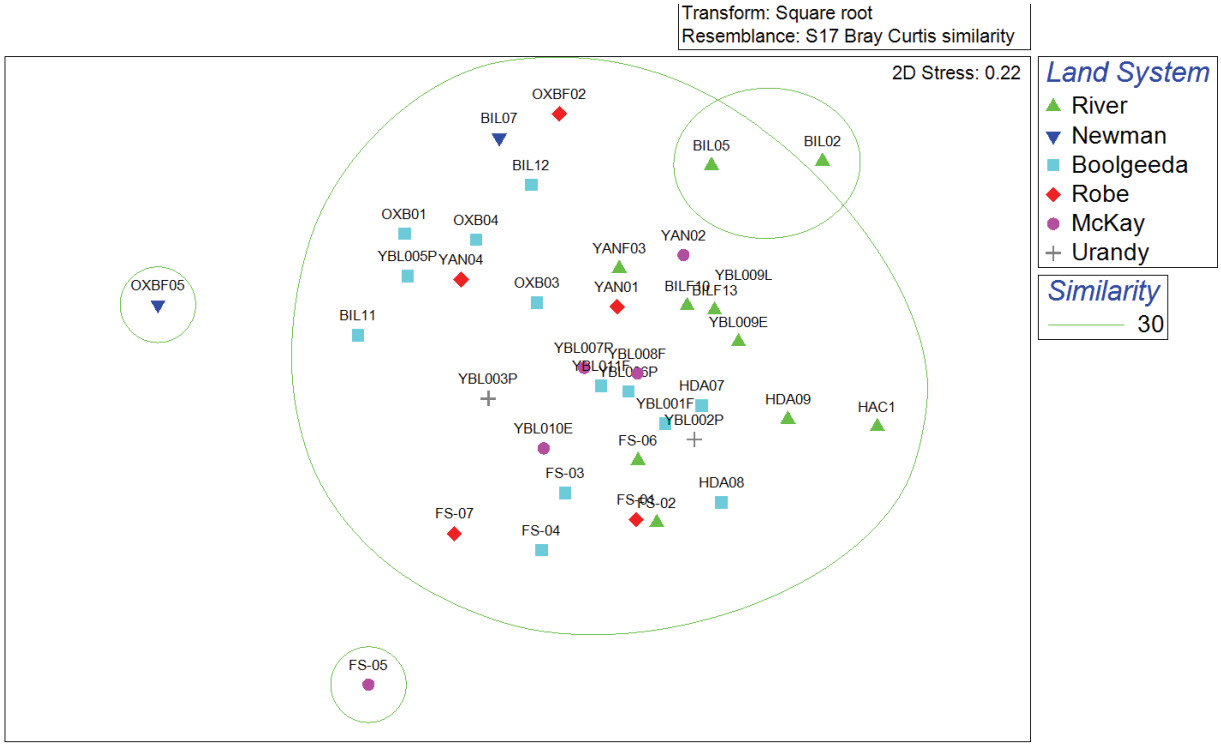

Figure 4.8: NMDS plot of Yandi survey sites based on avifauna composition and coded by land system. See Table 3.1 for explanation of locality codes.

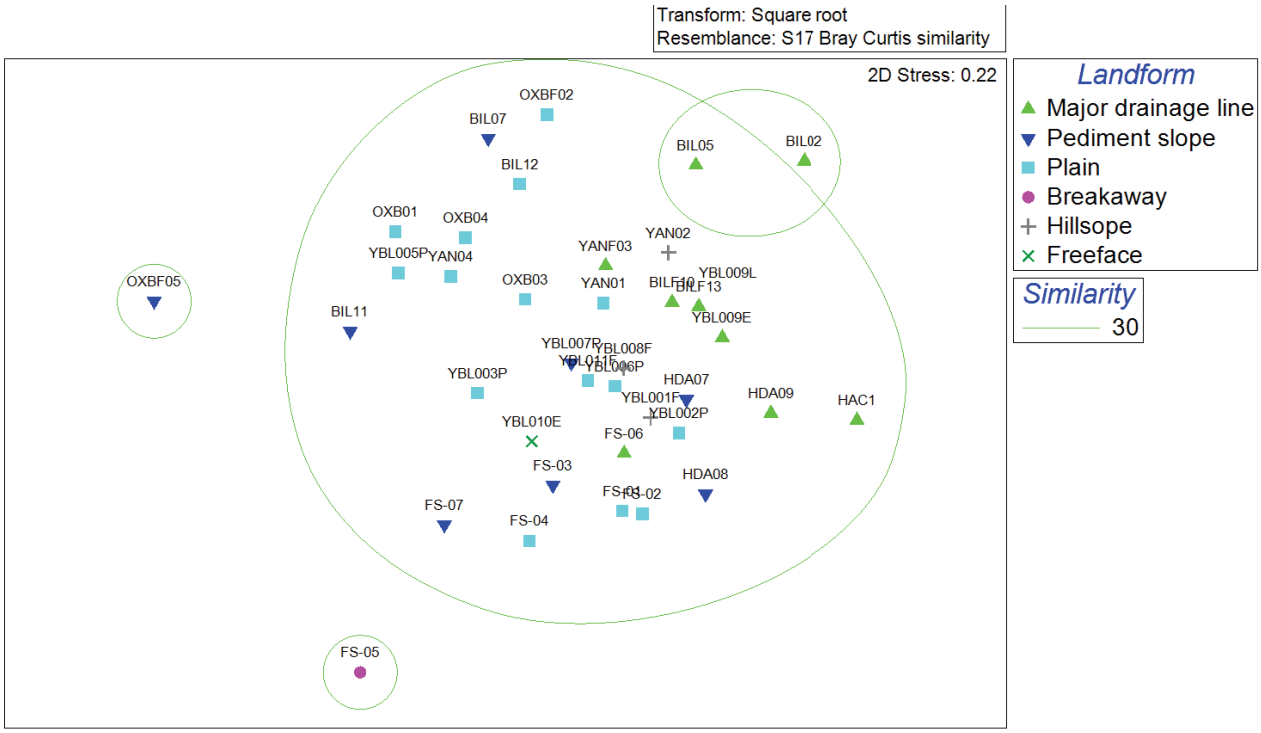

Figure 4.9: NMDS plot of Yandi survey sites based on avifauna composition and coded by landform. See Table 3.1 for explanation of locality codes.

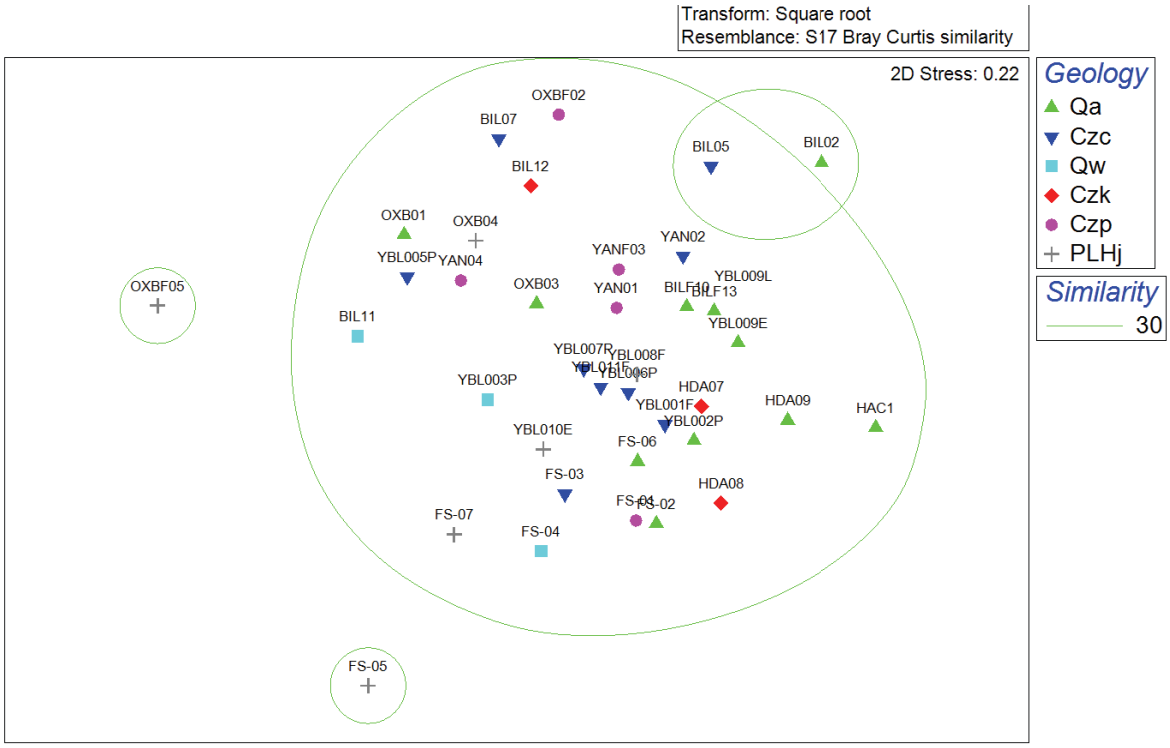

Figure 4.10: NMDS plot of Yandi survey sites based on avifauna composition and coded by geology. See Table 3.1 for explanation of locality codes.

4.7 Species Accumulation

Species accumulation curves for herpetofauna, avifauna and non-volant mammals are presented in Figure 4.11, Figure 4.12 and Figure 4.13 respectively. In all cases, the randomised curves generated by the Chao 1 and Jackknife 1 indices are asymptotic, indicating that few species are likely to be added with additional sampling effort. This indicates that the development envelope has been adequately sampled using the methods outlined in Section 3.2.

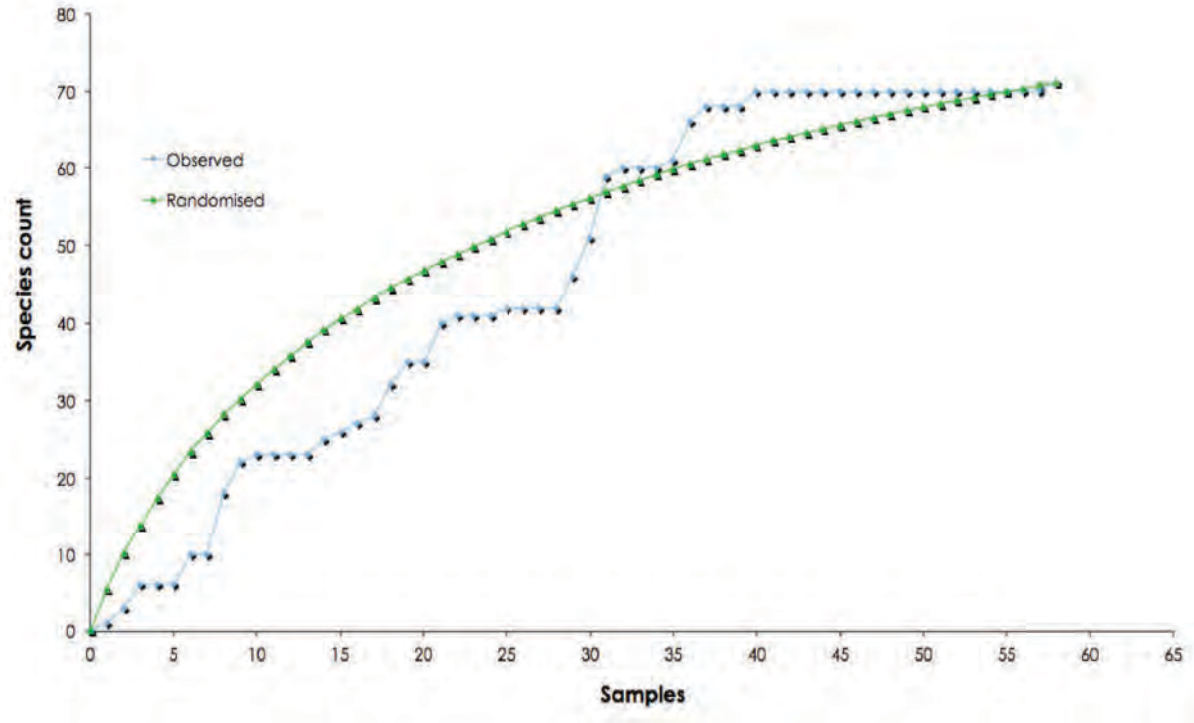

Figure 4.11: Yandi development envelope species accumulation curve for herpetofauna.

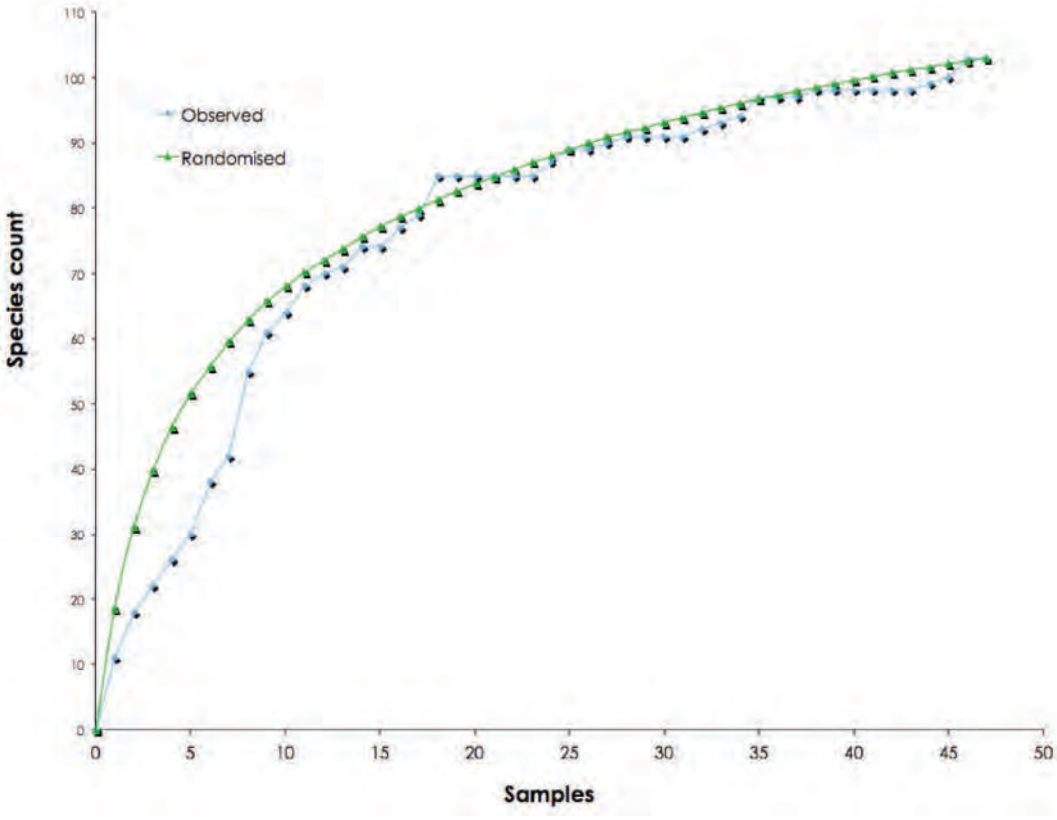

Figure 4.12: Yandi development envelope species accumulation curve for avifauna.

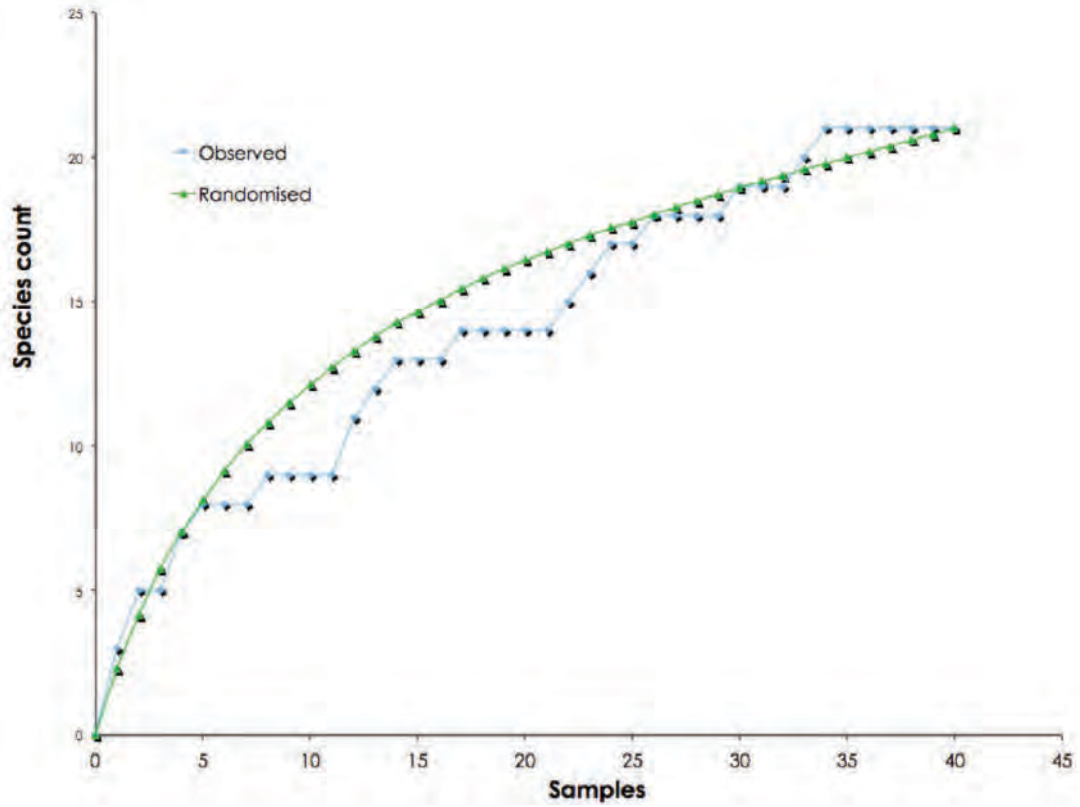

Figure 4.13: Yandi development envelope species accumulation curve for non-volant mammals.

The observed species richness for each vertebrate class was in accordance with the non-parametric estimators (Table 4.8). The total of 196 species recorded (excluding bats) represented approximately 85% of the mean estimates of total species richness, which suggested that on average 230 vertebrate species could occur in the development envelope (Table 4.8).

Table 4.8: Comparison of observed vertebrate species richness with estimator predictions.

		Estimators			
Group	Observed	Chao 1	Jackknife 1	Bootstrap	Mean
Herpetofauna	72	88	93	82	88
Ground mammals	21	21	28	24	24
Avifauna	103	118	124	113	118
Total	*196	227	245	219	230

*Note: accounting for recorded bat species, the total observed species count is 206 (see Section 4.2. As bat data are not quantitative, they could not be used in the species accumulation analysis.

4.8 Short Range Endemic Invertebrates

Two higher-order taxonomic groups with the potential to include SRE species were collected within the development envelope, comprising the pseudoscorpions and mygalomorph spiders. Sections 4.8.1 and 4.8.2 provide accounts of each group and detail the SRE status of each species (where known). Table 4.9 summarises the records by sites, components of the development envelope and land systems.

Table 4.9: Summary of potential SRE invertebrate fauna recorded from the development envelope.

Invertebrate Group Family	Taxon	No. of Specimens	Land Systems Represented	Development envelope	Sites Recorded in Development envelope	SRE Status	Occurs Outside of Development envelope?
Pseudoscorpions							
Olpiidae	*Beierolpium* sp.	6	River	PBS	YBLSRE02	Unlikely to be an SRE	Unknown
	Indet.	11	Boolgeeda, Newman, Robe	Oxbow	OXB04, OXBF05, OXBSRE05	Unlikely to be an SRE	Unknown
Mygalomorph Spiders							
Idiopidae	Idiopidae sp. I1	2	River	*Jinidi to Mainline	JML26	Potential SRE	Yes
	Idiopidae sp. I9	1	River	*Jinidi to Mainline	JML26	Potential SRE	Yes
Nemesiidae	Nemesiidae sp. N1	1	Boolgeeda	PBS	YBLSRE15	Not an SRE	Yes
	Nemesiidae sp. N16	6	Boolgeeda, McKay, River	PBS; and *Jinidi to Mainline	YBLSRE08, YBLSRE10, YBL007P, JML26, JML27	Not an SRE	Yes
	Nemesiidae sp. N42	3	Boolgeeda, River, Urandy	PBS; and *Jinidi to Mainline	YBLSRE21, YBL05P, JML20	Potential SRE	Yes
	Nemesiidae sp. N44	13	Boolgeeda, Newman, River	PBS; and *Jinidi to Mainline	YBLSRE04, YBLSRE19, YBLSRE20, JML23, JML26, JML27	Potential SRE	Yes

* Jinidi to Mainline refers to a survey conducted on behalf of BHP, which was subsequently assessed by the EPA at API level (Biota 2013c).

4.8.1 Pseudoscorpions

One family was represented amongst the pseudoscorpions collected from the development envelope. None of the pseudoscorpions recorded are considered to represent SREs.

4.8.1.1 Olpiidae

Beierolpium sp.

A total of 17 pseudoscorpion specimens of the family Olpiidae were recorded from the development envelope from underneath tree bark and rocks (Table 4.9). Specimens recorded during the YOX survey were not identified beyond the family level, however specimens recorded from the PBS survey were tentatively identified as belonging to the genus *Beierolpium.*

The taxonomic resolution of many Olpiids is deficient and as such, the distribution of putative species is uncertain (Mieke Strong, Biota, pers. comm. 2014). As a result, the SRE status of members of this family remains undetermined. However, the majority of pseudoscorpions collected from under surface rocks and tree bark are currently regarded as unlikely to have restricted ranges due to their phoretic (animal-assisted) mode of dispersal. This means that this taxon is not currently considered to represent an SRE.

4.8.2 Mygalomorph Spiders

4.8.2.1 Idiopidae

Idiopidae sp. I1 (genus *Aganippe*)

Distribution

Two specimens of Idiopidae sp. I1 (Plate 4.9 and Plate 4.10) were recorded from one sampling location within the development envelope (Table 4.9 and Figure 4.14). Morphologically, Idiopidae sp. I1 appears to be of the genus *Aganippe*. This putative taxon is known from 19 recorded specimens, the majority of which occur outside the development envelope. It has a documented distribution roughly concurrent with the Weeli Wolli Creek drainage, including its broader catchment in the vicinity of The Governor and Mt Robinson and the alluvial fan south of the Fortescue Marsh (Figure 4.14). Records occupy a minimum spanning area of approximately 2,559 km^2.

Habitat

Idiopidae sp. I1 has been recorded in heavy soils in areas low in the landscape, such as valley floors, drainage lines and alluvial fans.

SRE Status

This taxon has a relatively small known distribution and qualifies as a potential SRE species.

Plate 4.9: Idiopidae sp. I1 (Biota 2013c).

Plate 4.10: Idiopidae sp. I1 representative burrow entrance (Biota 2013c).

Idiopidae sp. I9 (genus *Eucyrtops*?)

Distribution

Idiopidae sp. I9 (Plate 4.11 and Plate 4.12) was recorded on one occasion within the development envelope. It is known from only four individuals recorded across three locations in the locality (Table 4.9 and Figure 4.14). Records occupy an area of approximately 65 km^2.

Habitat

The sites from which this taxon has been recorded are characterized by clay loam soils and support an overstorey that includes isolated stands of *Acacia aneura* (Mulga).

SRE Status

Given the limited known distribution of Idiopidae sp. I9 and its occurrence in isolated Mulga habitat, it is considered to be a potential SRE.

Plate 4.11: Idiopidae sp. I9 (Biota 2013c).

Plate 4.12: Idiopidae sp. I9 representative burrow entrance (Biota 2013c).

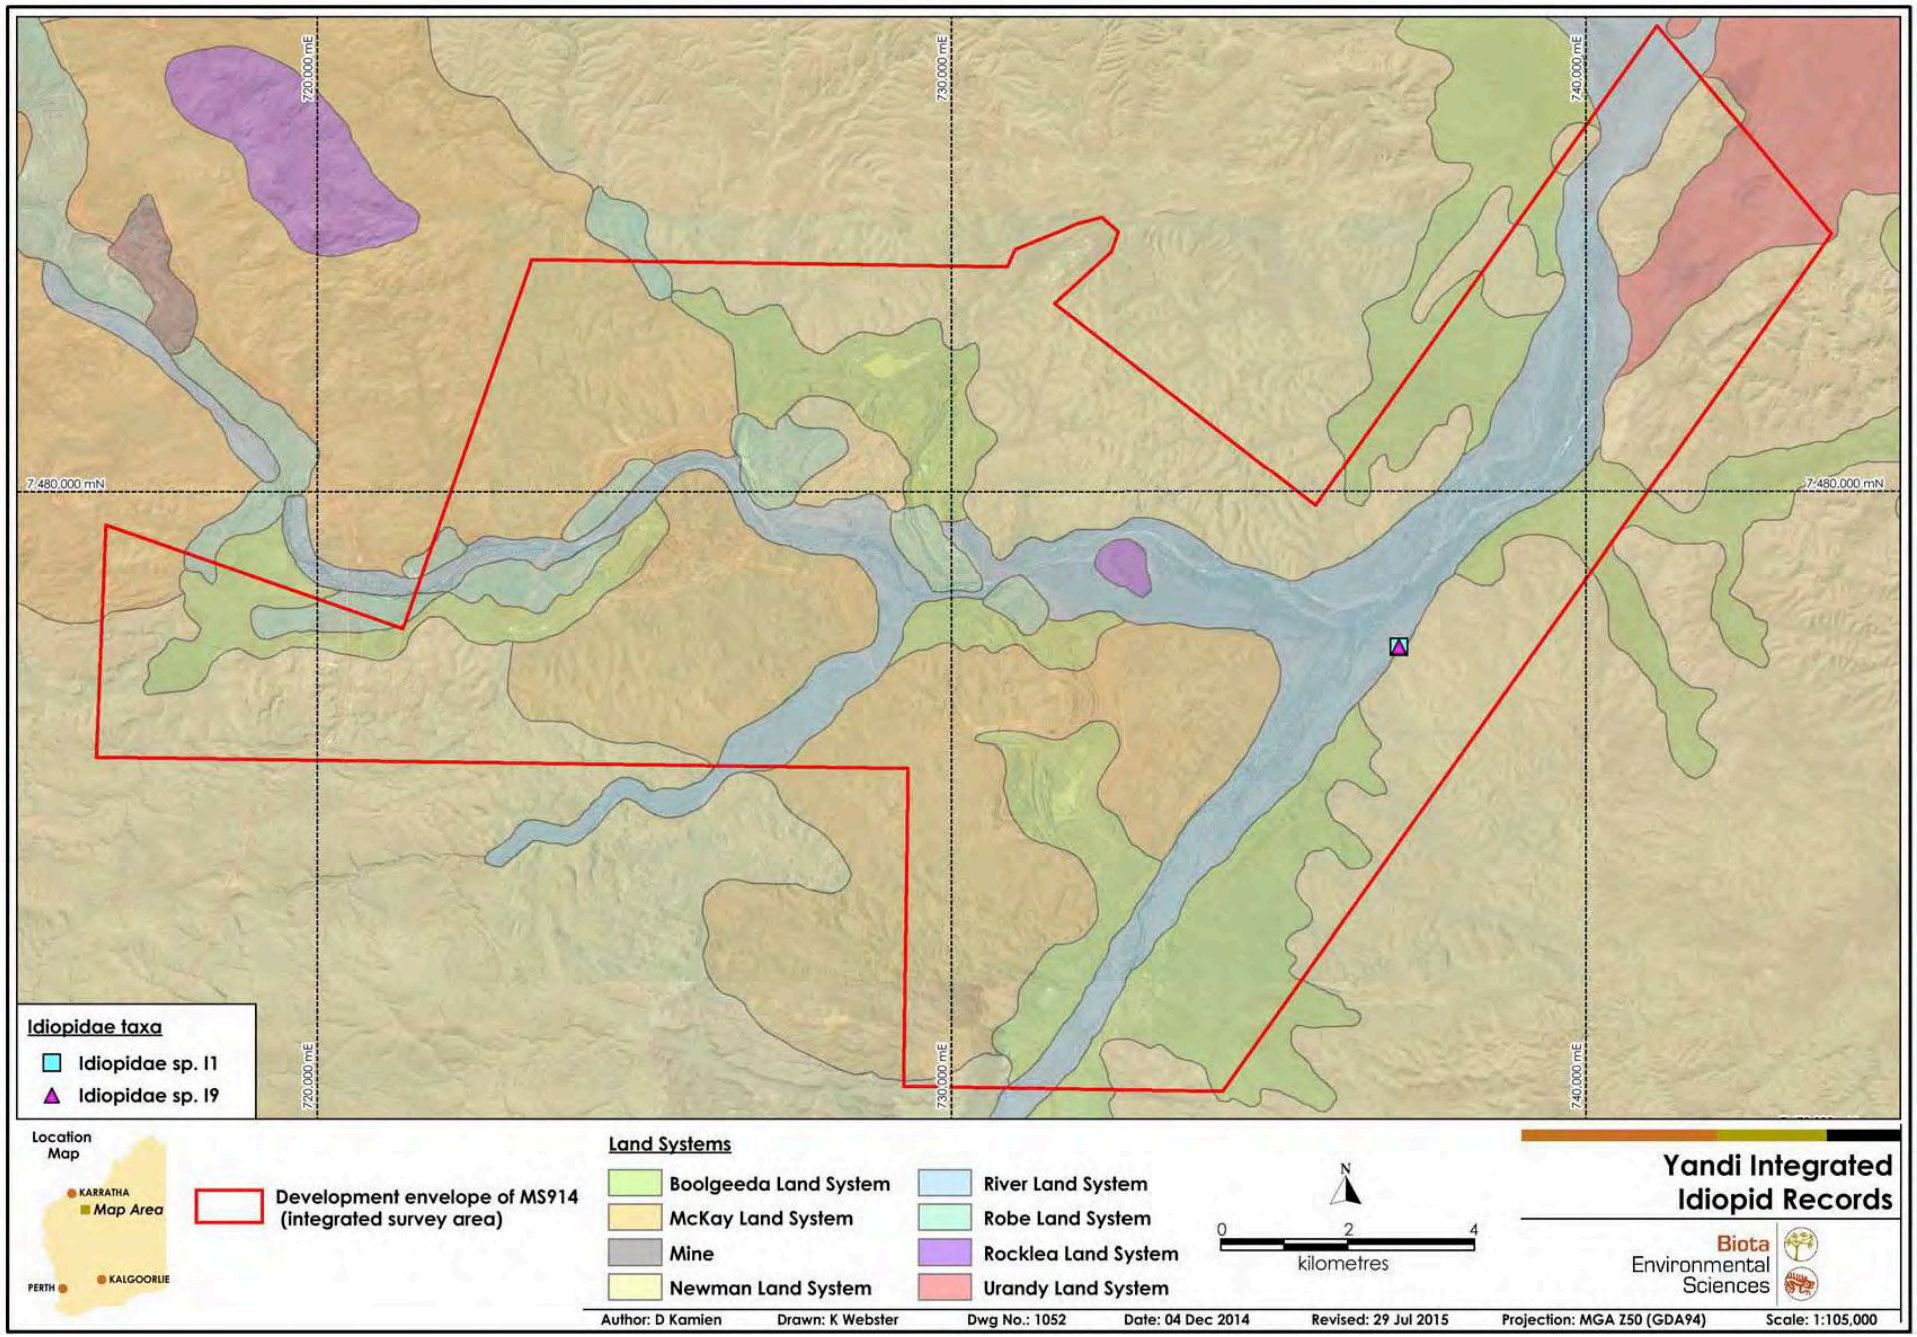

Figure 4.14: Distribution of Mygalomorph spiders of the family Idiopidae recorded in the development envelope.

4.8.2.2 Nemesiidae

Nemesiidae sp. N1

Distribution

Nemesiidae sp. N1 (Plate 4.13) is represented by one individual recorded at a single location in the northeast of the development envelope (Table 4.9 and Figure 4.15). This taxon belongs to the genus *Aname* and creates a hooded burrow entrance (Plate 4.14). To date, 108 individuals of this putative species have been recorded from 71 locations in the Central Pilbara (Biota 2012 and Biota internal database). The minimum spanning area is currently known to be approximately 13,913 km^2 (Figure 4.15).

Habitat

Nemesiidae sp. N1 is associated with clay loam soils in Mulga-dominated communities, as well as clay loams on alluvial and colluvial fans and broad plains.

SRE Status

The current known distribution of this putative species is greater than 10,000 km^2 and as a result it is not considered to be an SRE taxon as defined by Harvey (2002).

Plate 4.13: Nemesiidae sp. N1 (Biota 2012).

Plate 4.14: Nemesiidae sp. N1 representative burrow entrance (Biota 2012).

Nemesiidae sp. N16 = 'Hooded' = 'MYG001' (*Aname mellosa*; Harvey et al. (2012)).

Distribution

Nemesiidae sp. N16 (Plate 4.15) is represented by six individuals recorded at five locations within the development envelope (Table 4.9 and Figure 4.15). This putative molecular species forms part of the species complex currently known as *Aname mellosa* (Castalanelli et al. 2014) which creates a hooded burrow entrance (Plate 4.16). To date, 222 individuals of Nemesiidae sp. N16 have been recorded at 200 locations in the Central Pilbara (Biota 2012 and Biota internal database). The minimum spanning area is currently known to be approximately 12,836 km^2 (Figure 4.15).

Habitat

Specimens have been collected from loams soils in narrow drainage floors, and also from adjacent landforms (e.g. low slopes and stony plains) where a suitable soil profile exists. Within the development envelope, it was recorded from alluvial plains and slopes.

SRE Status

The current known distribution of this putative species is greater than 10,000 km^2 and as a result it is not considered to be an SRE taxon as defined by Harvey (2002).

Plate 4.15: Nemesiidae sp. N16 (M20140317YBL007P-02).

Plate 4.16: Nemesiidae sp. N16 representative burrow entrance.

Nemesiidae sp. N42 (genus *Kwonkan*)

Distribution

Nemesiidae sp. N42 (Plate 4.17 and Plate 4.18) is represented by 22 specimens in the Pilbara, of which three specimens were recorded from three sites within the development envelope (Table 4.9). The distribution of Nemesiidae sp. N42 exhibits a minimum spanning area of 113 km^2 (Figure 4.15).

Habitat

Specimens are typically recorded from loams or sandy loams in habitat that is not considered to be isolated or restricted.

SRE Status

Based on the current known distribution and habitat preferences, Nemesiidae sp. N42 may potentially be an SRE.

Plate 4.17: Nemesiidae sp. N42 (M20140313YBLSRE21-01).

Plate 4.18: Nemesiidae sp. N42 representative burrow entrance.

Nemesiidae sp. N44 (genus *Kwonkan*)

Distribution

Nemesiidae sp. N44 (Plate 4.19 and Plate 4.20) was recorded on 19 occasions from six locations within the development envelope. It is currently known from only two additional locations within 2 km of the development envelope (Table 4.9 and Figure 4.15). Based on known records it occupies a minimum spanning area of on 26 km^2.

Habitat

The specimens were recorded from loamy soils along Weeli Wolli Creek, mostly in the Boolgeeda land system with one record in the River land system.

SRE Status

Based on the current distribution data, this putative taxon is considered to be a potential SRE.

Plate 4.19: Nemesiidae sp. N44 (M20140315YBLSRE04-02).

Plate 4.20: Nemesiidae sp. N44 representative burrow entrance.

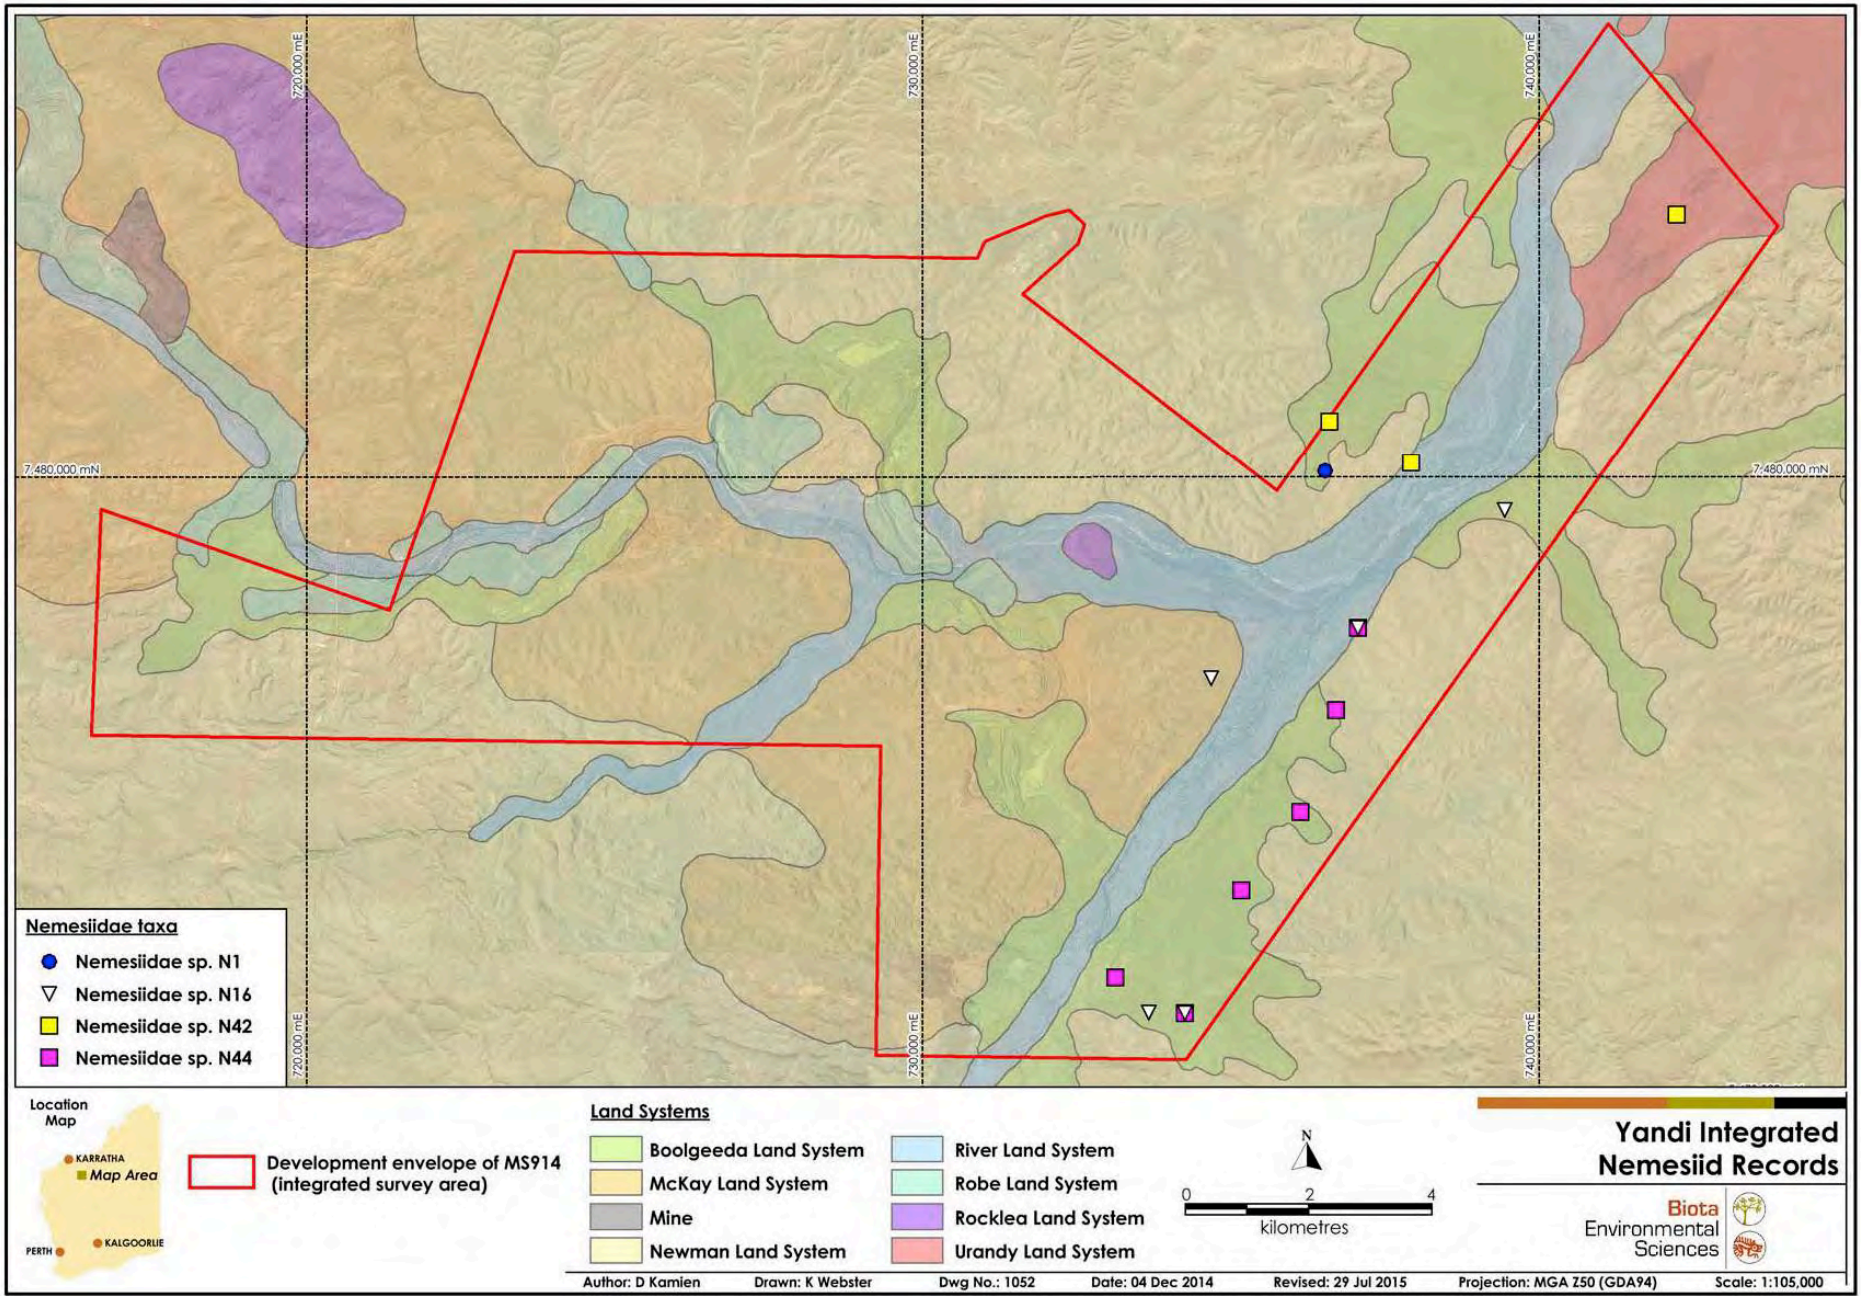

Figure 4.15: Distribution of Mygalomorph spiders of the family Nemesiidae recorded in the development envelope.

4.9 Species of Conservation Significance

A total of five species of elevated conservation significance were recorded from the development envelope (Table 4.10). This total included five Schedule species listed under the State *Wildlife Conservation Act 1950,* four of which are also listed under the Commonwealth *EPBC Act 1999* (Table 4.10).

Four species listed as Priority 4 by the Department of Parks and Wildlife were also recorded from the development envelope. Appendix 3 sets out the conservation categories used at State level in Western Australia.

Table 4.10: Number of individuals of Threatened fauna recorded from the development envelope.

Species Name	Common Name	Conservation Status		Locality					
		State	Commonwealth	JSW	HDA	YOX	BIL	JDM	PBS
Liasis olivaceus barroni	Pilbara Olive Python	Schedule 1	Vulnerable	–	–	–	–	–	1
Merops ornatus	Rainbow Bee-eater	Schedule 3	Migratory	7	12	–	14	2	52
Apus pacificus	Fork-tailed Swift	Schedule 3	Migratory	–	–	–	–	–	9
Ardea modesta	Eastern Great Egret	Schedule 3	Migratory	–	–	–	–	–	1
Falco peregrinus	Peregrine Falcon	Schedule 4	–	–	–	–	–	1	–
Ardeotis australis	Australian Bustard	Priority 4	–	–	1	–	–	1	15
Neochmia ruficauda subclarescens	Star Finch (Western form)	Priority 4	–	1	–	–	–	–	12
Dasycercus blythi	Brush-tailed Mulgara	Priority 4	–	–	–	–	–	–	3
Pseudomys chapmani	Western Pebble-mound Mouse	Priority 4	–	–	–	7	2	1	18

The locations where species of conservation significance were recorded are overlain on land systems mapping in Figure 4.16. The use of land systems in this section allows for records of species of conservation significance to be placed into subregional and regional habitat context, including their relationship with findings from other similar studies (e.g. Biota 2012b, 2012c).

The Rainbow Bee-eater *Merops ornatus* (State: Schedule 3; Commonwealth: Migratory) was the most frequently recorded listed species, with 87 individuals recorded from 23 sites in the development envelope (Appendix 2). The Western Pebble-mound Mouse was also widely recorded with 28 records from 22 locations within the development envelope. This is in keeping with the widespread and common status of these species in the Pilbara bioregion (Biota, unpublished data).

Overview accounts of the species of conservation significance and their occurrence within the development envelope are presented below. More detail is provided in the supporting source reports (Biota 2004, 2010d, 2014a).

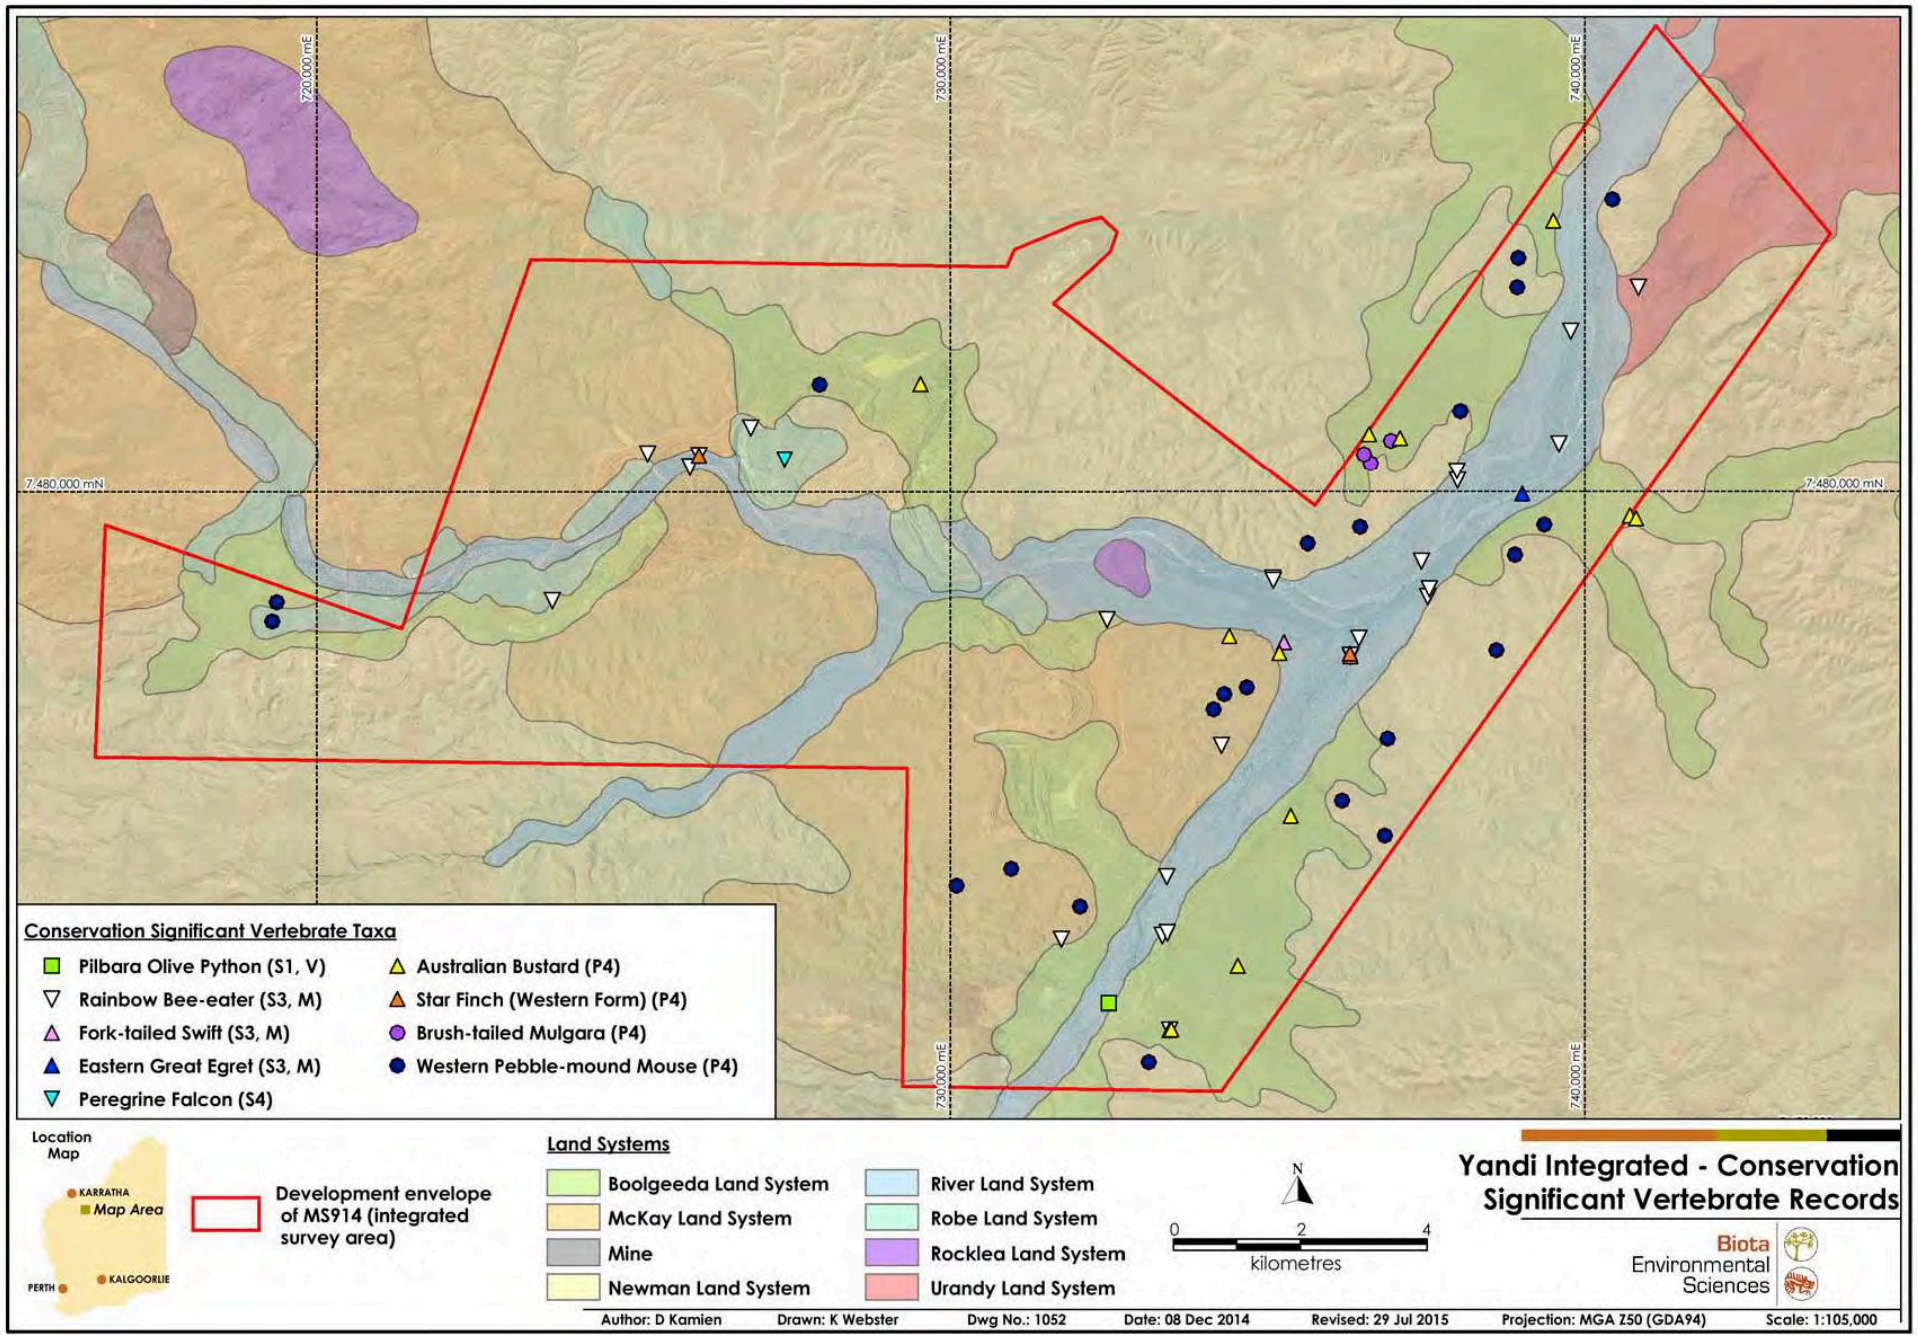

Figure 4.16: Conservation significant vertebrates recorded in the development envelope.

4.9.1 Schedule Species

Pilbara Olive Python *Liasis olivaceus barroni* (State: Schedule 1; Commonwealth: Vulnerable)
Regarded as a Pilbara endemic, this subspecies has a distribution that coincides roughly with the Pilbara bioregion (Department of the Environment 2015). The Pilbara Olive Python (Plate 4.21) typically occurs in rocky areas, showing a preference for gorges containing water in streams and rock pools. One individual was recorded opportunistically swimming in Weeli Wolli Creek (Biota 2014a). This species is not commonly observed.

Plate 4.21: Pilbara Olive Python recorded in the PBS study area (Biota 2014a).

Rainbow Bee-eater *Merops ornatus* (State: Schedule 3; Commonwealth: Migratory)
The Rainbow Bee-eater is a regular breeding migrant to most of Australia, with the exception of Tasmania. The species nests in small holes excavated in sandy banks or flat sandy surfaces, occurring in landforms that provide suitable soil for nesting and a tall stratum of vegetation for perching (Johnstone and Storr 1998).

The Rainbow Bee-eater is very common regionally, with Biota's database including records from over 500 separate locations in Western Australia (Biota unpublished data). Within the Yandi development envelope, this species was recorded from 23 systematic locations across all source surveys (Table 4.10). The species showed little preference for specific land systems, occurring in five different types (Figure 4.16).

Fork-tailed Swift *Apus pacificus* (State: Schedule 3; Commonwealth: Migratory)
The Fork-tailed Swift has a cosmopolitan distribution throughout Australia (Simpson and Day 2004). Fork-tailed Swifts are thought to be exclusively aerial in Australia as they breed in the northern hemisphere, migrating south to the Australasian region from October to April. Irregular summer visitor to the Pilbara during November to early April (Johnstone et al. 2013).

Within the development envelope, nine individuals of this species were opportunistically observed flying overhead during Phase 1 of the PBS survey (zone 50, 735255 mE, 7477626 mN). This species is expected to be a transient visitor to the development envelope and would not rely on any terrestrial habitats within the development envelope.

Eastern Great Egret *Ardea modesta* (State: Schedule 3; Commonwealth: Migratory)
The Eastern Great Egret is largely dependent on the presence of significant water bodies, which may be temporally available in waterways throughout the Pilbara following periods of rainfall, particularly when drying pools result in an accumulation of tadpoles and fish.

An opportunistic observation of this species was made during Phase 2 of the PBS survey, when a single bird was observed flying in the vicinity of Weeli Wolli Creek (739001 mE, 7479968 mN). The single observation within the development envelope during multiple phases suggests that the Eastern Great Egret is either uncommon or is an irregular visitor within the development envelope.

Peregrine Falcon *Falco peregrinus* (State: Schedule 4)
The Peregrine Falcon has an almost cosmopolitan distribution, but is absent from most deserts and the Nullarbor Plain (Johnstone and Storr 1998). It occurs in a wide range of habitats but especially cliffs, rocky outcrops and rocky coastal islands (Pizzey and Knight 2007).

One individual was recorded within the development envelope during the JDM survey (Table 4.10 and Figure 4.16). The species would not be solely reliant on the habitats of the development envelope for breeding as it typically utilises ledges in cliffs and granite outcrops for nesting (Johnstone and Storr 1998). The Peregrine Falcon is considered uncommon and is mostly recorded as single individuals or pairs in the Hamersley Range (Johnstone and Storr 1998).

4.9.2 Priority Species

Western Pebble-mound Mouse *Pseudomys chapmani* (Department of Parks and Wildlife: Priority 4)
The Western Pebble-mound Mouse is typically found on stony hillsides with hummock grasslands (Menkhorst and Knight 2011) and is common to very common in suitable habitat within the Hamersley and Chichester subregions of the Pilbara bioregion.

The Western Pebble-mound Mouse constructs extensive mounds of small stones covering areas from 0.5 to 9.0 square meters (van Dyck and Strahan 2008) (see Plate 4.22). Within the development envelope, pebble-mounds were recorded at 22 locations (Figure 4.16).

Plate 4.22: Active pebble mound recorded within the PBS study area.

Australian Bustard *Ardeotis australis* (Department of Parks and Wildlife: Priority 4)
The Australian Bustard occurs over much of Western Australia, with the exception of the more heavily wooded southern portions of the state (Johnstone and Storr 1998). Bustards are typically nomadic, occupying large home ranges in open or lightly wooded grassland including *Triodia* sandplains. They occur in a relatively broad range of habitats and are considered to be common depending on season and availability of suitable. They are often observed in recently burnt areas, with open groundcover (Marchant and Higgins 1993). Australian Bustards were observed on 17 occasions from 11 locations within the development envelope (see Figure 4.16).

Star Finch Neochmia *ruficauda subclarescens* (Department of Parks and Wildlife: Priority 4)
The western subspecies of Star Finch occurs in the north of Western Australia and into the Northern Territory (Johnstone and Storr 2004). It is most common around major watercourses, and is typically confined to rushes, reed beds and adjacent vegetation communities along major waterways and permanent pools in the Pilbara, where it feeds on the seed of sedges. This species is considered to be resident in most of its range but is generally uncommon and is patchily distributed in the Pilbara. In total, 13 records were noted at two locations within the development envelope during the combined surveys.

Brush-tailed Mulgara *Dasycercus blythi* (Department of Parks and Wildlife: Priority 4)
The Brush-tailed Mulgara occurs in spinifex sand plain habitat across the arid zone of Western Australia, the Northern Territory and Queensland. Mulgara were formerly widespread in sandy deserts but they are now rare and patchily distributed. Recent records include those occurring in the Pilbara bioregion (NatureMap database).

The Brush-tailed Mulgara inhabits spinifex grasslands, and larger colonies coincide with relatively well-watered areas such as paleo-drainage channels or drainage lines in sandplain or sand dune habitats (Maxwell et al. 1996). Their diet includes small vertebrates and larger invertebrates. Mulgara burrows were recorded in both phases of the PBS survey (Appendix 2), however no individuals were captured. The burrows were thought to be inactive, as no signs of fresh diggings, scats or tracks were noted. The records were made at three locations in close proximity in the northeastern section of the development envelope.

5.0 Discussion

5.1 Survey Adequacy

The combined Yandi survey effort across the development envelope of MS914, comprised two targeted surveys, four single-phase surveys and four two-phase surveys encompassing seven localities (see Section 3.1). With 54 systematic vertebrate sampling sites, the surveys provided coverage of the range of habitats present in the development envelope. In regards to the surveys' spatial extent, adequate sampling of vertebrate fauna was conducted within the development envelope, however the eastern side of the development envelope (the PBS study area) was sampled more thoroughly than other sections of the development envelope (Figure 3.3 and Figure 3.4).

Dedicated SRE sampling was conducted even more extensively in the east of the development envelope compared to the west (Figure 3.5), which is a function of the greater emphasis on SREs in recent years. That is, more surveys were conducted recently in the east of the development envelope, while more of the historic surveys were conducted in the west at times when SREs were not a primary focus of EIA.

The timing of the survey work was optimal, with the majority of contributing surveys including at least one phase undertaken during warm to hot conditions following the wet season. This is the period in which the greatest faunal diversity is typically recorded.

The species accumulation curves demonstrated asymptotic patterns, indicating that few additional species (approximately 34 vertebrate species; Section 4.7) would be added with further sampling using the same techniques. The non-parametric estimates for the entire vertebrate assemblage imply that 85% of the fauna are likely to have been documented via the methods used during the surveys. This is consistent with the species tallies relative to other comparable scale surveys in the Pilbara bioregion (Table 5.1), and consistent with the relatively high proportion of the theoretical total species assemblage for the locality that was recorded (see Section 4.7).

Table 5.1: Comparison of Yandi surveys with other large-scale Pilbara vertebrate fauna assessment surveys.

Survey (Reference)	No. of Sites	Total Area Surveyed (ha)	Herpetofauna	Mammals	Avifauna	Total Species
Yandi (current study)	54	19,351	72	31	103	206

Cloud Break Mine (BCE 2005)	8	Unspecified	29	25	99	153

5.2 Conservation Significance

When considering the faunal value of the fauna habitats within the development envelope, the following criteria may be used to assess areas of higher habitat value:

- habitat supporting fauna of conservation significance;
- habitat that is uncommon in the region; and
- habitat supporting unique faunal assemblages.

5.2.1 Vertebrate Fauna

When assessing the value of habitat in the development envelope, it is prudent to determine the core habitat of individual species. Core habitat for species of conservation significance equates to "habitat critical to the survival of a species" (DEWHA 2009, DSEWPaC 2011, DotE 2013). Such habitat includes those that are known, or are likely to be utilised by listed species for key ecological activities such as denning, roosting, breeding, refugia and important foraging areas. As a result, it is assumed that some proportion of this habitat must be maintained across the species' range to ensure the persistence of the species in the region.

Using the above criteria, major drainage lines, free faces and breakaway habitats in the development envelope are considered to be the landforms that represent the habitat of highest value to conservation significant fauna. Specifically, these habitats represent core habitat for the Pilbara Olive Python (*Liasis olivaceus barroni*), which was the only Schedule 1 species recorded within the development envelope, as well as the Northern Quoll (*Dasyurus hallucatus*) and Orange Leaf-nosed Bat (*Rhinonicteris aurantius*). The major drainage lines also represent core habitat for the Priority 4 Star Finch *Neochmia ruficauda subclarescens*. None of these landforms are confined to the development envelope and none are uncommon in the region.

Regarding the Schedule 3 (Migratory) species recorded within the development envelope, the Rainbow Bee-eater is widespread throughout much of Australia and typically occurs in open country in most vegetation and landform types (Johnstone and Storr 1998). The Fork-tailed Swift would not rely on any terrestrial habitats within the development envelope. The habitats in the development envelope are therefore not considered to be core habitat for these species. Although the Eastern Great Egret is largely dependent on the presence of significant water bodies, such habitats are not confined to the development envelope.

Four Department of Parks and Wildlife Priority 4 listed species were recorded from the development envelope:

1. Australian Bustard – common throughout most of Australia;
2. Western Pebble-mound Mouse – relatively common on stony country in much of the Pilbara, particularly in the Hamersley Range;
3. Star Finch – common about major watercourses, but typically confined to rushes, reed beds and adjacent vegetation communities along major waterways.
4. Brush-tailed Mulgara – habitat specific in that they occur in spinifex sandplain habitat across the arid zone, and as such, they are patchily distributed.

Although there are no TECs or PECs present, the Weeli Wolli and Marillana Creeks are recognised as having high conservation value as a fauna habitat. Areas such as this containing water for extended periods are considered to represent significant refugia for many fauna species in the Pilbara bioregion, especially during dry years. The habitat would also provide resources for conservation significant fauna, as described above.

NMDS analysis of the herpetofauna assemblage revealed seven clusters of sites, which were grouped based on the 30% assemblage similarity level. Survey locality was the only factor influencing species composition, with the assemblage recorded at the PBS sites being noticeably different to that recorded at other sites during other surveys. It appears that this result is caused by a significantly greater number of species and higher abundance of herpetofauna recorded during the PBS survey compared to the other surveys (Table 4.5). This is likely to be an artefact of greater sampling effort, rather than a real trend based on sampling location, as the trapping effort used during the PBS survey was almost double that of the survey with the next greatest trapping effort (Table 3.2).

NMDS plots of the mammal and avifauna assemblages showed no indication that different assemblages were determined by the factors of interest (locality, land systems, geology and landform). Additionally, the avifauna assemblage showed a limited number of clusters, with the majority of sites grouped into one cluster, thus indicating that in most cases bird assemblages were not fundamentally different between sites. Conversely, the ground mammal assemblage

was separated into many clusters, often with one site in each cluster, indicating that in most cases, assemblages were fundamentally different between sites.

At many of the sites surveyed, no or very few mammals and birds were recorded, thereby compromising the robustness of the data. That is, rather than emphasizing trends in the data, the analysis highlighted the weakness of the dataset from an analysis perspective. As a result, analyses of these assemblages in regards to environmental factors were ineffectual.

The combined fauna assemblage of 206 vertebrate species recorded from the Yandi development envelope is extensive (Section 5.1), but also typical of that which would be realistically expected for an area of similar size in this locality. Although the development envelope contains habitats and species of conservation value, the suite of species present is representative of the fauna commonly recorded within both the Pilbara bioregion and the Hamersley subregion.

5.2.2 Short Range Endemic Invertebrates

This study has documented the existence of potential SRE fauna within the broader Yandi development envelope. Two broad taxonomic groups with the potential to include SREs (pseudoscorpions and mygalomorph spiders) were recorded. Of these, only the mygalomorph spiders included species that potentially represent SREs:

- Idiopidae sp. I1 – This taxon was recorded in the River land system within the development envelope. It occurs in seven different land systems within its recorded distribution (Biota database). It has been recorded in heavy soils in areas low in the landscape, such as valley floors, drainage lines and alluvial fans.
- Idiopidae sp. I9 – This taxon was recorded in the River land system within the development envelope. It is known from three different land systems in its broader distribution, all on alluvial plains or drainage line landforms.
- Nemesiidae sp. N42 – This taxon was recorded in the Boolgeeda, River and Urandy land systems within the development envelope. Specimens are typically recorded from loams or sandy loams in habitat that is not considered to be isolated or restricted. However, records also exist from the Newman land system in rocky habitat.
- Nemesiidae sp. N44 – Specimens were recorded from loamy soils in the vicinity of Weeli Wolli Creek, mainly in the Boolgeeda land system.

All potential SRE taxa recorded within the survey are also known to occur outside of the development envelope. As a result, there is a reduced risk that disturbance within the development envelope will adversely affect these species populations.

All of the potential SRE mygalomorph spiders have been recorded from multiple land systems, and varying substrate types suggesting a lower level of dependence on specific landscape-scale habitat units and therefore a lower risk of small-scale restrictions in the distribution of these species.

S = Schedule; P = Priority; M = Migratory.

Appendix 3

Commonwealth and State Conservation Status Categories

Native fauna species that are rare, threatened with extinction, or have high conservation value are specially protected by law under the WA *Wildlife Conservation Act 1950*. In addition, many of these species are listed under the Commonwealth *EPBC Act 1999*.

Commonwealth *EPBC Act 1999*

Fauna species of national conservation significance are listed under the *EPBC Act 1999*, and have been classified as 'critically endangered', 'endangered', 'vulnerable' or 'conservation dependent' (broadly consistent with International Union for Conservation of Nature (IUCN) categories: http://intranet.iucn.org/webfiles/doc/SSC/RedList/redlistcatsenglish.pdf).

Migratory wader species are also protected under the *EPBC Act 1999*. The national List of Migratory Species consists of those species listed under the following International Conventions:

- Japan-Australia Migratory Bird Agreement (JAMBA);
- China-Australia Migratory Bird Agreement (CAMBA);
- Republic of Korea-Australia Migratory Bird Agreement (ROKAMBA); and
- Convention on the Conservation of Migratory Species of Wild Animals (Bonn Convention).

Western Australian *Wildlife Conservation Act 1950*

Classification of rare and endangered fauna under the *Wildlife Conservation (Specially Protected Fauna) Notice 2013* recognises four distinct schedules of taxa:

Schedule 1 - being fauna that is rare or likely to become extinct and are declared to be fauna in need of special protection;

Schedule 2 - being fauna that is presumed to be extinct and are declared to be fauna in need of special protection;

Schedule 3 - being birds that are subject to an agreement between the government of Australia and the governments of Japan, China and the Republic of Korea relating to the protection of migratory birds and are declared to be fauna that is in need of special protection; and

Schedule 4 - being fauna that is in need of special protection, otherwise than for the reasons mentioned in paragraphs (1), (2) and (3).

In addition, the Department of Parks and Wildlife maintains a list of Priority species (specially protected fauna notice) that have not been assigned statutory protection under the *Wildlife Conservation Act 1950*. Species on this list are considered to be of conservation priority because there is insufficient information to make an assessment of their conservation status or they are considered to be rare but not threatened and are in need of monitoring.

Five Priority codes apply to such fauna:

Priority One – Taxa with few, poorly known populations on threatened lands.
Taxa that are known from a few specimens or sight records from one or a few localities on lands not managed for conservation. The taxon needs urgent survey and evaluation of conservation status before consideration can be given to declaration as threatened fauna.

Priority Two – Taxa with few, poorly known populations on conservation lands, or taxa with several, poorly known populations not on conservation lands.
Taxa that are known from few specimens or sight records from one or a few localities on lands not under immediate threat of habitat destruction or degradation. The taxon needs urgent survey and evaluation of conservation status before consideration can be given to declaration as threatened fauna.

Priority Three – Taxa with several, poorly known populations, some on conservation lands.
Taxa that are known from few specimens or sight records from several localities, some of which are on lands not under immediate threat of habitat destruction or degradation. The taxon needs urgent survey and evaluation of conservation status before consideration can be given to declaration as threatened fauna.

Priority Four – Taxa in need of monitoring.
Taxa that are considered to have been adequately surveyed or for which sufficient knowledge is available and which are considered not currently threatened or in need of special protection, but could be if present circumstances change. These taxa are usually represented on conservation lands. Taxa that are declining significantly but are not yet threatened.

Priority Five – Taxa in need of monitoring.
Taxa that are not considered threatened but are subject to a specific conservation program, the cessation of which would result in the species becoming threatened within five years.

EXECUTIVE SUMMARY

The setting of the Pocket and Billiard South (PBS) Project is on the broader floodplain of Weeli Wolli Creek, in proximity to riparian zones. The riparian zones are characterised by comparatively high water availability and likely sensitivity to change in this regard. In this setting the importance of the riparian zones is empathised through Ministerial Statement 914 (2012) relevant to the RTIO Yandicoogina Mine. Further, is the definition of a Riparian Exclusion Zone on Weeli Wolli Creek that is intended to limit disturbances to the highest conservation value riparian floristic stands that extend to distances up to about 600 m from the low-flow channel.

In the baseline settings, the riparian zones on Weeli Wolli Creek were interpreted to be predominantly dependent on surface water and pore water derived from direct rainfall, overland flow and episodic stream flow events. Depths to the water table in the range 12 to 20 m provided low groundwater dependency.

Since about 2007, the discharge of surplus groundwater into Weeli Wolli Creek increased the water availability through the presence of wetting fronts. The wetting fronts represent the transport, dissipation and fates of the surplus groundwater within the local surface water, surface water to groundwater and groundwater receiving environments. Mechanisms for dissipation include infiltration, interception by evaporation and transpiration and, though-flow in the groundwater environment. Since 2007, the surface water wetting front has been waxing and waning over a 4 km reach of Weeli Wolli Creek. This characteristic was interpreted to represent quasi-steady-state conditions wherein the infiltration, evaporation and transpiration mechanisms were reasonably consistent over time. Under these circumstances, the predominant dissipation mechanism is through-flow in the groundwater environment, controlled by the effective transmissivity of the floodplain and CID aquifer system. The cumulative losses due to evaporation and transpiration tend to be comparatively small, amounting to 15 to 25 per cent of the total water balance. Of these losses, evaporation is subordinate to transpiration.

The observed wetting fronts and interpreted fates of the surplus water (Dogramaci, et al., 2015a and, Pettett and Pearcey, 2014) provide indications of a high-transmissivity aquifer system beneath the northern reaches of Weeli Wolli Creek and Poonda Plain. In 2013, this aquifer system transmitted about 54 GL, with comparatively limited expression in terms of the amplitudes in water table mounding.

The changed surface water and groundwater environments provided potential for increased groundwater use (medium dependency) within the riparian zone, commensurate with reduced surface water and pore water dependencies. Decay of water availability to the riparian zones would be inevitable once the discharge of surplus water ceases or is substantially reduced.

The proposed mining at Pocket and Billiard South (PBS) would impose changes to the water availability on Weeli Wolli Creek. Perennial stream flow in the low-flow channel and opportunities for flooding of adjacent riparian zones would be largely undisturbed. Dewatering of the proposed pit would, however, substantially lower the water table, with rate of decline beyond natural variation. Ultimately the water table would be lowered to

below baseline elevations, with associated potential deficits in the available water and declines in potentials for groundwater dependency.

Contextually, the water availability risks to the riparian zone would predominantly have aspects that reflect the adaptability of riparian floristics:

- In drawing from alternative sources when groundwater availability is reduced by 12 to 22 percent from current scenarios.
- Reverting to baseline dependencies on surface water and pore water.
- To net reductions of 3 to 9 per cent in total water availability compared to baseline.
- Waterlogging due to mounding of the water table and persistence of stream flow.

Ecological Water Requirements of the riparian zones on Weeli Wolli Creek would be supported by the following:

- Retention of perennial surface water flows, at least initially.
- Limiting changes to periods of high floodwater.
- Avoidance of drawdown of the water table.

The PBS scenario captures two of these processes, but not retention of groundwater availability. Under these circumstances, the riparian groundwater dependent floristics would probably experience drought-like conditions, with associated water availability stress. The percentage scale of the changes in the water availability has been used to define potential risks. In this regard, low risks reflect changes of less than 10 per cent; medium risks between 10 to 18 per cent; medium-high risks 18 to 25 per cent and high risks greater than 25 per cent.

The interpreted changes in water availability within the riparian zones may be partially off-set by sustaining stream flow in the low-flow channel.

1 THE POCKET AND BILLIARD SOUTH PROJECT

1.1 Overview

Brownfield expansion plans for the RTIO Yandicoogina Mine include the development of the Pocket and Billiard South (PBS) Project. Both Pocket and Billiard South deposits represent downstream extensions of the Channel Iron Deposits (CID) currently being developed. The setting of the PBS Project is on the floodplain of Weeli Wolli Creek, near the confluence with Marillana Creek, as shown on Figure 1-1.

The floodplain on Weeli Wolli Creek forms an area of comparatively high water availability which supports a locally significant riparian woodland (Figure 1-2). The mapped riparian areas shown on Figure 1-2 form a Riparian Exclusion Zone wherein disturbance is proposed to be limited. Within the Riparian Exclusion Zone *Eucalyptus camaldulensis* (River Red Gum) and *E. victrix* (Coolibah) form a riparian fringe over-storey along the local reaches of the Weeli Wolli Creek, together with woodlands and open stands of *Acacia citrinoviridis (Black Mulga), A. coriacea subsp. pendens,* and *M. glomerata* with a mix of shrubs and grasses.

Surface water and pore water dependence with a lesser and variable degree of groundwater dependence typically characterise the riparian zone. The floodplain and associated riparian zone is underlain by alluvium and Tertiary detritals, including CID, that form a significant aquifer system. Both surface water and groundwater from the Weeli Wolli Creek flow to the north, traversing the Poonda Plain before terminating within the Fortescue Marsh.

A Public Environmental Review (PER) is in preparation to support regulatory processes in the PBS development. Conservation of the riparian zone is an important element of PBS to be addressed within the PER.

1.2 Context to Historical Mining Activities

The water resources of the PBS setting on Weeli Wolli Creek have been altered by cumulative influences of the BHPBIO Yandi, RTIO Yandicoogina and Hope Downs 1 mines. Each mine extends below the water table and consequently excavations are accompanied by groundwater abstraction to dewater the local aquifer systems. Water surplus to on-site operational and iron ore beneficiation demands has been discharged to Marillana Creek and Weeli Wolli Creek.

Under baseline conditions the occurrence of wetlands, pools and shallow water table on lower Weeli Wolli Creek extended several kilometres downstream from Weeli Wolli Spring. Discharge of the surplus water has contributed to a surface water wetting front on Weeli Wolli Creek that extends for approximately 25 km downstream of Weeli Wolli Spring (Hamersley HMS, 2010), thus about 6 km downstream of the Marillana Creek confluence. The wetting front is characterised by sustained expressions of stream flow and pools on Weeli Wolli Creek.

A brief outline of each mine and associated surplus water discharge is provided below. Locations in context to the PBS Project are shown on Figure 1-3.

1.2.1 BHPBIO Yandi Mine

The BHPBIO Yandi Mine is located on Marillana Creek upstream of the RTIO Yandicoogina Mine. Operations commenced in 1991, including limited surplus water discharge to Marillana Creek at an outlet termed Anniversary Drive. In 2007, the outlet was relocated downstream to the Railway site immediately upstream of RTIO Yandicoogina mine operations on the State Agreement tenement boundary. Typically, about 5GL/annum is discharged into Marillana Creek from the BHPBIO Yandi Mine; however the project is licensed for 15GL/annum, with peaks of 9GL/annum recorded.

1.2.2 RTIO Yandicoogina Mine

The Yandicoogina Mine is located near the junction of the Marillana and Weeli Wolli creeks and commenced open pit operations in 1998. Mining concurrently occurs within the Junction South West, Junction Central and Junction South East deposits (Figure 1-1), each aligned on CID in proximity to Marillana Creek.

Pit dewatering activities at the RTIO Yandicoogina Mine commenced in 1998, predominantly associated with the Initial Mining Area (IMA) and Junction Central settings on Marillana Creek. Dewatering in the vicinity of Weeli Wolli Creek commenced with the operating of the RTIO Yandi Southern Borefield within the Junction South East deposit during August 2006. The date was commensurate with reinjection (RTIO Yandicoogina Billiard Reinjection) of surplus water from the Junction South East Deposit into the CID aquifer beneath Weeli Wolli Creek in the PBS setting. The discharged water has pH 6.8 to 9.6 and TDS concentrations in the range 370 to 780 mg/L.

1.2.3 Hope Downs 1 Mine

The Hope Downs 1 Mine is located within the upper catchment of Weeli Wolli Creek; upstream of Weeli Wolli Spring. Hope Downs Management Services, (2000) predicted groundwater abstraction of up to 38GL/annum to enable reasonably dry mining conditions.

Groundwater abstraction and associated discharge up to 33 GL/annum commenced in late-January 2007. Initial rates of abstraction were comparatively low. Revised forecasts of the peak rates of abstraction from the Hope Downs 1 Mine range up to 40GL/annum (Kellogg Browne and Root Pty Ltd, 2007); a 40 GL/annum rate of abstraction was not achieved prior to 2013.

The predominant fate of the discharged water is the reach of Weeli Wolli Creek downstream of Weeli Wolli Spring. After the first month of discharge, the surface water expression was recorded at a distance of approximately 13 km downstream of the outfall at Weeli Wolli Spring (Kellogg Browne and Root Pty Ltd, 2007). By September 2007, about nine months after commencement of discharge, the surface water expression progressed to approximately 19 km downstream from the discharge outlet.

1.3 Riparian Zone Aspects

1.3.1 Water Availability

Riparian zones are defined as low-lying areas within and adjacent to the low-flow channel of Weeli Wolli Creek and subject to episodic flooding by stream flow and overland flow (sheet flow) (Junk and Welcomme 1990). The low-lying areas form the immediate channel bank settings and may extend up to about 1 km from the low-flow channel. The riparian zone is characterised by comparatively high water availability and likely sensitivity to change in this regard. In the baseline environment, water availability in the riparian zone is supported by:

- Flooding during episodic stream flow events.
- Soil profiles formed by floodplain deposits, with clay and silt beds providing capacity to store soil water (pore water).
- Groundwater where depths to the water table are comparatively shallow.

Commonly, the floristics within the riparian zone are characterised by xeromorphic adaptations; these enable the draw of water from different sources and matching of water demand to available water. Mature eucalypts (such as *E. camaldulensis*) are recognised (Graham, 2001; O'Grady et al. 2005) as having tap-root systems that may extend to deep water table settings. Conversely, *E. victrix, M. argentea* and acacia woodlands have not been observed as having deep tap-root systems in excavations (Batini, 2008). At the Coolibah Woodlands, Marandoo, the conceptualisation of *E. victrix* rooting depths is to about 13 m (Batini, 2009)

Broad-scale distributions of the riparian vegetation on the lower reaches Weeli Wolli Creek are outlined in Table 1-1 and on Figure 1-2a. Recent vegetation mapping has added detail to the riparian floristic community distributions. The results of this detailed mapping are shown on Figure 1-2b. Important attributes of the detailed mapping include:

- The predominance of *E. victrix* open woodland over *Acacia citrinoviridis* within the Riparian Exclusion Zone, particularly in settings outside of the low-flow channel and incised channel of Weeli Wolli Creek.
- Preferable alignment of the *E. camaldulensis, E. victrix* and *M. argentea* woodland communities on the low-flow channel and incised channel of Weeli Wolli Creek.
- Limited distributions of *E. camaldulensis* co-dominated communities on and immediately adjacent to low-flow channel scour beds.
- Limited, discrete and discontinuous distributions of E. camaldulensis co-dominated communities with transient Melaleuca argentea populations on and immediately adjacent to low-flow channel scour beds on Weeli Wolli Creek and Marillana Creek.

Table 1-1 Distributions of Riparian Floristics on Weeli Wolli Creek (April 2010)

Creek Setting	Main Vegetation
WW1 – Narrow riparian vegetation corridor; larger trees line the banks of the creek.	*E. victrix* *Acacia citrinoviridis*
WW2 – Wide floodplain with extensive vegetation growth.	
WW3 – Confluence with Marillana Creek; wide floodplain with extensive vegetation growth.	*E. victrix* *E. camaldulensis*
WW4 – Wide floodplain with extensive vegetation growth.	*E. victrix* *Acacia citrinoviridis*
WW5 – Alluvial plain supporting smaller plant species.	Mulga species Shrublands/grasslands

1.3.2 Ministerial Conditions

The importance of the riparian ecosystems in context of the RTIO Yandi Mine was emphasised through Ministerial Statement 914 (October 2012):

- Condition 6-1: “that the discharge of excess water as a result of mining does not cause long term impacts to environmental values of the Weeli Wolli Creek System”.
- Condition 6-2: “develop an Environmental Values Statement for the Weeli Wolli Creek System that defines the environmental values of the Weeli Wolli Creek System”.
- Condition 6-3: “ensure that dewatering discharge from the Yandicoogina Iron Ore Project – Expansion to include JSW and Oxbow deposits does not cause water flow or pooling further than 17 km downstream from the Marillana Creek and Weeli Wolli Creek system confluence”.
- Condition 7-1: ”that groundwater abstraction does not cause clearing or loss of vegetation for groundwater dependent ecosystems outside Zones 1, 2, 2a, 3, 3a, 4 and 5 as shown in Figure 1”.
- Condition 7-2: “dewatering discharge does not cause clearing or loss of vegetation or groundwater dependent ecosystems outside Zones 1, 2, 2a, 3, 3a, 4 and 5”.
- Condition 7-3: “there is no irreversible impact to riparian vegetation or groundwater dependent ecosystems” within specified reaches along both Marillana and Weeli Wolli Creeks”.
- Condition 7-4: “prepare a Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan”.
- Condition 7-5: ”The Vegetation and Groundwater Dependent Ecosystems Monitoring and Management Plan shall enable:
  - *The maintenance of the flow paths, quantity and quality of water within Marillana, Yandicoogina and Weeli Wolli Creeks and the underlying aquifers to protect the surface water and groundwater dependent ecological systems.*

- *Identify potential impact monitoring and control sites between the Oxbow pit and the Fortescue Marsh.*
- *Design a survey to acquire baseline biotic data, including health and abundance parameters and environmental data.*
- *Definition of health and abundance parameters.*
- *Identification of criteria to measure any decline in health.*
- *Definition of critical correlative environmental parameters, including groundwater drawdown.*
- *Definition of trigger levels for no impact.*
- *Definition of trigger levels for no irreversible impact".*

1.4 Conservation of Fortescue Marsh

The Fortescue Marsh forms the receiving environment for the Upper Fortescue River and its tributaries, including Weeli Wolli Creek, upstream of terminations formed by Goodiadarrie Hills. It is considered a unique and nationally important wetland (Australian Natural Resources Atlas (ANRA), 2007, Kingsford et al., 2005) and is therefore of high conservation value. Further, the marsh is a species-rich ecosystem with endemic species and refuges for flora and fauna. The Department of Parks and Wildlife (DPaW) also lists the wetland as a Priority 1 Priority Ecological Community (PEC). Further, the marsh meets one Ramsar Convention criterion for listing as a Wetland of International Importance (Jaensch and Watkins, 1999). Fortescue Marsh is also designated as a wetland of national importance under criteria 1, 2, 3 and 6 of the Directory of Important Wetlands in Australia.

From a water-resource perspective, it is understood that the Fortescue Marsh is characterised by:

- Disconnection from the lower Fortescue River Valley by a natural barrier at Goodiadarrie Hills.
- Recharged during flood events. Discharge of surface water and groundwater by evaporation and transpiration. A regional surface water and groundwater sink wherein salt is accumulated.

The Department of Water (DoW) in collaboration with the DPaW, Department of State Development and the Environmental Protection Authority (EPA, 2013) have issued guidelines for management of projects in the vicinity of Fortescue Marsh. The guidelines reflect the importance of the Fortescue Marsh as an environmentally sensitive area and recognise potentials for altered water balances due to cumulative changes linked to mining projects. Management zones defined by the guidelines reflect relative priorities in terms of environmental values (Figure 1-4). The Poonda Plain management areas encroach on the lower reaches of the Weeli Wolli Creek (about 5 km north of the Marillana Creek confluence). On the Poonda Plain the primary water resources management guidelines include:

- Maintaining the natural flow systems of tributaries entering Fortescue Marsh.
- Conservation of the hydrological and ecological integrity of the major tributaries by limiting changes to occurrences and rates of stream flow.

The guidelines recognise that activities, for example by discharge of surplus water, outside of the management zones may impose changes to the hydrology.

1.5 Report Objectives

The scope of work addressed herein is focussed on the delivery of cumulative change and environmental risk assessments associated with development of PBS. These assessments focus on the potential surface water and groundwater changes and risks to sensitive environmental areas of Weeli Wolli Creek and Fortescue Marsh. Discrete assessments provide surface water and groundwater contexts regarding five tasks:

- Footprints where the water table is lowered by groundwater abstraction and or mounded by surplus water discharge in context to ecological water requirements for riparian vegetation on Weeli Wolli Creek and in Fortescue Marsh. The intention is to define the likely net change in available water on reaches of Weeli Wolli Creek in the immediate vicinity of PBS.
- Cumulative influences on the change footprints and environmental risk linked to existing projects (including BHPBIO Yandi, RTIO Yandicoogina and Hope Downs 1 mines) and the development of PBS.
- Potential future cumulative influences on the change footprints and environmental risks linked to concurrent project developments that may include Jinidi, Iron Valley and Nyidinghu.
- Environmental risks of the cumulative change footprints propagating significantly onto the Poonda Plain management zone of the Fortescue Marsh.
- Preparation of an overall summary report on the surface water and groundwater interactions.

In particular, the deliverable (this report) encompasses:

- The baseline surface water and groundwater environments, with relevant contexts to conceptual models and integrated water resources availability to local ecosystems.
- Cumulative change assessments for the surface water and groundwater environments of Weeli Wolli Creek linked to the RTIO Yandicoogina, BHPBIO Yandi and Hope Downs 1 mining projects. These assessments were coupled to the conceptual models to describe how the water resources systems function, together with the mechanisms that have promoted the known changes to date. Both aspects provide analogies that inform future changes to the integrated water resources availability to local ecosystems.
- An environmental risk assessment in context to surface water and groundwater availability changes associated with PBS. This assessment considers potential cumulative changes due to concurrent development of the existing BHPBIO Yandi, RTIO Yandicoogina and Hope Downs 1 operations.
- Consideration of cumulative future changes that may be associated with new mining projects such as the BC Iron's Iron Valley (below water table), Jinidi and Nyidinghu deposits.

2 PHYSICAL SETTING

2.1 Rainfall

Rainfall events in the Pilbara are characteristically widely variable both spatially and temporally. Average monthly rainfall data collected at Tarina (Bureau of Meteorology (BoM) Site No. 505040 approximately 8 km south of the PBS Project) and Waterloo Bore (BoM Site No. 505041, approximately 8 km north of the PBS Project) are presented in Table 2-1 and on Figure 2-1 (with data from Waterloo Bore). The Tarina and Waterloo Bore data indicate local annual average rainfall in the range 360 to 400 mm, with the majority of rainfall occurring between January and March

Table 2-1 Average Monthly Rainfall at Tarina and Waterloo Bore

Month	Rainfall (mm)	
	Tarina[1]	Waterloo Bore[2]
January	79.5	89.1
February	90.0	94.9
March	46.9	62.1
April	21.5	22.9
May	16.1	16.2
June	20.0	22.9
July	11.2	11.0
August	7.7	5.2
September	4.6	3.9
October	5.9	5.3
November	14.8	10.4
December	45.2	53.4
Annual Totals	363.4	397.3
Notes:		
1 Bureau of Meteorology Site No. 505040; data from 1986 to 2013.		
2 Bureau of Meteorology Site No. 505041; data from 1986 to 2013.		

Rainfall is episodic and widely variable; the annual recorded rainfall for the region ranges from 180 to 810 mm. This variability is predominantly due to the random nature of tropical cyclones and localised thunderstorms. The numbers of annual average rain days (BoM website) includes:

- About 30 days for events greater than or equal to 1 mm depth.
- 10 days for events greater than or equal to 10 mm depth.
- 3 to 5 days for events greater than or equal to 25 mm depth.

Larger than average annual rainfall was recorded in the Weeli Wolli Creek Catchment in 1973, 1975, 1994 to 2005, and in 2006. Numerous cyclones and tropical low rainfall systems have passed in vicinity of the catchment in the period 1970 to present, including:

- Kerry in January 1973; Wittenoom and Rhodes Ridge recorded 218 and 215 mm rainfall depth respectively.
- Joan in December 1975; approximately 200 mm rainfall at Weeli Wolli Creek.
- Bobby in February 1995;approximately 200 mm rainfall at Weeli Wolli Creek over four days, including 107 mm on 18 February; 1:20-year ARI.
- Rachael in January 1997; 319 mm over six days; 1:4-year ARI.
- Thelma in December 1998; 175 mm rainfall at Newman over two days.
- John in December 1999; 365 mm over several days including 267 mm on the 15th December; 1:20 to 1:50-year AR1.
- Norman in February 2000; 139 mm.
- Thunderstorms in December 2002.
- Un-named tropical low In January 2003: 321 mm over six days including 234 mm on 25th January; 1:20-year ARI.
- Clare in January 2006; 172 mm.
- Emma in February 2006; 164 mm
- Un-named tropical low in December 2007.
- Tropical Low 2, 23 February to 6 March 2009, with 146 mm rainfall recorded in 1 March.

The period 1985 to 1993 was drier than normal. Conversely, the period 1994 to 2005 was characterised by unusually high rainfall.

2.2 Evaporation Potentials

Evaporation potentials in the Pilbara range from 3,200 to 3,600 mm/annum (Van Vreeswyk, 2004).

2.3 Major Landforms

The major landform units are:

- Hamersley Plateau.
- Fortescue River Valley.

Both landform settings are discussed below and contexts to Weeli Wolli Creek are shown on Figure 1-4.

2.3.1 Hamersley Plateau

The Hamersley Plateau landscape is one of rounded hills and ranges, with escarpments that front onto the Fortescue River Valley. It is a fossil landscape that rises from 550 to 700 m AHD, with hills locally to 1,150 m AHD, and is predominantly stripped of soil cover and incised by major watercourses of the Weeli Wolli, Coondiner and Kalgan creeks.

The plateau landscape reflects differential erosion processes and complex drainage patterns. The dominant landscape features are ephemeral watercourses of the Marillana Creek Catchment that shed surface water east to the confluence with Weeli Wolli Creek, then northerly into the Fortescue Marsh. Erosion and fluvial processes have shaped the fossil landscape, with watercourses meandering between resistant low-lying mesas and rounded hills.

2.3.1.1 Weeli Wolli Creek

The catchment of Weeli Wolli Creek occurs within the Hamersley Plateau physiographic unit. The total Weeli Wolli Creek Catchment area upstream of the Fortescue Marsh is 4,717 km² and is characterised by northward flow on an approximate main stream length of 112 km. Upstream of the Weeli Wolli Spring the catchment area is 1,877 km^2. Weeli Wolli Creek has a linear alignment, possibly controlled by structural fabrics in the underlying bedrock.

Locally at Weeli Wolli Spring, perennial stream flow is enabled by baseflow. The perennial stream flow from Weeli Wolli Spring supports riparian habitats, wetlands, pools and shallow water table on the downstream reaches that under baseline conditions extended several kilometres downstream of Weeli Wolli Creek.

Weeli Wolli Creek drains into the southern Fortescue Marsh approximately 40 km north of the confluence of Weeli Wolli and Marillana creeks. Upon exiting the Hamersley Plateau, the Weeli Wolli Creek has formed an extensive delta that hosts bifurcate channels and ancestral palaeochannels. At present, the main watercourse has a north-westerly orientation across the upper slopes of the delta; the location of this channel would have changed over time. Flow on the deltaic landforms during episodic flood events will occur in numerous channels. From the delta, the Weeli Wolli Creek channels extend northwards into the Fortescue Marsh.

2.3.1.2 Marillana Creek

Marillana Creek, a major tributary of Weeli Wolli Creek, has a total catchment area of 2,230 km^2 and main stream length of 110 km that provides drainage from west to east. Marillana Creek is a wide, gravel-bed watercourse that generally flows only following significant rainfall events.

2.3.2 *Upper Fortescue River Valley*

The Upper Fortescue River Valley occupies a trough between the Hamersley and Chichester plateaus, extending westward to Goodiadarrie Hills. The Goodiadarrie Hills and associated geological characteristics isolate stream flow within the Upper Fortescue River Valley from that of the Lower Fortescue River, leading to the presence of Fortescue Marsh.

The surface water catchments of the Upper Fortescue River Valley are shown in Table 2-2. Groundwater contributions also support the water balance of the Fortescue Marsh.

Table 2-2 Surface Water Catchments of the Upper Fortescue River

Catchment	Sub-Catchment	Approximate Area (km^2)	Percent of Upper Fortescue River Catchment
Fortescue Marsh	-	5,588	19
Upper Reaches of Fortescue River	-	16,783	56
Mindy Mindy and Coondiner Creek	-	2,664	9
Weeli Wolli Creek Catchment	Marillana Creek	2,230	8
	Lower Reaches (below Weeli Wolli Spring and excluding Marillana Creek)	610	2
	Upper Reaches (upstream of Weeli Wolli Spring)	1,877	6
Total		**29,752**	**100**

Within the Upper Fortescue River Valley there are a number of subsidiary landform units that conform to management zones of the Fortescue Marsh. These include sand plains, outwash plains, valley plains and flood-out zones. Typically, the extensive valley plains and flats within the Fortescue River Valley are characterised by earthy clays, with subordinate cracking (gilgai) clays, shallow loams and hard red soils. These subsidiary landform units include:

- Poonda Plain.
- Marillana Plain.
- Calcrete Flats.
- Fortescue Marsh.

Each landform is briefly described below.

2.3.3 Poonda Plain

Poonda Plain hosts the upper slopes of outwash fans of the Weeli Wolli, Coondiner and Kalgan creeks on the perimeter of the Hamersley Plateau and is characterised by alluvial, stony and/or sandy plain intersected by numerous watercourses. The outwash fans provide recharge areas for stream flow and runoff from the Hamersley Plateau and, a hydrological buffer to Fortescue Marsh. Riparian and extensive mulga woodlands with mixed Acacia shrublands dominate the vegetation on heavy alluvial soils; Acacia shrublands and spinifex grasslands prevail on sandy plains. The riparian vegetation provides ecological connectivity to the Marsh from upstream ecosystems.

The shallow groundwater resources beneath upland areas of Poonda Plain tend to be fresh and brackish, but become increasingly saline and hypersaline further north and beneath Marillana Plain.

2.3.4 Marillana Plain

Marillana Plain includes gravelly, sandy and gilgai surfaces on the outwash fan mid-slopes and foot-slopes for the Weeli Wolli, Coondiner and Kalgan creeks. The outwash fans provide areas for rainfall and stream flow infiltration to the water table. Vegetation is dominated by mixed Acacia mulga woodlands and shrublands.

Beneath the plain, significant thicknesses of alluvial floodplain strata provide a large groundwater storage capacity and discharge pathways for the regional groundwater flow systems, including Weeli Wolli Creek.

2.3.5 Calcrete Flats

The calcrete flats predominantly comprise low calcrete platforms and alluvial floodplain/sandplain, with scattered clay pans.

The groundwater environment is characterised by shallow thin brackish lenses in calcrete overlying saline resources, with fresh recharge from episodic rainfall events.

2.3.6 Fortescue Marsh

Fortescue Marsh is an extensive, approximately 100 km long and 10 km wide, episodically inundated samphire marsh. Stream flow is typically ephemeral; surface water flows generated by runoff only occur after short lived episodic rainfall events. Stream flow accumulates in Fortescue Marsh where there is discharge by evaporation and consequent accumulation of salts. The episodic wetting and drying processes result in the cyclic transformation of the Fortescue Marsh from a fresh water lake ecosystem (when water levels are high) through to a saline lake and subsequent playa under influences from progressive drying (Skrzypek et al., 2013; Rouillard et al., 2015).

2.4 Stratigraphy and Lithology – PBS Setting

The Weeli Wolli creek overlies a basement formed of the Hamersley Group comprising a number of Archaean to Early Proterozoic geological formations. Locally, one of these formations known as the Weeli Wolli Formation, forms the majority of the basement and is characterised by Banded Iron Formation (BIF), chert, shale and jaspilite. Further to the north, beneath the Poonda Plain, the Brockman Iron Formation and Wittenoom Formation form the basement. The basement rocks have been folded into a broad syncline (termed the Yandicoogina Syncline) and traversed by faults and intrusive dolerite dykes.

Overlying the basement are Quaternary alluvial and Tertiary detrital sediments. The Tertiary detritals include CID, which is present in steeply incised erosional troughs beneath the present-day watercourses. The CID is reasonably continuous and consistent in thickness (about 50 m) and width; an exception occurs downstream of the Marillana Creek confluence where the depth to bedrock is locally comparatively shallow and the CID less developed. Overlying the CID beneath the floodplain of Weeli Wolli Creek, there are alluvial and colluvial deposits, which are predominantly gravelly clays, but also buried river channels. For example, beneath the present-day watercourses there are often unconsolidated beds of river gravels and conglomerates up to 5 m in thickness that are characterised by clasts of BIF, shale, siltstone and chert.

A 1:10,000 geology mapping investigation (Youngman, 1997) particularly associated with the CID settings on the lower reaches of Marillana Creek, including Yandicoogina Creek and extending beneath Weeli Wolli Creek, defined four predominant lithology and stratigraphic successions. These successions are described in Table 2-3 and typical distributions are illustrated in cross-section with context to Weeli Wolli Creek on Figure 2-2.

Table 2-3 Local Stratigraphy

Age	Group	Formation	Estimated Typical Thickness (m)	Description
Cainozoic	Overburden	Alluvium/Colluvium	5	Unconsolidated gravels in clay matrix
		Weathered CID		
	Tertiary CID	Goethite Vitreous Upper	20	Hydrated iron oxides, predominantly goethite and hematite
		Goethite Vitreous Lower	25	
		Clayey Basal Zone Limonite-Goethite Channel	16	Clay-rich and ochreous limonite
		Altered Basement Basal Clay Conglomerate	8	BIF, chert and shale with clay matrix where weathered
Archaean to Early-Proterozoic	Hamersley Group	Basement Weeli Wolli Formation	Indefinite	

Lithological descriptions include:

- Quaternary and Tertiary overburden: unconsolidated, very coarse, poorly-sorted angular to rounded BIF, chert, reworked CID and dolomite gravels in a sandy clay matrix. Overlying the CID is a weathered channel horizon characterised by low-iron-content pisolite with clayey matrices.
- Early-Tertiary CID: formed of detritals that have been altered by *in situ* chemical precipitation of hydrated iron oxides and variable matrices predominantly of goethite and limonite.
- Clayey basal zone – irregular limonite-goethite channel predominantly formed of clay-rich, yellow ochreous limonite with localised inclusions of vitreous.
- Proterozoic altered basement - basal clay conglomerate: lateritic profiles and weathered basement rocks typically including clasts of BIF, chert and shale in a clay matrix.
- Archaean and early-Proterozoic basement: consisting of BIF, shale, dolerite and dolomite of the Weeli Wolli Formation.

The palaeovalley beneath Weeli Wolli Creek that hosts the CID has a linear alignment and usually consistent channel form. Exceptions occur:

- Below the lower reaches of Weeli Wolli Creek at a distance about 4 km downstream of the Marillana Creek confluence. In this vicinity, the CID channel is substantially diminished on reaches that traverse a resistant bedrock shelf.
- In transition zones from the Hamersley Plateau to Poonda Plain landforms the palaeovalley bifurcates and deepens under the influence of structural fabrics within the bedrocks. The CID persists in the bifurcate channels and includes a basal peat lithology (Fowers et.al; 2013).

2.5 Stratigraphy and Lithology – Poonda Plain

For this study, the understanding of the stratigraphic and lithological profiles beneath Poonda Plain has been informed by:

- Comparatively wide-spaced mineral resource and groundwater exploration investigations by the proposed Marillana Project (Aquaterra, 2010).
- A regional groundwater exploration programme focussed on Fortescue Marsh and associated management zones (McLean and Sanderson, 2013 in draft).
- A transect within the proposed Nyidinghu Project, broadly where Weeli Wolli Creek enters Poonda Plain (Fowers et al.; 2013).

Data from these references have been collated and interpreted to define the broad-scale stratigraphic and lithological units, including:

- Quaternary and Tertiary detritals, alluvium and colluvium. This unit blankets the Poonda Plain, with thickness typically 10 to 20 m, but ranging up to about 45 m. Upper successions are predominantly alluvial and colluvial, associated with the outwash fan from Weeli Wolli Creek. Interspersed within and below these deposits are clay-rich alluvial beds and, hematite and pisolitic detritals.

- Calcrete and facies equivalent CID, pisolitic gravels and hematite detritals. The calcrete tends to be massive and crystalline in thicknesses of 10 to 15 m.
- Tertiary detritals, including palaeochannel successions and basal clay conglomerate that form interspersed beds of alluvium, colluvium, hematite, pisolitic detritals sands and peat. These successions rest on basement and reflect ancestral depositional environments in floodplain and incised palaeovalley settings, representing the downstream extensions of the CID beneath Weeli Wolli Creek. Bottom elevations of the ancestral floodplain settings typically occur in the range 340 to 390 m AHD. The palaeovalley features appear deeply incised; mapping at the Nyidinghu Project (Fowers et al.; 2013) shows bottom elevations of the palaeochannel in the range 270 to 305 m AHD. It is anticipated that the predominant palaeovalley feature is aligned with Weeli Wolli Creek and associated structural defects in the basement.
- Archaean to Early-Proterozoic Hamersley Group, with local predominance of the Wittenoom Formation.

The interpreted distributions of the stratigraphic and lithological profiles are shown in cross-section view on Figure 2-3. Plan views of the data distributions and interpreted elevations for selected basal contacts are shown on Figure 2-4 (a to c).

3 BASELINE SURFACE WATER RESOURCES ENVIRONMENTS

Weeli Wolli Creek is the focus of the baseline assessments of the surface water environment. It occurs in the watershed of Fortescue Marsh and this aspect is also considered.

3.1 Weeli Wolli Creek

3.1.1 Episodic Stream Flow

Long-term stream flow records (1985/1985 to present) at Tarina and Waterloo Bore provide baseline data of surface water flow on Weeli Wolli Creek. Natural perennial flows on the Weeli Wolli Creek occur at Weeli Wolli Spring, located approximately 4.5 km upstream from Tarina.

Historical observations indicate Weeli Wolli Creek was ephemeral, flowing only once or twice per year during episodic rainfall events. Baseline flow was widely variable with the initiation of runoff strongly dependent on antecedent conditions and the intensity and spatial distribution of rainfall. Baseline storm flows tended to be flashy at Tarina with runoff quickly removed or lost to the underlying aquifer. As a result, storm response was widely variable between Tarina and Waterloo Bore with Waterloo Bore, in general, requiring a higher magnitude rainfall event to initiate runoff. On average Tarina experienced 28 days of continuous flow during baseline conditions in comparison to 12 days of continuous flow at Waterloo Bore. Flow events could typically be characterised as 1- to 5-year ARI events. Numbers of days of flow at Tarina and Waterloo Bore, respectively, for selected events (RTIO, 2013) includes:

- February 1995: 1.7 and 4.2 days for 1:20-year ARI rainfall event.
- January 1997: 10 and 25 hours for 1:4-year ARI rainfall event.
- December 1999: 25 and 40 hours for 1:50-year ARI rainfall event.
- January 2003: 20 and 30 hours for 1:20-year ARI rainfall event.

There is historical evidence from pre-mining aerial photographs that Weeli Wolli Creek was characterised by wetlands, pools and a shallow water table on reaches extending several kilometres downstream from Weeli Wolli Spring. As flow is not perennial at Tarina this suggests a large proportion of the overflow from Weeli Wolli Spring is transmitted as through-flow in the groundwater environment.

During dry years, in which less than 300 mm of rainfall was experienced (1989 to 1991 and 1996), surface water runoff was generally not sufficient to generate flow at either Tarina or Waterloo Bore. Based on an analysis carried out by CSIRO (2013), the mean rainfall threshold for runoff commencement at Tarina is 36 mm during a single storm event. This was a mean derived value; the actual runoff threshold for each flow event would depend on the antecedent moisture conditions of the catchment. In the 25-year period from 1985 to 2010, 40 storm events of at least 36 mm depth were recorded, and therefore were likely to have generated stream flow in the catchment. Hence it was likely that at least one flow-generating rainfall event would occur every year. The remaining rainfall events were generally less than 10 mm, as illustrated on Figure 3-1, and therefore unlikely to trigger surface water flows in the system.

The predicted design flood peaks estimated for Weeli Wolli Creek at PBS and confluence of Marillana/Weeli Wolli Creek are outlined in Table 3-1.

Table 3-1 Design Flood Peaks for Weeli Wolli Creek

ARI (year)	Rainfall depth (mm)	Critical duration[1] (hour)	Design flood peaks (m^3/s)		Design flood peaks (GL/year)	
			PBS	Weeli Wolli and Marillana Confluence	PBS	Weeli Wolli and Marillana Confluence
1	42	12	5.2	9.9	164	312
2	54	9	76	110	2,397	3,469
5	90	12	240	440	7,569	13,876
10	112	12	490	1,160	15,453	36,582
20	175	24	950	2,660	29,959	83,886
50	227	24	2,200	6,600	69,379	208,138
100	270	24	4,070	9,810	128,352	309,368

Notes:

1. Critical duration is the duration of a particular storm event that generates the largest flood peak.

Under natural conditions, the rainfall and runoff data indicate that the duration of a stream flow and flood event would be approximately 10 to 14 days (1985 to 1997; Table 3-2), depending on the ARI.

Spot-height bottom elevations of the low-flow channel of the Weeli Wolli Creek are shown on Figure 3-2. A comparison of the flood extents for the 2-, 5- and 10-year ARI design events for Weeli Wolli Creek are shown on Figure 3-3, and a comparison of the respective stream depths at cross section A-A'; (marginally downstream of Marillana Creek confluence) is provided on Figure 3-4.

At cross-section A-A' (Figure 3-3), predicted (Cheng, 2013) water depths during 2-, 5- and 10-year ARI events flood events were 1.6 m, 2.7 m and 3.5 m, respectively. It was anticipated that water depth for the 1-year ARI flood would be about 1.0 m.

Table 3-2 Observed Tarina and Waterloo Bore Baseline Stream Flow Characteristics

Description	Year and Period													
	1985	1986	1987	1988	1989	1990	1991	1992	1993	1994	1995	1996	1997	1985 to 1997 Average
Tarina Gauging														
Average Yearly Flow (m^3/s)	-	-	-	2	-	5	-	7	5	3	3	-	3.54	4
Maximum Flow (m^3/s)	-	-	-	140	-	118	-	76	76	12	484	-	189	156[1]
Number of Flow Days per year	-	0	0	58	0	9	0	4	8	4	143	0	112	28
Waterloo Bore Gauging														
Average Yearly Flow (m^3/s)	-	-	5	16	-	5	-	2	10	8	52	-	20	15
Maximum Flow (m^3/s)	-	-	62	269	-	118	-	11	11	28	2,127	-	445	384
Number of Flow Days per Year	-	0	6	34	0	-	0	6	7	1	29	0	54	13

Notes:

1 This is the mean of the non-zero flows rather than the mean annual maximum flow which should include the no-flow years; under these circumstances it would be 84. This attribute highlights the skew and natural variability in the flow record.

3.2 Surface Water to Groundwater Interactions

Observations of the local water table show a response (rise) after high rainfall and associated episodic flood events. The timing and amplitude of water table rises were synchronised with recharge from flood footprints on Weeli Wolli Creek. Evidently, the episodic flooding re-wet the unsaturated profile recharging the bank of pore water (soil water) beneath riparian zones on Weeli Wolli Creek.

Conceptual models for surface water to groundwater interaction (Winter et al.; 1998) provide three templates that characterise water exchange, infiltration or seepage mechanisms. A losing seepage flux indicates downward flow from surface water to the groundwater environment. The three seepage mechanism templates include:

- Disconnected losing stream, where the seepage flux is transmitted from the stream through an unsaturated profile to the underlying water table. The local and downstream reaches of Weeli Wolli Creek formed a disconnected losing system under baseline conditions. In the Pilbara, disconnected losing systems are typically characterised by episodic presence of surface water and comparatively poorly defined riparian zones. Under these circumstances, the seepage flux is controlled by infiltration and limited to areas wetted by stream flow.
- Connected losing stream, where stream flow is transmitted to a shallow water table that is mounded to provide direct interaction with the stream bed. On Weeli Wolli Creek, the reaches immediately downstream of Weeli Wolli Spring are characterised by permanent pools, dense riparian vegetation and shallow water table conform to a connected losing stream.
- Gaining stream, where the stream represents groundwater providing direct baseflow contributions to stream flow. On Weeli Wolli Creek the permanent water features associated with Weeli Wolli Spring provide circumstances compatible to a gaining stream.

The conceptual models are illustrated on Figure 3-5. The stream flow to groundwater seepage fluxes can vary along a watercourse and also over time in response to episodic flood and associated groundwater recharge events. Most variability commonly occurs in shallow water table settings associated with extended periods of drought or unusual frequency of flood events.

For the disconnected losing stream reaches of Weeli Wolli Creek, the seepage flux can be accessed by riparian vegetation within a limited footprint that has close proximity to the low-flow channel. Episodic events that inundate the floodplain would support the broader riparian zones.

3.3 Fortescue Marsh

Fortescue Marsh forms a large-scale wetland. The water balance reflects a terminal basin within which inflows are predominantly derived from large-volume episodic stream flow events (Skrzypek et.al, 2013). The wetlands are rapidly inundated by fresh water during these events; water may temporarily cover more than 1,000 km^2, with subsequent progressive drying as water loss occurs by infiltration and evaporation. Accompanying the drying is salt accumulation that reflects concentration by evaporation loss.

Weeli Wolli Creek forms about 16 per cent of the watershed of Fortescue Marsh. The gauged flows at Waterloo Bore (Table 3-2) provide indications of the annual stream flow contributions from Weeli Wolli Creek to Fortescue Marsh. There are orders of magnitude differences in the gauged average yearly flows, maximum flow rates and numbers of flow days each year during the period 1985 to 1997. These attributes likely reflect wide variations in contributions to Fortescue Marsh from Weeli Wolli Creek.

4 BASELINE GROUNDWATER ENVIRONMENT

The baseline groundwater environment was characterised in context to the Weeli Wolli Creek, Poonda Plain and Fortescue Marsh settings. Baseline characteristics of each setting are discussed below.

4.1 Weeli Wolli Creek

4.1.1 Aquifer System – Lower Weeli Wolli Creek

The local aquifer system is described in context with three settings:

- Floodplain aquifer.
- CID aquifer.
- Basement - Weeli Wolli Formation Aquifer.

These aquifer systems are schematically presented in a cross-section view of Weeli Wolli Creek on Figure 4-1.

The floodplain and CID aquifer system occurs beneath Weeli Wolli Creek downstream of Weeli Wolli Spring. Typically the aquifer system is developed across widths from 500 to 1,500 m. The floodplain and CID setting is interpreted to be predominantly bounded by low-transmissivity basement formed by the Weeli Wolli Formation, thus forming a channel aquifer system. There may be transmissive structures in the basement aligned beneath Weeli Wolli Creek (Fowers et.al; 2013).

The individual aquifer systems are discussed below.

4.1.1.1 Floodplain Aquifer

The floodplain aquifer is interpreted to form the primary zone for the transmission of rainfall and stream flow recharge to the CID aquifer. The floodplain aquifer system is interpreted to have two contributing successions, including:

- Creek-bed alluvium: coarse colluvium and alluvium, including river gravels, incised into the floodplain sediments and forming the bed of and immediately underlying the low-flow channel of Weeli Wolli Creek. Drill-hole geological sequences suggest alluvial depths of approximately 9 to 40 m beneath Weeli Wolli Creek.
- Floodplain sediments: poorly sorted conglomerates of gravels, sand, silt and clay that unconformably overlie the *in situ* weathered basement adjacent to the CID.

The coarse river gravels of the creek bed alluvium may be highly transmissive; groundwater flow is expected to occur on preferred flow paths within the river gravels and coarser successions within the floodplain aquifer. The floodplain aquifer is expected to be widely anisotropic, commensurate with wide variability in the lateral and vertical distributions of clay, sand and gravel beds.

Clay beds have been locally intersected in drill-holes within the alluvium beneath Weeli Wolli Creek. Lateral extents of the clay beds are unknown. Where present, the clay beds may locally impede vertical infiltration, with consequential potential occurrence of temporary or seasonal perched water tables (Rio Tinto, 2010).

4.1.1.2 CID Aquifer

The CID aquifer has a channel form incised into the Weeli Wolli Formation. Chemical alteration has formed iron ores and provided a typically porous and vuggy texture that has overprinted the original detrital succession's primary porosity and formed preferred groundwater flow paths.

The local CID stratigraphy includes aquifer zones formed by:

- Goethite-vitreous. These beds predominantly form the ore zones.
- Limonite-goethite channel; commonly developed as an undulating surface defining the base of iron ores. The limonite-goethite channel is of variable thickness from 2 to 30 m, average about 16 m.

The limonite-goethite channel typically has a clayey fabric, but may locally include vugs, cavities and transmissive vitreous pods.

Observations show several metre rises in water table elevations after significant episodic rainfall, stream flow and flood events. Discharge from the CID occurs by through-flow beneath Weeli Wolli Creek.

4.1.1.3 Weeli Wolli Formation Aquifer

The Weeli Wolli Formation includes basal clay conglomerate as a weathered and potentially reworked upper expression. The basal clay conglomerate typically has a clayey fabric, but may locally include isolated transmissive vitreous pods. The basement successions are expected to host a remnant structural fabric and locally form a fractured rock aquifer. Groundwater occurrence and flow would preferentially be aligned with zones of preferential weathering on fractures. Effective transmissivity is expected to widely vary, be dependent on remnant structural fabric and weathering characteristics, and show anisotropic attributes.

Massive zones within the weathered and fresh basement profile, where the structural fabric is weak, would tend to be characterised by limited groundwater occurrence and low-transmissivity.

4.1.2 Aquifer Hydraulics

4.1.2.1 Test Pits in Creek-Bed Alluvium

The hydraulic conductivity of alluvium beds of Marillana Creek was measured at three sites using tests pits excavated to 2 m depth (Peck and Associates, 1995). The excavated strata were very poorly sorted alluvial sediments with particle sizes ranging from fine sand or silt to very coarse gravels (rocks to about 100 mm with a few to 300 mm). There was evidence of vertical stratification, including macroscopic layering and flat-bedding of individual pieces of

shale. It was considered likely that the creek bed alluvium consisted of about 2 m of high-transmissivity strata overlying beds of silt and clay.

At each site, unconsolidated sediments collapsed below where the pits intercepted the water table.

Pumping from the individual test pits at rates in the range 320 to 480 kL/day and measurement of associated drawdown enabled estimates of hydraulic conductivity shown in Table 4-1.

Table 4-1 Hydraulic Conductivity of Creek Bed Alluvium

Location	Interpreted Hydraulic Conductivity (m/day)
Pit 1	2,700 to 4,000
Pit 2	18,000 to 24,000
Pit 3	1,800
Average	10,100
Median	4,000
Geometric Mean	6,100

These results show very high hydraulic conductivity of the creek-bed alluvium, consistent with the particle size of the sediments and the low fractions of silt and sand. Notably, the hydraulic conductivity of the creek-bed alluvium varies by up to an order of magnitude between the test pits.

4.1.2.2 Aquifer Tests in Floodplain and CID Strata

Hydraulics characteristics of the floodplain and CID aquifers have been interpreted by numerous projects at RTIO Yandicoogina (Peck, 1998; PPK, 1998; Liquid Earth, 2002 and 2005; and RTIO, 2009 and 2010) and for the proposed Marillana Project on the Poonda Plain (Aquaterra 2010). A summary of interpreted hydraulic conductivity is provided in Table 4-2.

The tabulated data indicate an aquifer system characterised by widely variable and anisotropic preferred groundwater flow paths, predominantly within the river-bed gravels and CID successions.

Table 4-2 Interpreted Aquifer Hydraulics beneath Weeli Wolli Creek

Stratigraphy	Thickness (m)	Hydraulic Conductivity (m/day)		
		Weeli Wolli Creek	Poonda Plain	Vertical
		Horizontal		
Floodplain alluvium	70 - 80	5 - 250	0.2	0.02 - 1.0
Tertiary hematite detritals		-	2 – 5	0.2 – 0.5
Calcrete		-	6	0.6
CID		5 – 60	3 - 25	0.1 – 2.0
Basal clay conglomerate	-	-	-	-
Alluvium and weathered bedrock	Up to 25	-	-	0.5 – 1.0
Fresh Weeli Wolli Formation	220	0.001 – 0.25	0.003	0.0003 – 0.01
Wittenoom Formation	-	-	0.1	0.091

A brief review of recent hydrogeological work (Rio Tinto, 2010) provides supporting data, interpreted to show:

- The CID succession forms the predominant aquifer zone, with comparatively high transmissivity.
- Transmissive successions of the floodplain aquifer provide lateral extensions to the CID aquifer.
- High vertical hydraulic conductivity through the floodplain and CID aquifers. The hydraulic connection between the floodplain aquifer and the CID is consistent throughout the floodplain area.
- Occurrence of a vertically integrated surface water and groundwater environment and potentials for vertical/sub-vertical preferred infiltration and groundwater flow paths.

4.1.3 Recharge

Recharge to the floodplain aquifer predominantly occurs by infiltration of stream flow and flood waters from Weeli Wolli Creek that propagate across the riparian zones. The recharge is predominantly event-based and episodic (Johnson and Wright, 2001; Aquaterra, 2007); recharge from infiltration of rainfall was interpreted to be subordinate.

The estimates of annual recharge in the catchments of the Pilbara typically range from 0.5 to 3 percent of annual average rainfall. Recharge beneath watercourses, riparian zones and shallow water table settings may range up to 5 to 6 percent of annual average rainfall.

A number of specific references regarding recharge rates include:

- 1.2 to 4.8 GL/annum; equivalent to about 0.2 to 0.8 per cent of annual average rainfall (Hedley, et al., 2009).
- 4.8 to 9.0 GL/annum; equivalent to about 0.8 to 1.5 per cent of annual average rainfall based on chloride ion analyses (URS-Parsons Brinckerhoff, 2011).
- 3.85 GL/annum; equivalent to about 0.6 per cent of annual average rainfall (Aquaterra, 2007).

Based on these estimates, a net recharge rate in the range 0.5 to 1.5 per cent of annual average rainfall (377 mm/annum) appears to be reasonable.

The range of interpreted recharge from 0.5 to 1.5 percent of annual average rainfall is analogous to recharge to the water table beneath the lower reaches of Weeli Wolli Creek in the range 1.1 to 2.3 GL/annum.

4.1.4 Water Table Settings beneath Weeli Wolli Creek

A number of studies have used groundwater level data from 1974 and 1999 to interpret the baseline water table elevations beneath the lower reaches of Weeli Wolli Creek. A snapshot (early-1995) interpretation of baseline water table elevations (Rio Tinto, 2010) is shown on Figure 4-1 (cross-section) and Figure 4-2 (plan view) and indicates:

- Interpreted water table elevations of 480 to 485 m AHD beneath the lower reaches of Marillana Creek.
- Typically the water table was hosted by the floodplain aquifer.
- Within RTIO Yandicoogina Junction South East, water table elevations were measured in YM117 and YM118 from March 1991 to November 1997. The observed water table elevations were comparatively steady in the range from about 487 to 495 m AHD prior to 1995, with flow east to southeast toward Weeli Wolli Creek. Subsequently during 1995 to 1997, the water table elevations increased by about 10 m. This increase was predominantly attributed to higher rainfall occurrence with commensurate increases in stream flow and associated recharge to the CID aquifer.
- At the confluence of the Marillana Creek CID and the Weeli Wolli Creek CID, the interpreted early-1995 water table elevation was about 478 m AHD.
- Interpreted water table elevations of 418 to 478 m AHD beneath Weeli Wolli Creek. These interpreted water table elevations were sourced from monitoring bores including 99YYJWB02, 99YYJWB04, YM119 and 99YYJWB01.
- Interpreted water table elevations of 418 m AHD in the vicinity of 99YJWB01. The water table at this comparatively low elevation reflects changes in conditions and hydraulics beneath the northern reaches of Weeli Wolli Creek.
- A typical lateral hydraulic gradient of 0.002 (dimensionless) in the PBS setting.
- Interpreted depths to the water table commonly exceeded 15 m to 20 m, though increase significantly to the north, to about 45 m in the vicinity of 99YJWB01. Figure 4-3 shows the interpreted baseline depths to the water table beneath local reaches of Weeli Wolli Creek.

- The CID aquifer is recharged by vertical downward seepage from the floodplain aquifer.
- It is recognised that the water table elevations show spatial and temporal variations in response to rainfall, stream flow and evapotranspiration.

Across the Pilbara there is evidence of water table responses to episodic recharge events and intervening dry periods that span numerous years. During extended periods of above-average rainfall and/or repetitive occurrence of high rainfall events (with associated occurrence of stream flow), the water balance changes to reflect increased recharge compared to discharge, with outcomes reflected in elevated water table settings. Conversely, if the rainfall and stream flow is comparatively low, then the water table elevations progressively decay in response to reduced recharge. The hydrographs for local monitoring bores indicate water table elevations can rise by up to 8 m, predominantly through the infiltration of stream flow and flood waters associated with episodic high rainfall events. The observed natural rates of water table elevation decline after episodic recharge events include:

- 99YYJWB04, located on Weeli Wolli Creek near the Marillana Creek confluence, with estimated decline of 1.4 to 2.2 m/year.
- YM119, located on the downstream Weeli Wolli Creek, with estimated decline of 2.9 m/year.

4.1.5 Groundwater Quality - Weeli Wolli Creek

Baseline groundwater quality is typically characterised by TDS concentrations of about 500 mg/L.

Groundwater hosted by the floodplain aquifer tends to be comparatively high in salinity, with measured TDS concentrations up to 1,290 mg/L. At greater depth, within the CID aquifer, known groundwater qualities (Kirkpatrick and Dogramaci, 2010) occur in the range 370 to 780 mg/L TDS and pH from 7.2 to 8.5.

Typically, the chloride concentration in the CID aquifer is recognised (Kirkpatrick and Dogramaci, 2010) to be about 30 percent lower than in the floodplain aquifer. This difference is attributed to the processes of direct evaporation and evapotranspiration by riparian vegetation along Marillana Creek, which acts to concentrate salts, over time, in the stream flow, any perched water table setting, and shallow soil water. Residence times of incident waters within zones subject to potential evaporation losses would be needed to enable a 30 percent increase in chloride concentrations. Reasonable residence times may be provided by lateral flow in the floodplain aquifer towards preferred infiltration zones, temporary storage in perched aquifer settings and typical infiltration rates that increase the water availability in the unsaturated profile.

4.2 Poonda Plain and Fortescue Marsh

4.2.1 Aquifer Systems – Poonda Plain

The aquifer systems of the Poonda Plain can be considered as lateral extensions of the floodplain, CID and basement aquifers that prevail beneath Weeli Wolli Creek. For example:

- Floodplain aquifer – hosted by the Tertiary detritals, in palaeochannels and beneath the broader expanses of the deltaic outwash fan in ancestral floodplain settings. The aquifer is widely inhomogeneous, but predominantly characterised by sediments with clay, silt and sand matrices. Ancestral creek-bed deposits form laterally semi-continuous and vertically stacked zones of preferred groundwater flow.
- CID aquifer – hosted within incised palaeochannels that propagate northward from Weeli Wolli Creek. It is anticipated the main palaeochannel propagates north-northeast beneath the plain on a structural alignment compatible to and parallel to Weeli Wolli Creek. There may be bifurcation of and tributaries to the main palaeochannel, including CID mapped by the Marillana Project (Aquaterra, 2010) beneath the foot slopes of the Hamersley Plateau.
- The CID aquifer is poorly defined. It is expected, however, that the major flow paths are aligned with the incised palaeochannels and of high transmissivity.
- Basement aquifer – transitions from Weeli Wolli Formation to Brockman Iron Formation (at the Nyidinghu Project) and Wittenoom Formation beneath the wider Poonda Plain and Fortescue Marsh. The transmissivity of the basement aquifer may be significantly enhanced by structural defects. At the Nyidinghu Project (Fowers et al.; 2013) numerous interpreted faults transverse the basement strata, with the Weeli Wolli Fault system aligned with Weeli Wolli Creek and the Poonda Fault demarking the escarpment to the Hamersley Plateau. The interpreted faults influence the positions of the incised palaeovalley and iron mineralisation.

4.2.2 Aquifer Systems – Fortescue Marsh

Groundwater flows to, and terminates beneath or in, the Fortescue Marsh. The groundwater environment of Fortescue Marsh is a lateral extension of that beneath the Poonda Plain. The groundwater environment beneath the Fortescue Marsh is hosted by:

- Quaternary unconsolidated colluvial and alluvial silt, sand and gravel sediments that form alluvial deltas where the major watercourses, including the Weeli Wolli and Coondiner creeks, traverse the escarpments and enter the Fortescue River Valley. In structural settings, such as beneath Weeli Wolli Creek, palaeovalley features (Fowers et al., 2013) that host thick successions of colluvial, alluvial and lacustrine sediments propagate beneath the Fortescue River Valley from the Hamersley Range escarpment.
- Tertiary lacustrine carbonate (including calcrete), silcrete and mudstone successions of the Oakover Formation (Clout, 2011) deposited in the palaeovalley associated with the Fortescue River.
- The underlying Wittenoom Formation, with associated karstic dolomite successions.

4.2.3 Hydraulics from Falling Head Tests

Falling head tests were conducted in a number of monitoring bores installed by the Marillana Project (Aquaterra, 2008 and 2010). The interpreted results based on analyses by the Hvorslev (1951) method are shown in Table 4-3.

Table 4-3 Interpreted Hydraulics - Falling Head Tests

Monitoring Bore	Strata	Test Interval (m)	Hydraulic Conductivity (m/day)	Transmissivity (m^2/day)

4.2.4 Water Table Elevations beneath Poonda Plain and Fortescue Marsh

Information on the water table beneath the Poonda Plain was predominantly derived from groundwater exploration snapshots associated with the Marillana Project (Aquaterra, 2010) and the Fortescue Marsh groundwater investigation (McLean and Sanderson, 2014 in draft). These data points are wide-spaced. A collage of data from these sources was used to interpret the water table elevations for an early-2010 snapshot (Figure 4-4). The interpreted water table shows a subdued reflection of the topography, with flow to the northeast, sub-parallel to the escarpment of the Hamersley Plateau and towards Fortescue Marsh.

On a local scale, the interpreted water table elevations:

- Show a groundwater discharge configuration within the interpreted incised palaeovalley beneath the lower reaches of Weeli Wolli Creek. This configuration would reflect comparatively high transmissivity within the floodplain and CID channel aquifer system.
- Indicate preferential flow towards the northeast, intuitively aligned with extensions of the incised palaeovalley beneath the Poonda Plain.
- Suggest there is a smaller scale discharge configuration associated with the mapped CID (Aquaterra, 2010) beneath the foot slopes of the Hamersley Plateau.

- Show an interpreted mounded configuration within the alluvial outwash fan of Weeli Wolli Creek in areas adjacent to the incised palaeovalley. The interpreted mounding may indicate:
  - Lower transmissivity on the palaeovalley perimeters crests.
  - A domain of enhanced recharge on the outwash fan, linked to sheet wash during episodic rainfall and flood events.
  - Propagation of the groundwater wetting front, through mounding of the water table and filling storage, from surplus water discharge.

The water table attributes and comparative elevations may change in response to episodic flood events.

Depths to the water table were observed to commonly occur up to 45 m beneath the escarpments to the adjoining ranges and progressively becoming shallower towards Fortescue Marsh. In the middle of the marsh, the water table occurs at the ground surface (Skrzypek et.al, 2013), though this may vary seasonally and/or episodically. These attributes provide indications of surface water and groundwater interaction and connection directly beneath wetland areas of the marsh.

4.2.4.1 Groundwater Quality - Poonda Plain and Fortescue Marsh

Quality data for the water table and Hamersley Group groundwater environments beneath the Poonda Plain and Fortescue Marsh were sourced from the Marillana Project (Aquaterra, 2010), groundwater investigations of Fortescue Marsh (McLean and Sanderson, RTIO; 2014 in draft) and, Skrzypek et.al (2013) based on sampling at 48 locations within the upper Fortescue River Valley during May 2010, October 2010, May 2011 and December 2011. Isohalines interpreted from the water table and Hamersley Group data (McLean and Sanderson, 2014 in draft) are shown on Figure 4-5 and Figure 4-6, respectively. These interpretations show.

- Measured shallow groundwater salinities range from less than 500 to 17,400 mg/L TDS, increasing towards Fortescue Marsh under northeast gradients sub-parallel to the escarpment of Hamersley Plateau.
- Measured Hamersley Group salinities in the range 2,100 to 89,300 mg/L TDS, also increasing towards Fortescue Marsh.
- In both shallow and deep groundwater environments, the lowest salinity profile is aligned to interpreted incised palaeovalley flow paths.
- Lateral and vertical salinity stratification, with wide variations in the stratification gradients. This aspect may reflect different recharge, through-flow and mixing mechanisms together with variations in the vertical integration of aquifer systems and salt source terms.

The 48 locations (Figure 4-7) sampled by Skrzypek et.al (2013) produced 206 samples which were analysed to determine $\delta^{18}O$ and $\delta^{2}H$ concentrations together with TDS, EC and major ion (including chloride, bromide and strontium) concentrations. Results from the sampling showed there is a wide range of groundwater TDS beneath the Fortescue Marsh (Skrzypek et.al, 2013). Typically, the groundwater is fresh directly beneath the escarpments and with trends of increasing TDS on flow paths towards the wetlands in lower elevation settings of the

Fortescue River Valley. There is also vertical TDS stratification, with the water table zone commonly of lower TDS than groundwater in the Wittenoom Formation. At times of episodic inundation, the surface water environment would potentially provide recharge to the water table. Beneath the lower elevation settings, the shallow groundwater was lower in salinity than groundwater in the Wittenoom Formation; which was hypersaline, with TDS concentrations commonly exceeding 100,000 mg/L (ranging up to 190,000 mg/L TDS; Skrzypek et.al, 2013; Dogramaci et al., 2015a). These attributes reflect a salt-sink environment, with salt accumulation over time due to groundwater discharge. A comparative overview of the sampling data is provided in Table 4-4.

Table 4-4 Fortescue Marsh Groundwater Chloride, $\delta^{18}O$ and $\delta^{2}H$ Concentrations

Source	Chloride Concentration (mg/L)	$\delta^{18}O$ Concentration (‰)	$\delta^{2}H$ Concentration (‰)
High Rainfall Events	1.4	-12 to -11	-76.9
Hamersley Basin Groundwater	-	-8.2 ∓ 0.83 -6.46 ∓ 1.28	6.13 ∓ 0.16
Groundwater Beneath Outwash Fans	250	-9.5 to -7.5	-64 to -52
Fresh to Brackish Groundwater	40 to 5,000	-8.0∓ 0.90	-56.2∓ 5.3
Brackish to Saline Groundwater	5,000 to 96,000	-7.2 to +2.5	-10.3 to -51.6
Shallow Groundwater under the Marsh	4,000 to 56,000	-1.6 to +2.5	-33 to -11
Deep Groundwater under the Marsh	Up to 96,000	-1.6 to +2.5	-33 to -11
14-Mile Pool (Wet Season)	40	-2.3	-28.8
14-Mile Pool (Dry Season)	2,920	16.3	72.7

The groundwater sampling also indicated (Skrzypek et.al, 2013):

- Groundwater beneath the outwash fans of the Weeli Wolli and Coondiner creeks was fresh, with $\delta^{18}O$ concentrations of about -9.5‰; characteristic of infiltration from high rainfall events.
- The major ion, $\delta^{18}O$ and $\delta^{2}H$ compositions of the sampled groundwater indicate rainfall-derived origins, with recharge by rapid infiltration after limited volume loss by evaporation. Rates of water loss determined by increasing concentrations of chloride and $\delta^{18}O$ are however different, indicating that other processes combine with evaporation to provide the measured TDS concentrations.
- Fresh to brackish groundwater (TDS less than 10,000 mg/L) is of the magnesium-calcium-bicarbonate type, and chloride/bromide ratios occur in the range 200 to 2,000, commonly higher than those (288) for seawater.
- Brackish to saline groundwater (TDS greater than 10,000 mg/L) is of the sodium-chloride type, and chloride/bromide ratios occur in the range 800 to 12,000.
- The increases in chloride concentrations with depth in the brackish to saline groundwater corresponds to a gradual enrichment in $\delta^{18}O$ and $\delta^{2}H$

- The concentration ratio for chloride/bromide would be similar to seawater if evaporation was the predominant ion enrichment process. That chloride enrichment occurs reflects bromide removal through cyclic drying and precipitation in halite salts. The chloride/bromide ratio subsequently increases in dissolution processes because of the comparatively high chloride/bromide ratio in halite (Dogramaci et al., 2015b).
- Concentration ratios for strontium/calcium, sulphate/calcium and magnesium/calcium increase associated with increasing chloride concentrations (Figure 4-8). The increased ratios may indicate calcite mineral precipitation (thus removal of calcium and bicarbonate from solution) as the TDS concentration increases. A repetitious calcite and gypsum mineral precipitation and dissolution process, due to cyclic wetting, drying and surface water infiltration episodes, is the likely process for the increasing strontium/calcium, magnesium/calcium ratios in the brackish to saline groundwater (Skrzypek et.al, 2013). The progressive precipitation of calcite and gypsum allows the concentrations of sulphate to increase whilst bicarbonate in solution decreases.
- δ^{18}O concentrations for the fresh to brackish groundwater were -8.0 ∓ 0.9 ‰ . The consistency and limited range of these concentrations indicated low evaporation potentials from the shallow groundwater.
- δ^{18}O concentrations in the brackish to saline groundwater from alluvium and Wittenoom Formation beneath the Fortescue Marsh were -1.6 to +2.5 ‰.
- δ^{2}H concentrations for the fresh to brackish groundwater were -56.2 ∓ 5.3 ‰ .
- δ^{2}H concentrations for the brackish to saline groundwater were -10.3 to -51.6 ‰.
- **T**he measured δ^{18}O and δ^{2}H concentrations for the fresh to brackish groundwater fall slightly below the Local Meteoric Water Line and indicate partial evaporation prior to recharge.
- The mixing between relatively fresh surface water recharge with deeper saline groundwater was the only explanation of the observed salinity stratification coupled with a broad range of δ^{18}O enrichment in the brackish to saline groundwater. An isotope and chloride lumped-parameter mixing model was used to replicate measured groundwater compositions. The consolidated results from the mixing model using median input parameters, indicated:
  - Evaporation of about 17 per cent of the rainfall and stream flow volumes prior to recharge, providing δ^{18}O concentration enrichment from -11.6‰ (rainfall) to -7.4‰**.**
  - Mixing of the recharge with saline groundwater (chloride 96,000 mg/L and δ^{18}O concentration enrichment up to +2.5‰ as observed in deep saline groundwater)**.** The mixing would occur in varying ratios and proportions, ranging up to 59 per cent of fresh water to replicate the measured compositions.
  - Mixing would tend to predominantly occur where enabled by lateral and vertical transmissivity. Comparatively high transmissivity zones would promote rapid infiltration of recharge in settings where the vertical groundwater flow is predominant compared to lateral flow.

– Precipitation of calcite and gypsum enables enrichment of sulphate and concurrent diminishment of bicarbonate. For example, the stoichiometry of calcite precipitation indicates the removal of two moles of bicarbonate for each mole of calcium. As such, there would be a comparative enrichment of calcium in solution. The precipitation of calcite alone, however, does not explain the observed increases in strontium/calcium and magnesium/calcium ratios. Continuous precipitation and re-dissolution of carbonate minerals and gypsum, due to cyclic wetting and drying, is required under these circumstances.

A consolidation of the chloride, $\delta^{18}O$ and $\delta^{2}H$ data indicates that Fortescue Marsh temporarily forms a connected surface water and groundwater environment at times after episodic stream flow events. Connection is enabled by vertical infiltration of fresh stream flow that temporarily mounds the water table. Over time, under the influence of evaporation and infiltration, the water table becomes disconnected from the surface water environment.

The marsh forms a salt sink. Evaporation processes, episodic flooding and re-wetting provide flow dynamics driven by hydraulic and density gradients that promote fluxes from the marsh to the groundwater environment and also vertical mixing within the groundwater environment. Vertical mixing within the groundwater environment has manifest as both lateral and vertical salinity stratification beneath the marsh and its surrounds.

5 ALTERED WATER RESOURCES ENVIRONMENTS

5.1 Overview

The mines at RTIO Yandicoogina, BHPBIO Yandi, and Hope Downs 1, extend below the water table. Groundwater abstraction is required to lower the water table and enable mining. Surplus water has historically been discharged to Marillana Creek since 1991, and directly to Weeli Wolli Creek since 2007.

Both the groundwater abstraction and subsequent discharge alter the water resources available to riparian environments on the Weeli Wolli Creek. The groundwater abstraction lowers the water table and removes groundwater from storage. Conversely, the surplus water forms wetting fronts in the surface water and groundwater environments. The wetting fronts represent perennial stream flow in the low-flow channels of Weeli Wolli Creek and recharge to and consequent mounding of the water table.

Drawdown of the water table due to groundwater abstraction potentially limits water availability in the riparian zones. The wetting fronts in the surface water and groundwater environments potentially increase water availability to the riparian zone, including the presence of perennial stream flow. These aspects are discussed below and supporting this discussion is Figure 5-1 that shows relevant transient water balance information since 1991, including:

- A summary of the episodic stream flow events on Weeli Wolli Creek (at Waterloo Bore).
- Dates that indicate commencement of surplus water discharge from the BHPBIO Yandi, RTIO Yandicoogina and Hope Downs 1 mines together with local dewatering and reinjection activities in proximity to or on Weeli Wolli Creek.
- Discretised annual surplus water discharge volumes from the BHPBIO Yandi, RTIO Yandicoogina, and Hope Downs 1 mines.

5.2 Groundwater Abstraction and Drawdown of the Water Table

Groundwater abstraction to enable mining has been focussed on the CID aquifer associated with Marillana Creek. The abstraction has lowered the local water table and removed groundwater from storage. A conceptualised cross-section view of the drawdown linked to groundwater abstraction by the RTIO Yandicoogina Mine is shown on Figure 5-2. At present, the drawdown of the water table is predominantly associated with the CID aquifer in proximity to Marillana Creek.

The drawdown evident in proximity to Marillana Creek has not propagated beneath Weeli Wolli Creek. For example, drawdown from Junction South East operations of the RTIO Yandicoogina Mine has not created a noticeable deficit in perennial stream flow in the low-flow channel on Weeli Wolli Creek derived from the Hope Downs 1 Mine. In essence, the perennial stream flow forms a significant recharge front and the drawdown footprint is sufficient only to intercept a small portion of this front. Therefore, locally on Weeli Wolli Creek within the PBS area, potentials for drawdown of the water table have been off-set by:

- Recharge linked to surplus water discharge at DO6 (Figure 1-3) and from the Hope Downs 1 Mine.
- Injection activities (RTIO Yandicoogina Billiard Reinjection), Figure 1-3.

These factors have contributed to the aquifer system beneath local reaches of Weeli Wolli Creek currently being perennially recharged and full to a natural capacity. When compared to baseline, the water table beneath these reaches is typically mounded by 10 to 15 m (as schematically shown on Figure 5-3).

5.3 Historical Groundwater Discharge

The historical annual abstraction volumes for mines BHPBIO Yandi, RTIO Yandicoogina, and Hope Downs 1 are summarised in Table 5-1 and shown on Figure 5-1. A RTIO comparison of the range of annual water surpluses and design flood volumes for 1-, 2-, 5- and 10-year ARI events (Cheng, 2013) is shown in Table 5-2.

Table 5-1 Annual Volumes of Surplus Water Discharge

Year	Surplus Water Source (GL)				Totals (GL)	
	BHPBIO Yandi Mine	RTIO Yandicoogina Mine		Hope Downs 1 Mine	Annual	Cumulative
		Watercourse	Reinjection			
1991	0.1	-	-	-	0.1	0.1
1992	0.1	-	-	-	0.1	0.2
1993	0.1	-	-	-	0.1	0.3
1994	0.1	-	-	-	0.1	0.4
1995	0.3	-	-	-	0.3	0.7
1996	0.8	-	-	-	0.8	1.5
1997	6.6	-	-	-	6.6	8.1
1998	6.1	5.8	-	-	11.9	20.0
1999	8.1	4.8	-	-	12.9	32.9
2000	13.4	6.0	-	-	19.4	52.3
2001	8.3	4.3	-	-	12.6	64.9
2002	5.9	4.4	-	-	10.3	75.2
2003	5.4	5.9	-	-	11.3	86.5
2004	4.7	4.9	-	-	9.6	96.1
2005	2.5	4.3	-	-	6.8	102.9
2006	7.0	7.0	2.1	0.1	16.2	119.1
2007	7.9	11.9	4.4	17.6	41.8	160.9
2008	5.2	16.3	3.5	20.8	45.8	206.7
2009	4.7	16.1	2.7	24.7	48.2	254.9
2010	2.5	16.6	2.6	32.2	53.9	308.8
2011	5.4	20.2	4.5	31.1	61.2	370.0
2012	10.4	20.2	6.0	35.5	72.1	442.1
2013	8.8	24.9	1.6	36.4	71.7	513.8

Table 5-2 Comparison of Design Flood and Surplus Water Volumes

ARI (year)	Weeli Wolli Creek Design Flood Volumes (GL)	Maximum Annual Surplus Water Volumes (GL)		
	At Confluence with Marillana Creek	1991 to 1997 BHPBIO Yandi Mine	1998 to 2006 BHPBIO Yandi and RTIO Yandicoogina Mines	2007 to 2013
1	312	6.6	19.4	70.1
2	3,469			
5	13,876			
10	36,582			

From the information presented in Table 5-2 it can be seen that the water discharged into the local watercourses represents comparatively small volumes. For example, the discharged groundwater is equivalent to:

- About 2 to 22 per cent of 1-year ARI stream flow volumes on Weeli Wolli Creek at the confluence with Marillana Creek.
- Typically less than 2 per cent of the 2- and 5- year ARI stream flow volumes.
- Typically less than 0.2 per cent of the 10-year ARI stream flow volumes.

The surplus water is transmitted only within the low-flow channel of Weeli Wolli Creek, with resultant stream flow depths typically less than 0.2 m. On a cross-section view (Figure 3-4), the stream flow depth for a 103 GL/annum discharge rate (Cheng, 2013) was approximately 0.12 m and is shown to be significantly lower than simulated stream flow depths of 1.0, 1.6, 2.7 and 3.5 m for 1-, 2-, 5- and 10-year ARI events, respectively. These data show the perennial surface water footprint is comparatively minor in context to the flow depths and volumes (Table 5-2) derived from episodic events.

5.4 Wetting Fronts

Since 2007, the surface water and groundwater environments on Weeli Wolli Creek have changed as a cumulative response to discharge of surplus water. The discharged water forms wetting fronts that represent the processes of assimilation which represent transport and fates within the local receiving environments. Wetting fronts occur in the surface water, surface water to groundwater interaction and groundwater environments. The wetting fronts are linked to:

- Perennial stream flow and or presence of surface water in low-flow channels of Weeli Wolli Creek. The perennial presence of water represents the surface water wetting front.
- Interception and loss of water in the low-flow channels by infiltration, evaporation and transpiration. These aspects represent surface water to groundwater interaction within the unsaturated profile above the water table.

- Infiltration to the water table, with associated saturation of available storage and mounding of the water table beneath Weeli Wolli Creek. The mounding of the water table represents the groundwater wetting front.

The wetting front characteristics are predominantly a function of low-flow channel surface area, infiltration rates, aquifer system hydraulics and aquifer storage.

The wetting front characteristics are discretely discussed below.

5.4.1 Surface Water Wetting Fronts

The cumulative effects of surplus water discharge have included stream flow and saturated creek-bed conditions on local watercourses downstream of the discharge points (RTIO, 2011). The stream flow resultant from the surplus water discharge is perennial and persists only in the low-flow channel of Weeli Wolli Creek, with depths typically less than 0.2 m (Figure 3-4).

The presence of sustained stream flow on Weeli Wolli Creek compares to:

- Average baseline stream flow occurrences at the Tarina and Waterloo Bore gauges of 28 and 12 days/annum, respectively.
- Predicted 10 to 14-day periods of stream flow and flood presence (Cheng, 2013) during episodic events, with variation depending on ARI.
- Up to about 22 per cent of 1-year ARI stream flow volumes on Weeli Wolli Creek.
- Typically less than 2 per cent of the 2-, 5-, and 10- year ARI stream flow volumes.

Since late-2007 and early-2008 (linked to commencement of discharge from the Hope Downs 1 Mine) the surface water wetting front on Weeli Wolli Creek propagated 5 to 7 km downstream of the Marillana Creek confluence. Since 2009 the surface water wetting fronts have varied from confluence to about 6 km beyond the confluence (Figure 5-4).

The waxing and waning of the wetting front over distances of 4 km (as shown on Figure 5-4 for the period 2007 to 2011) depends on climatic conditions and rates of surplus water discharge, but have not steadily propagated to the north since 2007. These attributes tend to reflect steady-state conditions. Under steady-state conditions, there is no change in storage. Therefore the fact that the stream flow is fully dissipated reflects interception by evaporation and transpiration and transmission within the underlying groundwater environment.

It was interpreted (Cheng; 2013) that the discharged surplus water would have minimal influence on the natural hydrological functions in terms of flood peaks, flow volume and flood footprints on the local reaches of Weeli Wolli Creek.

5.4.2 Surface Water to Groundwater Interaction

The surface water to groundwater interaction involves processes of infiltration (recharge) to the water table and interception of water by evaporation and transpiration. Infiltrates progressively wet and saturate the residual storage above the water table and replace volumes lost by evaporation, transpiration and through-flow. The fates of surface water from Weeli Wolli Creek were assessed based on:

- Chloride concentrations and stable isotopes of oxygen ($\delta^{18}O$) and hydrogen ($\delta^{2}H$) compositions on reaches downstream of Weeli Wolli Spring (Dogramaci, et al., 2015b). This assessment was based on the understanding that all three analytes would become progressively enriched on downstream flow paths as portions of the water resources are intercepted by evaporation and transpiration. Sampling occurred in June and December 2010 and July 2011. Sampling was from 12 surface water points (WW1 to WW20) at 1.0 to 2.5 km intervals extending about 27 km downstream of Weeli Wolli Spring and groundwater monitoring bores 99YJWB04, WWA, YM119, D08YJ188 and 99YJWBO1. The surface water sampling sites included:
  - Sites WW12, WW14, WW16, WW18 and WW20 upstream of PBS, with WW20 closest to Weeli Wolli Spring.
  - Site WW10 upstream of DP2, within the southern limits of PBS.
  - Sites WW1, WW4, WW6, WW8 and WW10 on reaches upstream of the confluence with Marillana Creek, thus adjacent to PBS.
  - Sites WWE, WW3 and WW2 on northern reaches, with WWE northernmost and situated nearby to monitoring bore D08YJ188.

  At the times of sampling, Weeli Wolli Creek was supplemented by 95 and 25 ML/day surplus water discharged from the Hope Downs 1 Mine (referred to as DP1) and the RTIO Yandicoogina Mine (DO6; referred to as DP2), respectively. Perennial stream flow was evident. Given the two different supplementation sources, the sample sites were designated into reaches upstream (Section A) and downstream (Section B) of DP2, respectively.

  The sampling sites are shown on Figure 5-5. Measured chloride, $\delta^{18}O$ and $\delta^{2}H$ concentrations for the surface water samples are shown in Table 5-3 and for the surface water samples on Figure 5-6, with context to distance from DP1. Transient groundwater chloride concentrations in monitoring bores 99YJWB01 and 99YJWB04 are shown on Figure 5-7.

  Loss rates calculated from the chloride and isotope mass balance have been also used to interpret the transpiration, evaporation and recharge components of the local water balance (Bourke el. al., 2014; Dogramaci, et al., 2015b; Bourke el. al., 2014).

- Stream flow measurements on discrete reaches of Weeli Wolli Creek (Pettett and Pearcey, 2014) to enable interpretation of loss rates by infiltration.

  The findings of the interpreted fates of the surplus water are summarised in Table 5-4. The infiltration potentials on Weeli Wolli Creek were interpreted to range from 0.02 to 13.15 ML/km/day. The cumulative losses due to evaporation and transpiration tend to be comparatively small, amounting to 15 to 25 per cent of the total water balance.

  The interpreted transpiration losses increased by nearly an order of magnitude in reach B compared to reach A as does the comparison between transpiration and evaporation losses. The increased transpiration losses may be linked to broadening of the riparian zone and changes in floristics on downstream reaches, particularly north of the Marillana Creek confluence.

The evaporation losses are subordinate compared to those by transpiration and reasonably consistent in the range 0.23 to 0.35 ML/km/day. These losses may progressively decline from upstream to downstream reaches, possibly reflecting reductions to the perennial stream flow channel widths.

The findings of both methods show progressive increases in infiltration rates from upstream to downstream reaches of Weeli Wolli Creek. Also, the interpreted cumulative loss rates over the assessed reaches of Weeli Wolli Creek are similar; 110.3 and 112.7 ML/day.

Within the riparian zones on Weeli Wolli Creek, marginally downstream of the Marillana Creek confluence, a small number of infiltration measurements (Pettett and Pearcey, 2014) provided vertical hydraulic conductivity values in the range 40 to 1,050 m/day. These values indicated potential for the shallow alluvium to vertically transmit large volumes of rainfall and surface water at times when water is present.

Table 5-3 Measured Chloride, $\delta^{18}O$ and $\delta^{2}H$ and Interpreted Water Losses (after Dogramaci et. al, 2015a)

Reach	Surface Water to Groundwater Attributes	Sample Location	Distance from DP1 (km)	Chloride Concentration (mg/L)	$\delta^{18}O$ (‰, VSMOW[1])	$\delta^{2}H$ (‰, VSMOW[1])	Cumulative Volume Loss (per cent)		Calculated Chloride Concentration Due to Evaporation (mg/L)

Notes:						
1 Dogramaci, et. al., 2015a. The data also show increasing loss rates on northern reaches where the water table is disconnected from Weeli Wolli Creek.						
2 Pettett and Pearcey, 2014.						

hydrographs have also been used to characterise the surface water to groundwater interaction. In particular, monitoring bores YM119, 99YJWB01, 99YJWB02, 99YJWB03, 99YJWB04, DO8YJ126, DO8YJ165 and DO8YJ216 provide long-term groundwater level records, and these have been used to define the transient surface water to groundwater wetting front, as summarised in Table 5-5.

Table 5-5 Transient Surface Water to Groundwater Interaction in Selected Monitoring Bores

Monitoring Bore	Surface Water to Groundwater Interaction		
	Baseline	Progressive Wetting	Aquifer Full
Floodplain and CID aquifer associated with Upper Weeli Wolli Creek			
99YJWB002	Disconnected Losing System	From Early-1995 To March 1997	Connected Losing System from March 1997 Episodic wetting overprints from flood events
99YJWB003			
99YJWB004			
D08YJ126			
YM119			
Floodplain and CID aquifer associated with lower Weeli Wolli Creek			
D08YJ216	Disconnected Losing System	From Early-1995 to Date	Approaching a Connected Losing System
D08YJ165			Aquifer Wetting and Not Full
99YJWB001			

The available data indicate that the floodplain aquifer is full and connected to Weeli Wolli Creek in Section A and throughout Section B downstream at least to monitoring bore YM119. Further downstream, the surface water and water table disconnect. Evidently, the discharge of surplus water into Weeli Wolli Creek has predominantly saturated the residual storage in the underlying aquifer system, mounded the water table and over the majority of Weeli Wolli Creek provided circumstances where the surface water wetting front is connected to the water table.

Where the water table is connected to the low-flow channel, the losses can predominantly be attributed to aquifer through-flow. Progressive increases in loss rates to the north, reflect higher aquifer transmissivity (due to broadening and thickening of the alluvium successions together with presence of the CID) and progressive steepening of hydraulic gradients. At the leading edge of the surface water wetting front where the stream flow is disconnected from the water table, the interpreted loss rates are highest; see Figure 5-8 (Dogramaci et.al , 2015a and Table 5-4 – 13.15 ML/km/day; Pettett and Pearcey, 2014). In this setting, in the vicinity of WWE and D08YJ188, there is also:

- A step-change in both chloride and $\delta^{18}O$ enrichment.
- Differences between the surface water and groundwater sample analyses.

Data from 99YJWB01, the northernmost sampling point was dissimilar, forming significant outliers in a disconnected losing system. The groundwater environment intersected by 99YJWB01 was significantly lower in chloride and $\delta^{18}O$ concentrations compared to all other samples and probably reflects a different groundwater genesis and flow environment.

5.4.3 Groundwater Wetting Fronts

In the groundwater environment, the presence and distribution of the groundwater wetting front is evident based on transient changes in water table elevations within selected monitoring bores located adjacent to Weeli Wolli Creek. The baseline water table elevations provide a benchmark for change assessments. Further, the aquifer system beneath Weeli Wolli Creek has finite storage. Therefore, the available storage provides a control on the groundwater wetting fronts; once the available storage above the baseline water table elevation has been filled the surface water and groundwater wetting fronts would progressively propagate downstream.

It was recognised that the baseline environment is dynamic and characterised by episodic recharge fluctuations and subsequent decay in water table elevations. In particular, the period 1994 to 2005 was unusually wet providing episodic recharge to the groundwater environment associated with cyclones Bobby, Rachael, Thelma, John, Norman and Terri together with an un-named tropical low in January 2003. These natural groundwater wetting fronts provided cumulative signatures that masked concurrent changes linked to the groundwater wetting fronts from the surplus water discharge (RTIO, 2010).

The groundwater wetting fronts have been characterised by several means, including:

- Review of monitoring bore hydrographs.
- Aquifer storage assessments.
- Estimation of hydraulic gradients and aquifer through-flow.

- Rates of water table rise.

These aspects are discretely discussed below.

5.4.3.1 *Review of Monitoring Bore Hydrographs*

Monitoring bores (YM117 and YM118) in proximity to Marillana Creek and Weeli Wolli Creek (YM119, 99YJWB01, 99YJWB02, 99YJWB03 and 99YJWB04, DO8YJ126, DO8YJ165 and DO8YJ216) provide longer-term groundwater level records. These records have been used to interpret the groundwater wetting fronts. Also, the collective hydrographs typically show trends that are strongly mimicked from one bore to another. Given this aspect, the monitoring bores were discretised based on representation of:

- Monitoring Bore YM119. This monitoring bore provides a record on Weeli Wolli Creek from 1991 and was used as a template for the wetting fronts on the water table.
- Marillana Creek settings (YM117 and YM118).
- Upper reaches of Weeli Wolli Creek, including PBS area and broad riparian zones extending about 2 km north of the confluence with Marillana Creek (YM119, 99YJWB02, 99YJWB03 and 99YJWB04 and DO8YJ126).
- Lower Weeli Wolli Creek (99YJWB01, DO8YJ165 and DO8YJ216).

The YM119 template was used to differentiate transient changes in the groundwater environment, including:

- Baseline within a disconnected losing stream flow system:
  - Natural cyclic decay of water table elevations under hydraulic mechanisms.
  - Episodic wetting and water table mounding due to infiltration during flood events. Each wetting has unique characteristics. The hydrographs reflect this by demonstrating variable durations over which the wetting provided progressive water table mounding and peaks after selected flood events. For example:
    - Cyclone Bobby in February 1995: 25th February to 1st April, 35 day period of progressive water table mounding.
    - Cyclone Rachael in January 1997: 26th January to 1st March, 34 day period of wetting.
    - Cyclone John in December 1999: 16th December to 1st May, 135 day period.
    - Un-named tropical low in January 2003: 25th January to 2nd February, 9 day period.
- Progressive wetting within a disconnected losing stream flow system:
  - Cumulative wetting due to surplus water discharge, with masking by episodic wetting from repetitive flood events.
  - Cyclic decay by hydraulic mechanisms, without returning to baseline water table elevations.

- Aquifer system full to capacity; cyclic losing and gaining steam flow system with saturated connection due to perennial wetting by surplus water discharge:
  - Episodic wetting from flood events superimposed on a full aquifer.
  - Cyclic decay of the water table elevations by hydraulic mechanisms and discharge to the low-flow channel on Weeli Wolli Creek.

The surface water to groundwater wetting front interpretations from these monitoring bores are illustrated on Figure 5-9 (YM119), Figure 5-10 (YM117, YM118 and YM119), Figure 5-11 (99YJWB02, 99YJWB03 and 99YJWB04, DO8YJ126 and YM119) and Figure 5-12 (99YJWB01, DO8YJ165, DO8YJ216 and YM119). Interpretations from monitoring bore hydrographs show the groundwater wetting front occurs in the upper Weeli Wolli Creek settings from early-1995. Further, the water table becomes connected to the low-flow channel from early-2000 in monitoring bores YM119, 99YJWB02, 99YJWB03 and 99YJWB04. In each monitoring bore, the aquifer system was full or almost full at the time of Cyclone John in January 2000.

Further north in 99YJWB01, DO8YJ165 and DO8YJ216, the wetting front was evident in subtle expressions also from about early-1995. In these settings, however, the aquifer systems have to-date not become full to capacity. This aspect was linked to several factors, including:

- Increase depths to the water table, providing larger storage volumes.
- Lateral changes in aquifer hydraulics and flow gradients in the north, linked to:
  - Higher transmissivity due to increased saturated thickness of the aquifer system.
  - Higher transmissivity due to structural defects within the Hamersley Group.
  - Different aquifer geometry associated with proximity to the escarpment of the Hamersley Plateau and transition to the Fortescue River Valley.

Interpretations of the current cyclic-low and episodic-high water table elevations are shown on Figure 5-13 and Figure 5-14, respectively. The water table elevation peaks during and in short-term after episodic flood events. Thereafter the water table elevations progressively wane over periods that commonly span two to three years. Compatible snapshots of episodic-high and cyclic-low interpreted depths to the water table are shown on Figure 5-15 and Figure 5-16, respectively.

5.4.3.2 Aquifer Storage Assessments

The floodplain and CID aquifer system has finite storage above the water table. Therefore, the available storage provides a control on the groundwater wetting fronts. Once the available storage has been filled the surface water and groundwater wetting fronts would progressively propagate downstream. A reconciliation of available aquifer storage volumes compared to the transient annual surplus water volumes provided indications of potential rates at which the groundwater wetting front would propagate.

The estimation of available aquifer storage was informed by a baseline hydrology assessment for Yandicoogina mine discharge (RTIO, 2012). In this assessment, both the Marillana (downstream of the RTIO Yandicoogina Mine) and lower Weeli Wolli creek were discretised into six reaches, with each reach described in context to length and riparian zone width. These data were used to estimate widths of the floodplain aquifer and typical depths from the low-flow channel to the baseline water table elevation. An outline of the estimated aquifer storage under baseline water table conditions is provided in Table 5-6. It was assumed the specific yield of the unsaturated zone was 0.1 (dimensionless).

The data in Table 5-6 show that where the water table is now connected to Weeli Wolli Creek (on Reach 5 (after Cheng, 2012); also see Figure 1-1), the cumulative baseline storage was estimated at 80.1 GL. Comparisons between the surplus water discharge volumes 513.8 GL; (Table 5-1) and changes in storage from early-1995 (80.1 GL) provide indications of a substantial mismatch. The available storage (up to 45.4 GL) beneath the upper reaches of Weeli Wolli Creek was filled comparatively quickly between early-1995 and early-2000. During this period, the cumulative surplus water volume was 32.9 GL and the wetting fronts were enhanced by episodic recharge from flood events. Subsequently, the wetting provided by the surplus water discharge was not manifest in the same rates of aquifer filling beneath northern reached of Weeli Wolli Creek as observed further south. In the northern settings (within the groundwater environments monitored by DO8YJ216, DO8YJ165 and 99YJWB01) mounding of the water table is evident, but not at rates that:

- Account for the surplus water volumes.
- Off-set the measured infiltration rates from 9.41 to 13.15 ML/km/day (Dogramaci et. al, 2015a; Pettett and Pearcey, 2014).

These attributes indicate a likely change in aquifer hydraulics beneath northern reaches of Weeli Wolli Creek.

Table 5-6 Estimates of Baseline Aquifer Storage

Stream Reaches	Length (m)	Riparian Zone Width (m)	Floodplain Aquifer Width (m)	Depth to Water Table (m)	Estimated Storage (GL)	Sub-Totals Cumulative Storage (GL)
Marillana Creek Downstream of Yandi Mine

5.4.3.3 Estimation of Hydraulic Gradients and Aquifer Through-flow

The estimation of hydraulic gradients between selected monitoring bores was used to guide assessments of lateral changes in hydraulics of the aquifer system beneath Weeli Wolli Creek. Data on the water table elevations under baseline conditions and when the water table was connected to Weeli Wolli Creek were used to calculate hydraulic gradients. The estimated hydraulic gradients are shown in Table 5-7.

Table 5-7 Estimated Hydraulic Gradients

Selected Reaches	Reach Chainage (m)	Estimated Hydraulic Gradients				
		Baseline	Local Aquifer Full		Progressive Wetting Aquifer Zones	
			Low-Flow Channel Discharge Point	Peaks during Episodic Flood Events	February 2010	Early-2014
Upstream Reaches of Weeli Wolli Creek						
99YJWB02	0	-	-	-	-	-
99YJWB02 to 99YJWB03	2,100	0.0010	0.0040	0.0048	-	-
99YJWB03 to 99YJWB04	3,814	0.0008	0.0020	0.0016	-	-
99YJWB04 to D08YJ126	2,343	0.0028	0.0024	0.0021	-	-
D08YJ126 to YM119	514	0.0068	0.0068	0.0068	-	-
Average	**-**	**0.0028**	**0.0038**	**0.0038**	**-**	**-**
Transition Zone						
YM119 to D08YJ216	1,543	**0.0159**	-	-	**0.0140**	-
Downstream Reaches of Weeli Wolli Creek						
D08YJ216 to D08YJ165	2,229	0.0067	-	-	0.0066	0.0085
D08YJ165 to 99YJWB01	871	0.0052	-	-	0.0049	0.0080
Average	**-**	**0.0060**	**-**	**-**	**0.0058**	**0.0083**

The hydraulic gradients are comparatively steep (0.0140 to 0.0159) in the transition zone between YM119 to D08YJ216. In this zone, the hydraulic gradients are about 6 times steeper than beneath the upstream reaches of Weeli Wolli Creek. This range from 0.0140 to 0.0159 is probably conservatively low given it considers the entire chainage (1,543 m) from YM119 to D08YJ216; it may be that the gradients within the transition zone are steeper, with the transition occurring over a limited distance.

The hydraulic gradient informs the aquifer through-flow hydraulics based on Darcy's Law:

Q = kiA where:

- Q = total discharge (kL/day) from natural through-flow. Assume this is 53.8 GL (71.7 GL as per surplus water volumes in 2013 in Table 5-1 less 25 per cent losses to evaporation, transpiration and storage). This amounts to about 147,000 kL/day.
- k = bulk or effective hydraulic conductivity (m/day).
- i = hydraulic gradient (m/m). Assume this is 0.014. This estimate is probably conservatively low; it could be an order of magnitude steeper.
- A = cross-sectional area of the flow path. Assume this is 1,500 m width (Table 5-6) x 50 m saturated thickness of aquifer, thus 75,000 m^2.

Solving the equation shows the bulk of effective hydraulic conductivity would be about 140 m/day. Under a steeper hydraulic gradient of 0.14, the hydraulic conductivity would be about 14 m/day. Contextually, these values represent the effective hydraulic conductivity of the floodplain and CID aquifer system. As such, they can be directly compared to the values in Table 4-2.

5.4.3.4 Rates of Water Table Rise and Wetting Front Propagation

The calculated hydraulic gradients (Table 5-7) and observed rates of water table rise in monitoring bores D08YJ216, D08YJ165 and 99YJWB01 (Figure 5-12) have been used to assess the groundwater wetting front beneath northern reaches of Weeli Wolli Creek. For assessments using the calculated hydraulic gradients it was assumed:

- The local hydraulic gradients in the range 0.0049 to 0.0080 (Table 5-7) extend to the north beneath the Poonda Plain.
- The water table mounding in D08YJ165 and 99YJWB01 by early-2014 was of amplitudes 21.5 and 19.0 m, respectively.

By dividing the water table mound heights by the hydraulic gradients it was calculated that the leading edge of the groundwater wetting front would occur in the range 2.4 to 4.4 km north of D08YJ165 and 99YJWB01.

The rates of water table rise inform the groundwater wetting front in regard to:

- Rates of propagation to the north.
- Timetable for the transition from a disconnected system (Figure 5-12) to a connected losing system.

The hydrographs for D08YJ216, D08YJ165 and 99YJWB01 (Figure 5-12) inform the rates of water table rise. In the period from early-2008 to early-2014 (six years) these included:

- D08YJ216: 445 to 463 m AHD; an average annual rise of 3.0 m and total 18 m rise.
- D08YJ165: 433 to 444 m AHD; a rise of 11 m, with average annual rise of 1.8 m.
- 99YJWB01: 430 to 437 m AHD; a rise of 7 m, with average annual rise of 1.2 m.

Assessments of the rates of northern lateral propagation of the wetting front and timetable for filling aquifer profiles to the low-flow channel elevation of Weeli Wolli are summarised in Table 5-8 and Table 5-9, respectively.

Table 5-8 Timetable for Wetting Front Saturation of Local Aquifer Profiles

Monitoring Bore	Annual Rate of Water Table Rise (m)	Local Aquifer Full Elevation (m AHD)	Thickness of Unsaturated Zone (m)	Timetable for Filling of Local Aquifer (years)
D08YJ216	3.0	468	5.0	1.7
D08YJ165	1.8	465	21.0	11.5
99YJWB01	1.2	462	25.0	21.4

Table 5-9 Annual Rates of Wetting Front Propagation to the North

Monitoring Bore	Annual Rate of Water Table Rise (m)	Hydraulic Gradients	Annual Rate of Wetting Front Propagation (m)	
			Maximum	Minimum
D08YJ216	3.0	0.0049 to 0.0080	612	375
D08YJ165	1.8		374	229
99YJWB01	1.2		238	146

These assessments assume the rates of surplus water discharge and recent wetting front characteristics would be retained in the future. Differences in the observed rate of water table rise in D08YJ216, D08YJ165 and 99YJWB01, with progressive decreases beneath the downstream northern reaches of Weeli Wolli Creek are noteworthy. The differences probably reflect:

- Lateral changes in aquifer hydraulics, to higher transmissivity downstream.
- Transition to a broad alluvial delta and high-transmissivity fractured bedrock profile beneath the Poonda Plain.
- The volumes of available storage beneath the Poonda Plain represent a substantial (orders of magnitude) increase from those beneath Weeli Wolli Creek.

5.4.4 Discussion

It is evident that the water table is connected to the low-flow channel on Weeli Wolli Creek for the majority of the length of the surface water wetting front (Figure 5-17). The surface water wetting front on Weeli Wolli Creek has waxed and waned over distances of several kilometres north of the Marillana Creek confluence. There has not been substantial change in the northward propagation of the wetting front due to the commencement of surplus water discharge from the Hope Downs 1 Mine from early-2007. That the wetting front has waxed and waned over several years reflects a near-steady-state condition where the losses from the surface water environment have been balanced by losses through infiltration, evaporation and transpiration, storage in previously unsaturated profile, and through-flow in the local aquifer system. This conceptualisation is illustrated on Figure 5-18. It is only on the northern reaches of Weeli Wolli Creek, over a distance of about 4 km at the leading edge of the surface water wetting front, where the stream flow is disconnected from the water table (Figure 5-18). In this setting, the groundwater wetting front is evident, but propagating to the north at comparatively slow rates.

The findings by Dogramaci *et al.* (2015a) and Pettett and Pearcey (2014) indicate that the surplus water present as surface water is progressively assimilated by infiltration along Weeli Wolli Creek. The groundwater wetting front attributed to cumulative influences of high-frequency stream flow recharge events and surplus water discharges into Marillana Creek. It was anticipated that the groundwater wetting front propagated to beneath Weeli Wolli Creek and filled the local aquifer system to the vicinity of monitoring bore YM119 by early-2000. Upstream of this setting, the water table was connected to the low-flow channel of Weeli Wolli Creek. North of YM119 there is a transition zone within which, the water table becomes disconnected from Weeli Wolli Creek. North of the transition zone, wetting trends are evident from early-2000, but the groundwater wetting front has comparatively limited expression in terms of the amplitudes in water table mounding. Also, within the groundwater environment, aquifer storage in monitoring bores D08YJ215, D08YJ165 and 99YJWB01 is being consumed, albeit at comparatively slow rates. Therefore, the groundwater wetting front in the vicinity of D08YJ165 and 99YJWB01 transmits the majority of the surplus water; there are subordinate volumes intercepted by evaporation and transpiration.

The wetting front attributes together with supporting data provided by measured infiltration rates, aquifer storage assessments, calculations of hydraulic gradients and assessments of rates of water table rise indicate a significant change in the characteristics of the aquifer system beneath the northern reaches of Weeli Wolli Creek. The comparatively limited expression of the groundwater wetting front was interpreted to reflect a significant increase in the effective transmissivity of the aquifer systems.

5.4.5 Altered Groundwater Quality

The increases in water availability and discharge by transpiration and evaporation result in salt accumulation within the groundwater environment. A chloride ion increase of about 50 mg/L along the 27 km surface water wetting front on Weeli Wolli Creek was attributed to salt accumulation due to evaporation and transpiration losses along the flow path (Dogramaci et.al; 2015a).

6 LIKELY CHANGE ASPECTS FROM MINING AT PBS

6.1 Flood Mitigation

The development of PBS would conserve the low-flow channel of Weeli Wolli Creek and the majority of the riparian zone through avoidance measures. Flood protection bunds located about 100 m from the western crests of the proposed pits would not significantly limit flood footprints to the riparian zone; the broader floodplain areas (that host the proposed pits) would not be inundated by episodic events. Diversion drains on the eastern pit limits would intercept surface water shedding from the local catchment.

Designs of the flood protection bunds were informed (Cheng, 2013) by predictive TUFLOW hydraulic simulations. These simulations characterised the baseline flood depths, flood extents and flow velocities under baseline conditions up to a 200-year ARI event, and for the same event, with the flood protection bunds in place. The PBS diversion drains have been sized to convey 50-year ARI flows from local catchments behind the pits into Weeli Wolli Creek. Any flow larger than this event will overtop the drain into the pit. Comparative results of the predictive modelling are shown on Figure 6-1 and indicate:

- Increased depths of stream flow, particularly within the low-flow channel and closely associated bifurcate and or braided channels.
- Changes in stream flow velocity, with broader areas where the velocity was increased compared to baseline.
- Reduced flood footprint, by about 60 per cent, with the flood protection bund limiting inundation of the floodplain to the east of the riparian zone (where the proposed pit would be).
- Interception of flow paths from tributaries and alluvial fans on the eastern perimeter of the floodplain to Weeli Wolli Creek. The diversion drains would intercept flows from a 40.2 square km catchment area; this area represents about 2.5 per cent of the Weeli Wolli Creek catchment upstream of the confluence with Marillana Creek.

Further to these changes, it is recognised that the eastern diversion drains, together with the physical presence of the pits, would interfere with the watersheds from local catchments on the eastern banks of Weeli Wolli Creek. Both would tend to isolate, divert and or intersect surface water, unsaturated zone flows and groundwater originating from the eastern catchments, and associated alluvial fans that front onto the riparian zone along Weeli Wolli Creek.

6.2 Groundwater Abstraction and Discharge

Groundwater abstraction for pit dewatering is intended to lower the water table to near the base of the CID succession. Local drawdown within the floodplain and CID aquifer system would be in the order of 45 to 50 m to enable dry mining conditions. Drawdowns of this magnitude would preferentially propagate along the CID aquifer.

The Yandicoogina – Pocket and Billiard South Model (Lim, 2014) was used to predict groundwater abstraction for pit dewatering. The model was refined and enhanced from an earlier Visual MODFLOW MODSURFACT version (Inverarity, 2011) used to support the RTIO Yandicoogina Mine. One refinement was the inclusion of the Stream Flow Package to

represent perennial and episodic flow events on Weeli Wolli Creek. Model calibration was focussed on groundwater levels evident in monitoring bores from January 1998 to January 2014. This period reflects conditions when the floodplain aquifer was full and connected to Weeli Wolli Creek. Simulated hydraulics provide vertical integration of the floodplain and CID channel aquifers.

Predictions (Lim, 2014) of annual groundwater abstraction to 2032 are outlined in Table 6-1. Note that these volumes include all sources at the RTIO Yandicoogina Mine, including PBS. These forecasts show annual abstraction volumes in the range 37.4 to 82.2 GL, with an average of 54.6 GL.

Table 6-1 Predicted Annual Pit Dewatering Abstraction (2014 to 2032)

Year	Groundwater Abstraction (GL/annum)
2014	39.4
2015	51.3
2016	43.8
2017	49.4
2018	74.4
2019	64.7
2020	70.1
2021	70.3
2022	66.9
2023	82.2
2024	73.7
2025	57.9
2026	51.6
2027	46.7
2028	37.4
2029	39.1
2030	39.5
2031	39.8
2032	40.0
Average	**54.6**
Cumulative	**1,038.2**

The simulated pit dewatering abstractions concurrently drain both the floodplain and CID aquifers. Further, the predicted cumulative abstraction volumes of 1,038 GL is an order of magnitude greater than the estimated storage (derived from Table 5-6; assuming depths to the water table of 40 to 50 m) in the local aquifer systems. This aspect indicates that the abstraction volumes are being substantially supplemented by interception of perennial stream flow from surplus water discharge. In this regard, the model's water balance shows that volumes from 30 to 33 GL/annum are typically intercepted from Weeli Wolli Creek and abstracted as groundwater (thus included in the annual, average and cumulative abstraction

data provided in Table 6-1). These volumes are closely compatible to the simulated abstraction volumes from the Hope Downs 1 Mine. The predicted estimated aggregate volume of surface water predicted to be intercepted from Weeli Wolli Creek was about 608 GL; this volume represents about 60 per cent of the total abstraction.

The predictive simulations provide indications that the pit dewatering abstractions would:

- Draw-down the water table beneath the low-flow channel of Weeli Wolli Creek. A disconnected losing system would occur in the short-term after commencement of groundwater abstraction, as the water table is lowered.
- Promote increased surface water to groundwater interaction, given the disconnection of the stream flow from the water table would provide storage for infiltration.
- Intercept a portion of the perennial stream flow on Weeli Wolli Creek.
- Locally dewater the floodplain and CID aquifers by removal of free-draining groundwater from storage. Predicted transient drawdown snapshots provided by the Yandicoogina – Pocket and Billiard South Model (Lim, 2014) are shown on Figure 6-2 to Figure 6-6, inclusive. These snapshots are for December 2017 (about one year after commencement of abstraction at PBS), December 2019, December 2023, December 2027 and December 2032.
- Potentially intercept through-flow from the local catchment areas on the western and eastern banks of Weeli Wolli Creek. Also, the physical presence of the PBS pits would present a barrier to, and intersect water migrating in, the unsaturated profile.

In several regards, these changes would alter the surface water and groundwater wetting fronts, reverting to circumstances similar to baseline conditions.

Surplus water would be discharged to the lower reaches of Marillana and Weeli Wolli creeks at designated outlets. Forecasts of groundwater abstraction, groundwater use and volumes in excess of demand are summarised in Table 6-2.

Table 6-2 Forecast Groundwater Abstraction, Use and Discharge (to 2043)

Aspect	Groundwater Abstraction, Use and Discharge (GL/annum)				
	Dewatering	Use			Discharge
		Processing	Injection	Total	
Minimum	27.8	5.0	nil	5.0	22.8
Average	46.6	5.3		5.3	41.3
Maximum	82.2	5.9		5.9	76.3

6.3 Groundwater Wetting Fronts

A groundwater model was developed to investigate and inform the potential characteristics of the groundwater wetting front beneath northern reaches of Weeli Wolli Creek. This model domain captured the northern reaches of Weeli Wolli Creek, north of YM119, with objectives of conceptualising groundwater flow paths that extend beneath the Poonda Plain.

Adaption of the Yandicoogina – Pocket and Billiard South Model (Lim, 2014) was undertaken to enable simulation of the groundwater wetting front. Adaptation was required because the original model domain did not extend onto the Poonda Plain and both the model form and parametrisation were predominately based on data from the PBS RTIO Yandicoogina Mine settings. None of these attributes suited the model objectives. Ultimately, the adapted model was simplified, to streamline the required simulations, by excising the domain from the Yandicoogina – Pocket and Billiard South Model.

The model was conceptualised and formulated based on information that included:

- A cross-section transect within the Nyidinghu Project where Weeli Wolli Creek enters Poonda Plain (Fowers et al.; 2013). The cross-section represents the local geology at a distance of 4 to 5 km north of D08YJ165 and 99YJWB01.
- A regional groundwater exploration programme focussed on Fortescue Marsh and associated management zones (RTIO, 2012). This report included groundwater level data beneath the Poonda Plain.

In particular, the cross-section of the Nyidinghu Project (Fowers et al.; 2013) shows the presence of a deeply incised bifurcate palaeovalley aligned with Weeli Wolli Creek and structural defects (northeast striking faults termed the Weeli Wolli Fault System that form a zone of deformation up to 2 km in width) in the underlying bedrocks. The intersected palaeovalley (termed the Weeli Wolli Creek Palaeovalley) shows bottom elevations in the range 270 to 305 m AHD, thus indicating thicknesses of 155 to 190 m assuming ground surface elevation of 460 m AHD. This range of thicknesses shows significant change from settings further south beneath Weeli Wolli Creek where typical depths to basement rocks are about 75 m. A northwest striking Poonda Fault was also described by Fowers et.al. (2013) underlying the scarp of the Hamersley Range.

The model form, capturing the deeply incised and structurally controlled Weeli Wolli Creek Palaeovalley on west to east and south to north cross-sections is illustrated on Figure 6-7 and Figure 6-8, respectively. The west to east cross-sections in particular show the downstream transformation of the palaeovalley in transects from YM119, 99YJWB01 and northern reaches. Baseline data on the groundwater environment are limited and consequently steady-state and transient calibration of the model was based on:

- The perspective that the groundwater wetting fronts beneath southern reaches of Weeli Wolli Creek (represented by YM119) had quasi-steady-state attributes since early-2000, with the water table connected to the low-flow channel of the creek. The water table elevation was 474.7 m AHD.
- D08YJ215 and D08YJ165 being in the transition zone, with increasing northward disconnection between the water table and the low-flow channel.
- Water table data from 99YJWB01 during early-2000. The water table elevation was 424.0 m AHD and disconnected from the water table.
- Interpreted early-2010 water table elevations beneath Poonda Plain (Figure 4-4).
- Both YM119 and 99YJWB01 forming focal points of the calibration. This position was informed, understanding that the nature of the transition zone was poorly defined, as were the actual hydraulic gradients on transect from YM119 to D08YJ165. The calibration hydrographs for both monitoring bores are shown on Figure 6-9.

- Recharge to the water table compatible to the annual abstraction volumes shown in Table 6.1. The recharge was applied only to the northern reaches of Weeli Wolli Creek where the water table was disconnected from the creek. This approach recognised that the majority of the surplus water volumes were being transmitted within the groundwater environment and provided reasonable worst-case attributes to the model.

The transient calibration covered the period from 1997 to 2013, thus reflecting the period when the recharge was highest due to the inclusion of the wettest period over the last two centuries that included four major consecutive cyclones (1994 to 2005; Rouillard et al., 2015).

The calibrated model was run forward in time to predict changes to the groundwater wetting front based on predicted pit dewatering volumes described by the Yandicoogina – Pocket and Billiard South Model (Lim, 2014). The results of the model suggest that the groundwater wetting front would peak within two years after commencement of the PBS abstraction, with subsequent waxing and waning during the period to 2024. After 2024, the predicted wetting front shows steady decay. The 99YJWB01 hydrographs show the local wetting front attributes across a range of hydraulic conductivity sensitivity analyses. These analyses show compatible water table trends with indications that water table elevations in 99YJWB01 would attain a maximum elevation of about 453 m AHD (approximately 10 m above the current elevation). The predictions indicate the nearby low-flow channel (elevation 466 m AHD) would remain disconnected from the water table. The maximum predicted water table is commonly tens of metres below the ground surface and the groundwater wetting front does not connect to Weeli Wolli Creek downstream of the DO8YJ165.

It was recognised that the outlined model form, parameterisation, calibration and predictive outcomes are sensitive to the assumptions regarding the physical attributes of the interpreted palaeovalley, including dimensions (breadth, depth and length; which are unknown north of the Nyidinghu Project) and hydraulics. Whilst the attributes of the palaeovalley are only developed at a conceptual level, they do provide a reasonable fit to the available data, develop logic associated with changes to the hydraulics of groundwater environment beneath northern reaches of Weeli Wolli Creek, and an improved understanding regarding the potential fates of the surplus water discharged to Weeli Wolli Creek.

7 CONCEPTUALISATION OF RIPARIAN ZONE WATER AVAILABILITY

7.1 Overview

Riparian zones are considered as adaptive features of the natural landscape and likely to be sustainable, albeit in different forms, under changing environmental conditions, including variations in actual water availability. In this regard, the riparian zones do not represent a steady-state, rather a snapshot of individual and responses to near-term antecedent conditions, including available water, and other stresses. These characteristics are particularly relevant in the Pilbara where the semi-arid to arid climate and episodic nature of rainfall and stream flow events impart significant controls on the water availability in riparian zones.

Significant temporal and spatial variations in flooding and hence water availability impose a wide heterogeneity within the riparian floristics. As such the riparian zones can be viewed (Stromberg, 2001) as a mosaic of diverse and dynamic habitats (Malanson, 1993, Naiman and Décamps, 1997) that show temporal and spatial variations linked to water and nutrient availability. Typically, riparian habitats comprise complex gradients of predictable vegetation communities that have developed and changed over time depending on flood frequency, depth or duration. In frequently flooded areas, the riparian vegetation is influenced primarily by physical and chemical attributes of the habitats. Younger stands commonly occur in more frequently flooded areas, likely reflecting recruitment in areas of increased water reliability, but also where fluvial disturbances may compromise longevity (Gregory et al., 1991; Pettit et al., 2001). Annual and ephemeral species may be common as they complete their life cycles between inundation events (Menges, 1986; Trebino et al., 1996; Capon, 2003 and 2005). Conversely, however, woody shrubs such as *Acacia* spp. and members of the Chenopodiaceae family can be intolerant of waterlogged soils, dying following long periods of flooding (Pettit et al., 2001; Capon, 2003).

During drought, the composition of riparian vegetation is dependent on competition for available water and nutrients together with herbivory (Blom et al., 1990; Lenssen et al., 1999). Further, the seedling and canopy composition in riparian zones can substantially change depending on water availability provided by flooding. The riparian canopy changes may occur over both short-term and long-term time scales (Jones et al., 1994) depending on transient water availability. Drying trends are accompanied by vegetation composition changes as only species tolerant to arid (xeric) conditions of reduced water availability tend to survive.

Based on the described riparian zone attributes there may be expectation that individual trees and zonation gradients within the broader riparian zones have unique opportunism in how they intercept locally available water and nutrients to sustain life and support growth. Further, this opportunism may change, as the trees mature and water demands increase, and to reflect the preferential use of different water sources at different times depending on availability and competition.

7.2 Riparian Habitats

In baseline settings, the physical attributes of the climate, surface water hydrology, geomorphology and flood frequency are considered the predominant aspects controlling water availability and hence the temporal and spatial riparian vegetation diversity (Gregory et al., 1991; Blom et al., 1994; Naiman and Décamps, 1997; Stromberg, 2001). Flooding is considered to be the primary factor regarding water availability and supporting vegetation in

riparian habitats (Naiman and Décamps, 1997). Even when there is perennial stream flow, as now occurs on Weeli Wolli Creek, the water availability to the broader riparian zones is generally strongly influenced by the frequency and duration of flood events.

The Pilbara climate is semi-arid to arid, with widely varied annual rainfall patterns and distributions. These attributes influence stream flow and flood event frequency and consequently, the riparian zone water availability and habitats. Riparian zones reflect flood event frequency and footprints and also depths to the water table (Loomes, 2013). Accordingly, the riparian zone on Weeli Wolli Creek was subdivided based on physical geomorphology, position in the local landscape and associated likely variations in water availability based on flood footprints (Figure 7-1). In this regard, the discretised riparian zones on Weeli Wolli Creek included:

- Low-flow channel. The low-flow channel transmits a wide range of fluvial events. This was assumed to incorporate:
  - A 6 m width zone that transmits all of the perennial stream flow.
  - A 20 m width corridor either side of the low-flow channel wherein the riparian vegetation is able to gain access to perennial stream flow or associated pore water (pers comm Pauline Grierson, March 2015).
  - An overall total width of 46 m.
- Incised channel. There may be different vegetation habitats between lower elevation channel bank and levee bank settings due to local changes in these attributes (Naiman and Décamps, 1997). The incised channel was assumed to be a 100 m width, inundated by 1-year and 2-year ARI stream flow events.
- Riparian zone floodplain. This zone recognises that the riparian zone is preferentially developed along the main low-flow channel of Weeli Wolli Creek and where captured by secondary braided channels. The riparian zone floodplain was assumed to be a 450 m width, inundated by 2-year to 5-year ARI stream flow events.
- Broader floodplain. Perimeter riparian zones assumed to be 1,800 m in width and infrequently inundated by 5-year to 10-year ARI stream flow events. This habitat diminishes laterally from the low-flow channel dependent on elevation and flood characteristics (Capon, 2003 and 2005).

In this context it was recognised that the low-flow channel, incised channel and riparian zone floodplain domains form the riparian conservation zone shown on Figure 1-2. Within the riparian conservation zone:

- The low-flow channel accounts for about 8 per cent of the overall footprint.
- The incised channel accounts for about 17 per cent of the area.
- The riparian zone floodplain represents about 76 per cent of the conservation zone.

7.3 Weeli Wolli Creek Riparian Floristics

Riparian zones typically have higher soil moisture and nutrient content than neighbouring upland systems (Megonigal et al., 1997). The riparian vegetation communities are distributed, structured and characterised based on the availability of water; watercourses such as the Weeli Wolli Creek, and associated riparian zones are characterised as areas of comparatively high water availability. In these settings, stream flow occurrences are focussed within channels in valley-floor settings and underlain by soils with capacity to store soil water predominantly derived from infiltration of flood water. Spatial patterns in riparian vegetation composition and structure also occur along longitudinal gradients within river catchments (Ward et al., 2002). For example, populations of River Red gums (*E. camaldulensis*) in the riparian zones of numerous Australian rivers are known to depend on floods that promote regeneration (e.g. Bren and Gibbs, 1986; Chesterfield, 1986; Dexter et al., 1986; Bren, 1987 and Bren, 1988). In general, maximum species diversity tends to occur in riparian habitats of the middle reaches or a river catchment. Riparian plant species richness is also often higher in proximity to the main channel rather than on tributaries (Nilsson et al. 1994). Conversely, the extended absence of flood events or major changes to hydrology has had considerable impact on the health of *E. camaldulensis* (Bacon et al. 1993, Mensforth et al. 1994, Stone and Bacon 1994, Thorburn et al. 1994, Stone 1999, Chisholm and Stone 2003).

Commonly, the riparian floristics include phreatophytic communities that source groundwater to meet water demands (Land & Water Australia, 2007a). *M. argentea* is regarded as an obligate phreatophyte which primarily draws water from the water table (Masini, 1988; Graham, 2001; O'Grady et al,,. 2005) and is dependent on shallow groundwater sources and or perennial surface water. An earlier study (AGC Woodward-Clyde, 1992) concluded that the depth to groundwater is crucial to the distribution of *M. argentea* on Marillana Creek and suggested the likely maximum rooting depths of *M. argentea* is less than 5 m.

The larger eucalypt trees potentially have roots that may enable variable dependency on groundwater; for example *E. camaldulensis* and *E victrix* meet water demands predominantly from flood water, with groundwater a subordinate source, with mature trees more reliant on groundwater than young (Overton and Jolly, 2004). Eucalypts are termed facultative phreatophytes where groundwater dependency may be limited, change over time and/or be opportunistic depending on the presence of alternative water sources. These tree species are believed to rely on water available within the soil profile above the water table. This suggests these species prefer unsaturated soil conditions with episodic rewetting from flood waters and direct infiltration of rainfall. *E. camaldulensis* has rooting depths to about 10 m study (AGC Woodward-Clyde, 1992).

On Weeli Wolli Creek, the low-flow channels of major creek lines are characterised by floristics that predominantly include *E. camaldulensis* (River Red Gum), and *E. victrix* (Coolibah) over *M. argentea* (Cadjeput) and *M. glomerata* (Inland Tea-tree) and acacia low open woodlands. The incised channel and broader riparian floodplain supports E. victrix scattered trees over acacia low woodlands and open hummock grassland. A broad-scale summary of the typical potential groundwater dependency of the predominant riparian floristics of Weeli Wolli Creek is provide in Table 7-1 (after Astron, June 2009). It was recognised that numerous natural factors influence the water use by the riparian vegetation and hence local characteristics of riparian zones. These factors may be both causal and responsive given change may occur dependent on water availability. The factors present and/or significant at local or broader scales include:

- Soil properties.
- Individual tree and species morphology.
- Proportional and transient change in water use from different sources.
- Depth to the water table.
- Water quality.

Table 7-1 Typical Potential Groundwater Dependency of Riparian Floristics

Floristics	Potential Groundwater Dependence	Comment
Melaleuca argentea	High	Obligate phreatophyte in settings along watercourses where water table depths are less than 3 m.
Eucalyptus camaldulensis	Medium-High	Facultative phreatophyte generally on creek lines underlain by shallow depth to groundwater.
Melaleuca glomerata	Medium	Facultative phreatophyte on creek lines. This was based on evidence on Kunada Creek, a tributary to Robe River, in west-Pilbara settings.
Eucalyptus victrix	Medium and Low to Medium	Facultative phreatophyte and commonly the dominant over-story species on creek lines and floodplains in settings of lower water availability. There is a widespread distribution of *E. victrix* in Pilbara riparian zones with substantial wide differences in depths to the water table and groundwater availability.
Acacia low woodlands	Low	Not phreatophytic.

Riparian plant species are commonly characterised by physiological or morphological adaptations that enable survival despite significant temporal changes in water availability and/or submergence by flood waters. These adaptations may include:

- Tolerance of different water availability during drought and floods (Lemcoff et al., 2001; Yunusa et al., 2010). The tolerance may be explained by dormancy and/or reduced metabolism during drought and initiation of leaf and flower production in response to rainfall or submergence. For example, *E. victrix* and *E. camaldulensis* limit water demands by closing stomata and reducing transpiration. This is recognised as a common trait for semi-arid and arid plant species (Yunusa et al., 2010).
- Ability to vary transient water sources in response to changes in water availability (Snyder and Williams, 2000; Drake and Franks, 2003).

- Timing of reproduction to coincide with regular flood cycles that reflect periods of improved water availability. Recruitment of riparian trees and shrubs is commonly related to flooding. This aspect is recognised to include:
  - Ability by selected species to delay flowering and seed production until recession of episodic flood waters (Blom et al., 1990).
  - Production of large persistent soil seed banks that lie dormant until occurrence of suitable conditions for germination (Leck and Brock, 2000).
  - Seeds which germinate in conditions (temperature, light and oxygen availability) that occur during recession of episodic floodwater (Leck, 1989; Pautou and Arens, 1994). Riparian trees species including *E. camaldulensis* and *E. victrix* commonly germinate following inundation (Capon, 2002; Woolfrey and Ladd, 2001). Survival of seedlings and saplings is dependent on further flooding (Dexter, 1967).
  - Dispersal of seeds by flood waters.
  - Ability to rapidly elongate stems and petioles upon submergence, allowing plants to emerge from the low light conditions of flood waters (Blom and Voesenek, 1996).
  - Development of plant tissues that host comparatively large spaces between cells (aerenchyma) in stems and roots, enabling storage and diffusion of metabolic gasses.
  - Development of adventitious roots or initiate increased branching of lateral roots when flooding occurs (Blom et al., 1990; Boulton et al., 2010).
  - Ability to alternate metabolic pathways so respiration and growth can continue or occur under anoxic and waterlogged conditions (Hook, 1984; Boulton et al., 2010; Fellman et al., 2011).
  - Unique perforations and arrangement of cells (stomata) in the leaves (Gomes and Kozlowski, 1980; Lemcoff et al., 2001) enabling gas and water exchange, as evident in *E. camaldulensis*.
  - Defoliation and loss of limbs together with stunting of growth during prolonged drought.

7.4 Analogies for Riparian Zone Water Availability

Analogies for riparian zone water availability have been derived from:

- Observations on Weeli Wolli and Marillana creeks. Riparian zones on both creeks are likely to be sustained using water from different sources including soil water, perched groundwater and surface water (Graham et al., 2001 and O'Grady et al., 2009). The sources may vary according to the distribution of specific environmental conditions, therefore influencing the distribution and vigour of the riparian zone.
- Site investigations within the Mt Bruce Coolibah Wetlands. These investigations show increased water availability linked to episodic flood events and associated surface water, surface water to groundwater interactions and groundwater wetting fronts.

Both analogies are discussed below to provide context to potential future changes in water availability to the riparian zones on Weeli Wolli Creek.

7.4.1 Observations on Weeli Wolli and Marillana Creeks

Airborne multispectral imagery has been used since 1993 to interpret potential changes in riparian zone conditions on the lower reaches of Marillana Creek. The observed changes in vegetation patterns were predominantly adjacent to the surplus water discharge outlets and nearby pools where the surface water was attenuated above a shallow water table. This imagery detected:

- Increased density of riparian vegetation associated with prolonged availability of surplus water downstream of discharge outfalls.
- Increases and decreases of the Plant Cell Density Index.

Remote sensing imagery between 2002 and 2008 showed changes in tree canopy cover, density and condition. Interpretations of this imagery (Specterra, 2008) indicated the changes were predominantly linked to fire and tree loss/damage caused by flood events.

Riparian *E. victrix* and *E. camaldulensis* health has been monitored on a quarterly basis since 2005 and 2006 on the Weeli Wolli and Marillana creeks (RTIO, 2012). The monitoring captures 22 sites and 233 trees on Weeli Wolli Creek, and 11 and 144 trees in riparian zones on Marillana Creek.

Monitoring of riparian zone condition and health has also been undertaken by Mattiske Consulting Pty Ltd since 2008. This monitoring has been aligned along Weeli Wolli Creek, including reaches downstream of the confluence with Marillana Creek.

The monitoring has not detected significant differences in riparian vegetation responses in undisturbed settings compared to disturbed settings influenced by drawdown of the water table or surplus water discharge. Overall, the observations from the RTIO Yandicoogina Mine indicate:

- A small percentage of *E. victrix* trees being monitored have declined in health or have died, which appear to be a result of waterlogging due to surplus water discharge. These trees are limited to the areas of permanent water in the low-flow line (incised channel).
- Absence of significant trends in tree density or condition of mature trees.
- That natural fluctuation in riparian tree density and condition seen at reference sites on Weeli Wolli, Mindy Mindy and Coondiner creeks are compatible with changes observed on Weeli Wolli Creek.
- Similarities in foliage cover trends on the Weeli Wolli, Mindy Mindy and Coondiner creeks suggesting drawdown of the water table may not be changing foliage cover at various structural levels within riparian stands.
- No significant discrepancy in understorey richness in comparisons between the reference sites on Weeli Wolli, Mindy Mindy and Coondiner creeks and reaches of Weeli Wolli Creek influenced by drawdown or surplus water discharge.
- Over time, riparian zones subjected to increased water availability, including saturation of root zones and mounded water table elevations commonly aligned with surplus water discharge outlets, may show increased recruitment and increased leaf area index of some species. In particular, an increase in healthy stems of *M. argentea* was recorded within the surface water wetting fronts. Increases in riparian vegetation and sapling

density may also appear to be linked to extended periods of above-average rainfall and frequency of flood events.

- Lowering of the water table and dewatering of the soil profiles beneath riparian vegetation stands (due to pit dewatering) has the potential to decrease water availability and as a consequence induce stress in eucalypts.
- Tree health may selectively decline due to sudden reductions in water availability.

7.4.2 Mt Bruce Coolibah Woodlands

The Mt Bruce Coolibah Woodlands are located in a topographic depression on the Mt Bruce Flats. The woodlands solely comprise *E. victrix* (Coolibah), with a dense understorey of native grasses (Batini, 2008). Locally, the stratigraphy is dominated by Tertiary detrital and palaeochannel successions overlying dolomite of the Wittenoom Formation (Figure 7-2).

The woodlands are temporarily inundated by episodic flood events; inundation occurred in January 2006 (after about 180 mm rainfall), but not subsequently to 2011. The wet soil condition flowing inundation is understood (Florentine, 1999) to initiate germination of *E. victrix* seeds. It was considered (Batini, 2009) that there was considerable storage of soil water which predominantly supported the *E. victrix* stands and enabled survival during periods between flood events. That is, the *E. victrix* was not dependent on groundwater.

There have been a number of site investigations associated with the Mt Bruce Coolibah Woodlands. Those forming the focus of recent assessments (RTIO, 2011) included:

- Interpretation of water table mounding in monitoring bores due to recharge from flooding in January 2006. This concept is shown on Figure 7-3. There is evidence in monitoring bore hydrographs (RTIO, 2011) that flood events provide the predominant source of recharge to the water table. These data indicated flood waters infiltrate the unconfined aquifer beneath the Coolibah Woodlands.

The hydrographs of monitoring bores in the aquifer system beneath Weeli Wolli Creek also show rapid response to recharge from flood events. This reflects vertical integration of the surface water to groundwater flow system, with limited impedance of infiltration of rainfall and or flood water.

- Soil moisture contents (gravimetric) ranged from 5 to 20 per cent in top 5 m (Figure 7-4), tending to increase from 4 to 14 per cent in the top 2 m in individual bores (RTIO, 2011). Below 5 m depth, the moisture contents vary widely.
- Preliminary assessments of tree water use using stable isotope analysis (Grierson and Skrzypek, 2011) showed *E. victrix* twig water collected in November 2010 had $\delta^{18}O$ values of -7.6± 0.8 ‰ (Figure 6-3). These values were consistent with the soil water $\delta^{18}O$ values and considered to reflect the stable isotope composition of the water sources of the trees. The $\delta^{18}O$ values (-7.6± 0.8 ‰) for *E. victrix* were observed in the soil water at depths below 6 to 11 m, depending on where the trees were located within the Woodland. The assessments indicated *E. victrix* generally acquires water from the unsaturated zone, at depths from 6 to 13 m (Grierson and Skrzypek, 2011) or below.

The twig sampling occurred over a number of years after the woodlands were inundated. Pfautsh and Adams (2011) showed that water loss in *E. victrix* using sap flow instruments,

was regulated by climatic conditions, with water use by *E. victrix* declining as availability of soil water declined. These data together with the stable isotope results indicated water use in *E. victrix* was dynamic. At the time of the twig sampling, the trees were sourcing deep soil water rather than groundwater. These data indicated:

- A 5-year ARI flood event may sustain the local *E. victrix* stands.
- Flood events alone may sustain the riparian zone.
- Transient changes in water availability naturally occur, and are reflected in changes in riparian zone distributions, floristics, stress (leaf and canopy density) and mortality.

These characteristics are compatible and supported by evidence on Weeli Wolli Creek which show the riparian zone may wax and wane during periods of increased water availability (flood events) and drought, respectively.

7.5 Factors That May Limit Use of Available Water

There are numerous natural factors that may limit surface water and groundwater use by riparian plant species despite it being present. These factors are likely to include:

- Individual tree and species morphology.
- Different sources being present and changes in sources over time linked to drought and flood.
- Inability for water to enter the root zones, linked to:
  - Infiltration rates.
  - Lateral and vertical flow paths within the unsaturated profile and propensity for perched water tables.
  - Physicochemical composition and characteristics of soils, including porosity, field capacity and moisture retention characteristics.
  - Vertical and lateral hydraulics of the soils which influence the attenuation and wetting front characteristics within the unsaturated profile.
- Depths to the water table.
- Water quality.

Given these perspectives, it was recognised that apparent changes in water availability, such as perennial presence of surface water or mounding of the water table, may be indicative only, and possibly misleading in context to use by riparian zone plant species. For example:

- The presence of perennial water in the low-flow channel of Weeli Wolli Creek does not reflect increased water availability to the majority of the riparian zone. Only trees in the immediate vicinity of the low-flow channel would have direct access to the surface water.
- Mounding or drawdown of the water table does not necessarily reflect change in predominant water source of the riparian zone vegetation. Mounding of the water table may increase water availability, but not necessarily proportional use from this source.

- Opportunistic adaptions by individual trees to source new water sources would not be immediate but could change over time.

Adaptations to intercept new water sources would add to the opportunistic water source options, not exchange one for another. Further, the adaptations would likely provide only a portion of the water demands. This portion may vary from tree to tree and over time.

7.6 Assessments of Water Availability

Water sources that may be available to the riparian zones of Weeli Wolli Creek have been estimated with an objective to characterise potential changes from baseline, current and PBS scenarios. Key attributes of the conceptualisation of water availability include:

- Stream flow in the low-flow and incised channel of Weeli Wolli Creek and flooding of adjacent riparian zones would be largely undisturbed. Flood protection bunds associated with the proposed mining (Figure 6-1) may subtly influence the local hydrology. For example, reductions in overland flow from the east as a result of the diversion drain on the eastern perimeter of PBS have been factored into the water availability assessment. Overall, the flood protection bunds do not significantly change water availability associated with episodic stream flow and flooding events.
- Infiltration from stream flow would predominantly have vertical to sub-vertical flow paths, thus have limited availability at short distances from the low-flow channel. Therefore, the perennial stream flow would not contribute to the available water laterally in the incised channel and riparian zone floodplain domains.
- Dewatering of the proposed pit would lower the water table beneath Weeli Wolli Creek and the riparian zone. Predicted drawdown distributions (Figure 6-2 to Figure 6-3, in particular) were used to define changes in depths to the water table. Schematic cross-section representations of the changes in water table settings from baseline, current and PBS mining situations are shown on Figure 7-5 and Figure 7-6 for the southern (Pocket) and northern (Cue) settings, respectively. In lowering the water table:
  - Stream flow on Weeli Wolli Creek would be intercepted, in part, and the water table would become disconnected from the low-flow channel. The disconnection of the water table from the low-flow channel would broadly replicate the baseline settings, albeit there would be perennial recharge to the water table from stream flow in the low-flow channel. The perennial stream flow would sustain the surface water to groundwater interaction beneath the low-flow channel. Assuming that the interpreted loss rates (0.02 to 9.24 ML/km/day) for local reaches of Weeli Wolli Creek (Dogramaci, et al., 2015a; and Pettett and Pearcey, 2014) remain representative, perennial stream flow on Weeli Wolli Creek would prevail on reaches upstream of the Marillana Creek confluence. Calculations based on the interpreted loss rates indicate that stream flow of 35 GL/annum derived from Hope Downs 1 Mine would progressive dissipate over reaches of Weeli Wolli Creek to distances of 21.7 to 22.6 km downstream of Weeli Wolli Spring. These distances extend about 4 km downstream of the Marillana Creek confluence.
  - Stream flow would sustain the surface water and pore water availability beneath the low-flow channel domain.

- Beneath selected local reaches of Weeli Wolli Creek adjacent to PBS the simulated wetting fronts and other circumstances tend to limit the predicted drawdown as shown on Figure 6-2 to Figure 6-6, inclusive. These reaches were represented with the floodplain aquifer being perennially recharged from stream flow and underlain by low-transmissivity Weeli Wolli Formation.
- Drawdown of the available groundwater sources was predicted to propagate beneath the entire local riparian zone, albeit at different magnitudes and tending to typically increase over time.
- Based on the Figure 6-2 and Figure 6-3 predictive drawdown snapshots was a reasonable worst-case expectation that over a one-year to three-year period, drawdown in the range from 20 to 30 m could occur beneath all of the local riparian stands. Drawdown of this magnitude broadly equates to lowering of the water table at rates of 0.5 to 1.0 m per month. A schematic that provides perspective for the change in water table settings in context to interpreted root depths of *E. victrix* is shown on Figure 7-7.

The water availability assessments have been based on the stream flow and groundwater resources data, with consideration in context to riparian zone water availability. Templates (Figure 7-8) for the conceptualisation of water availability were developed to support this assessment given the presence of surface water and groundwater wetting fronts on Weeli Wolli Creek, and proposed future groundwater abstraction for mining of PBS. The templates conceptually represent the four identified riparian zone domains (low-flow channel, incised-channel, riparian floodplain and broader floodplain) together with the water table settings on a cross-section within the northern portion of the PBS project area. These templates reasonably typify the local water availability circumstances under baseline, current and PBS scenarios. In settings outside of the predicted PBS drawdown footprint, the current water availability circumstances would prevail for the duration of the PBS Project assuming Hope Downs 1 Mine continues to discharge surplus groundwater.

Applications of these data were made recognising a number of reasonable insights and/or assumptions, including:

- Weeli Wolli Creek, as with other creeks, forms a focus for both surface water and groundwater flows. In comparative terms, the associated riparian zone represents a setting of enhanced water availability.
- The riparian zones are mature and sustainable landforms. Therefore the baseline surface water and groundwater availabilities provide reasonable guides on future water demands required to maintain the existing systems.
- The riparian zones may not represent steady-state conditions. It was recognised that water availability varies widely in the natural environment. Episodic flood frequencies together with drought provide influences that cause the waxing and waning of riparian zone distributions and health. Therefore, the riparian zones are considered as adaptive features of the natural landscape and likely to be sustainable, albeit in different forms, under changing environmental conditions, including variations in actual water availability. In this regard, the riparian zones are unlikely to represent a steady-state, rather a snapshot of responses to antecedent conditions, including available water, competition and other stresses. As such there is an expectation that the riparian zones

and associated conditions may wax and wane from a typical distribution and condition depending on water availability.

- Three water sources were interpreted to support the riparian zone, including:
  - Surface water flows, including direct rainfall, stream flow (in the low-flow and incised channels) and overland flow (from the hinterland and from flood events).
  - Surface water to groundwater interaction, thus flow and water in storage in the unsaturated profile represented by pore water in the interstitial fabrics of the alluvial and CID successions.
  - Groundwater from settings below the water table.
- The baseline settings provide indications of riparian zone function, including:
  - Recognition that the riparian zone is preferentially developed along the main low-flow channel of Weeli Wolli Creek and where captured by secondary braided channels.
  - Perimeter zones located away from the major watercourses of Weeli Wolli Creek also provide information on water availability and predominant sources.

  These aspects reinforce the importance of surface water in the riparian zone functionality, particularly, understanding that there is progressive degradation of riparian zone consistency, condition and character in moving away from the surface water source areas. In fundamental terms, the riparian zone functions every day of the year; so there is water available, with surface water being the initial source that episodically rewets the system. Based on this fundamental, there should be a 365 day supply equation. The riparian zones would appear not to be dependent on the presence of surface water because it has limited presence over much of the year. Similarly, deep water table settings are not aligned with themes of groundwater dependency. For example, the perimeter riparian zones are infrequently inundated and underlain by comparatively deep water table settings. By extension, therefore, the predominant water dependency for the riparian zone would be pore water, with contributions from surface water and groundwater being subordinate. These attributes support indications of riparian zone functionality based predominantly on surface water wetting and pore water availability. Riparian zones that are wetted more frequently have similar characteristics, but with increased density and diversity, and improved condition, due to increased pore water availability linked to increased frequency of surface water rewetting events.

- Water availability would be different within the discretised low-flow, incised channel, riparian zone floodplain and broader floodplain domains of Weeli Wolli Creek.
- Direct rainfall provides a source for available water. It was assumed that a 10 mm daily rainfall event was the minimum depth required to contribute to the available water. On average events of 10 mm depth or greater occur during 10 days each year (Chapter 3.1.1 and Chapter 5.4.1)
- The local watershed from catchment areas adjoining the floodplain to Weeli Wolli Creek also contributes to the available water. On average it is assumed that the events of 10 mm depth or greater that provide stream flow also provide overland flow contributions during 10 days each year.
- The records for Tarina and Waterloo Bore provide reasonable baseline attributes for stream flow occurrences on Weeli Wolli Creek. It was assumed that stream flow in the

low-flow channel and incised channel is 20 days per annum, thus between the 13 to 38 day range measured at Tarina and Waterloo Bore.

- Pore water, within the unsaturated zone above the water table, is typically available year-round, but may not be the preferential source during periods of overland flow and/or re-wetting by surface water. This aspect recognised the natural balance between water availability and demand that enables the riparian zone presence. Monitoring bore hydrographs for settings beneath the riparian zone floodplain and broader floodplain show episodic wetting linked to overland flood flows that respond shortly after the rainfall events, peak in terms of recharge to the water table up to six months later, and decay over extended periods of three years or more. It was assumed that similar wetting characteristics could be reasonably applied to the unsaturated zone, understanding that after periods of saturation or high water pore water contents that may occur over six month periods, there would be progressive decay linked to interception by evaporation, vertical drainage and use by riparian vegetation (transpiration and respiration).
- The surface water and pore water sources cumulatively form a year-round (365 day) perennial water availability within the riparian zone settings where there is no groundwater dependency.
- Groundwater was assumed to be a potential perennial year-round source for water table depths to a maximum of 20 m; for depths to the water table greater than 20 m it was assumed that groundwater was unavailable to any component of the riparian zone. It is only Eucalypts that may access the deep groundwater; most floristic components of the riparian zone would not have access to groundwater at this depth. Therefore, for groundwater it was also recognised that there may be variable demand depending on depths to the water table; the groundwater is available year-round but may not be preferentially sourced. In this regard, five water table zones were discretised and used to factor reduced groundwater demand under progressively deeper water table settings. The five discrete water table zones included:
  - 0 to 2 m Depth: It was assumed that groundwater in this setting was available for 85 per cent of each year (310 days).
  - 2 to 6 m Depth: It was assumed that groundwater in this setting was available for 60 per cent of each year (219 days).
  - 6 to 12 m Depth: It was assumed that groundwater in this setting was available for 30 per cent of each year (110 days).
  - 12 to 20 m Depth: It was assumed that groundwater in this setting was available for 10 per cent of each year (37 days).
  - Greater than 20 m depth: It was assumed that groundwater at this depth was not available to support the riparian vegetation.

A consolidation of the interpreted water availability and persistence each year across the four discretised riparian zones for the baseline, current and PBS scenarios is shown in Table 7-2. The conceptualisation of the annual water dependency across the riparian zones is also shown on Figure 7-9, Figure 7-10 and Figure 7-11 for the baseline, current and PBS scenarios, respectively. The available water is also discretised for the three different potential sources. For the PBS scenario the assessment was informed by the overlay of predicted drawdown on the riparian zones as shown on Figure 7-12.

Subsequently, the information in Table 7-2 was used to provide context to potential riparian zones annualised dependency on surface water, pore water and groundwater (Table 7-3). In this regard, each source had a maximum annual availability of 365 days. For the groundwater sources, the 365-day availability described in Table 7-2 was further rationalised assuming decreasing dependency as the depth to the water table increased, as follows:

- Groundwater from the water table at 0 to 2 m depth was assumed to be available for 85 per cent of each year (310 days).
- 2 to 6 m depth: groundwater availability for 60 per cent of each year (219 days).
- 6 to 12 m depth: groundwater availability for 30 per cent of each year (110 days).
- 12 to 20 m depth: groundwater availability for 10 per cent of each year (37 days).

It was recognised that the groundwater availability was probably conservatively high. This recognition was informed by realisation that i) available water would be preferably sourced and depleted from shallow depths before being drawn from deeper groundwater settings; ii) significant portions of the water availability profile would be unaltered in transition from the current to PBS scenarios; iii) the groundwater environment filled from the bottom up (thus not from the top down) and consequently did not enhance surface water and pore water availability throughout the majority of the riparian zone; and iv) groundwater availability is unlikely to reflect use, particularly for the deeper water table settings. With reference to Figure 7-8 it was reconciled that typically:

- The upper-most 25 per cent of the incised channel profile would be unaltered in transition from current to PBS scenarios. In this profile, presumably where the root architecture is preferentially developed the surface water and pore water availability would not be changed.
- Similarly the upper-most 30 and 50 per cent of the riparian zone floodplain and broader floodplain would be unaltered in context to available water.

These aspects were not applied to the low-flow channel due to the persistence of surface water across all scenarios.

These perspectives were used to further limit the groundwater availability from that described above. For the respective incised channel, riparian zone floodplain and broader floodplain, the groundwater availability was reduced 25, 30 and 50 per cent respectively to account for the absence of disturbance to the upper-most root zones. This approach limits some of the conservatism in the estimated groundwater availability and highlights where most change may have or may occur.

Thereafter, the annual dependency for the surface water, pore water and groundwater sources was determined based on the linear interpolation between their availability (days per annum) and the cumulative (total annual availability of all sources) water availability.

In Table 7-4, the annualised water dependencies for the individual sources (from Table 7-3) were collated and compared to reflect:

- Percentage contributions from each source.

- Net percentage changes in the dependency contributions from each source compared to the baseline. This simply reflects the difference between the baseline contributions and corresponding contribution from the current or PBS scenario in the same setting.
- Relative percentage changes in water dependency based on proportional widths of the low-flow, incised channel and riparian zone floodplain domains to the total width of the riparian conservation zone. For example, the low-flow channel domain width is 8 per cent of the total riparian conservation zone width. Therefore for this zone, the net percentage change was multiplied by 0.08.

The tabulated and illustrated (Figure 7-2 to Figure 7-4, inclusive) conceptualisation of water availability, dependency and change provide indications that the discharge of surplus water to Weeli Wolli Creek has enriched water availability. In particular this is evident within the low-flow channel domain where surface water is perennially present together with a shallow water table. The presence of perennial stream flow represents a transparent enrichment of water availability whilst that associated with a shallow water table environments is less apparent.

In settings not influenced by drawdown of the water table due to dewatering of PBS, the current scenario of water availability would prevail whilst the Hope Downs 1 Mine continues to discharge surplus groundwater.

Table 7-2 Interpreted Persistence of Available Water Sources within a One-Year Period

Water Source	Persistence of Potential Riparian Zone Water Sources (days per annum)											
	Baseline				Current				PBS			
	Low-Flow	Incised Channel	Riparian Zone	Broad Plain	Low-Flow	Incised Channel	Riparian Zone	Broad Plain	Low-Flow	Incised Channel	Riparian Zone	Broad Plain
Surface Water												
Direct Rainfall[1]	10	10	10	10	10	10	10	10	10	10	10	10
Local Watershed[2]	10	10	10	10	10	10	10	10	10	10	10	0
Stream Flow[3]	25	0	0	0	365	0	0	0	365	0	0	0
Flood[4]	0	18	12	2	0	18	12	2	0	18	12	0
Total	**45**	**38**	**32**	**22**	**385**	**38**	**32**	**22**	**385**	**38**	**32**	**10**
Surface Water to Groundwater Interaction (Pore Water)												
Pore Water[5]	365	365	365	365	365	365	365	365	365	365	365	365
Water Table Zone[6]												
0 to 2 m Depth	-	-	-	-	365	-	-	-	-	-	-	-
2 to 6 m Depth	-	-	-	-	-	365	365	-	-	-	-	-
6 to 12 m Depth	-	-	-	-	-	-	-	365	-	-	-	-
12 to 20 m Depth	365	365	365	-	-	-	-	-	365	-	-	-
>20 m Depth	-	-	-	365	-	-	-	-	-	365	365	365

Notes:

1 Direct Rainfall of at least 10 mm occurs on average 10 days each year.

2 Local Watersheds were assumed to provide overland flow to the riparian zone at times that daily rainfall exceeds 10 mm depth.

3 Stream Flow in low-flow channel being 25 days per annum, thus midway between the 13 to 38 days range measured at Tarina and Waterloo Bore.

4 Flood events that extend beyond the incised channel (less than 2-year ARI for the incised channel and less frequent than 20-year ARI for the wider floodplain areas.

5 It was assumed that pore water is typically available year-round, but may not be the preferential source during periods of overland flow and or re-wetting by surface water. This assumption was based on monitoring bore hydrographs and understanding that similar wetting characteristics could be reasonably applied to the unsaturated zone, recognising also that after periods of saturation or high water pore water contents that may occur over six month periods there would be progressive decay linked to interception by evaporation, vertical drainage and use by riparian vegetation.

6 Based on observed typical depths to the water table and prediction of drawdown for Billiard South.

Table 7-3 Change Assessment of Water Availability and Interpreted Annualised Dependency

Interpreted Aspects	Change Assessment on Riparian Zone Water Availability (days per annum)											
	46 m Low-Flow Channel			100 m Incised Channel			450 m Riparian Zone Floodplain			1,800 m Broader Floodplain

Groundwater	109	30	18	106	31	0	102	31	0	45	0	0

Notes:

1 This dependency is based on a linear relationship between comparably percentage availability of individual sources and dependency.

Table 7-4 Comparisons of Changes in Water Dependency Compared to Baseline

Interpreted Aspects	Water Dependency Change Assessment Compared to Baseline (percent)											
	46 m Low-Flow Channel			100 m Incised Channel			450 m Riparian Zone Floodplain			1,800 m Broader Floodplain		
	Current	Baseline	PBS	Current	Baseline	PBS	Current	Baseline	PBS	Current	Baseline	PBS
Zone Width	8			17			76			Not Assessed		
Availability[1]	365	100	365	141	100	92	142	100	92	117	100	88
Interpreted Source Contributions to Water Dependency[2]												
Surface Water	35	10	48	7	9	9	6	7	8	5	6	3
Pore Water	35	82	48	64	83	91	66	84	92	83	94	97
Groundwater	30	8	5	29	8	0	28	9	0	12	0	0
Interpreted Net Percentage Changes in Dependency Sources Compared to Baseline[3]												
Surface Water	25	-	38	(2)	-	1	(2)	-	1	(1)	-	(3)
Pore Water	(47)	-	(34)	(19)	-	8	(18)	-	8	(12)	-	3
Groundwater	22	-	(3)	21	-	(8)	20	-	(9)	12	-	0
Relative Percentage Changes Across the Riparian Conservation Zones[4]												
Surface Water	2	-	3	0	-	0	(2)	-	1	-	-	-
Pore Water	(4)	-	(3)	(3)	-	1	(18)	-	6	-	-	-
Groundwater	2	-	0	3	-	(1)	19	-	(6)	-	-	-

Notes:

1 The changes in availability reflect percentage differences in the cumulative potential water availability (days) described in Table 2. Where there is perennial surface water presence, the availability is 365 days.

2 This dependency is based on a linear relationship between comparably percentage availability of individual sources and dependency.

3 The changes in dependency sources compared to baseline are discrete assessments within the specified low-flow channel, incised channel, riparian zone floodplain and broader floodplain domains.

4 The relative changes across the riparian conservation zones rationalise that the interpreted dependency changes in the low-flow channel, incised channel and riparian zone floodplain zones respectively, represent 8, 17 and 76 per cent of the 600 m width Riparian Conservation Zone.

Values in parentheses are negative; less than, compared to baseline.

7.7 Discussion on Water Availability and Dependency

There are a number of other important attributes of the water availability assessments. For the surface water and pore water sources these include:

- The baseline environments reflect surface water and pore water dependencies. The available water was predominantly sourced from direct rainfall and episodic flood events.
- Retention of perennial stream flow in the low-flow channel would sustain the surface water and pore water availability within the low-flow channel domain. As the water table is lowered by pit-dewatering abstractions, the perennial stream flow would provide continuous wetting fronts that in effect provide an irrigation source that replenishes pore water. As a general rule, water availability would remain comparatively high but as pore water and not groundwater.
- There was an assumed reduction in surface water and pore water dependency because of the increased presence of groundwater.

Table 7-5 contextualises the changes in surface water and pore water dependency (low, medium and high) for the different local riparian floristic communities (as shown on Figure 1-2) across the baseline, current and PBS scenarios. The changes in dependency were contextualised based on:

- Cumulative surface water and pore water availability of greater than 85 per cent correlates to High dependency.
- Cumulative water availability of about 60 per cent correlates to Medium-High dependency.
- Cumulative water availability of about 30 per cent correlates to Medium dependency.
- Cumulative water availability of about 10 per cent correlates to Low dependency.

This approach is compatible to that used to determine the groundwater dependency, with similar percentage contributions (Table 7-3) used to define low to high surface water and pore water dependency.

Note that the PBS scenario reflects drawdown of the water table to provide dry mining conditions. In settings where there is no drawdown the current scenario; perennial surface water in the low-flow channel and associated groundwater wetting fronts would prevail.

Table 7-5 Potential Surface Water and Pore Water Dependency of Riparian Floristics

Setting	Floristics[1]	Scenarios and Potential Dependence on Cumulative Surface Water and Pore Water		
		Current	Baseline	PBS
Low-Flow Channel	Major Creek Line: *E camaldulensis* and *E. victrix* woodland over *M. argentea*, *M. glomerata* and Acacia low open woodland.	Medium – High	High	High
	Scoured Creek Channel: *E. camaldulensis* and *E. victrix* scattered trees over Acacia woodlands and *M. glomerata*.			
Incised Channel	Major Creek Line: *E camaldulensis* and *E. victrix* woodland over *M. argentea*, *M. glomerata* and Acacia low open woodland.	Medium - High	High	High
	Scoured Creek Channel: *E. camaldulensis* and *E. victrix* scattered trees over Acacia woodlands and *M. glomerata*.			
Riparian Floodplain	Floodplain: *E. victrix* or *E. xerothermica* scattered trees over Acacia low woodland.	Medium – High	High	High
Broader Floodplain	*E. victrix* or *E. xerothermica* scattered trees over Acacia low woodland.	High	High	High
Notes:				
1 From Figure 1-2.				

For the groundwater environment it was recognised that the dependency was initially based on baseline water availability and subsequently these were applied to altered baseline scenarios. This approach may tend to overestimate groundwater dependencies for the altered baseline scenarios. Also for the groundwater sources there are other attributes of the water availability assessments, including:

- There may be change to the groundwater dependency, with potential deficits due to lowering of the water table.
- Contextually, the most significant changes in water availability are linked to:
  - The presence of perennial stream flow in the low-flow channel.
  - Lowering of the water table due to abstractions for pit dewatering.

As such, the different local riparian floristic communities (as shown on Figure 1-2) were considered in context to potential changes in groundwater dependency (high, medium and low) across the baseline, current and PBS scenarios. This assessment was informed by the changes in depths to the water table outlined in Table 7-3 and Table 7-4 with the understanding that:

- Groundwater availability of greater than 85 per cent correlates to High dependency.
- Groundwater availability of about 60 per cent correlates to Medium-High dependency.
- Groundwater availability of about 30 per cent correlates to Medium dependency.
- Groundwater availability of about 10 per cent correlates to Low dependency.
- Below 20 m depth there is no dependency.

The findings on changes regarding groundwater dependency are outlined in Table 7-6. The tabulated high, medium and low groundwater dependencies reinforce that the baseline settings may be atypical in context to normal expectations for Pilbara riparian zones. In particular, there are noticeable differences between the low-flow channel and incised channel settings where the presence of *M. argentea* and *E. camaldulensis* would indicate high groundwater dependencies, but the baseline water table is comparatively deep. The presence of *E. camaldulensis* and *M. argentea* woodland is limited to the southern project area and possibly attributed to surface water and pore water wettings fronts associated with perennial baseflow from Weeli Wolli Spring. Elsewhere beneath the riparian floodplain and broader floodplain domains, the comparatively low baseline water table settings reflect lower groundwater dependency than typically expected.

These themes are similar to those identified (Loomes, 2010) in determining water level ranges of Pilbara riparian trees.

Table 7-6 Potential Groundwater Dependency of Riparian Floristics

Setting	Floristics[1]	Scenarios and Potential Groundwater Dependence			
		Typical[2]	Current	Baseline	Billiard South
Low-Flow Channel	Major Creek Line: *E. camaldulensis* and *E. victrix* woodland over *M. argentea*, *M. glomerata* and Acacia low open woodland.	High	Medium	Low	Low
	Scoured Creek Channel: *E. camaldulensis* and *E. victrix* scattered trees over Acacia woodlands and *M. glomerata*.	Medium			
Incised Channel	Major Creek Line: .*E camaldulensis* and *E. victrix* woodland over *M. argentea*, *M. glomerata* and Acacia low open woodland.	High	Medium	Low	None
	Scoured Creek Channel: *E. camaldulensis* and *E. victrix* scattered trees over Acacia woodlands and *M. glomerata*.	Medium			
Riparian Floodplain	Floodplain: *E. victrix* or *E. xerothermica* scattered trees over Acacia low woodland	Low - Medium	Medium	Low	None
Broader Floodplain	*E. victrix* or *E.* xerothermica scattered trees over Acacia low woodland	Low - Medium	Medium	None	None
Notes:					
1 From Figure 1-2.					
2 As interpreted from Table 7-1					

The water availability and dependency assessments indicate that the surface water and groundwater wetting fronts have reduced surface water and pore water dependencies, with commensurate increases in groundwater dependency. Further:

- The sustained stream flow within the low-flow channel in the transition from current to PBS scenarios provides the latter scenario with higher water availability compared to the baseline setting.
- There was no change in the interpreted surface water and pore water availability for the incised channel and riparian zone floodplain domains across all three scenarios.
- The interpreted maximum dependency on groundwater ranged from 12 to 30 per cent of the overall water dependency, thus representing a subordinate supply source.
- There are potential deficits in the available water within the incised channel and riparian zone floodplain during the PBS scenario compared to the baseline setting.

A summary of the potential implications of the described changes in water availability and source dependencies is provided in Table 7-7. The perspectives described reflect both changes from baseline and those that would occur linked to the PBS scenario. As such, the changes account for the sustained presence of wetting fronts and conversely drawdown of the water table in different settings on Weeli Wolli Creek. The cumulative changes would reflect:

- Increased water availability in transition from baseline to current scenarios.
- Reduced water availability in the transition from current to PBS scenarios.

Increased water availability was linked to surface water and groundwater wetting fronts providing perennial stream flow and mounding of the water table. In Table 7-4, this change was described as a 25 per cent increase in surface water availability in the low-flow channel and 12 to 22 per cent increases in available groundwater. The cumulative reductions in groundwater availability derived from Table 7-4 range from 12 to 29 per cent.

Reduced water availability was linked to drawdown of the water table and rapid depletion of the available groundwater above the baseline water table. In practise, all of the available groundwater would not dissipate; there would be residual field capacity in the alluvial soils that would initially be available. Therefore it was assumed that about 20 per cent of the 12 to 22 per cent losses would be off-set by the presence of pore water. The 20 per cent reflects typical differences between porosity and wilting point might be expected in alluvial soils. Cumulative reductions in groundwater availability in the transition from current to PBS scenarios have been estimated as:

- Low-flow channel – 21 per cent.
- Incised channel – 25 per cent.
- Riparian zone floodplain – 25 per cent.
- Broader floodplain – 10 per cent.

In relative terms, the implications associated with the incised channel and riparian zone floodplain would be most significant given these two domains account for 17 and 76 per cent of the riparian conservation zone areas, respectively.

Table 7-7 Potential Implications of Changes in Water Availability as a Result of the PBS Project

Setting	PBS Change Aspect	Interpreted Implications	Magnitude of Change	Predicted Ecological Consequence of Change
Low-Flow Channel	Presence of perennial stream flow.	Waterlogging of soils and permanent inundation of deeper root zones on reaches to the north of PBS (from the proposed discharge point on Marillana Creek).	Interpreted 25 per cent increase in surface water and 22 per cent increase I available groundwater, with commensurate decrease in pore water availability in the range 34 to 47 per cent compared to baseline. Waterlogging would be associated with a portion of these changes.	• Decline in canopy cover of mature eucalypts with death of some individuals. • Greater decline and tree deaths for *E. victrix* relative to *E. camaldulensis,* however, *E. camaldulensis* individuals may also exhibit reduced canopy cover. • Increase or no change in canopy cover of mature *M. argentea.* • Increase in juvenile eucalypt and *M. argentea* biomass with increase in relative abundance of *M. argentea* within riparian vegetation community over time. • Increase in understorey vegetation biomass, particularly an increase in cover/abundance of some aquatic macrophytes (e.g. Typha).
		Increased groundwater availability; groundwater dependency raised from Low to Medium.	Groundwater dependency to reduce from Medium to Low.	• Increase in foliage cover of *E. camaldulensis* and *E. victrix*. • Increase or no change in canopy cover of mature *M. argentea.* • Increase in juvenile eucalypt and *M. argentea* biomass with potential increase in relative abundance of *M. argentea* over time. • Increase in understorey vegetation biomass where surface water and pore water availability has increased.
		Increased surface water and pore water availability. Surface water and pore water dependency reduced from High to Medium-High.	Surface water and pore water dependency to increase from Medium - High to High.	
	Drawdown of the water table below current elevations.	Groundwater availability deficit.	Limited assuming the stream flow source is sustained and adequately offsets current dependencies on groundwater.	• Decline in canopy cover of *M. argentea*, *E. camaldulensis* and *E. victrix*. • Stabilisation over time of *M. argentea, E. camaldulensis* and *E. victrix* as majority of individuals acclimatise to stream flow irrigation and baseline natural rainfall and flooding events.
Incised Channel Riparian Zone Floodplain Broader Floodplain	Surface water and groundwater wetting fronts have raised the water table.	Increased groundwater availability from less than 10 to within the range 12 to 30 per cent.	Interpreted 12 to 22 per cent increase in available groundwater, with 8 to 19 per cent reduction in pore water availability beneath the incised channel and riparian zone floodplain compared to baseline. Waterlogging would be associated with a portion of these changes.	• Increase in foliage cover of *E. camaldulensis* and *E. victrix*. • Increase or no change in canopy cover of mature *M. argentea*. • Increase in juvenile eucalypt and *M. argentea* biomass with potential increase in relative abundance of *M. argentea* over time.
		Groundwater dependency change from Low to Medium.		
		Waterlogging of deeper soil profiles and root zones on reaches to the north of PBS.		
	Drawdown of the water table at least 20 m below current elevations.	Rapid depletion of the available groundwater. Short time for adaptation to residual pore water.	Revert to baseline availability on surface water and pore water. Groundwater dependency would reduce from Medium to Low and over time to None.	• Rapid decline in canopy cover of *M. argentea*, and *E. camaldulensis* and *E. victrix* previously accessing groundwater. • Death of *M .argentea* beyond influence of groundwater discharge wetting fronts. • Potential death of some E*. camaldulensis* but stabilisation over time of *E. camaldulensis and E. victrix* as some individuals acclimatise to baseline natural rainfall and flooding events. • Fluctuating eucalypt canopy cover over time in response to rainfall and flood events with potentially significant declines in canopy cover during periods of prolonged drought. • Reduced recruitment of *M. argentea* and eucalypts due to absence groundwater to sustain post-germination growth. • Little or no impact to trees established within the broader floodplain assuming natural rainfall and flood events are maintained.
		Groundwater availability deficit compared to current scenario.	Interpreted decreases ranging from 12 to 22 per cent. A portion of this potential change would be off-set by pore water. It was assumed that pore water would provide a 20 percent off-set to this change, decreasing the future change magnitudes to 10 and 18 per cent.	
	Drawdown of the water table to lower than the baseline elevations.	Water availability deficit.	Groundwater dependency reduced from Low to None.	
			From 3 to 9 per cent compared to baseline.	

Perspectives on potential changes in water availability linked to drought periods and a flood event have been used to provide context for the estimated cumulative reductions in water availability and the range of natural variability. The drought scenarios were derived from measured rainfall and stream flow (Table 3-2) during the period 1989 to 1992, inclusive. This period was characterised by low rainfall (about half the annual average) and low stream flow. Conversely, 1997 had high rainfall and high stream flow. These perspectives based on are shown in Table 7-8.

Table 7-8 Perspectives on Water Availability Changes during Drought and Flood

Water Budget	Percentage Change from Typical Annualised Water Availability			
	Low-Flow Channel	Incised Channel	Riparian Zone Floodplain	Broader Floodplain
1-Year Drought	15	14	14	18
4-Year Drought	27	29	33	54
1997 Flood	8	5	4	2

Based on the data in Table 7-8 it may be expected that the typical natural range of change from one year to the next may be less than 15 per cent. An extended drought would likely lead to significant stress and change given reductions in water availability in the range 30 to 50 per cent from normal (typical) conditions.

8 RIPARIAN ZONE ENVIRONMENTAL RISK ASSESSMENT

8.1 Formalities

The concepts of water availability are significant in regard to understanding the functionality of riparian zones. This risk assessment is based on the understanding of potential changes to water availability. The riparian zone environmental risk assessment is focussed on the receptors formed by riparian zones on Weeli Wolli Creek.

The current surface water and groundwater environments are temporary and cannot be sustained. Future changes would be inevitable once the discharge of surplus water ceases, or is substantially reduced. Under these circumstances, the water availability for the riparian zone associated with Weeli Wolli Creek would decline towards baseline conditions. Reductions to stream flow and associated surface water wetting fronts would occur in immediate terms. Limited changes to the local hydrology would however preserve the surface water and pore water re-wetting mechanisms and hence availability. The water table would progressively return to baseline settings at rates of decline from 2.0 to 2.5 m per annum; this rate would tend to mimic that observed from monitoring bore hydrographs after episodic recharge events.

It is difficult to quantify the potential increase in riparian zone dependency on the enriched water availability, both in context to surface water and groundwater sources. Further, there may be differences in the adaptability of riparian vegetation stands to changes in both water availability and sources of available water. Recent evidence (McLean, Ludwig and Grierson, 2011; McLean, 2013; Argus, Colmer and Grierson, 2014) shows that riparian zone vegetation may respond in different ways to episodic drying and flood cycles and, may be vulnerable (particularly for *M. argentea*) to changes in the availability of surface water and near-surface water sources. This evidence suggests there is not one set of rules that dictates likely responses for individual species, genera or within discrete domains in the riparian zone. As such heterogeneous and unique responses to changes in water availability and sources should be expected. These attributes of the riparian zones make it difficult to benchmark potential risks when there is a change in water source and water availability. In general, however, riparian vegetation is likely sensitive to significant changes in water availability and dependency sources. Therefore, the risk would predominantly depend on the adaptability of riparian floristics:

- To increase surface water and groundwater availability, including potential waterlogging of root zones.
- Perennial presence of stream flow and water table mounding into root zones.
- To alternative water sources in circumstances of reduced groundwater availability.
- To revert to baseline dependencies on surface water and pore water.
- To net reductions in total water availability.

Ecological Water Requirements (EWR) of the riparian zones (Loomes, 2013) on Weeli Wolli Creek may be maintained by the following sources of water availability:

- Retention of perennial surface water flows, at least initially, to support gradual adaption.
- Limiting changes to periods of high floodwater availability.
- Avoidance of drawdown of the water table.

The PBS scenario captures two of these linkages, but not retention of groundwater availability; albeit that it is not a natural occurrence. Lowering of the water table for mining would rapidly deplete the groundwater availability in the CID aquifer, and would also result in lowering of the water table in the alluvial successions supporting the riparian vegetation. There would, however, be an increase in the residual pore water. Under these circumstances, the riparian Eucalypt and Melaleuca floristics would probably experience drought-like conditions. The scale of the changes in the water availability may lead to changes in and decay of riparian floristics, particularly the reduction/loss of groundwater dependent species such as *M. argentea*, and decline of some Eucalypt species (typically over-story species) adapted to the shallow water table. This may also have an impact on riparian vegetation structure. The maintenance of riparian vegetation would be dependent on numerous independent factors, including:

- Influences of sustained and episodic waterlogging of root zones and associated access to and adaptability of riparian vegetation to alternative water sources.
- Actual groundwater dependency. That is, the degree of dependency on existing (increased) groundwater compared to pore water.
- Ability of the riparian vegetation to revert to pore water sources as groundwater availability declines due to drawdown of the water table.
- Pore water availability off-setting the reduction in groundwater dependency.
- Rates of decay of the available groundwater.
- Rates of decay of the available pore water.
- Competition for the available water.
- Abilities of individual trees to become dormant or reduce water demand as water availability declines below critical levels (for example individual trees shedding biomass as water availability declines). It is recognised that this is a trait of *E. victrix*.

Perspectives regarding changes in health and condition of selected riparian tree species under a range of change circumstances associated with lowering of the water table (drawdown) and reductions in groundwater availability have been developed based on observations on Weeli Wolli and Marillana creeks. These perspectives and collated general change themes are described in Table 8-1 and Table 8-2. Note that the outlined perspectives are semi-quantitative. Also, they do not address perspectives linked to increased water availability and waterlogging. Note in context to the changes in depth to the water table that:

- The natural rates of water table decline after episodic events are 2.0 to 2.5 m/annum. Over time these rates decrease as the hydraulic gradients are lowered.
- A fluctuation of 2 to 5 m is within the observed range of episodic mounding of the water table after recharge events.

The observational-based perspectives shown in Table 8-1 and Table 8-2 when considered in context to the detailed vegetation mapping (Figure 1-2b) provide indications that most sensitivity and risk to changes in water availability would be closely aligned with the Low-Flow and Incised Channel settings and associated *E. camaldulensis* co-dominated communities and *E. Camaldulensis* co-dominated communities with transient *M. argentea* populations (Figure 1-2b) that have high and medium-high groundwater and or surface water dependence.

Based on the observational perspectives, the *M. argentea* is most sensitive to reduced water availability, with high-risk thresholds associated with:

- Drawdown of 10 to 20 m, particularly in the absence of perennial stream flow.
    - A drawdown of 10 m is compatible to changes in groundwater availability beneath the Riparian Exclusion Zone from 8 to 17 per cent (Table 7-4).
    - A drawdown of 20 m is compatible to changes in groundwater availability beneath the Riparian Exclusion Zone from 25 to 29 per cent (Table 7-4).
- Reduced groundwater availability by greater than 30 per cent.

The *E. victrix* open woodlands over Acacia low woodlands and tussock grasslands and other *E. victrix* dominated communities appear less sensitive to drawdown of the water table and reductions in groundwater availability. Conversely, it has been recognised that *E. victrix* may be sensitive to waterlogging.

The observational and water availability perspectives tend to focus the risk assessment on:

- The *E. camaldulensis* and *M. argentea* habitats within the low-flow and incised channel settings of Weeli Wolli Creek.
- Settings where drawdown of the water table exceeds 20 m, again with a focus on *M. argentea* and *E. camaldulensis* stands.

In both regards, the *E. camaldulensis* demonstrates more robustness to change when compared to *M. argentea*. The *M. argentea* stands are sensitive and susceptible to reductions in groundwater availability, hosting the highest risk attributes particularly in the absence of proximity to perennial stream flow.

There was recognition that the developed risk assessment metrics are semi-quantitative, providing guidance rather than facts. In applying the metrics to assess the risk, there is intuition that low risk and high-risk domains would not abut in the low-flow channel and incised channel settings. The tendency in these settings was therefore to progressively transition the risk from low to medium, to medium-high and to high rankings dependent on water availability changes and predicted drawdown distributions.

Table 8-1 Perspectives on Riparian Tree Species Change due to Drawdown of the Water Table

Change in Depth to Water Table (m)	Descriptions of Expected Change Circumstances						Descriptions of Expected Change Circumstances – General Themes
	E. victrix	*E. xerothermica*	*E. camaldulensis*	*M. argentea*			
				Within 5 to 10 m of Low-Flow Channel	Within 10 to 25 m of Low-Flow Channel	Limited Proximity to Low-Flow Chanel	
Less than 2	Little to no change.	Little to no change.	Little to no change.	Little or no change.		Reduced condition.	Little influence beyond minor reduction in condition of obligate groundwater dependent species.
2 to 5				Reduced condition of mature trees.		Reduced condition and some potential for defoliation.	Little impact to eucalypts but some minor to moderate reduction in condition of obligate phreatophytes – particularly new recruits and individuals established under current hydrological regime.
5 to 10.	Potential for reduced condition during extended periods without flood flows.		Potential for reduced condition during extended periods without flood flows.	Potential defoliation with low potential for complete defoliation and apparent death (may revive).		Reduced condition and defoliation.	Minor reduction in eucalypt condition manifest during periods of extended drought and significant reduction in condition of obligate phreatophytes – particularly new recruits and individuals established under current hydrological regime.
10 to 15.	Reduced condition during extended periods without flood flows.	Potential for reduced condition.	Reduced condition with potential for defoliation during extended periods without flood flows.	Reduced condition.	Defoliation with potential for apparent death (may revive).	Defoliation likely with potential for fatality.	Minor reduction in eucalypt condition manifest during periods of extended drought and significant reduction and potential death of obligate phreatophytes – particularly new recruits and individuals established under current hydrological regime.
15 to 20.	Reduced condition during extended periods without flood flows.	Potential defoliation in some situations.	Defoliation with potential limb loss and some potential for fatality during extended periods without flood flows in historically enhanced (hydrological) situations.	Reduced condition and potential for defoliation.	Defoliation with increased potential for apparent death (may revive).	Fatality likely in some circumstances.	Moderate decline in eucalypt condition manifest during periods of extended drought and significant reduction and death of obligate phreatophytes – particularly new recruits and individuals established under current hydrological regime.
Greater than 20.	Reduced condition and defoliation during extended periods without flood flows.		Defoliation and limb loss with potential for fatality during extended periods without flood flows both in normal and historically enhanced (hydrological) situations.	Reduced condition and some defoliation.	Defoliation with increased potential for fatality.	Fatality likely.	Significant decline in condition and potential death of eucalypt during periods of extended drought and significant decline and death of obligate phreatophytes – particularly new recruits and individuals established under current hydrological regime.

Table 8-2 Perspectives on Riparian Tree Species Change due to Reduced Water Availability

Percentage Change in Groundwater Availability	Descriptions of Expected Change Circumstances						Descriptions of Expected Change Circumstances – General Themes
	E. victrix	*E. xerothermica*	*E. camaldulensis*	*M. argentea*			
				Within 5 to 10 m of Low-Flow Channel	*Within 10 to 25 m of Low-Flow Channel*	*Limited Proximity to Low-Flow Chanel*	
Less than 10	Little to no change.	Little to no change.	Little to no change.	Little or no change.		Potential for reduced condition.	Little influence beyond minor condition changes to highly groundwater sensitive species.
10 to 20	Potential for reduced condition.		Potential for reduced condition.	Reduced condition likely, some defoliation potential with low potential for complete canopy defoliation (apparent death; may revive).		Reduced condition and defoliation likely.	In the typical spatial distribution zones of these species (in relation to surface and sub-surface water) little influence beyond moderate condition changes and potential for defoliation of highly groundwater sensitive species.
20 to 30	Reduced condition.	Potential for reduced condition.	Reduced condition probable with potential for some defoliation.	Potential for reduced condition.	Some defoliation likely, with potential for complete canopy defoliation (apparent death; may revive).	Defoliation likely with potential for fatality.	In the typical spatial distribution zones of these species (in relation to surface and sub-surface water) potential significant influence on outlying highly groundwater sensitive species, with some potential for influence on sensitive eucalypt condition.
30 to 40		Reduced condition probable with potential defoliation in some situations.	Reduced condition likely with potential for defoliation and some potential for fatality in historically enhanced (hydrological) situations.	Reduced condition likely, with potential for some defoliation.	Varying degrees of defoliation likely with increased potential for complete canopy defoliation (apparent death; may revive).	Fatality likely in some circumstances.	In the typical spatial distribution zones of these species (in relation to surface and sub-surface water) potential fatality for outlying highly groundwater sensitive species, with potential for influence on sensitive (*E. camaldulensis*) eucalypt species particularly where biomass is enhanced.
40 to 50	Reduced condition likely.	Reduced condition likely, with potential defoliation in some situations.	Defoliation probable with potential limb loss and some potential for fatality in normal and historically enhanced (hydrological) situations.		Defoliation likely with increased potential for fatality.		In the typical spatial distribution zones of these species (in relation to surface and sub-surface water) some potential for significant fatality rates within outlying highly groundwater sensitive species populations, with potential for influence on sensitive (*E. camaldulensis*) eucalypt species particularly where biomass is enhanced.
50 to 60	Reduced condition likely, with potential defoliation in some situations.	. Defoliation in some situations likely, some potential for fatality in historically enhanced (hydrological) situations.	Defoliation and limb loss likely with fatalities both in normal and historically enhanced (hydrological) situations likely.	Reduced condition likely, defoliation likely, with potential for fatality increasing.	Defoliation highly likely with fatality likely in some areas.	Fatality likely.	In the typical spatial distribution zones of these species (in relation to surface and sub-surface water) potential significant fatality rates within outlying highly groundwater sensitive species populations (as well as increasing influence on well positioned individuals), with increasing potential for significant influence on sensitive eucalypt species (including fatality) particularly where biomass is enhanced.
60 to 75	Defoliation in some situations likely, some potential for fatality in historically enhanced (hydrological) situations.				Defoliation highly likely with fatality likely.		In the typical spatial distribution zones of these species (in relation to surface and sub-surface water) significant impacts to outlying highly groundwater sensitive species likely (as well as increasing influence on well positioned individuals), with impacts on sensitive *E. camaldulensis* species likely (including fatality), particularly where biomass is enhanced.

The risk assessment applies the water availability (Table 7-3), interpreted water dependency and changes therein (Table 7-4) and the perspectives provided in Table 7-5 and Table 7-6 to rationalise reasonable semi-quantitative outcomes. The matrix on change aspects and interpreted perspectives provided in Table 7-7, Table 7-8, Table 8-1 and Table 8-2 have been used to inform the risk assessment. In this regard it was also rationalised that:

- A drawdown of 5 to 10 m correlated to 10 to 18 per cent reduction on groundwater availability.
- A drawdown of 10 to 20 m correlated to 18 to 25 per cent reduction in groundwater availability.

It is considered that the risk assessment is precautionary, tending to lever more off the *M. argentea* and *E. camaldulensis* aspects rather than *E. victrix*.

For the risk assessment, low, medium, medium high and high risks were categorised for the *E. Victrix* dominated communities and co-dominated floodplain vegetation, *E camaldulensis* co-dominated communities and *M. argentea* co-dominated communities as follows:

Risk Attributes	Percentage Change in Water Availability			
	<10	10 to 18	18 to 25	>25
	Drawdown of the Water Table (m)			
	<5	5 - 10	10 - 20	>20
***E. victrix* Increased Water Availability and Waterlogging (beneath the Low-Flow Channel and Incised Channel)[1]**				
Low		-	-	-
Medium	-		-	-
Medium High	-	-		-
High	-	-	-	
***M. argentea* and *E. camaldulensis* Decreased Water Availability Due to Drawdown[2]**				
Low		-	-	-
Medium	-		-	-
Medium High	-	-		-
High	-	-	-	

Notes:

1 Applicable beneath northern reaches of Weeli Wolli Creek under the current scenario where there is perennial stream flow and the water table s connected to the stream bed. Elsewhere, beneath the local reaches of Weeli Wolli Creek the *E. victrix* dominated communities, open woodlands and co-dominated floodplain vegetation are interpreted as low risk domains.

2 Applicable to the drawdown footprint of PBS beneath the low-flow and incised channel settings.

Further, the risk assessment reflects:

- Changes from the baseline to current scenarios, with increased surface water and groundwater availability.
- Changes from the current scenario in reverting to baseline water availabilities and surface water and pore water dependencies.
- Subsequent changes from the baseline scenario to reflect the Billiard South scenario.

The risk assessment is shown in Table 8-3.

Table 8-3 Riparian Zone Water Availability and Water Dependency Risk Assessment

Setting	Change Aspect		Risk Assessment											
			Current to Baseline Scenarios				Baseline to PBS Scenarios				Current to PBS Scenarios			
			Low-Flow Channel	Incised Channel	Riparian Flood Plain	Broader Flood Plain	Low-Flow Channel	Incised Channel	Riparian Flood Plain	Broader Flood Plain	Low-Flow Channel	Incised Channel	Riparian Flood Plain	Broader Flood Plain
***E. victrix* Increased Water Availability and Waterlogging (beneath the Low-Flow Channel and Incised Channel)[1]**														
Low-Flow Channel	Waterlogging.		Medium High	-	-	-	Low	-	-	-	Medium High	-	-	-
Incised Channel			-	Medium	-	-	Low	-	-	-	-	Medium	-	-
***M. argentea* and *E. camaldulensis* Decreased Water Availability Due to Drawdown[2]**														
Low-Flow Channel[3]	Presence of perennial stream flow.		Low	-	-	-	Low	-	-	-	Low	-	-	-
	Drawdown of the water table below current elevations.		Medium	-	-	-	Low	-	-	-	Medium	-	-	-
Incised Channel	Drawdown of the water table below respective elevations and rapid depletion of sources that support groundwater dependency[4].	<5 m	-	Medium	-	-	-	Low	-	-	-	Medium	-	-
		5 – 10	-	Medium	-	-	-	Low	-	-	-	Medium	-	-
		10 – 20	-	Medium High	-	-	-	Low	-	-	-	Medium High	-	-
		>20	-	High	-	-	-	Low	-	-	-	High	-	-
Riparian Flood Plain	Drawdown of the water table below respective elevations and rapid depletion of sources that support groundwater dependency[4].		-	-	Medium	-	-	-	Low	-	-	-	Medium	
Broader Flood Plain			-	-	-	Low	-	-	-	Low	-	-	-	Low

Notes:

1 Applicable beneath northern reaches of Weeli Wolli Creek under the current scenario where there is perennial stream flow and the water table s connected to the stream bed. Elsewhere, beneath the local reaches of Weeli Wolli Creek the *E. victrix* dominated communities, open woodlands and co-dominated floodplain vegetation are interpreted as low risk domains.

2 Applicable to the drawdown footprint of PBS beneath the low-flow and incised channel settings.

3 It was assumed that the sustained stream flow source would irrigate the underlying strata and adequately offset current dependencies on groundwater.

4 It was recognised that baseline surface water and pore water availabilities would prevail, which made up more than 90 per cent of the riparian source. Further it was assumed that adaptation from groundwater to pore water dependency would be supported by residual pore water sources that would provide a 20 per cent off-set to potential groundwater deficiencies.

The risk assessment considers reasonable worst-case attributes in broad-brush perspectives. As the magnitude of drawdown beneath Weeli Wolli Creek diminishes with increased distances from the abstraction sources, there is a commensurate reduction in riparian zone water availability risks. Figure 8-1 provides a plan view of water availability risks based on the predicted drawdown footprint in December 2019. The predictive model calculates simulated changes from the current water table elevations under stresses imposed by dewatering of PBS. As such, Figure 8-1 reflects this scenario together with the sustained presence of wetting fronts on and beneath northern reaches of Weeli Wolli Creek. Figure 8-2 provides a plan view of the water availability risks in context to the mapped vegetation communities, particularly those aligned along the low-flow channel and incised channel landforms. The mapped vegetation polygons overlapping the water availability risk domains:

- Adds robustness and transparency to the risk assessment.
- Provides a set of connections to the tabulated drawdown and reduced water availability perspectives on the riparian vegetation outlined in Table 8-1 and Table-2, respectively.
- Reflects that the water availability risk assessments are indicative of the higher risk landforms, but that in several settings (due to local channel form and topography factors) the at risk vegetation stands propagate beyond the conceptual incised channel boundaries.

In this regard, Figure 8-2 illustrates the distributions of the mapped vegetation communities (Figure 1-2b) with comparative risk perspectives (listed in order of high to medium risk) that include:

1 *Melaleuca argentea* co-dominated communities – High Risk.
2 *Eucalyptus camaldulensis* co-dominated communities and *Eucalyptus victrix* and *Eucalyptus camaldulensis* co-dominated floodplain vegetation – Medium Risk.

8.2 Mitigation of Reduced Groundwater Availability

8.2.1 Relevant Perspectives

It was recognised that the water availability change assessments and associated implications for the riparian zones on Weeli Wolli Creek host a number of uncertainties. It is difficult to be quantitative in tying percentage changes in water availability to outcomes in terms of riparian zone conservation and health.

The implications of changes to the water availability and some dependencies may also be influenced by:

- Drought, with associated reduction in surface water and pore water availability.
- Cumulative changes, for example when drought or low rainfall conditions are coupled with reductions to existing available water sources.

From a precautionary perspective, changes in water availability from the current situation are likely to present some risks. It is recognised that the riparian zones have adapted to and become dependent in part on recent increases in water availability linked to surplus water discharge to Weeli Wolli Creek. The current situation is, however, not sustainable. For example:

- Under baseline environments the riparian zones were predominantly sustained by pore water derived from direct rainfall, overland flow and episodic flood events on Weeli Wolli Creek. Flood events that inundate large portions of the floodplain at frequencies of 2- to 5-year ARI were integral to water availability, episodically re-wetting the bank of pore water in the unsaturated profile.
- Surplus water discharge has created a perennial surface water wetting front and raised the water table thus enhancing groundwater availability and potentially increasing dependency on groundwater over time.
- The current water availability scenario is neither natural nor sustainable; it is temporary and dependent on surplus water availability.
- Future change due to cessation of surplus water discharge and groundwater abstraction would result in cessation of the surface water wetting fronts and lower the water table. Both actions would reduce water availability. Rates of change of water availability would be rapid.

With respect to maintenance of water requirements for riparian zones (Loomes, 2013) on Weeli Wolli Creek there are three predominant themes:

- Conservation of local hydrology and flood footprints.
- Presence of perennial stream flow in the low-flow channel.
- Limiting of water table decline, and rates of the decline to within the range of natural variation.

The Project Description enables conservation of the local hydrology and in doing so enables limited change to surface water and associated pore water availability. Also, predictive modelling of the groundwater abstraction for pit dewatering (Lim, 2014) provided indications that the present-day perennial stream flow on Weeli Wolli Creek would be preserved. The predictive model broadly conforms to the interpreted loss rates provided by Dogramaci el.al, 2015a and, Pettett and Pearcey, 2014. There is possibility that the predictive model underestimates stream flow losses by infiltration and hence it may occur that the perennial stream flow is not sustained. This possibility cannot be closely informed in the absence of large-scale groundwater abstraction to lower the local water table.

Limiting water table decline is not compatible with the Project Description. Groundwater abstraction and drawdown is required to enable mining. There is likelihood therefore that drawdown would intercept groundwater upon which the riparian zone has become dependent. Further, the rate of change would exceed natural rates of water table decline after episodic stream flow events, indicating there may be limited capacity for the riparian floristics to respond to the water table decline by usual mechanisms.

8.2.2 Change Mitigation Strategies

The proposed mitigation strategies provide a two-layer defence to limit the risks associated with changes to water availability and rates of change. The mitigation strategies are not designed to avoid the inevitable reversion back to baseline water availability condition from present day water availability conditions; they are intended to support the water requirements for the riparian zones and support the transition from present-day to baseline water availability. The mitigation strategies include sustaining stream flow in the low-flow channel.

Sustained flow in the low-flow channel would maintain the surface water wetting front and provide a recharge boundary that off-sets, in part at least, the magnitude and rate of drawdown of the water table. This is important initially, upon commencement of groundwater abstraction for pit dewatering, but may not be preferable over the entire period of operations.

9 CONCLUSIONS

9.1.1 Overview

The setting of PBS is alongside broader floodplain of Weeli Wolli Creek, with interaction of riparian zones. In this setting the importance of the riparian zones is empathised through Ministerial Statement 914 (2012) relevant to the RTIO Yandicoogina Mine. RTIO defined a broader Clearing Avoidance Zone on Weeli Wolli Creek intended to limit disturbances from existing operations to the broader floristic stands that extend to distances up to about 600 m from the low-flow channel.

In the baseline settings, the riparian zones on Weeli Wolli Creek were interpreted to be predominantly dependent on surface water and pore water derived from direct rainfall, overland flow and episodic stream flow events. Depths to the water table in the range 12 to 20 m provided low groundwater dependency.

Since about 1997, the discharge of surplus water into Weeli Wolli Creek (from the Hope Downs 1 and RTIO Yandicoogina mines) increased the water availability to the riparian zones. The increase was reflected in the presence of perennial stream flow and mounding of the water table to comparatively shallow depths. The changed surface water and groundwater environments provided potential for increased groundwater use (medium dependency) within the riparian zone, commensurate with reduced surface water and pore water dependencies.

The proposed mining at PBS would impose further changes to the water availability on Weeli Wolli Creek, however, perennial stream flow in the low-flow channel and opportunities for flooding of adjacent riparian zones would be largely undisturbed. Dewatering of the proposed pit would, however, substantially lower the water table in the CID with a high rate of decline. Ultimately in the adjacent alluvial floodplain which supports the riparian floristics, the water table would be lowered to below baseline elevations, with associated potential deficits in the available water and declines in potentials for groundwater dependency.

9.1.2 Baseline Environments

For the surface water environment, stream flow records at Tarina and Waterloo provide data for stream flow events on Weeli Wolli Creek. Historic observations indicate Weeli Wolli Creek was ephemeral, flowing only once or twice per year during episodic rainfall events. Baseline flow was widely variable dependent on intensity and spatial distribution of rainfall and, antecedent conditions. On average Tarina experienced 28 days of continuous flow during baseline conditions in comparison to 12 days of continuous flow at Waterloo Bore. Flow events could typically be characterised as 1- to 5-year ARI events. In dry years, surface water runoff may be insufficient to generate stream flow.

The floodplain aquifer system is interpreted to form the primary zone for the transmission of recharge from stream flow to the CID aquifer. The floodplain aquifer system is interpreted to have two contributing successions, including:

- Creek-bed alluvium: coarse colluvium and alluvium, including river gravels, incised into the floodplain sediments.
- Floodplain sediments: poorly sorted conglomerates of gravels, sand, silt and clay.

- Groundwater level data from 1974 and 1999 were used to define baseline water table elevations beneath Weeli Wolli Creek. An early-1995 snapshot from 99YYJWB02, 99YYJWB04, YM119 and 99YYJWB01 (Rio Tinto, 2010) shows baseline water table elevations of 418 to 478 m AHD. Water table elevations of 418 in the vicinity of 99YJWB01 reflect a change in conditions and hydraulics beneath the northern reaches of Weeli Wolli Creek.

Interpreted depths to the water table commonly exceeded 15 m to 20 m beneath the floodplain in the vicinity of PBS, though increased significantly to the north, being about 45 m depth below the ground surface in the vicinity of 99YJWB01 located about 6 km downstream from the northern limit of PBS. Water table elevations can rise by up to 8 m, predominantly through the infiltration of stream flow associated with episodic high rainfall events. The natural rates of water table elevation decline after episodic recharge events are defined in the hydrographs of selected monitoring bores, including:

- 99YYJWB04, located on Weeli Wolli Creek near the Marillana Creek confluence, with estimated decline of 1.4 to 2.2 m/year.
- YM119, located on the downstream Weeli Wolli Creek, with estimated decline of 2.9 m/year.

9.1.3 Wetting Fronts

It was recognised that the baseline environment is dynamic and characterised by episodic stream flow and associated recharge events linked to cyclone and thunderstorms. In particular, the period 1994 to 2005 was characterised by an unusually high frequency of high-rainfall events and recharge associated with cyclones Bobby, Rachael, Thelma, John, Norman and Terri together with an un-named tropical low in January 2003. These events provided cumulative recharge signatures that masked concurrent changes linked to wetting fronts from the surplus water discharge (RTIO, 2010).

Since 2007, surplus water discharged to Weeli Wolli Creek has formed wetting fronts which reflect transport, assimilation and fates within the local receiving environments. The wetting fronts occur in the surface water, surface water to groundwater and groundwater environments. The available storage above the baseline water table provides a control on the wetting fronts; once the available storage has been filled the surface water and groundwater wetting fronts would progressively propagate downstream. Evidently, the surplus water has predominantly wet and saturated the available storage in the underlying floodplain aquifer system, mounded the water table and over the majority of Weeli Wolli Creek provided circumstances where perennial stream flow is directly connected to the water table. The wetting front characteristics are summarised as follows:

9.1.3.1 Surface Water Wetting Fronts

Perennial stream flow in the low-flow channel of Weeli Wolli Creek. Since commencement of discharge from the Hope Downs 1 mine (late-2007 and early-2008), the perennial stream flow has propagated to and waxed and waned at distances 5 to 7 km downstream of the Marillana Creek confluence. The perennial stream flow has not propagated to the north (downstream) since 2007, reflecting quasi-steady-state conditions.

9.1.3.2 *Surface Water to Groundwater Wetting Fronts*

Involve processes that include infiltration (recharge) to the water table and interception of water by evaporation and transpiration. The infiltration potentials were interpreted (Dogramaci, et al., 2015a; Pettett and Pearcey, 2014) to range from 0.02 to 13.15 ML/km/day. The assessments by Dogramaci et al. (2015a) also show cumulative evaporation and transpiration losses range from 3 to 9 per cent of total surplus water volumes on reaches where the stream flow is connected to the water table. In northern settings where the water table is disconnected from the perennial stream flow and assuming all other circumstances are the same, these interpreted losses increase in the range 25 to 40 per cent.

Infiltration measurements (Pettett and Pearcey, 2014) in the range 40 to 1,050 m/day provided data that demonstrate the shallow alluvium has potentials to vertically transmit large volumes of surface water. The stream flow is connected to the water table in settings upstream of YM119. It is only on the leading edge of the surface water wetting front, over a distance of about 4 km north of YM119, where the stream flow is disconnected from the water table. In this setting, there was an associated step-change in both chloride and $\delta^{18}O$ enrichment (Dogramaci et.al, January 2015a) and increasing contrast between the surface water and groundwater sample analyses. Beneath the leading edge of the surface water to groundwater interaction, the quality data from 99YJWB01 form significant outliers, being significantly lower in chloride and $\delta^{18}O$ concentrations compared to all other samples. There data probably indicate a different groundwater genesis and flow environment in the vicinity of 99YJWB01.

9.1.3.3 *Groundwater Wetting Fronts*

Progressive wetting of available storage and mounding of the water table beneath Weeli Wolli Creek has occurred under the cumulative influences of recharge from repetitive flood events and surplus water discharge. Recharge from four major consecutive cyclones during the period 1994 to 2005 (the wettest period for two centuries; Rouillard et. al., 2015) provided significant and cumulative wetting fronts beneath Weeli Wolli Creek. From late-2007 to early-2008, the hydrographs show comparatively limited fluctuations, indicating the groundwater environment is filled to a natural capacity and with outflows balanced by inflows.

Monitoring bore hydrographs were recognised to show compatible signatures and consequently that for YM119 was used to provide a template for transient re-wetting, including the differentiation of:

- Baseline disconnected losing stream with episodic wetting from flood events and cyclic decay under hydraulic mechanisms.
- Progressive wetting, with masking from repetitive flood events.
- Transition to where the water table is connected to perennial stream flow.
- Episodic wetting from flood events superimposed on a full floodplain aquifer.
- Cyclic decay by hydraulic mechanisms and discharge to Weeli Wolli Creek.

The hydrographs show the wetting front occurred beneath Weeli Wolli Creek from early-1995. Further, the water table became connected to the perennial stream flow on Weeli Wolli Creek from early-2000 in monitoring bores YM119, 99YJWB02, 99YJWB03 and 99YJWB04. In each monitoring bore, the floodplain aquifer was full, or nearly so, at the time of Cyclone John in January 2000.

Comparisons between the aquifer storage (509.2 GL), surplus water discharge volumes (513.8 GL) and changes in storage from early-1995 (80.1 GL) provide indications of a substantial mismatch. The available storage beneath Weeli Wolli Creek in the vicinity of PBS was filled comparatively quickly between early-1995 and early-2000. Subsequently, the aquifer system in this setting has predominantly remained full. In the vicinity of 99YJWB01, the groundwater wetting front was interpreted to be evident in subtle expressions from about early-1995. In 99YJWB01, however, the aquifer systems have to date not become full to capacity. These attributes indicate a likely change in aquifer hydraulics beneath northern reaches of Weeli Wolli Creek. These attributes were linked to several factors, including:

- Increase depths to the water table, providing larger storage volumes.
- Deeply incised palaeochannel aquifer geometry beneath Poonda Plain and higher transmissivity due to increased aquifer thickness. A cross-section transect within the Nyidinghu Project (Fowers et al.; 2013) shows the presence a deeply incised bifurcate palaeovalley aligned with Weeli Wolli Creek. The intersected palaeovalley(termed the Weeli Wolli Creek Palaeovalley) shows bottom elevations in the range 270 to 305 m AHD, thus indicating thicknesses of 155 to 190 m assuming ground surface elevation of 460 m AHD. This range of thicknesses shows significant change from settings further south beneath Weeli Wolli Creek where typical depths to basement rocks is about 75 m.
- Higher transmissivity within structural defects in the Hamersley Group. Structural defects, including northeast striking faults terms the Weeli Wolli fault system (that form a zone of deformation up to 2 km in width) and a northwest striking Poonda Fault, are described (Fowers et.al, 2013) in the bedrocks beneath the Nyidinghu Project.

Assessments of the hydrographs for the D08YJ216, D08YJ165 and 99YJWB01 were used to predict rates of northward propagation of the groundwater wetting front and timetable for filling local aquifer profiles to elevations of the low-flow channel of Weeli Wolli Creek. These assessments for 99YJWB01 (the northern most monitoring) showed:

- Lateral wetting front propagation by 229 to 374 m/annum.
- A period of about 21 years for saturation of the 25 m zone above the current water table to the invert elevation of Weeli Wolli Creek.

The increases in water availability and discharge by transpiration and evaporation result in salt accumulation within the groundwater environment. A chloride ion increase of about 50 mg/L along the 27 km surface water wetting front on Weeli Wolli Creek was attributed to salt accumulation due to evaporation and transpiration losses along the flow path (Dogramaci et.al; January 2015a). This represents about a 10 per cent change in salinity.

9.1.4 Groundwater Wetting Front Predictions

A groundwater model was developed to predict the groundwater wetting front beneath northern reaches of Weeli Wolli Creek. This model domain extends north of YM119 in settings where there is limited public domain data. The model was conceptualised based on:

- A cross-section transect of the Weeli Wolli Creek Palaeovalley within the Nyidinghu Project (Fowers et al.; 2013).
- Groundwater exploration data on Fortescue Marsh (McLean and Sanderson, 2012 in draft).

The transient calibration covered the period from 1997 to 2013, thus reflecting the period when wetting fronts were present beneath northern Weeli Wolli Creek.

The calibrated model was run forward in time to predict changes in the groundwater wetting front based on surplus water discharge volumes described by the Yandicoogina – Pocket and Billiard South Model (Lim, 2014).

The predictions indicate that:

- The groundwater wetting front would peak within two years after commencement of the PBS abstraction, with subsequent waxing and waning during the period to 2024. After 2024, the predicted wetting front shows steady decay.
- The water table would remain disconnected from Weeli Wolli Creek in the vicinity of 99YJWB01.

The predictive outcomes show a groundwater wetting front not strongly dissimilar to that currently present.

The groundwater wetting front predictions when viewed in context to the quasi-steady-state aspects of the surface water wetting since 2007 provides indications that the observed high surface water infiltration capacities and high-transmissivity of the floodplain and CID aquifer system limit the propagation of the wetting front. Both of these characteristics together with the predictive module outcomes provide indications of limited future changes and hence low environmental risks in context to wetting fronts propagating significantly onto and beneath the Poonda Plain. Further, the capacity of the local environments and systems to transmit and dissipate the surplus water has not been exceeded beneath northern reaches of Weeli Wolli Creek. This provides a view of low cumulative environmental risks linked to existing projects and the development of PBS.

Given there is limited data that characterises the northern Weeli Wolli Creek Palaeovalley it is difficult to quantify the maximum capacities of surface water infiltration and through-flow in the groundwater environment. Under these circumstances it is difficult to frame the environmental risks that may occur due to concurrent below water table mining developments, such as Jinidi, Iron Valley and Nyidinghu. Of these projects, only Iron Valley is operating, as an above-water table development.

9.1.5 Water Availability

The baseline settings provided perspectives of riparian zone function, including importance of surface water and recognition of preferential development along the main low-flow channel of Weeli Wolli Creek and where captured by secondary braided channels. Three water sources were interpreted to support the riparian zone, including:

- Surface water flows, including direct rainfall, stream flow (in the low-flow and incised channels) and overland flow (from the hinterland and from flood events).
- Surface water to groundwater interaction, thus flow and water in storage in the unsaturated profile represented by pore water in the interstitial fabrics of the alluvial and CID successions.
- Groundwater from settings below the water table.

It was also recognised that water availability would be different within the discretised low-flow, incised channel riparian zone floodplain and broader floodplain domains of Weeli Wolli Creek. In this regard, the discretised riparian zones on Weeli Wolli Creek included:

- Low-flow channel: a 6 m width zone that transmits all of the perennial stream flow and 20 m width corridor either side.
- Incised channel: a 100 m width inundated by 1-year and 2-year ARI events.
- Riparian zone floodplain: a 450 m width zone flooded by 2-year to 5-year ARI events.
- Broader floodplain: 1,800 m in width and infrequently inundated by 5-year to 10-year ARI stream flow events.

The presence of the riparian zones was interpreted to reflect reasonably consistent water availability within an annual (365-day) supply equation. Surface water is the initial source that episodically rewets the system, but has limited persistence and is absent over much of the year. Similarly, deep water table settings are not strongly representative of groundwater dependency. By extension, therefore, the predominant water dependency for the baseline riparian zone would be pore water, with contributions from surface water and groundwater being subordinate.

The derivation of 365-day water availability equations was based on information from the local Weeli Wolli Creek setting including rainfall and stream flow records, simulated footprints for 1-year to 10-year ARI events (Cheng, 2013), infiltration and other loss factors (Dogramaci et al., 2015a and Pettett and Pearcey, 2014) and observed water table settings together with transient responses to episodic recharge events. Applications of these data were made using a number of insights and assumptions. These influence the risk assessment outcomes. In this context the most important assumptions include:

- The surface water and pore water sources cumulatively form a year-round (365 day) perennial water availability within the riparian zone settings where there is no groundwater dependency.
- Groundwater was assumed to be a potential perennial year-round source for water table depths to a maximum of 20 m; for depths to the water table greater than 20 m it was assumed that groundwater was unavailable to the riparian zone. For groundwater it was also recognised that there may be variable demand depending on depths to the water table. As such, four water table zones were discretised and in each zone a factor was applied to characterise potential groundwater availability assuming groundwater would not be the sole source. The four discrete water table zones included:

Depth to Water Table (m)	Groundwater Availability	
	Per Cent	Days per annum
0 to 2	85	310
2 to 6	60	219
6 to 12	30	110
12 to 20	10	37

- It was recognised that the groundwater availability was probably conservatively high. With reference to Figure 7-8 it was reconciled that typically the upper-most 25, 30 and 50 per cent of the incised channel, riparian zone floodplain and broader floodplain profiles respectively would be unaltered in transition from current to PBS scenarios. In these shallow profiles, presumably where the root architecture is preferentially developed, the surface water and pore water availability would not be changed. These perspectives were used to further limit the groundwater availability. For the respective incised channel, riparian zone floodplain and broader floodplain, the groundwater availability was reduced 25, 30 and 50 per cent to account for the absence of disturbance to the upper-most root zones.

The annual dependency for the surface water, pore water and groundwater sources was determined based on the linear interpolation between their availability (days per annum) and the cumulative (total annual availability of all sources) water availability.

9.1.6 Water Availability Risk Assessment

For the water availability risk assessment it is pertinent that the current surface water and groundwater environments are temporary and cannot be sustained. Future changes would be inevitable once the discharge of surplus water ceases or is substantially reduced. Further, it is difficult to gauge the potentials for increased riparian zone dependency on the increased water availability, both in context to surface water and groundwater sources. For example one risk aspect would be dependent on the adaptability of riparian floristics:

- To increase surface water and groundwater availability, including potential waterlogging of root zones.
- Perennial presence of stream flow and water table mounding into root zones.

It was also recognised that EWRs of the riparian zones on Weeli Wolli Creek would be supported by the following processes:

- Retention of perennial surface water flows, at least initially, to offset potential changes due to drawdown of the water table.
- Limiting changes to periods of high floodwater.
- Avoidance of drawdown of the water table.

The water availability risk assessment provides reasonable worst-case attributes based on:

- Stream flow being sustained in the low-flow channel.
- Avoiding disturbances to the low-flow channel.
- Limiting disturbances where practical to the local Riparian Exclusion Zone hydrology.
- Conservatively high groundwater dependency based on water table depths to 20 m.

As such, the PBS scenario captures two of the three EWRs, with avoidance of drawdown not practical. Under these circumstances, the drawdown of the water table is the predominant change mechanism regarding water availability. Contextually therefore, the water availability risks to the riparian zone would predominantly have aspects that reflect the adaptability of riparian floristics:

- In drawing from alternative water sources when groundwater availability is reduced by 12 to 22 percent from the current situation.
- Reverting to baseline dependencies on pore water and surface water.
- To net reductions of 3 to 9 per cent in total water availability due to drawdown below the baseline water table elevations.

Under these circumstances, the riparian groundwater dependent floristics would probably experience drought-like conditions, with associated water availability stress.

Percentage changes in the water availability have been used to define potential risks. In this regard, low risks reflect changes of less than 10 per cent; medium risks between 10 to 18 per cent; medium high risks 18 to 25 per cent and high risks greater than 25 per cent. The risk assessment is shown on the accompanying table for three scenarios:

- Current to baseline scenario.
- Baseline to PBS scenario.
- Current to PBS scenario.

The latter scenario captures the cumulative influences in transitioning from the current environments of increased water availability to deficits from baseline that would temporarily prevail during development of PBS.

The interpreted changes in water availability within the riparian zones may be off-set in part at least by sustaining stream flow in the low-flow channel.

Setting	Change Aspect		Risk Assessment											
			Current to Baseline Scenarios				Baseline to PBS Scenarios				Current to PBS Scenarios			
			Low-Flow Channel	Incised Channel	Riparian Flood Plain	Broader Flood Plain	Low-Flow Channel	Incised Channel	Riparian Flood Plain	Broader Flood Plain	Low-Flow Channel	Incised Channel	Riparian Flood Plain	Broader Flood Plain

11 LIMITATIONS

11.1 Geotechnical and Hydro Geological Report

URS Australia Pty Ltd (URS) has prepared this report in accordance with the usual care and thoroughness of the consulting profession for the use of Rio Tinto Iron Ore Pty Ltd and only those third parties who have been authorised in writing by URS to rely on the report.

It is based on generally accepted practices and standards at the time it was prepared. No other warranty, expressed or implied, is made as to the professional advice included in this report. It is prepared in accordance with the scope of work and for the purpose outlined in the proposals dated 31 March 2014 and 3 September 2014.

The methodology adopted and sources of information used by URS are outlined in this the Report.

Where this report indicates that information has been provided to URS by third parties, URS has made no independent verification of this information unless required as part of the agreed scope of work. URS assumes no liability for any inaccuracies in or omissions to that information.

This Report was prepared between 28 November 2014 and 30 June 2015.The information in this report is considered to be accurate at the date of issue and is in accordance with conditions at the site at the dates sampled. Opinions and recommendations presented herein apply to the site existing at the time of our investigation and cannot necessarily apply to site changes of which URS is not aware and has not had the opportunity to evaluate. This document and the information contained herein should only be regarded as validly representing the site conditions at the time of the investigation unless otherwise explicitly stated in a preceding section of this report. URS disclaims responsibility for any changes that may have occurred after this time.

This report should be read in full. No responsibility is accepted for use of any part of this report in any other context or for any other purpose or by third parties. This report does not purport to give legal advice. Legal advice can only be given by qualified legal practitioners.

This report contains information obtained by inspection, sampling, testing or other means of investigation. This information is directly relevant only to the points in the ground where they were obtained at the time of the assessment. The borehole logs indicate the inferred ground conditions only at the specific locations tested. The precision with which conditions are indicated depends largely on the uniformity of conditions and on the frequency and method of sampling as constrained by the project budget limitations. The behaviour of groundwater and some aspects of contaminants in soil and groundwater are complex. Our conclusions are based upon the analytical data presented in this report and our experience. Future advances in regard to the understanding of chemicals and their behaviour, and changes in regulations affecting their management, could impact on our conclusions and recommendations regarding their potential presence on this site.

Where conditions encountered at the site are subsequently found to differ significantly from those anticipated in this report, URS must be notified of any such findings and be provided with an opportunity to review the recommendations of this report.

Whilst to the best of our knowledge information contained in this report is accurate at the date of issue, subsurface conditions, including groundwater levels can change in a limited time.

Therefore this document and the information contained herein should only be regarded as valid at the time of the investigation unless otherwise explicitly stated in this report.

Except as required by law, no third party may use or rely on, this Report unless otherwise agreed by URS in writing. Where such agreement is provided, URS will provide a letter of reliance to the agreed third party in the form required by URS.

To the extent permitted by law, URS expressly disclaims and excludes liability for any loss, damage, cost or expenses suffered by any third party relating to or resulting from the use of, or reliance on, any information contained in this Report. URS does not admit that any action, liability or claim may exist or be available to any third party.

URS does not represent that this Report is suitable for use by any third party.

Except as specifically stated in this section, URS does not authorise the use of this Report by any third party.

It is the responsibility of third parties to independently make inquiries or seek advice in relation to their particular requirements and proposed use of the relevant property.

Any estimates of potential costs which have been provided are presented as estimates only as at the date of the Report. Any cost estimates that have been provided may therefore vary from actual costs at the time of expenditure.

GOVERNMENT OIL and GAS INFRASTRUCTURE POWER
INDUSTRIAL

URS is a leading provider of engineering, construction, technical and environmental services for public agencies and private sector companies around the world. We offer a full range of program management; planning, design and engineering; systems engineering and technical assistance; construction and construction management; operations and maintenance; and decommissioning and closure services for power, infrastructure, industrial and commercial, and government projects and programs.

Water Resource Evaluation / Projects & Development

Weeli Wolli Creek Ecohydrology – Yandicoogina Pocket and Billiard South Pre-Feasibility Study

30 April 2015

A study was carried out to identify the likely changes to surface water flow regime and the effects on riparian vegetation along Weeli Wolli Creek as a result of development of the Pocket and Billiard South deposits within the Yandicoogina mine. Mining of the deposits will require construction of flood protection infrastructures, which may alter the existing surface water flow conditions along Weeli Wolli Creek. Hydraulic modelling in 2D was undertaken to define the flow conditions under pre-development and operational catchment conditions when the proposed surface water infrastructures are in place. The degree and extent of change to the flow regime, and the associated impact on the riparian vegetation were determined by comparing the flood elevations and velocities for various events under pre- and post-development conditions.

Based on the model results, it was determined that disruption to the existing surface water flows along Weeli Wolli Creek is small during events of low flows. As the magnitude of the flood increases, changes to the flow regime also increase due to greater constriction and obstruction of flows imposed by the infrastructures along the creek.

Flooding characteristics and creek water supply for riparian vegetation during events of low and medium flows will likely remain unchanged during operation. For larger events, flood level will increase more prominently and the floodplain extends further to the west, thus larger area of vegetation, in particular those fringing the floodplain will be inundated during events of a lower AEP post-development.

Overall, the study demonstrated that the impact to surface water flow regime along Weeli Wolli Creek is confined to the section adjacent to the proposed mine and unlikely to influence the wider creek area during operation. However, it is recommended that appropriate management and monitoring be implemented to minimise long term impacts on the morphology and flow regime of the creek.

Introduction

1. Overview

The Weeli Wolli Creek riverine environment supports significant stands of riparian vegetation, including *Eucalyptus camaldulensis* (River Red Gum), *E. victrix* (Coolabahs) and low open woodlands of *Melaleuca argentea* (Silver Leaved Paperbark), and the distribution, density and survival of these tree species are most likely related to the water availability and hydrological regime of the creek system. The section of Weeli Wolli Creek, adjacent to the Pocket and Billiard South deposits at Yandicoogina, is categorised as an environment and heritage restriction zone. Development of the deposits will result in direct disturbance of the restriction area and construction of mine and flood protection infrastructure will encroach on the floodplain and modify the existing flow conditions of the creek. Flood levees, designed to the 0.5 % AEP event, will be constructed to protect the pit from Weeli Wolli Creek flood waters and an engineered creek crossing will be required to enable access from the Billiard South operation to the existing Yandicoogina mine. Changes to the existing hydrologic pattern and flood regime, as a result of these infrastructures, may affect riparian vegetation condition within Weeli Wolli Creek. Assessments to investigate the potential impacts to the Weeli Wolli Creek riverine environment as a result of mine development are therefore required to support government approval applications and comply with Rio Tinto standards.

As part of the Pocket and Billiard South Order of Magnitude (OoM) study, hydrologic and hydraulic assessments were undertaken to define the surface water hydrology and flow conditions of Weeli Wolli Creek as well as investigate conceptual flood levee options within the Weeli Wolli Creek floodplain (RTIO, 2013). This study adopts similar modelling approach but focuses on identifying potential environmental impacts as a result of the proposed mine development by comparing the flood regime in Weeli Wolli Creek under pre and operational catchment conditions. This is achieved by:

- Refining the existing (pre-mining) 2D hydraulic model to better capture the flow characteristics, including the flood extents, velocities and shear stresses, of the creek system;
- Development of an operational 2D hydraulic model, which incorporates the designs of the proposed flood and drainage infrastructure, to determine the flow characteristics of Weeli Wolli Creek during mining;
  and
- Describing the possible changes to the existing hydraulic regime of Weeli Wolli Creek during operation and determining the level of impacts and disruption to riparian vegetation within the creek as a result of the development of the Billiard South mine.

2. Terminology

Probability concepts are fundamental to design flood estimation. The terminology used in the communication of these concepts is paramount if it is to be effective for all stakeholders. The term ‘average recurrence interval’ or ‘ARI’ has generally been used within Rio Tinto and by industry professionals to describe the probability of a particular magnitude of flood occurring ie. ‘100 yr ARI’ or ‘1 in 100 year flood’.

Average Recurrence Interval (ARI) - the average period between occurrences equalling or exceeding a given value.

This description of flood events has often been misinterpreted by professionals, community members impacted by floods and other stakeholders as the probability of the chosen event is not explicitly defined. To ensure effective communication of event probabilities alternative terminology will be adopted by the Bureau of Meteorology and other industry bodies. Australian Rainfall and Runoff (ARR) has outlined the proposed terminology to be adopted (Engineers Australia 2013), and this follows.

Annual Exceedance Probability (AEP) - the probability of an event occurring or being exceeded within a year. For example a 1% AEP event has a 1% probability of being equalled or exceeded in any year.

The annual exceedance probability (AEP) expressed as a percentage, will be used to describe flood event probabilities for this study. Additionally, where appropriate, peak flows described as Q_y for the year ARI, will now be described as $Q_{n\%}$ AEP (including the percentage sign). Table 1 gives the AEP equivalent for ARI's commonly in used in flood studies.

Table 1: ARI and equivalent AEP

ARI	AEP (1 in x)	AEP %
1.44	2	50
4.48	5	20
9.49	10	10
20	20	5.0
50	50	2.0
100	100	1.0
200	200	0.50
500	500	0.20
1000	1000	0.10

3. Climate

3.1 Rainfall

The Yandicoogina area is a semi-arid to arid environment characterised by hot summers and warm winters. The region experiences climate extremes, where severe droughts and major floods can follow in close succession.

Rainfall records for Weeli Wolli Creek are available from Department of Water (DoW) gauging stations at Wonmunna (507012) from 1984, Tarina (505040) from 1985 and Waterloo Bore (505041) from 1985; all gauging stations are in operation and their locations are illustrated in Figure 1. Daily gridded rainfall data are also available for the period 1906 – 2011 for the catchment. Detailed analysis of observed rainfall records and gridded data were carried out as part of the OoM study and the long term mean annual rainfall (1906 to 2011) estimated for Billiard South is approximately 309 mm (RTIO, 2014). Rainfall is highly variable between years with the annual recorded rainfall for the region varying from 50 mm to 910 mm but a general increasing trend of 1.4 mm/year is shown in Figure 2. This rising trend has also been observed at other locations within the Pilbara. Rainfall is also highly seasonal with approximately 75 % of the annual total occurring between December and April. It is typically associated with tropical low pressure systems and thunderstorm activity from the monsoonal trough that develops over northern Australia during summer. Winters are typically dry and mild though winter rain events can occur in June and July as a result of tropical cloud bands that intermittently affect the area.

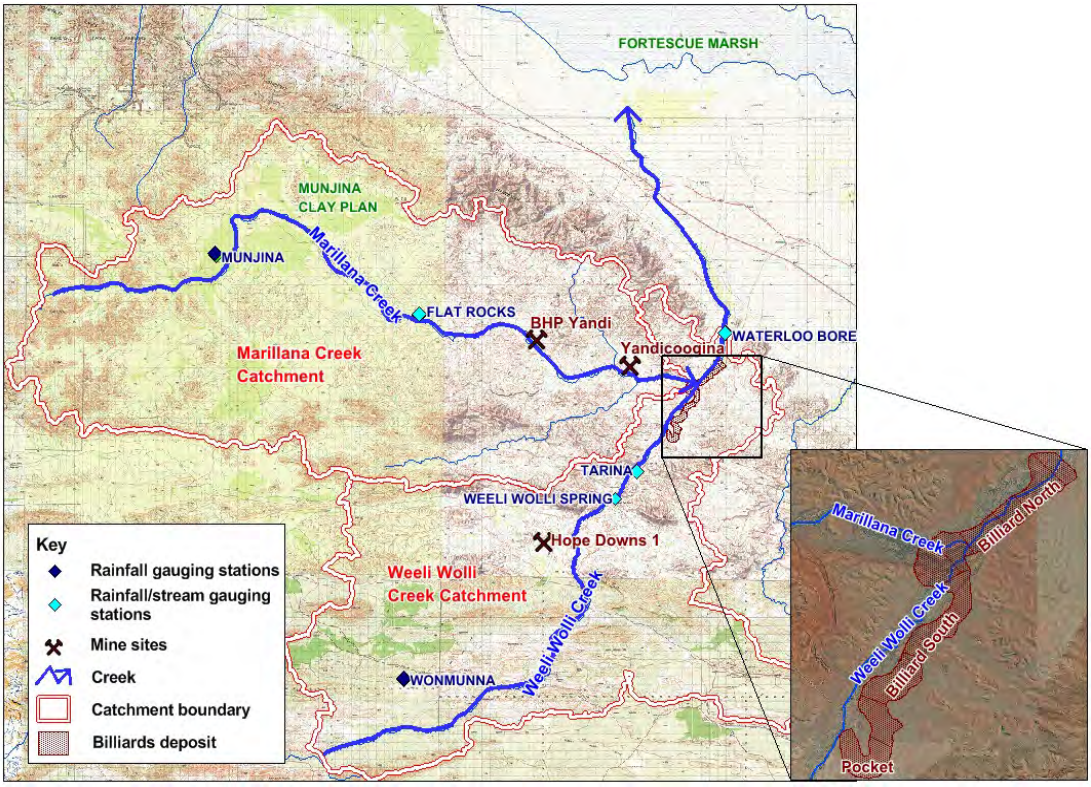

Figure 1: Weeli Wolli Creek regional catchment.

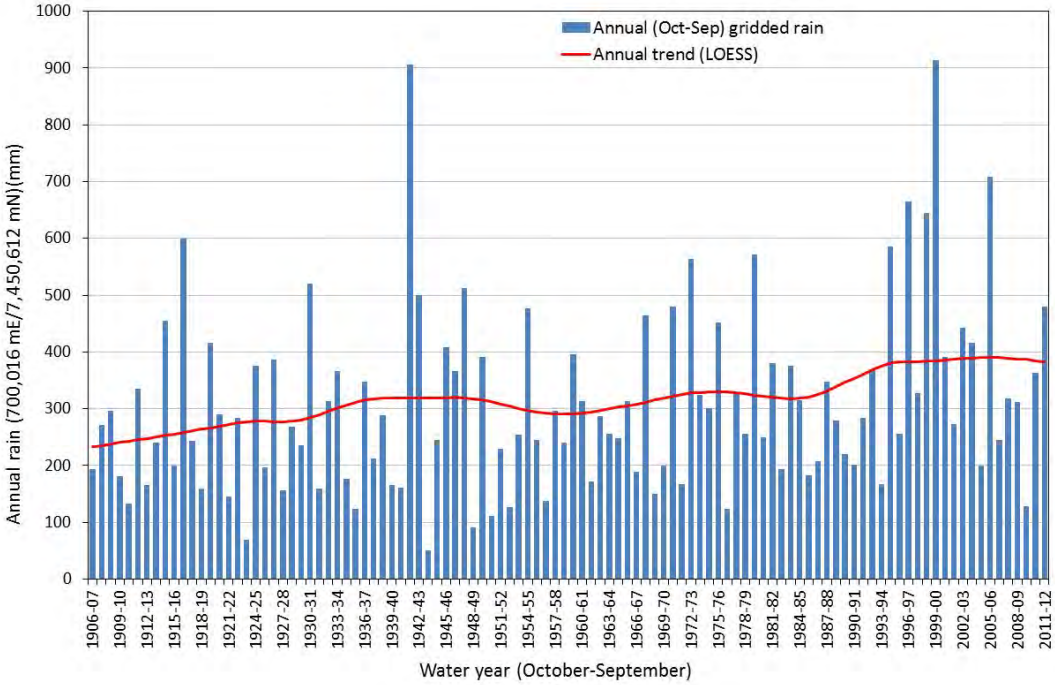

Figure 2: Annual (October-September) gridded rainfall for Billiard South.

A key component governing the hydrology of the Pilbara is the minimum rainfall required to initiate runoff, which can be referred to as the rainfall-runoff threshold. CSIRO has undertaken a detailed analysis of climate characteristics and hydrological catchment responses to define specific parameters and thresholds, including the rainfall-runoff threshold, for major creek systems within the Pilbara (CSIRO, 2013). Preliminary results of the analysis were presented for selected locations including Tarina at Weeli Wolli Creek within the Upper Fortescue River Basin. It was determined that the mean rainfall threshold for runoff commencement at Tarina is 36 mm, which means surface water flows within the Weeli Wolli Creek system will only occur when on average ≥ 36 mm of rainfall is received across the catchment during a single storm event. It is important to note that this value is a mean derived from examining rainfall sequence immediately prior to flow initiation at the gauge; the actual runoff threshold for each flow event will depend on the antecedent moisture conditions of the catchment.

Based on these findings, 30 minute rainfall data (1985 to 2012 water year), at Tarina was reviewed to quantify the occurrence of historical flow events along Weeli Wolli Creek. In the period of 1985 to 2012, 43 storm events of ≥ 36 mm were recorded, and therefore were likely to have generated surface flow in the catchment. Hence there is a probability that two flow generating rainfall events will occur every year on average. The remaining rainfall events were generally less than 10 mm, as illustrated in Figure 3, and therefore unlikely to trigger surface water flows in the system.

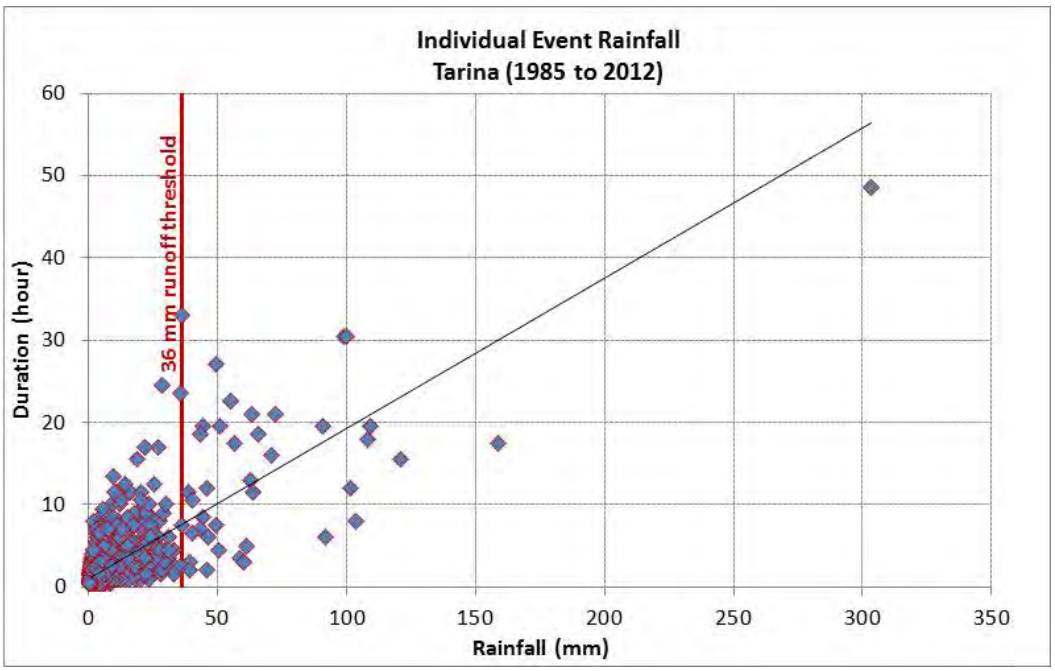

Figure 3: Individual event rainfall at Tarina 1985 to 2012. Majority of the rainfall events were less than 10 mm. During the 28 year period of record, 43 rainfall events were recorded to equal or exceed 36 mm (the runoff threshold established by CSIRO).

3.2 Evaporation

The mean annual Class A pan evaporation estimated for the region (from BoM gridded data, 1975 to 2000) is approximately 3,283 mm. The mean annual evaporation rate (sheltered free water surface) recorded at Yandi mine site weather station, between April 2004 and March 2009, is 1,898 mm/year, which exceeds the mean annual rainfall keeping the landscape typically arid. The conversion from Class A pan evaporation to sheltered free water surface, i.e. dam, conditions is 0.63 (Luke et al. 1987). Monthly evaporation rates are listed in Table 2.

The average point potential evapotranspiration (ET) rate estimated for the region by Bureau of Meteorology (BoM) is approximately 3,024 mm/year. Point potential ET is the ET that would take place, under the conditions of unlimited water supply, from an area so small that the local ET effects do not alter local air mass properties. Based on the information provided by BoM, point potential ET may be taken as a preliminary estimate of evaporation from small water bodies such as shallow water storages, which may include surface water pools within a creek system. The BoM annual actual aerial ET rate, for limited water supply replicating the natural environment rate, is approximately 346 mm/year.

Table 2: Evaporation rates estimated for the regional Weeli Wolli Creek catchment. Daily sheltered evaporation derived from Yandi site weather station (April 2004 to March 2009 sampling interval); Monthly Class A pan evaporation, Point potential and areal actual evapotranspiration obtained from BoM gridded data (1975 to 2005) and Class A pan evaporation conversion factor of 0.63 used to estimate sheltered monthly evaporation.

Month	Yandi sheltered evaporation (mm/day)				Class A pan	Point potential ET	Areal actual ET	Sheltered evaporation
	Min	Max	Mean	Std dev	(mm)	(mm)	(mm)	(mm)

4. Hydrology

Weeli Wolli Creek is currently gauged at two locations: Tarina (708013) approximately 8 km upstream of Billiard South and Waterloo Bore (708014) 11 km downstream. Detailed analyses of observed streamflow records at the gauging stations were carried out, as part of the OoM study, to define the existing hydrological regime of the creek system (RTIO 2013). Figure 4 and Figure 5 illustrate the flow duration curves (FDC) produced for Tarina and Waterloo Bore. The FDCs were generated for each complete water year on record in order to describe the hydrological regime of the section of Weeli Wolli Creek between the two gauges. The grey lines represent the FDC for individual water years, while the thicker black line describes the flow regime for the entire length of record.

The effects of surplus water discharge, from the Hope Downs 1 operation approximately 5 km upstream, on the existing flow regime at Tarina are clearly illustrated in the annual FDCs (Figure 4). Continuous flows are recorded at the gauge since 2007, an occurrence that is outside the natural envelope of existing flow based on available streamflow records at the gauge. The FDCs therefore demonstrate that the flow regime at Tarina has shifted from intermittent to perennial since artificial discharge from Hope Downs 1 begins in 2007.

For Waterloo Bore the wettest year, in terms of sustained flows, on record was 1999-2000, where positive flow was measured nearly 60 % of the time. The next wettest year experienced flows only 22 % of the time, in addition over 90 % of the daily flow record at Waterloo Bore is equal to zero. This suggests significant losses occur in the reaches upstream of the gauging station and that flows at Waterloo Bore will only occur during

severe/high intensity storms. This observation is consistent with the findings of the study conducted by Dogramaci et al, which evaluates the potential recharge along Weeli Wolli Creek based on a combination of numerical modelling and hydrochemistry measurements (Dogramaci et al., 2014). They have differentiated Weeli Wolli Creek into two sections (Figure 6 and Figure 7): Section A, which incorporates a 12 km section of the creek from Weeli Wolli Spring to the start of the Billiard South deposit, is underlain by impermeable Weeli Wolli Formation; this section contrasts to the lower part of Weeli Wolli Creek (Section B), which extends from Billiard South to Waterloo Bore and is underlain by a palaeochannel iron deposit (CID) aquifer that is characterised by a relatively high hydraulic conductivity (K = ~10 m/d). The study determined that groundwater is directly connected to the creek for the upper Section A, suggesting recharge is negligible along this reach of Weeli Wolli Creek. As the creek flows from Section A to Section B, the depth of the unsaturated zone increases and the hydrologic regime transitions from a connected to a disconnected creek, thus allowing recharge to occur (Dogramaci et al., 2014). The rate of recharge, i.e. the loss rate via infiltration, is estimated to increase substantially downstream as the depth to groundwater table increases from 0 m below ground level at Weeli Wolli Spring to 29 m near Waterloo Bore.

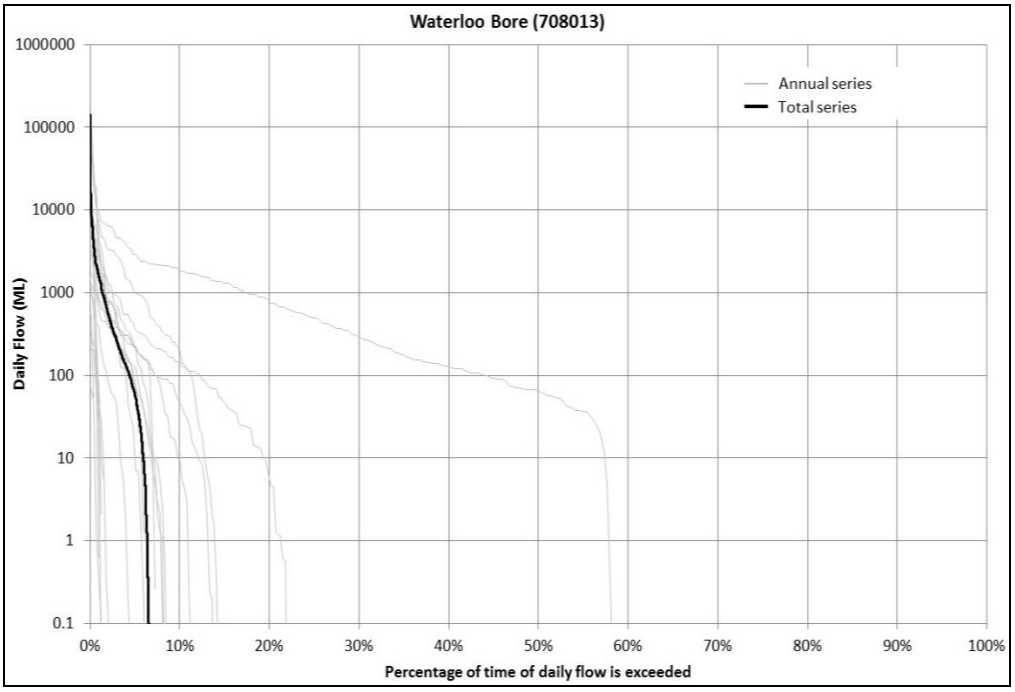

Figure 5: Flow duration curves at Waterloo Bore gauging station (708013) on Weeli Wolli Creek

Figure 6: Upper (Section A) and lower (Section B) Weeli Wolli Creek, including locations of groundwater bores and CID (Dogramaci et al., 2014).

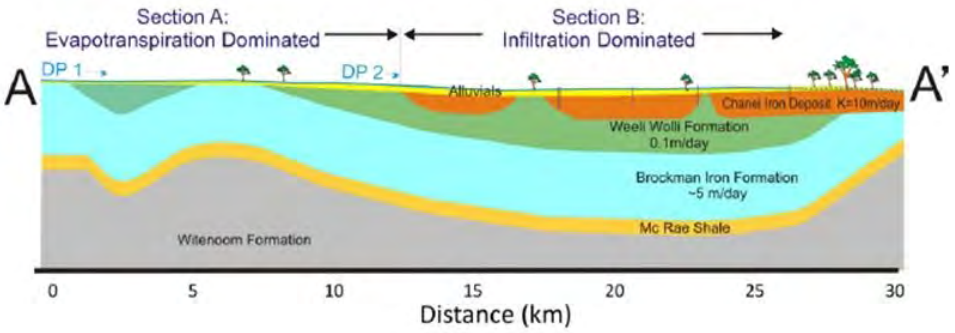

Figure 7: Long section A-A' showing the variation in geology below the creek (Dogramaci et al., 2014).

4.1 Cyclone Heidi

The most recent cyclone to generate significant flows along Weeli Wolli Creek is TC Heidi, which impacted the Pilbara region between 9 and 12 January 2012. The total rainfall recorded between 8 and 13 January at Tarina and Waterloo Bore are 225 mm and 166 mm, respectively. Maximum discharge was recorded on 13 January with flood peaks reaching 240 m^3/s at Tarina and 430 m^3/s at Waterloo Bore. A comparison of creek flows and rainfall volumes measured at the gauging stations are provided in Figure 8 and Figure 9.

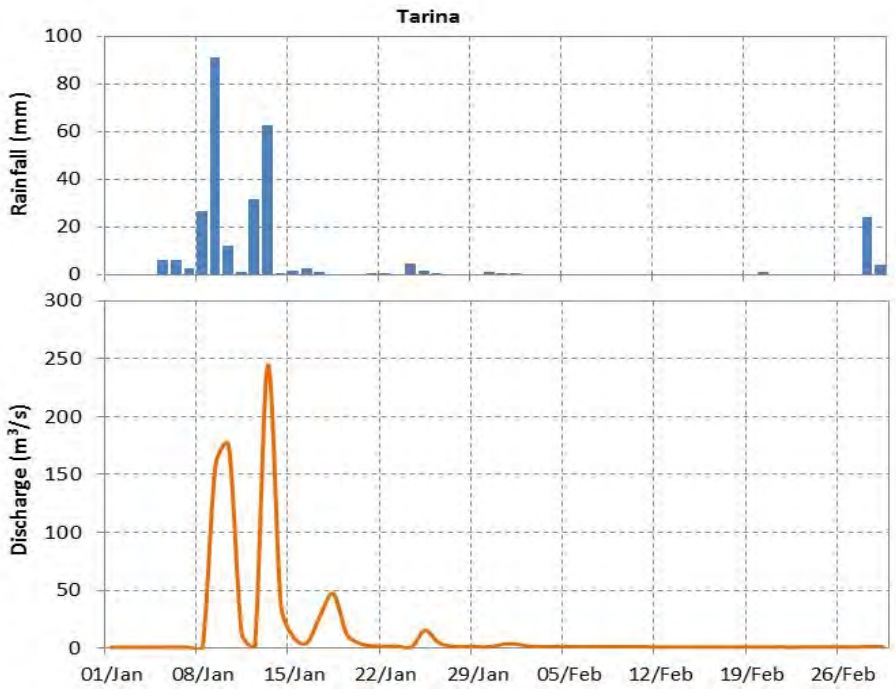

Figure 8: A comparison of rainfall depths and measured creek flows at Tarina gauging station during the period January to February 2012.

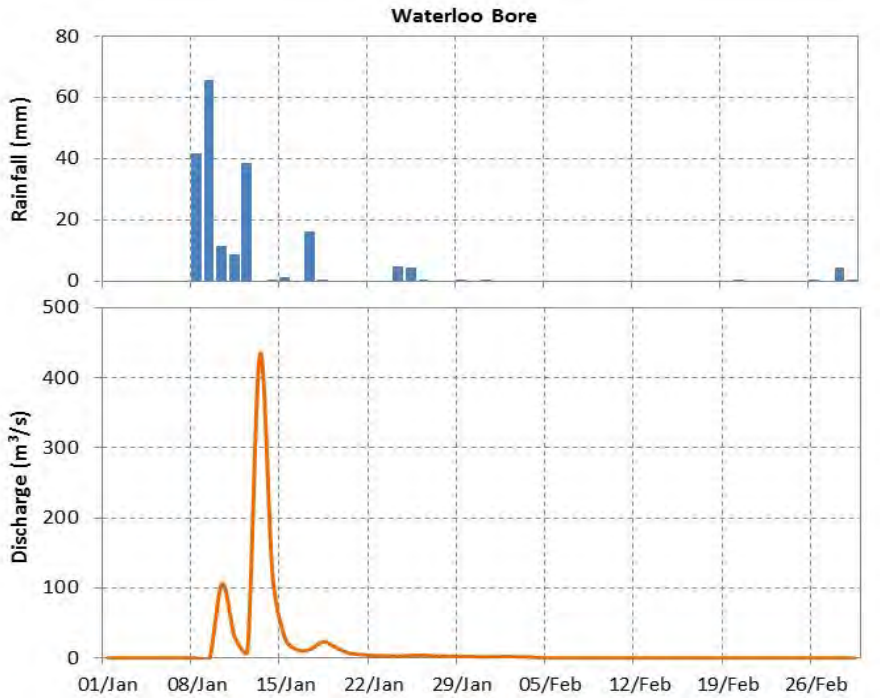

Figure 9: A comparison of rainfall depths and measured creek flows at Waterloo Bore gauging station during the period January to February 2012.

An attempt was made to evaluate the rate of recharge along Weeli Wolli Creek (Section B) in response to Cyclone Heidi by estimating the fluctuation in groundwater table at bores along the CID (Dogramaci et al., 2014). It was estimated that recharge increases downstream from < 1 mm/d at bore 99YJWB04 to approximately 20 mm/d at bore 99YJWB01 (bore locations are illustrated in Figure 6). Subsequently the recharge volumes per unit length calculated by the changes in groundwater levels range from < 0.1 m3/d/m at the confluence with Marillana Creek to 8.4 m3/d/m near Waterloo Bore (Figure x). This finding indicates that infiltration from flow events increases substantially downstream, due to the increase in storage capacity of the underlying aquifer system, thus likely explains the predominant zero flow recorded at Waterloo Bore.

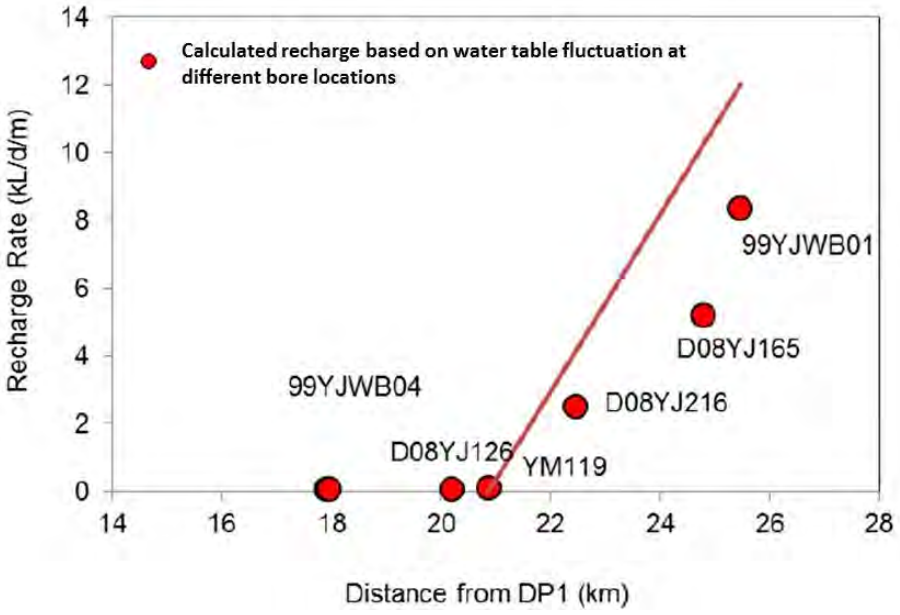

Figure 10: Calculated recharge rates downstream for Section B of Weeli Wolli Creek using the water table fluctuation method (Dogramaci et al., 2014)

4.2 Rainfall-runoff modelling

In order to determine the design flood peaks and hydrographs as required for the design of flood protection infrastructure at Billiard South, a rainfall-runoff routing model for the regional Weeli Wolli Creek catchment, which incorporates the catchment of Marillana Creek, was developed during the OoM (RTIO 2013). The model was calibrated to observed streamflow data at the gauging stations (Flat Rocks on Marillana Creek; Tarina and Waterloo Bore on Weeli Wolli Creek) within the catchment. The peak flow rates, at selected locations along Weeli Wolli Creek, for the 50 to 0.5 % AEP design events are listed in Table 3.

Table 3: Flood peaks produced from RORB model for the Weeli Wolli Creek catchment.

			Peak flow rates (m^3/s)			
AEP (%)	ARI (year)	Critical Duration (hr)	Weeli Wolli Creek at Tarina	Weeli Wolli Creek at Billiard South	Weeli Wolli Creek after Marillana inflow	Weeli Wolli Creek at Waterloo Bore
50	2	9	79	76	111	110
20	5	12	250	240	440	440
10	10	12	510	490	1160	1190
5	20	24	930	950	2660	2720
2	50	24	1960	2200	6600	6950
1	100	24	3700	4070	9810	10240
0.5	200	24	4630	4900	11090	11260

5. Hydraulic conditions

Design flood hydrographs produced from the rainfall-runoff modelling were inputted into a two dimensional (2D) hydraulic model, developed in TUFLOW, to determine the flood levels, velocities and floodplain extents for Weeli Wolli Creek at Billiard South (RTIO 2013). The original model is relatively coarse, incorporating a 2D grid comprised of 40 m by 40 m cells. This resolution is considered insufficient to capture the flow characteristics and resultant changes proposed by the flood levees, in particular along the low flow channel of the creek. Hence the model was refined, by reducing the cell size to 5 m by 5 m, to better capture the hydraulic conditions in the creek.

Flow conditions for the 50 to 0.5 % AEP design events were simulated in TUFLOW. Model results (maximum flood depths and velocity profiles) for the 50 %, 10 % and 1 % AEP events, representing the low, medium and high flow situations in Weeli Wolli Creek, are illustrated in Figure 11, Figure 12 and Figure 13, respectively. The velocity distribution is developed based on categories of permissible velocity, which is the velocity at which particles of a specified mean size begin to be mobilised and can be used as an indication of when channel erosion would occur. The categories of permissible velocity used in the assessment is summarised in Table 4. Cross sections at selected locations along Weeli Wolli Creek, adjacent to Billiards South, were also plotted (Table 5) to illustrate the changes in flood levels for different flow frequencies.

Table 4: Categories of permissible velocity and thresholds for sediment mobilisation

	Velocity (m/s)	Category
	0.0-0.5	OK for most areas
	0.5-1.0	Threshold for silts, fine sands and fine gravels
	1.0-1.5	Threshold for clays and gravels up to 25mm
	1.5-2.0	Threshold for gravels up to 50mm
	2.0-2.5	Threshold for gravels up to 150mm
	2.5-3.0	
	3.0-3.5	Threshold for riprap with d50 = 150-225mm
	3.5-4.0	Threshold for gravels and riprap with d50 = 300mm
	4.0-4.5	Threshold for gravels and riprap with d50 = 450mm
	4.5-5.0	Threshold for gravels and riprap with d50 = 450mm
	5.0-5.5	Threshold for riprap with d50 = 600mm, gabions and concrete
	5.5-6.0	Threshold for riprap with d50 = 600mm, gabions and concrete
	>6.0	High velocity for most areas

As shown in Figure 11, Weeli Wolli Creek is defined by an incised low flow channel that meanders within the floodplain of the creek system. Majority of the flows during the 50 % AEP are contained within the low flow channel with same minor break outs in the secondary channels, in particular downstream of XS4, signifying the transition from a more uniform to a braided system towards and downstream of the confluence with Marillana Creek. The maximum flood depth for the 50 % AEP event reaches 2 m along with the deepest section marked by XS3 where the low flow channel is most incised. Maximum velocity along the channel approaches 2 m/s for the 50 % AEP event, a velocity that is capable of mobilising gravels up to 50 mm along the creek bed.

During the 10 % AEP event, a proportion of the floodplain is activated, including several high flow channels in particular at locations marked by XS3 and XS5 (Figure 12). The maximum flood depth for the event reaches 4 m along the low flow channel with the floodplain inundated with water less than 1.5 m deep. There are isolated areas along the low flow channel where velocities exceed 3 m/s during the 10 % AEP flood. Those areas are areas where significant scour may occur and where pools may potentially form. Conversely, flow velocities along the floodplain and high flow channels are generally below 2 m/s during the event.

Outputs from the hydraulic model indicate that the floodplain of Weeli Wolli Creek is fully engaged in the 1 % AEP flood. As shown in Figure 13, flows are multidirectional and severely bifurcated, particularly at and downstream of the confluence with Marillana Creek. Water depths vary from less than 0.5 m along the perimeter of the flood extent to exceeding 6 m along the main channel. The low flow channel experiences extremely high flow velocities during the 1 % AEP flood with velocities at sections between XS1 and XS3, and at XS6 approaching 5 m/s. These velocities can uproot and transport large trees along the creek. Large woody materials, which appear to have been transported during large flow events, have been observed in the main channel as well as on the floodplain during the site visit of the geomorphological assessment.

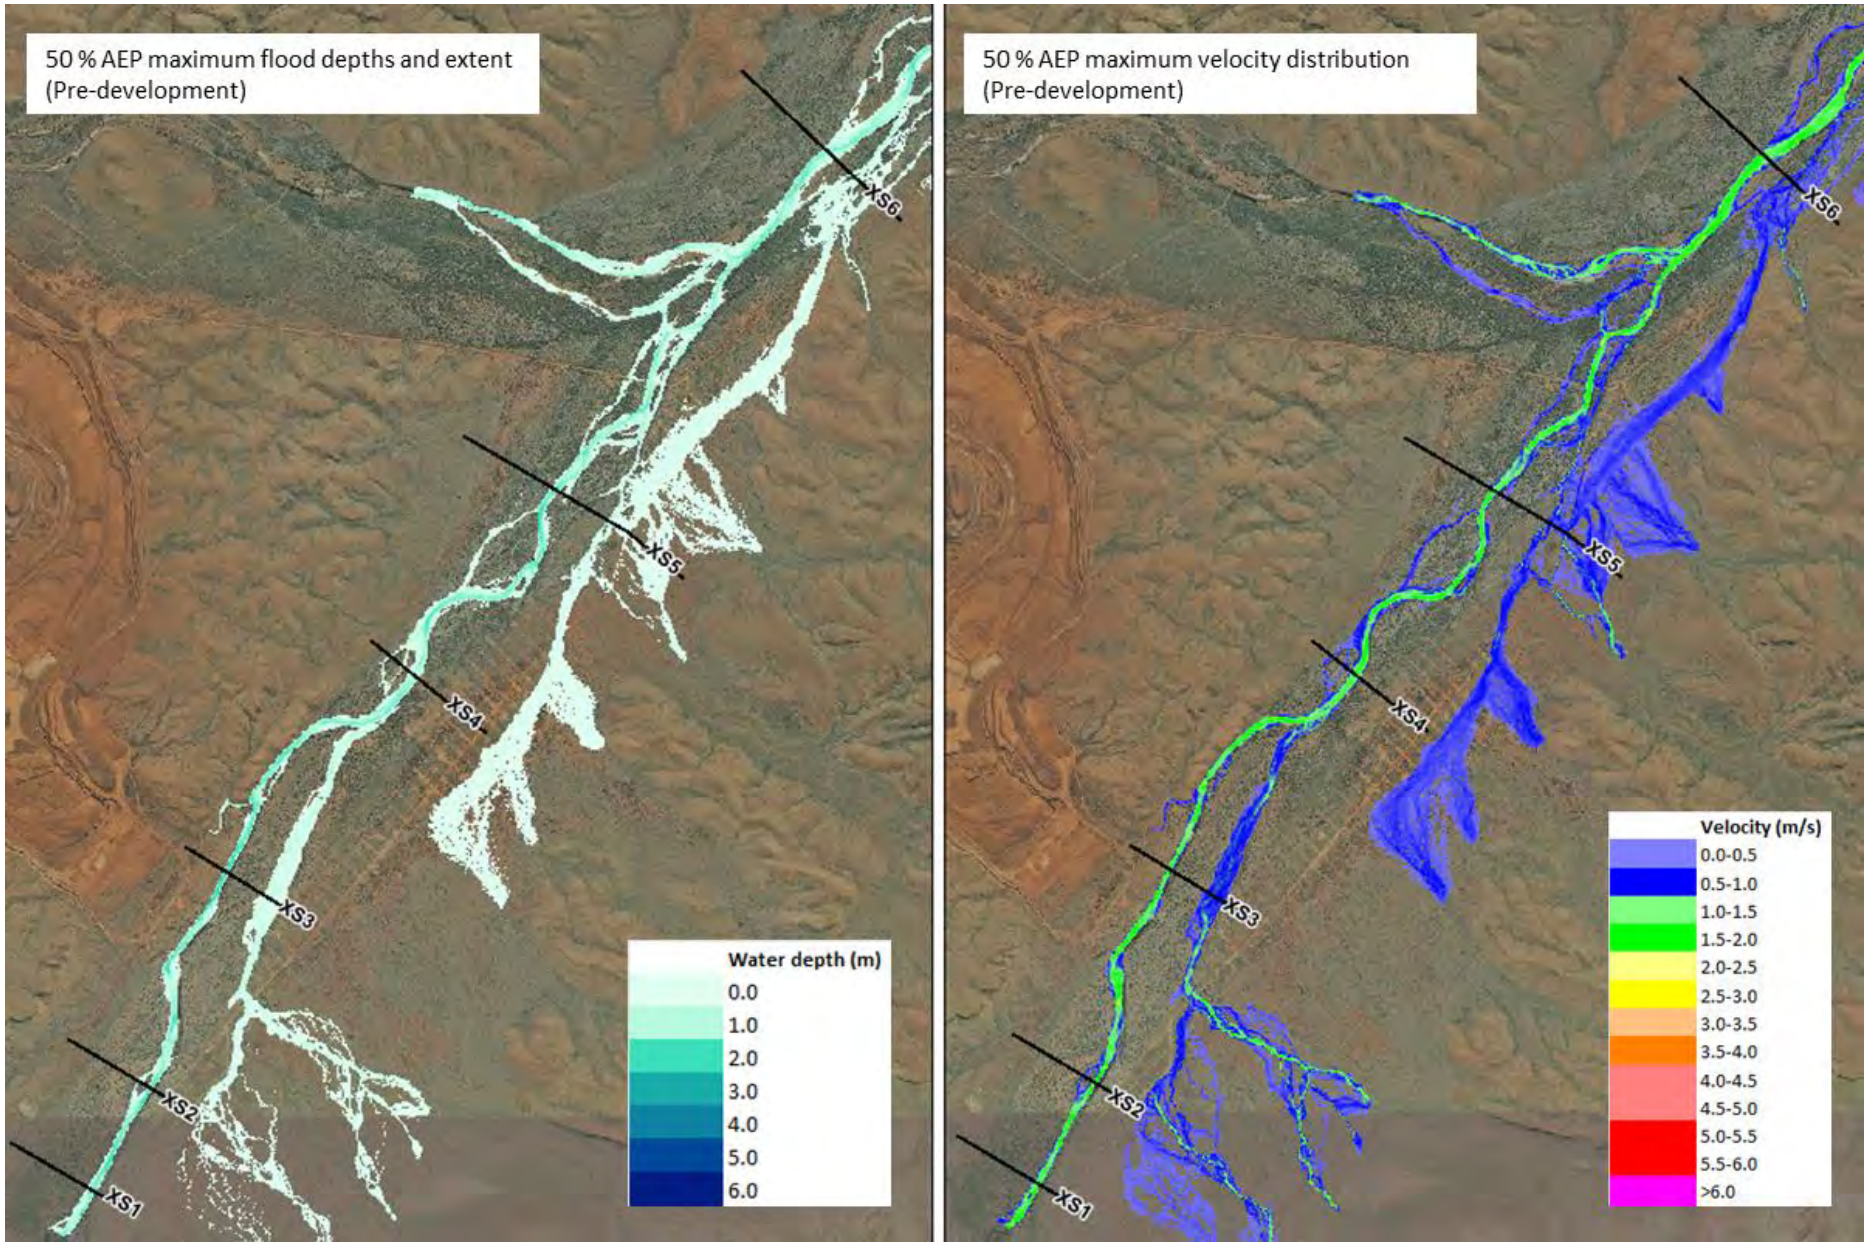

Figure 11: Maximum flood depths and velocity distribution for Weeli Wolli Creek during the 50 % AEP event under pre-development catchment conditions.

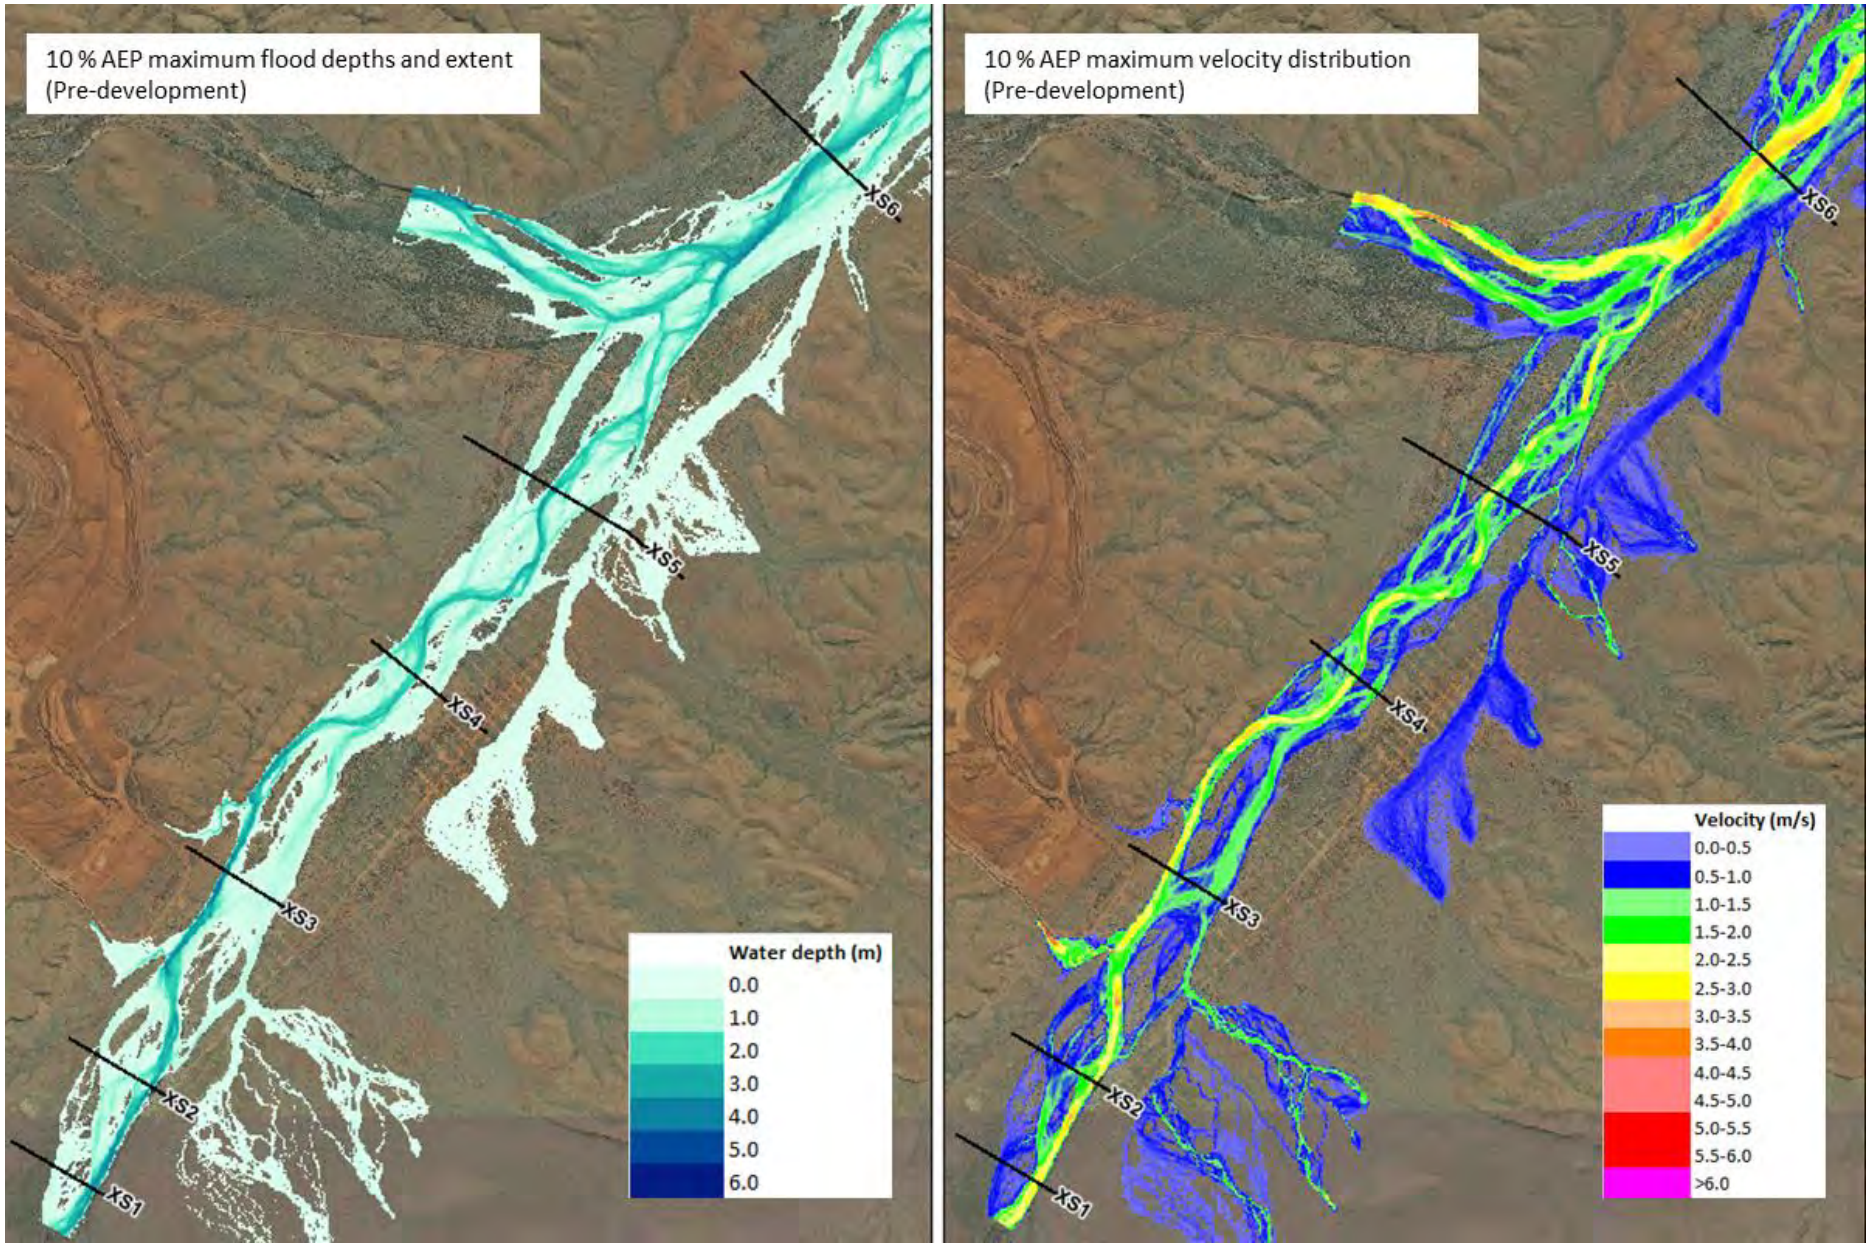

Figure 12: Maximum flood depths and velocity distribution for Weeli Wolli Creek during the 10 % AEP event under pre-development catchment conditions.

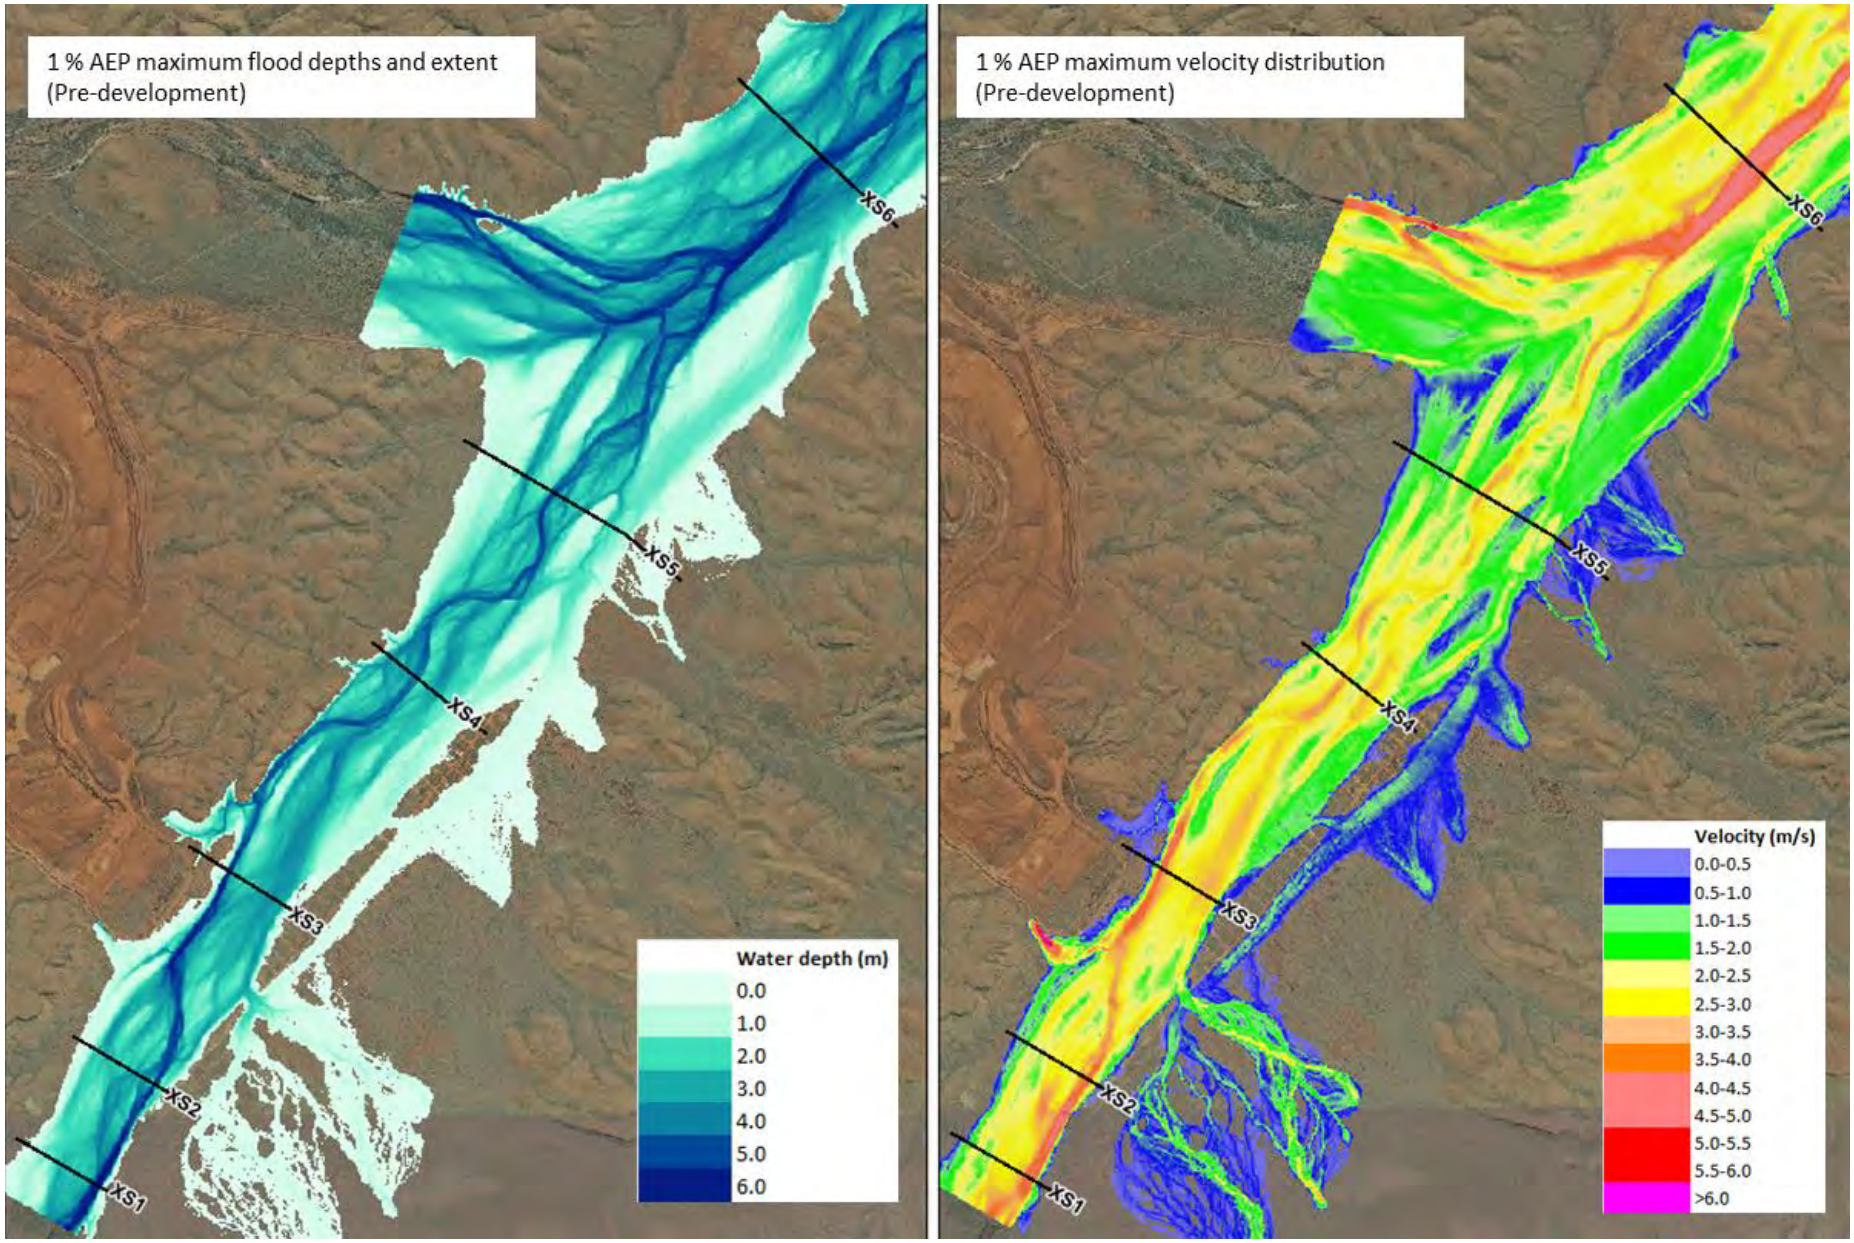

Figure 13: Maximum flood depths and velocity distribution for Weeli Wolli Creek during the 1 % AEP event under pre-development catchment conditions.

6. Sediment characteristics and regime

Detailed assessment has been carried out to identify the geomorphological conditions of Weeli Wolli Creek, adjacent to the Pocket and Billiard South deposits, to support government approval applications (MWH, 2014). Findings of the assessment indicate that the bed materials are predominately gravel, with the presence of large gravel bars in the low flow channel and the more active secondary or high flow channels where velocities are high during larger flow events. On the other hand, finer silty materials are found on the floodplain indicating lower velocities for sediment transport. Observations during the site visit indicate that the bed materials are more angular in the upstream part of the study area, suggesting fresh supply from a local source, while sediments are predominately more rounded further downstream. The increase in sphericity of the bed materials is indicative of greater fluvial reworking, which is supported by the outcomes of the hydraulic modelling where flows are shown to increasingly bifurcate further downstream.

Hydraulic loadings along the creek are episodic, occurring during larger events, and will vary longitudinally and laterally within the creek, reflecting variations in hydraulic conditions. Areas with high erosion potential are areas characterised by high velocity, while deposition will occur in areas when velocity drops. It was observed that the rate of surplus water discharge is too small to mobilise and transport bedload (MWH, 2014), indicating the release of surplus water has minimal effect on the existing geomorphological regime of the creek.

7. Vegetation

Vegetation type, distribution and density can be directly related to the water availability and hydrological regime of a creek system. Numerous vegetation and flora surveys have been carried out in the Yandicoogina region since 1994 and the latest, which incorporates the Billiards area along Weeli Wolli Creek, was conducted by Biota in July 2014. In addition, riparian vegetation monitoring is currently undertaken by Mattiske Consulting at 26 locations along Weeli Wolli Creek to assess the changes in flora and vegetation conditions within the creek as a result of dewatering and surplus discharge from the adjacent Hope Downs 1 and Yandicoogina mines.

Riparian vegetation in Weeli Wolli Creek is dominated by woodlands of *Eucalyptus victrix* (Coolibah) and *Acacia citrinovirdis* (Black Mulga). Patches of *E. camaldulensis* (River Red Gum) and *Melaleuca argentea* (Silver Cadjeput) are also found but they predominately occur in areas upstream of the Junction South East (JSE) operation and downstream of the Marillana Creek confluence. The tree species *E. camaldulensis, E. victrix* and *M. argentea* are common phreatophytic species[1] within riparian systems of the Pilbara bioregion and the presence of these species is often used to infer the existence of a groundwater dependent ecosystem (RTIO 2012). *M. argentea* is a groundwater dependent species, which primarily draws water from the saturated zone below the water table, hence its existence is indicative of permanently inundated pools and springs or where the water table is permanently close to surface. *E. camaldulensis* obtains its water from groundwater and river flooding, with mature trees more reliant on groundwater than young. Stands of River Red Gum are intimately associated with the surface flooding regime of the watercourses and related groundwater flow (CSIRO 2004). *E. victrix* has been shown to access groundwater in areas where the water table is shallow. However in non-riparian habitats or in areas that lack a permanently saturated regolith, the species will exploit shallow soil water to meet its transpiration needs following wet-season rains

[1] Plant species that draw water from the saturated zone or capillary fringe of the water table

(RTIO 2012). Vegetation types along Weeli Wolli Creek are shown at selected locations (XS1 to XS6) in Table 5. Classification of species is based on that established by Biota in their most recent survey in July 2014.

Artificial discharge of groundwater along ephemeral creeks and rivers may influence the growth and conditions of riparian vegetation by changing the hydrologic regime from intermittent to perennial. Monitoring carried out by Mattiske indicates that there have been some localised stress and loss of riparian eucalypts (E. *victrix* and E. *camaldulensis*) in sections subject to inundation, while in other areas the cover/abundance of saplings of M. *argentea* and riparian eucalypts have increased (RTIO 2012). However to date, the extent of change is considered relatively minor and insignificant when compared with regional trends in tree responses to seasonal conditions. Natural flooding in creeks can cause rapid and marked shifts in the understory species and sapling numbers within the creek channel and floodplain. The high flow velocities during these flood events can cause rapid losses in vegetation but the supply of water can also increase the cover/abundance of tree saplings within the creek system. Furthermore, the scouring effect of these events can create suitable habitat (e.g. pools) for tree growth in areas where such habitat did not exist previously (RTIO 2012). Monitoring results in Weeli Wolli Creek, upstream of the confluence with Marillana Creek, for the period 2007 to 2011 is illustrated in Figure 14; monthly rainfall for the same period is shown in Figure 15. There is a general increase in foliage cover when surplus discharge from Hope Downs 1 began in 2007. Changes in foliage cover subsequently stabilised and varied only in response to seasonal conditions between 2008 and 2010. However there was a notable drop in foliage cover from October 2010 to March 2011, potentially a reaction to the extremely low wet season rainfall for the 2009 water year where total rainfall was less than 150 mm from November 2009 to April 2010. This was followed by a general trend of increasing foliage cover from June 2011 as a result of the higher wet season rain for the 2010 water year. As shown in Figure 14, tree responses to artificial discharge varied spatially between the different monitoring sites and also temporally where some sites responded quicker than others. On the other hand, their reactions to notable changes in seasonal rainfall were more unanimous suggesting impacts caused by natural events are more significant than that caused by anthropogenic disturbances.

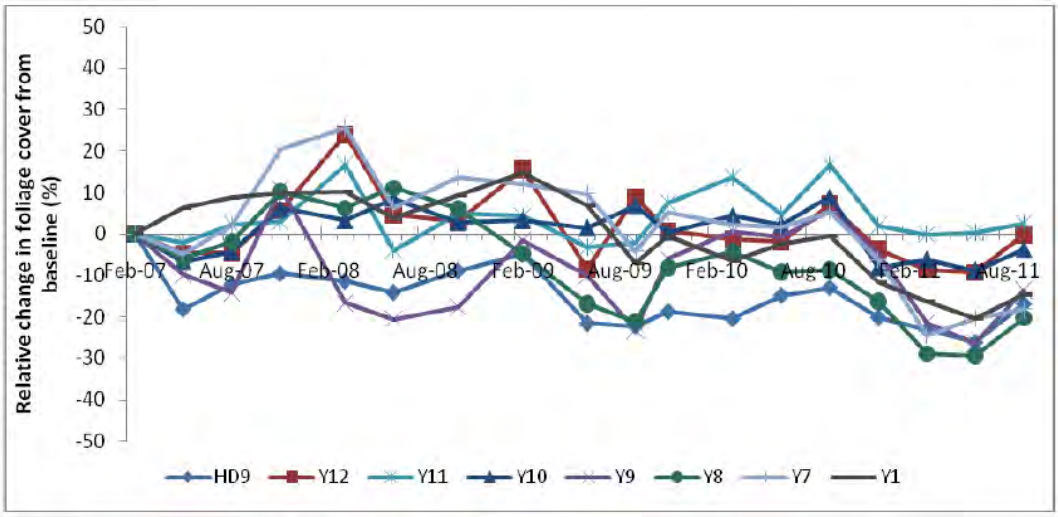

Figure 14: Changes in foliage cover through time at monitoring sites in Weeli Wolli Creek, upstream of Marillana Creek confluence (RTIO 2012).

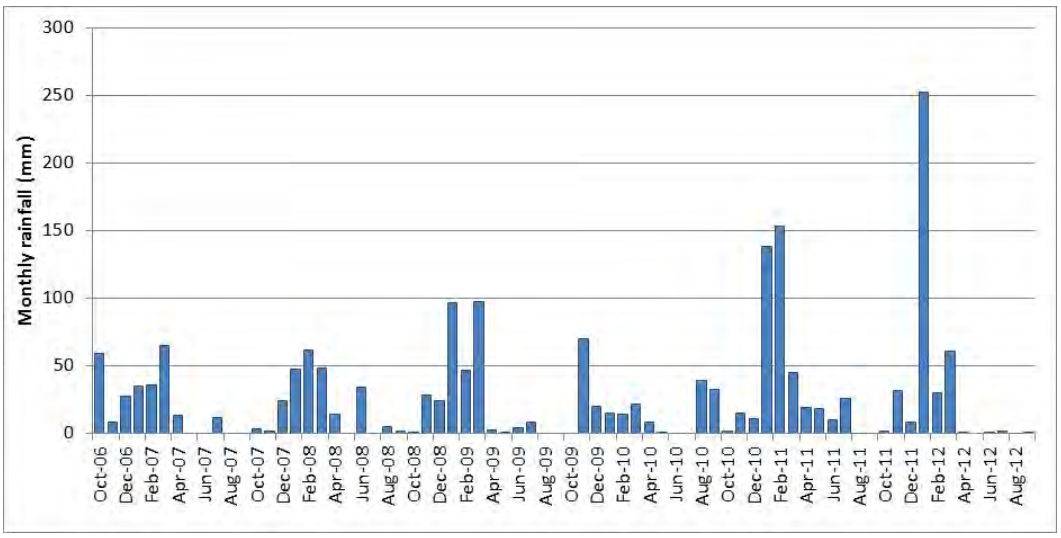

Figure 15: Monthly rainfall recorded at Tarina gauging station (2006 to 2011water year).

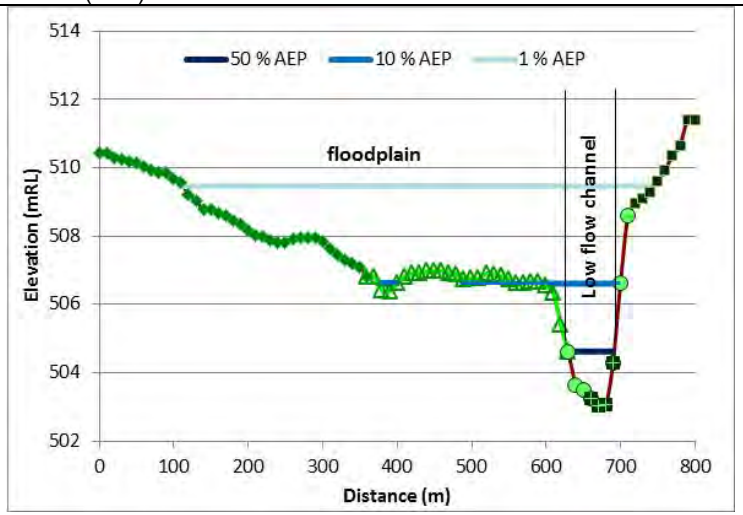
Table 5: Chosen cross section locations along Weeli Wolli Creek showing typical riparian vegetation and flood levels for the 50 %, 10 % and 1 % AEP events under pre-development catchment.

Cross section 1 (XS1)

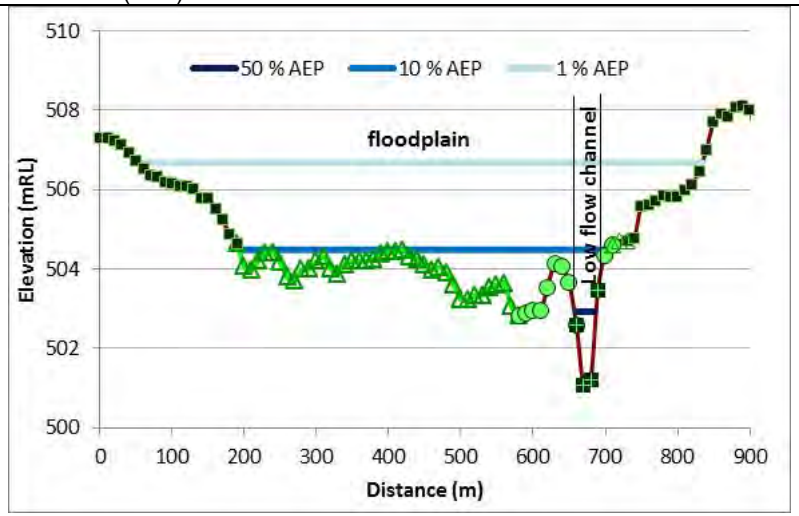


(F2)	*Acacia pruinocarpa, A. citrinoviridis* tall open shrubland
(C4)	*Eucalyptus victrix* open woodland over *A. citrinoviridis*
(C1)	*E. camaldulensis, E. victrix* woodland over *Melaleuca argentea*
(C3)	*E. victrix* scattered trees over *A. citrinoviridis*
(P4)	*A. pruinocarpa low open woodland over Triodia wiseana* open hummock grassland

Weeli Wolli Creek at XS1 is characterised by a relatively stable low flow channel with well-defined banks. This section of the creek is likely to experience high flow velocities during floods. Potential scouring and increased sediment loading may be expected along this section. Flows during the 50 % AEP event are contained within the low flow channel and further modelling indicates that the 20 % AEP flows are also confined within the main channel. Activation of the floodplain will likely occur during the 10 % AEP or greater events.

Tree species found along and lining the banks of the low flow channel include both of the riparian eucalypts as well as *Melaleuca argentea.* The presence of *M. argentea* indicates permanent water, which is likely a result of continuous discharge from the Hope Downs 1 mine. Under natural conditions, phreatophytic species within and along the low flow channel would receive water fairly frequently from the creek during low flow situations, while vegetation (type C4) along the left floodplain would only be flooded during a 10 % AEP or greater event. Flooding of vegetation (F2 and P4) within the floodplain would only occur during significant events in excess of 5 % AEP, signifying these species prefer unsaturated soil conditions with periods of drought broken by recharge from direct infiltration of rainfall and/or surface flows.

Cross section 2 (XS2)

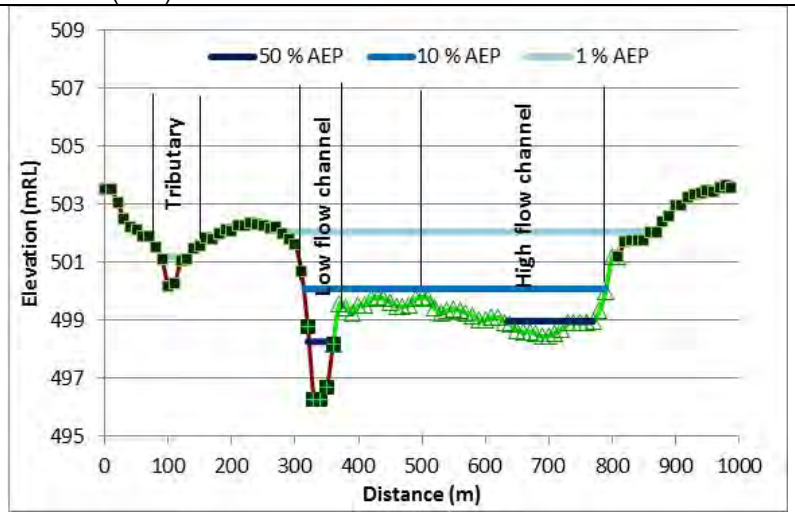


(C4)	*Eucalyptus victrix* open woodland over *A. citrinoviridis*
(C1)	*E. camaldulensis, E. victrix* woodland over *Melaleuca argentea*
(C3)	*E. victrix* scattered trees over *A. citrinoviridis*
(P4)	*A. pruinocarpa low open woodland over Triodia wiseana* open hummock grassland

XS2 marked the location of a semi-permanent pool in Weeli Wolli Creek. The low flow channel is narrower and more incised at this location. Based on the channel geometry and results from the hydraulic modelling, it is evident that flow velocities would be very high during floods and the scouring effects of the rapidly flowing water would likely have created the current morphology allowing the pool to form. Flows for more frequent events of 50 % AEP or less would contain within the low flow channel, while activation of the floodplain would occur during the 5 % AEP or larger events.

There is an abundance of type C1 vegetation adjacent to the low flow channel due to the presence of the pool, which is sustained by surplus discharge. These tree species would be flooded by the creek in a 20 % AEP event. Under natural conditions, stands of *E. victrix* that dominate the left floodplain would be inundated during the 10 % AEP flood. On the other hand, the type P4 vegetation that occurs along the boundary of the floodplain would only receive water from the creek during large events in excess of 5 % AEP.

Cross section 3 (XS3)

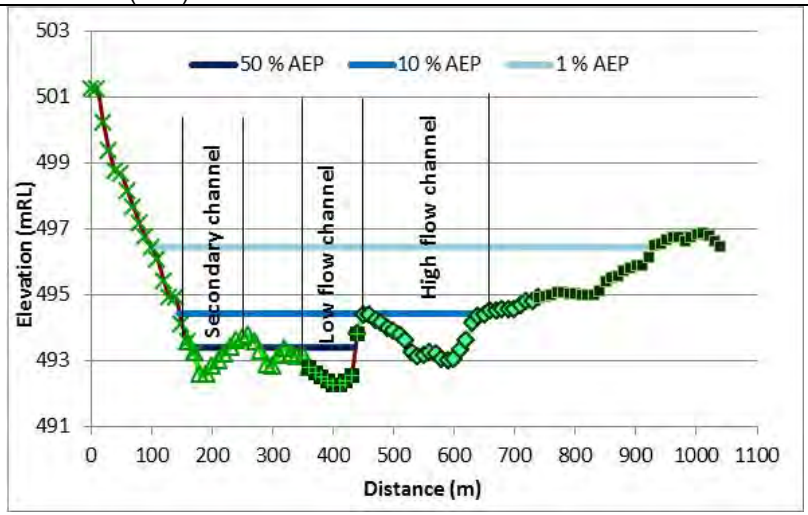


(P4) ■	*A. pruinocarpa low open woodland over Triodia wiseana* open hummock grassland
(C3) ▪	*E. victrix* scattered trees over *A. citrinoviridis*
(C4) △	*E. victrix* open woodland over *A. citrinoviridis*

XS3 is located immediately downstream of the JSE mine. Once again it represents a section of the creek that is characterised by an incised low flow channel, which will experience high flow velocity during a flood. Hydraulic modelling indicates that the high flow channel on the right would only receive surface water runoff from local catchments during the 50 % AEP event but activation by Weeli Wolli Creek would occur in a 20 % AEP or greater event. The tributary on the left is not explicitly modelled in TUFLOW hence water received in the channel is generated by backwater from Weeli Wolli Creek during a flood.

Vegetation mapping indicates the lack of *Eucalyptus camaldulensis* and *Melaleuca argentea* but the abundance of *E. victrix* in this area, suggesting a possible change in water source or availability along this section of the creek. Woodland of *E. victrix* on the right floodplain and within the high flow channel will receive water from Weeli Wolli Creek during a 20 % AEP or greater event. Flooding and inundation of vegetation (type P4) on the island between the tributary and the low flow channel would not occur until the 0.5 % AEP flood. Hence it is unlikely that this type of vegetation would rely on creek flows for water supply on an annual basis.

Cross section 4 (XS4)

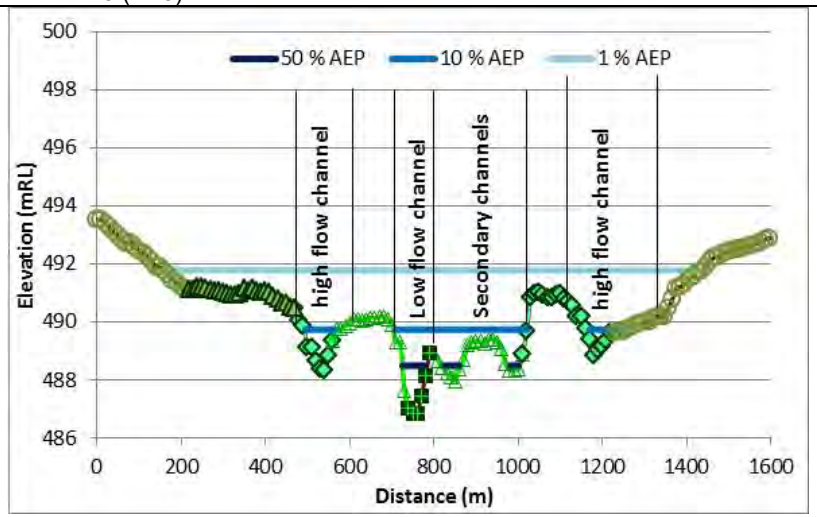


(H1) ×	*Eucalyptus leucophloia* scattered low trees over *Hakea chordophylla, Acacia inaequilatera*
(C4) △	*E. victrix* open woodland over *A. citrinoviridis*
(C3) ▪	*E. victrix* scattered trees over *A. citrinoviridis*
(P3) ◆	*A. pruinocarpa low open woodland over A. citrinoviridis, A. inaequilatera*
(P4) ■	*A. pruinocarpa low open woodland over Triodia wiseana* open hummock grassland

Weeli Wolli Creek transitions from a more uniform to a braided system downstream of XS4. The low flow channel is less incised at this location and the 50 % AEP event would likely activate the minor secondary channels on the left. The high flow channel on the right would be engaged during the 20 % AEP event and the wider floodplain would be inundated during the 5 % AEP storm.

Among the common phreatophytes found within Weeli Wolli Creek, only *Eucalyptus victrix* exists along this section of the creek. The extent of the 50 % AEP flood marks the occurrence of this species, indicating these trees would likely receive water from creek flows at a regular basis. Acacia species dominate the right-hand floodplain of the creek, with the type P3 found within the high flow channel; this vegetation type would be flooded during a 20 % AEP or greater storm. Type P4 vegetation occurs along the wider floodplain and would only receive water from the creek during larger events in excess of the 2 % AEP. Type H1 vegetation fringes the left-hand floodplain and extends towards the slope of the ridge. However, only the lower portion of this vegetation group will receive water from creek flows.

Cross section 5 (XS5)

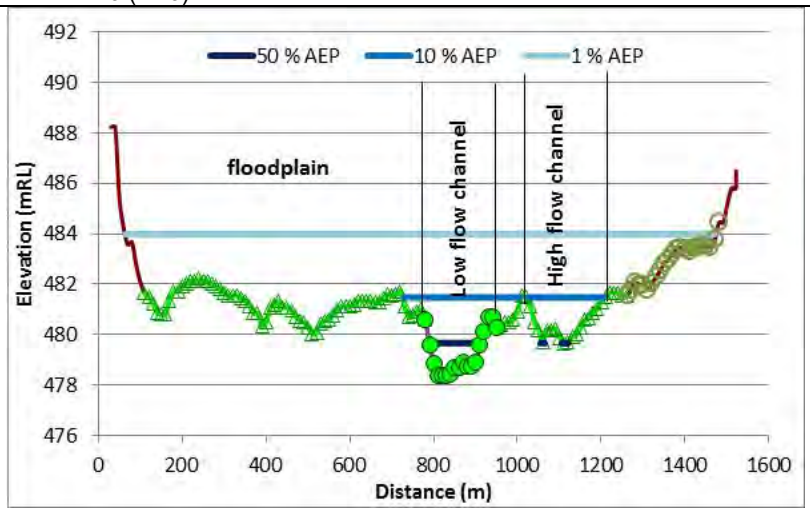


(P5) ○	*Eucalyptus leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia bivenosa, A. ancistrocarpa* open shrubland
(P6) ▲	*A. aptaneura* low open forest over *Eremophila forrestii* open shrubland
(P3) ◆	*A. pruinocarpa low open woodland over A. citrinoviridis, A. inaequilatera*
(C4) △	*E. victrix* open woodland over *A. citrinoviridis*
(C3) ■	*E. victrix* scattered trees over *A. citrinoviridis*

XS5 is located upstream of the Weeli Wolli and Marillana Creek intersection. The floodplain widens at this location with notable bifurcations activated by varying level of flows. Modelling results indicate that creek flows for more frequent events of 50 % AEP or smaller would confine within the low flow channel, while engagement of the high flow channels would occur during the 10 % AEP storm. Flood flows for events greater than the 2 % AEP would activate the wider floodplain at this location.

Once again, the frequency of flows dictates the types and occurrences of vegetation within the creek. Larger trees of *Eucalyptus victrix* are found in sections more frequently inundated; while Acacia species occur in abundance on the floodplain receiving water only occasionally from creek flows. Scattered trees of *E. leucophloia* and *E. gamophylla* in type P5 vegetation are found along the edges of the floodplain. This species will not receive water from the creek until the 2 % AEP flood.

Cross section 6 (XS6)



(C4) △	*Eucalyptus victrix* open woodland over *Acacia. citrinoviridis*
(C1) ●	*E. camaldulensis, E. victrix* woodland over *Melaleuca argentea*
(P5) ○	*E. leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *A. bivenosa, A. ancistrocarpa* open shrubland

XS6 illustrates the section of Weeli Wolli Creek immediately downstream of the confluence. This section is characterised by a braided, meandering creek system within a wide floodplain that stretches hundreds of metres across. Smaller flows of 50 % AEP or less would likely contain within the low flow channel but the 20 % AEP flood would activate the high flow channel on the right. Engagement of the floodplain to the left would occur in a 5 % AEP or greater event.

Riparian vegetation density increases substantially at and downstream of the confluence. Type C1 vegetation, which includes *Eucalyptus camaldulensis* and *Melaleuca argentea*, reappears at this location within the low flow channel and would likely sustain by creek flows at a regular basis. Woodland of *E. victrix* and *Acacia citrinoviridis* dominates the floodplain and these trees would be inundated during rarer events in excess of 5 % AEP.

8. Surface water infrastructure

Surface water infrastructures are required for the management of flood risks at Pocket and Billiard South. These include flood protection levees, local diversions and appropriate protection at road crossing along Weeli Wolli Creek. Locations and designs of these infrastructures are detailed as follow.

8.1 Weeli Wolli Creek flood protection

The Pocket and Billiard South deposits are positioned adjacent to and within Weeli Wolli Creek. Development of the deposits will encroach on the floodplain of the creek, and mining will be constrained by the natural flood extent unless mitigation measures are in place. It is proposed that flood levees be constructed along the deposits to prevent flooding from Weeli Wolli Creek. Two levee alignments are investigated: first the main levee, which offers protection for the Billiard South mine on the eastern side of the creek, its position maximises ore recovery but encroaches into the environmental restriction area within Weeli Wolli Creek, and second the pillar levee, which is located around the JSE mine in the east to allow expansion towards Weeli Wolli Creek. The proposed structures will be designed to accommodate the 0.5 % AEP flood level with a 0.5 m freeboard.

8.2 Weeli Wolli Creek crossing

A heavy vehicle road for Pocket and Billiard South is required to cross Weeli Wolli Creek in order to gain access to the services area as well as the processing plant within the existing Yandicoogina mine. The design of the road crossing is being carried out by MWH and Calibre, and it is proposed that the road be constructed as a floodway with culverts or bridge openings to accommodate low flows to a maximum of 125 m^3/s, while activation of the floodway will occur for all greater events (MWH, 2015). The proposed location and design of the floodway on the west bank require some minor excavations of the creek, upstream and downstream of the infrastructure, to prevent obstruction to flood flows. The current areas of excavation encroach into the Weeli Wolli Creek riparian zone but further work on the crossing will be carried out during the feasibility stage of the study to better determine the requirement for excavation and the area to be excavated.

Two crossing options have been investigated and they are summarised as follow:

- **Pipe culverts crossing** – this design positions eight 3.6 m diameter pipe culverts within the low flow channel and a floodway in the west to allow larger flows in excess of the capacity of the culverts to spill over the road. The crossing ties in with the Billiard South levee in the east and the pillar levee in the west..
- **Box culvert bridge crossing** – this design positions a 22 m wide, 3.6m tall box culvert bridge within the low flow channel. A floodway is located in the west to allow larger flows in excess of the bridge opening to spill over the road. The crossing ties in with the Billiard South levee in the east and the pillar levee in the west.

8.3 Local diversions

Deposits and associated mine infrastructure at Pocket and Billiard South are exposed to surface water runoff sourced from local catchments east of Weeli Wolli Creek. The ‘diversion’ surface water management is recommended to direct these runoffs away from

active areas of mining. Two diversion drains are proposed and each is designed to provide protection up to the 2 % AEP storm:

- **Southern diversion** is designed to capture runoff generated from local catchments above Pocket. Surface water flows from the drain will be diverted around Pocket and released into Weeli Wolli Creek, upstream of the operation.
- **Main diversion**, which runs parallel to the entire length of the Billiard South deposit, is designed to convey runoff sourced from the eastern catchments. Surface water flows captured by the drain will be discharged north back to Weeli Wolli Creek, downstream of the operation.

Unlike the flood levees and creek crossings, the diversions are not explicitly modelled in TUFLOW. However, surface water flows likely to be captured and discharged from the drains to Weeli Wolli Creek for each AEP event up to the 2 % AEP are modelled to represent the activation of the diversions by local runoff during a storm event.

9. Model results

Two operational TUFLOW models were developed to simulate the flow characteristics of Weeli Wolli Creek under the pipe culverts and box culvert bridge crossing options with the proposed Billiard South and pillar levee alignments. The position of the local diversions remained unchanged for both crossing options; hence the position of the outlets and the volume of local surface water runoff entering Weeli Wolli Creek remained the same for both models.

Operational flow conditions for the 50 to 0.5 % AEP design events were simulated and model results for the 50 %, 10 % and 1 % AEP storms are presented in this report to illustrate the low, medium and high flow situations in Weeli Wolli Creek during mining.

9.1 Peak flow rates and total flow volumes

Runoff hydrographs for each of the modelled AEP events were outputted at XS6, downstream of the operation, to determine the changes in flow rates and volumes through Weeli Wolli Creek under pre-development and operational catchment conditions. A comparison of the runoff hydrographs for the 50 %, 10 % and 1 % AEP storms are illustrated in Figure 16, Figure 17 and Figure 18, respectively.

Model results indicate minor increases in peak flow rates downstream of the operation during mining. Flood peaks are increased by no more than 16 % for all the modelled AEP events and the percentage difference in peaks decreases progressively with AEP, where less than 1 % change in flood peak is observed for the 0.5 % AEP storm. The increase in peak discharges, immediately downstream of the operation, could be resulted from the point source release of surface water from local diversion (North drain) to Weeli Wolli Creek. Surface water runoffs captured and transported by North drain will contribute quicker to Weeli Wolli Creek at XS6 than what can be expected under existing conditions, thus temporarily raising the flood peak at this location. However, as the magnitude of the storm/flood event increases, the influence of runoff contributing from the diversion decreases in comparison to surface water flows contributing from Weeli Wolli Creek, hence the impact to the overall flood regime, downstream of the operation, diminishes with AEP.

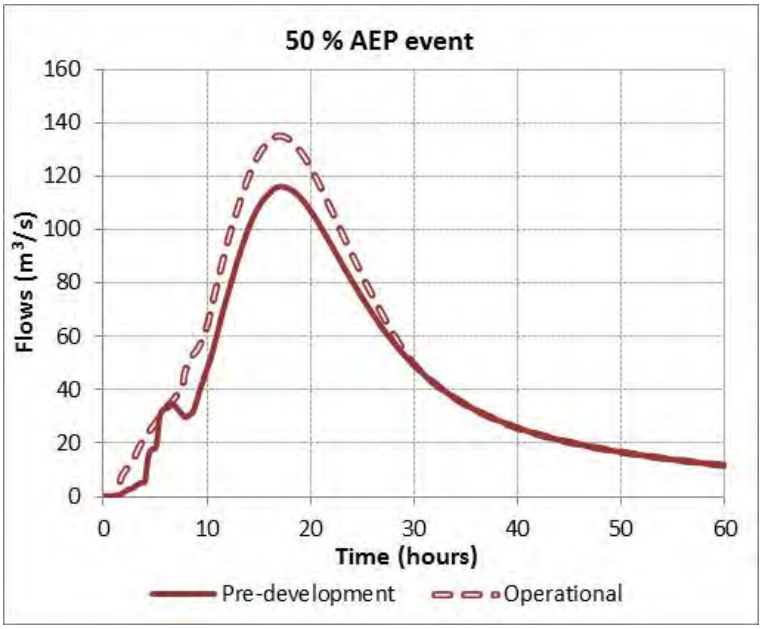


Figure 16: A comparison of the runoff hydrographs for the 50 % AEP event under pre-development and operational catchment conditions.

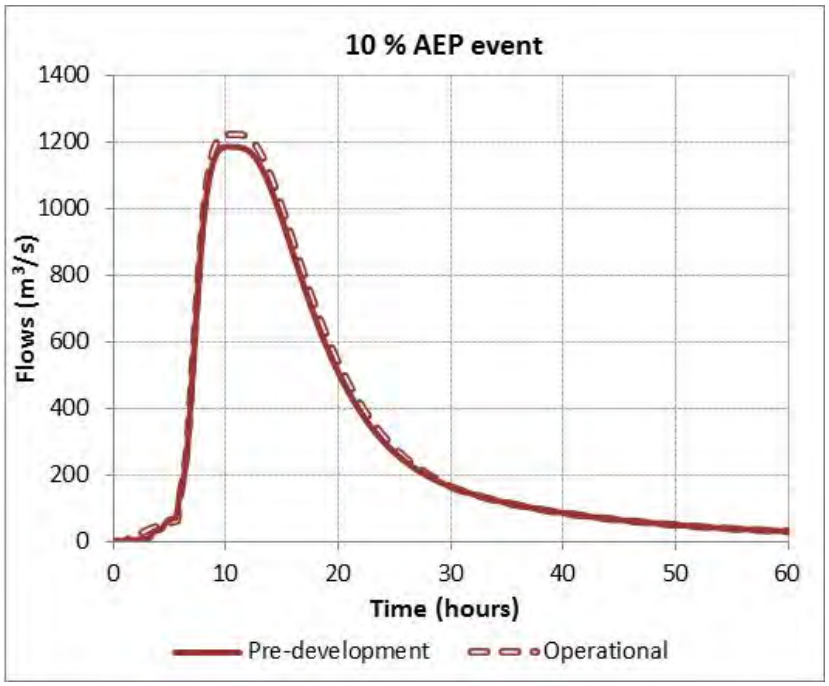

Figure 17: A comparison of the runoff hydrographs for the 10 % AEP event under pre-development and operational catchment conditions.

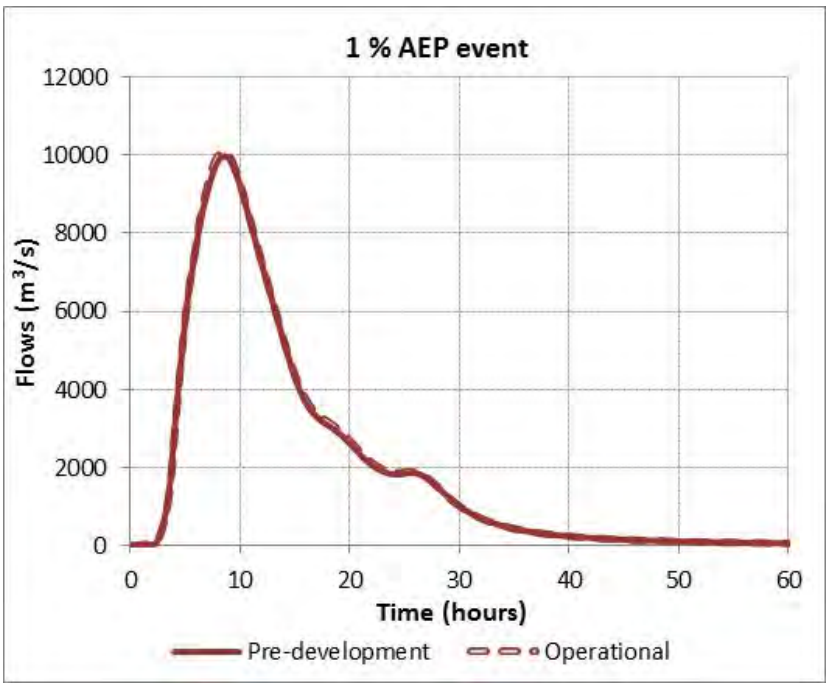

Figure 18: A comparison of the runoff hydrographs for the 1 % AEP event under pre-development and operational catchment conditions.

9.2 Flood levels and extents

Changes to the flood level and extent are to be expected due to flow constrictions and re-directions proposed by the levees and/or crossings along Weeli Wolli Creek. This modification to the flood regime may affect riparian vegetation, whose existence is likely linked to surface flooding characteristics and the frequency of over bank flow conditions during flood events. Increase or decrease in flood level will result in more or less water being available for flood dependent regeneration of riparian ecosystems and may over time alter the creek ecology and potentially the biodiversity of riparian environments. The degree and extent of change to the flood regime, and the associated impact on the riparian vegetation were assessed by comparing the flood elevations and extents for the 50 %, 10 % and 1 % AEP storms under pre-development and operational catchment conditions. Model results are presented in the form of flood difference maps and are plotted in XS1 to XS6 to illustrate the change in flood levels and the subsequent influence on riparian vegetation at selected locations along Weeli Wolli Creek.

TUFLOW simulations were carried out to determine the potential flood regime change along Weeli Wolli Creek under the pipe culverts and the box culvert bridge crossings with the Billiard South and pillar levees in place. A comparison of the model results (Appendix A) indicates minimal changes in flow regime for the two crossing designs, where less than ± 1 % change in flood level is observed at the selected cross sections (XS1 to XS6) along Weeli Wolli Creek. This suggests the two crossings behave or function similarly during a flood and therefore have similar influence on the flow regime of Weeli Wolli Creek during mining. For this reason, only results for the pipe culverts crossing are presented below.

Model results (maximum flood depths and flood depth differences) for the 50 %, 10 % and 1 % AEP storms are illustrated in Figure 21, Figure 22 and Figure 23, respectively. The flood difference maps identify changes in water elevations between the existing and developed catchment conditions. The differences are presented in three shades of

colour: the yellow shade indicates less than ± 0.25 m change in flood level; the orange shade indicates an increase in flood level (> 0.25 m increase); and the green shade shows a decrease (> 0.25 m decrease).

As shown in Figure 21, surface water flows along Weeli Wolli Creek during the 50 % AEP event do not interact with the levee hence disturbance to the regime for low flows is likely to be small during operation. However, a minor increase in water level is observed in vicinity of the crossing due to flow constrictions through the culverts causing flood level to rise temporarily near the infrastructure. A more significant change in flow regime is triggered not by disruption to surface water flows along Weeli Wolli Creek but by modification to local runoff from the eastern catchments causing water level to decrease or increase along the creek. A reduction in flood level is observed along the creek section between XS3 and XS4 due to re-direction of the local runoff upstream and downstream of the operation, terminating surface water flows that would naturally activate the high flow channel during the 50 % AEP event. Conversely, all surface water runoffs contributing to Billiard South are captured by the main diversion and released into Weeli Wolli Creek at XS6. This resulted in an increase in flood peak (as described in Section 9.1), which translated to an increase in flood level as shown in Figure 21. However, these impacts are likely to decrease with AEP when the influence of flows contributing from Weeli Wolli Creek exceeds those from the eastern catchments.

The 10 % AEP event (Figure 22), which has a flood peak of approximately 490 m^3/s at Billiard South, generates flows that exceed the capacity of the culverts and therefore activate the floodway of the road crossing. As expected, the greatest change in flow regime occurs in vicinity of the crossing where significant impoundment of flows is observed immediately upstream of the road. Water elevation is raised by approximately 1 m above the pre-development level and the effects of backwater propagated 300 m upstream due to flow constriction caused by the levee as well as the crossing where conveyance is restricted to the small opening through the culverts and the floodway in the west (Figure 19). Conversely, water level is reduced by more than 0.25 m along a short section of the creek between XS3 and XS4, possibly due to termination of runoff from the east but also a result of flow obstruction caused by the crossing further upstream. Again, water level is shown to increase immediately downstream of the main diversion where majority of the captured runoffs are released.

As the magnitude of the flood event increases, the impact proposed by the infrastructures also increases due to greater obstruction and constriction of flows through the creek. Significant flood level change is observed along the creek between XS2 and XS4 (approximately 4 km in length) during the 1 % AEP flood (Figure 23). The road crossing is completely submerged during this event and water level in vicinity of the crossing is increased by 3 m above the pre-development level, with the effects of backwater propagated approximately 2 km upstream (Figure *20*). Constriction of the floodplain caused by the levee also raises the water level, and at the same time pushes the flood extent further to the west. However, it is important to note that the extent of impact is restricted to the creek section between XS2 and XS4 and does not propagate beyond, where the change in depth is less than 0.25 m and therefore negligible. Model results suggest a decrease in water level at the outlet of main diversion drain. This is because the diversion is designed to accommodate up to the 2 % AEP storm hence any flows in excess of the design event will likely spill into the pit and not be diverted to Weeli Wolli Creek, thus causes a localised decrease in water level during the 1 % AEP storm.

Based on the modelling results, it can be seen that flood regime change caused by infrastructures, whether during events of high, medium or low magnitudes, is confined to the creek section adjacent to the proposed mine. Beyond the area of influence, modifications to flood levels and extents along the creek are likely to be small. The effects on riparian vegetation as a result of flood level change are illustrated in Table 6.

.

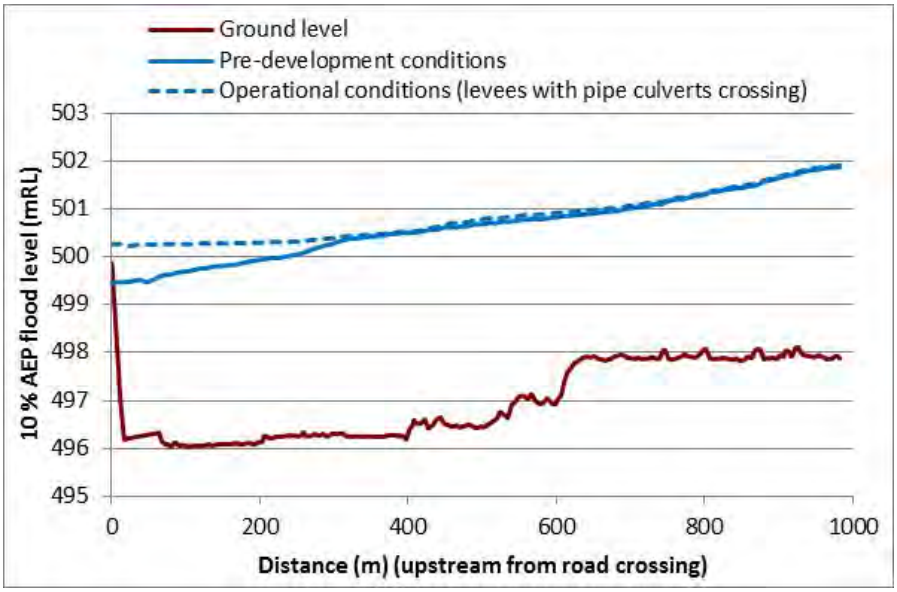

Figure 19: A comparison of the flood level for the 10 % AEP event, immediately upstream of the creek crossing, under pre-development and operational catchment conditions.

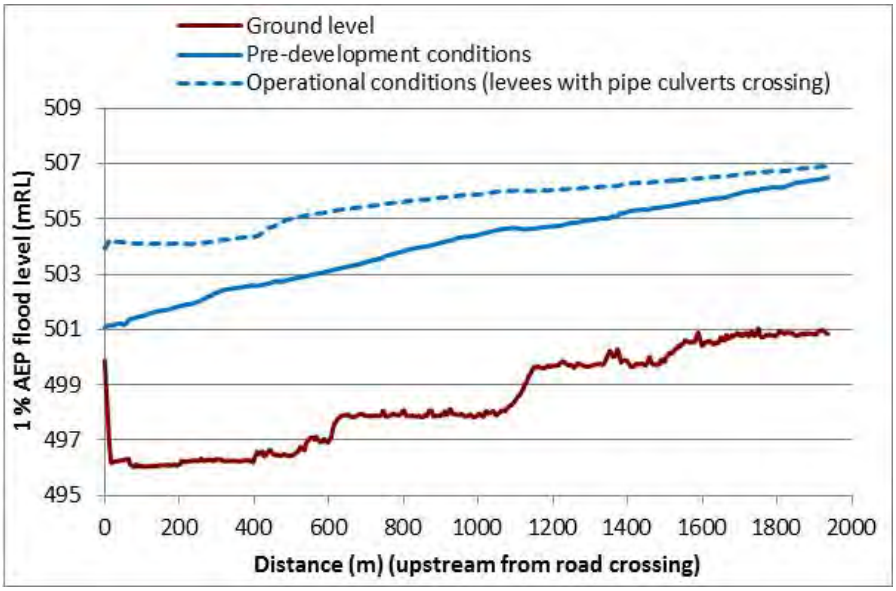

Figure 20: A comparison of the flood level for the 1 % AEP event, immediately upstream of the creek crossing, under pre-development and operational catchment conditions.

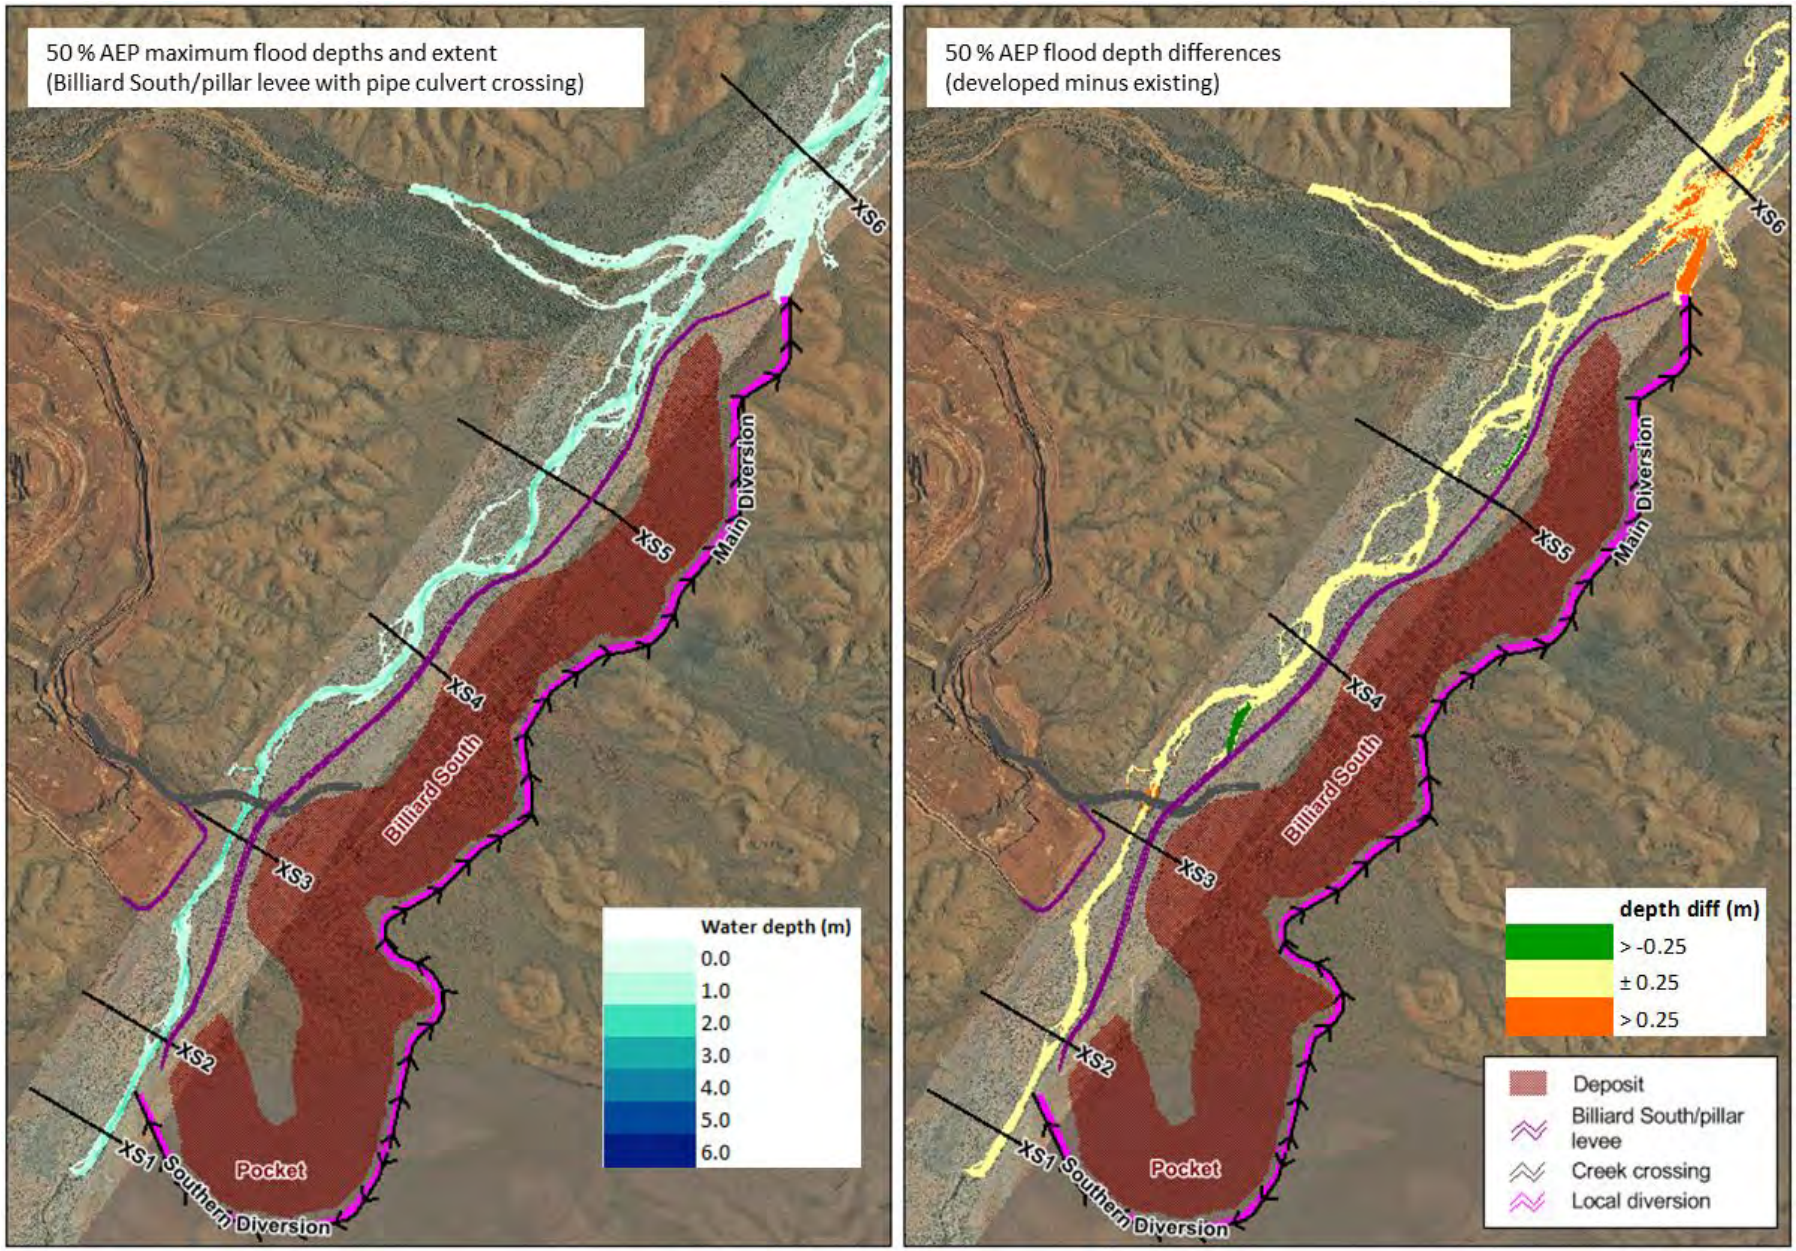

Figure 21: Maximum flood depths and flood depth differences for the 50 % AEP event.

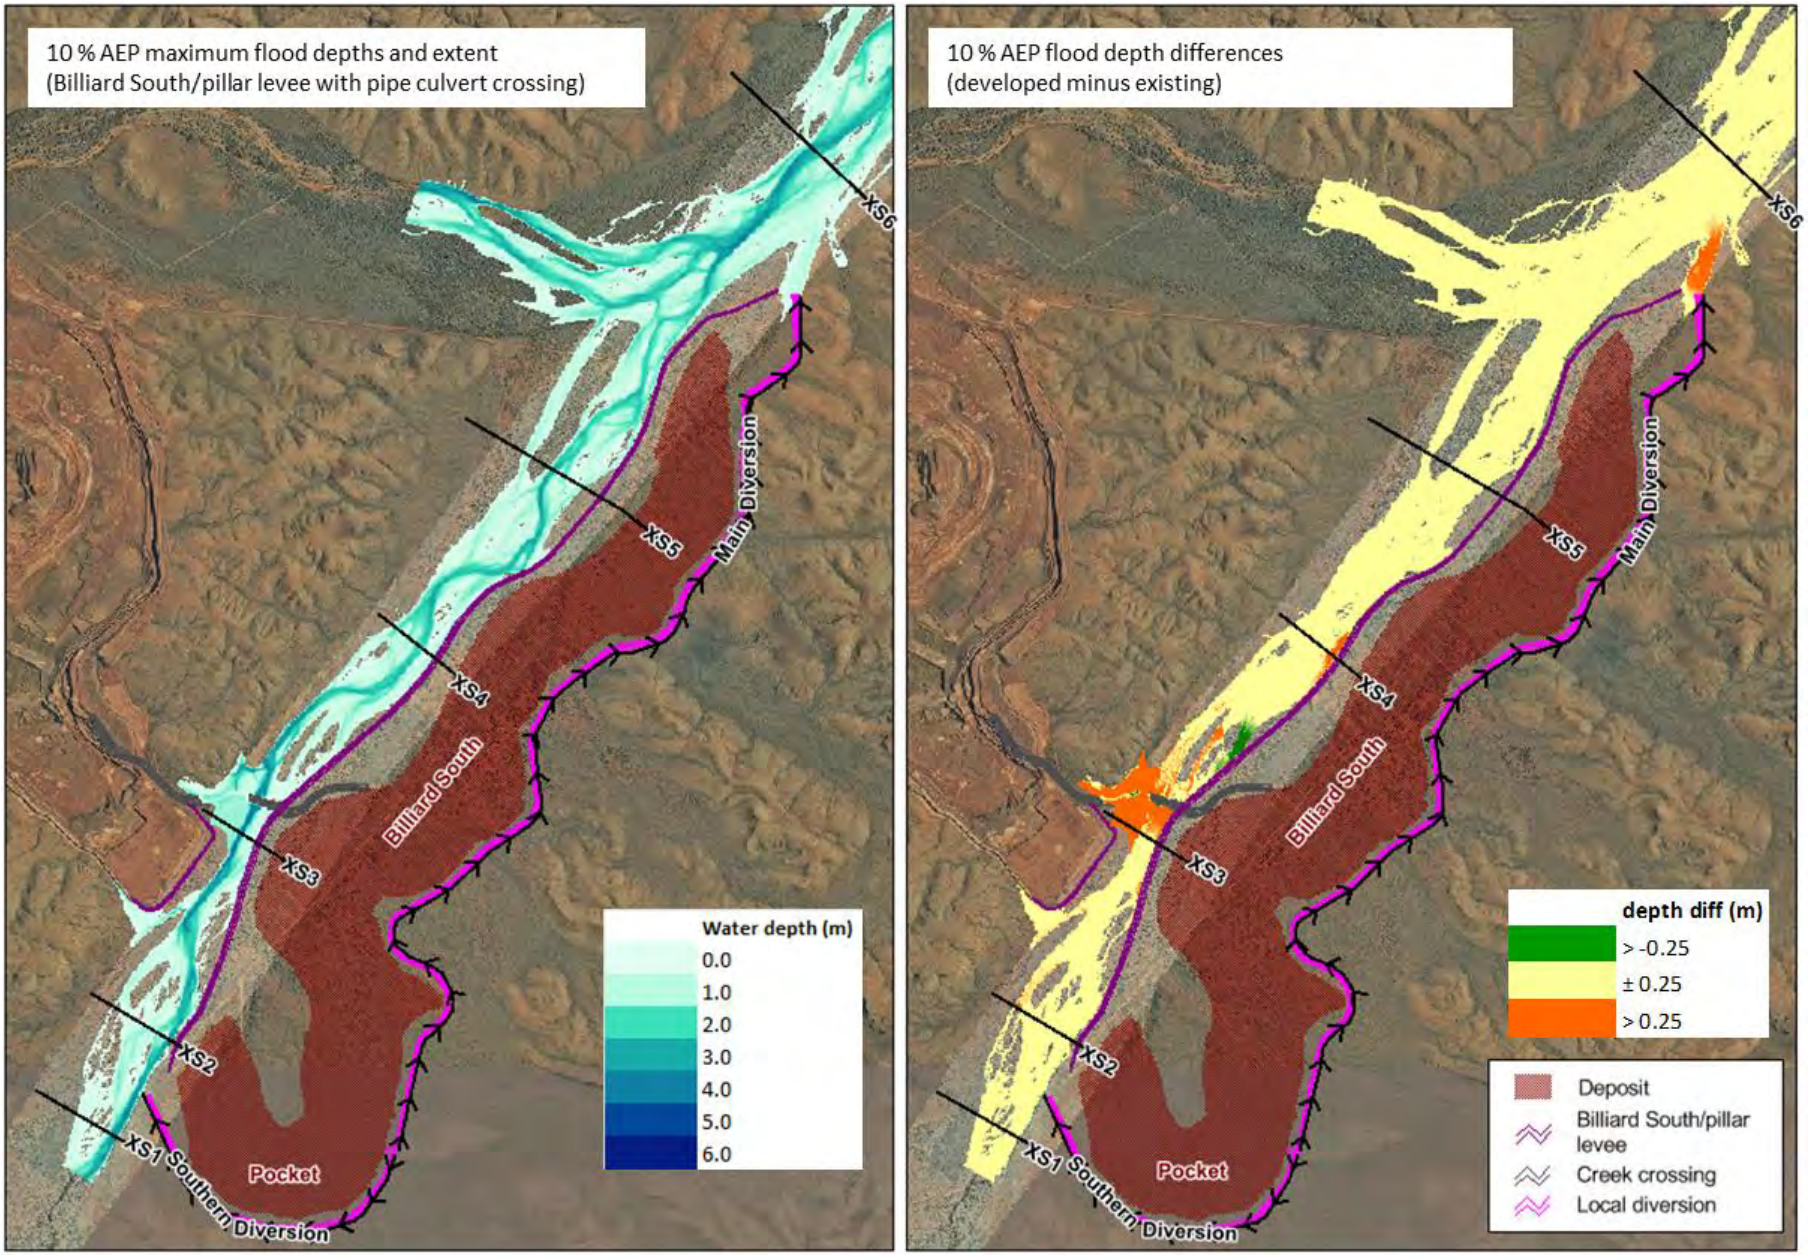

Figure 22: Maximum flood depths and flood depth differences for the 10 % AEP event.

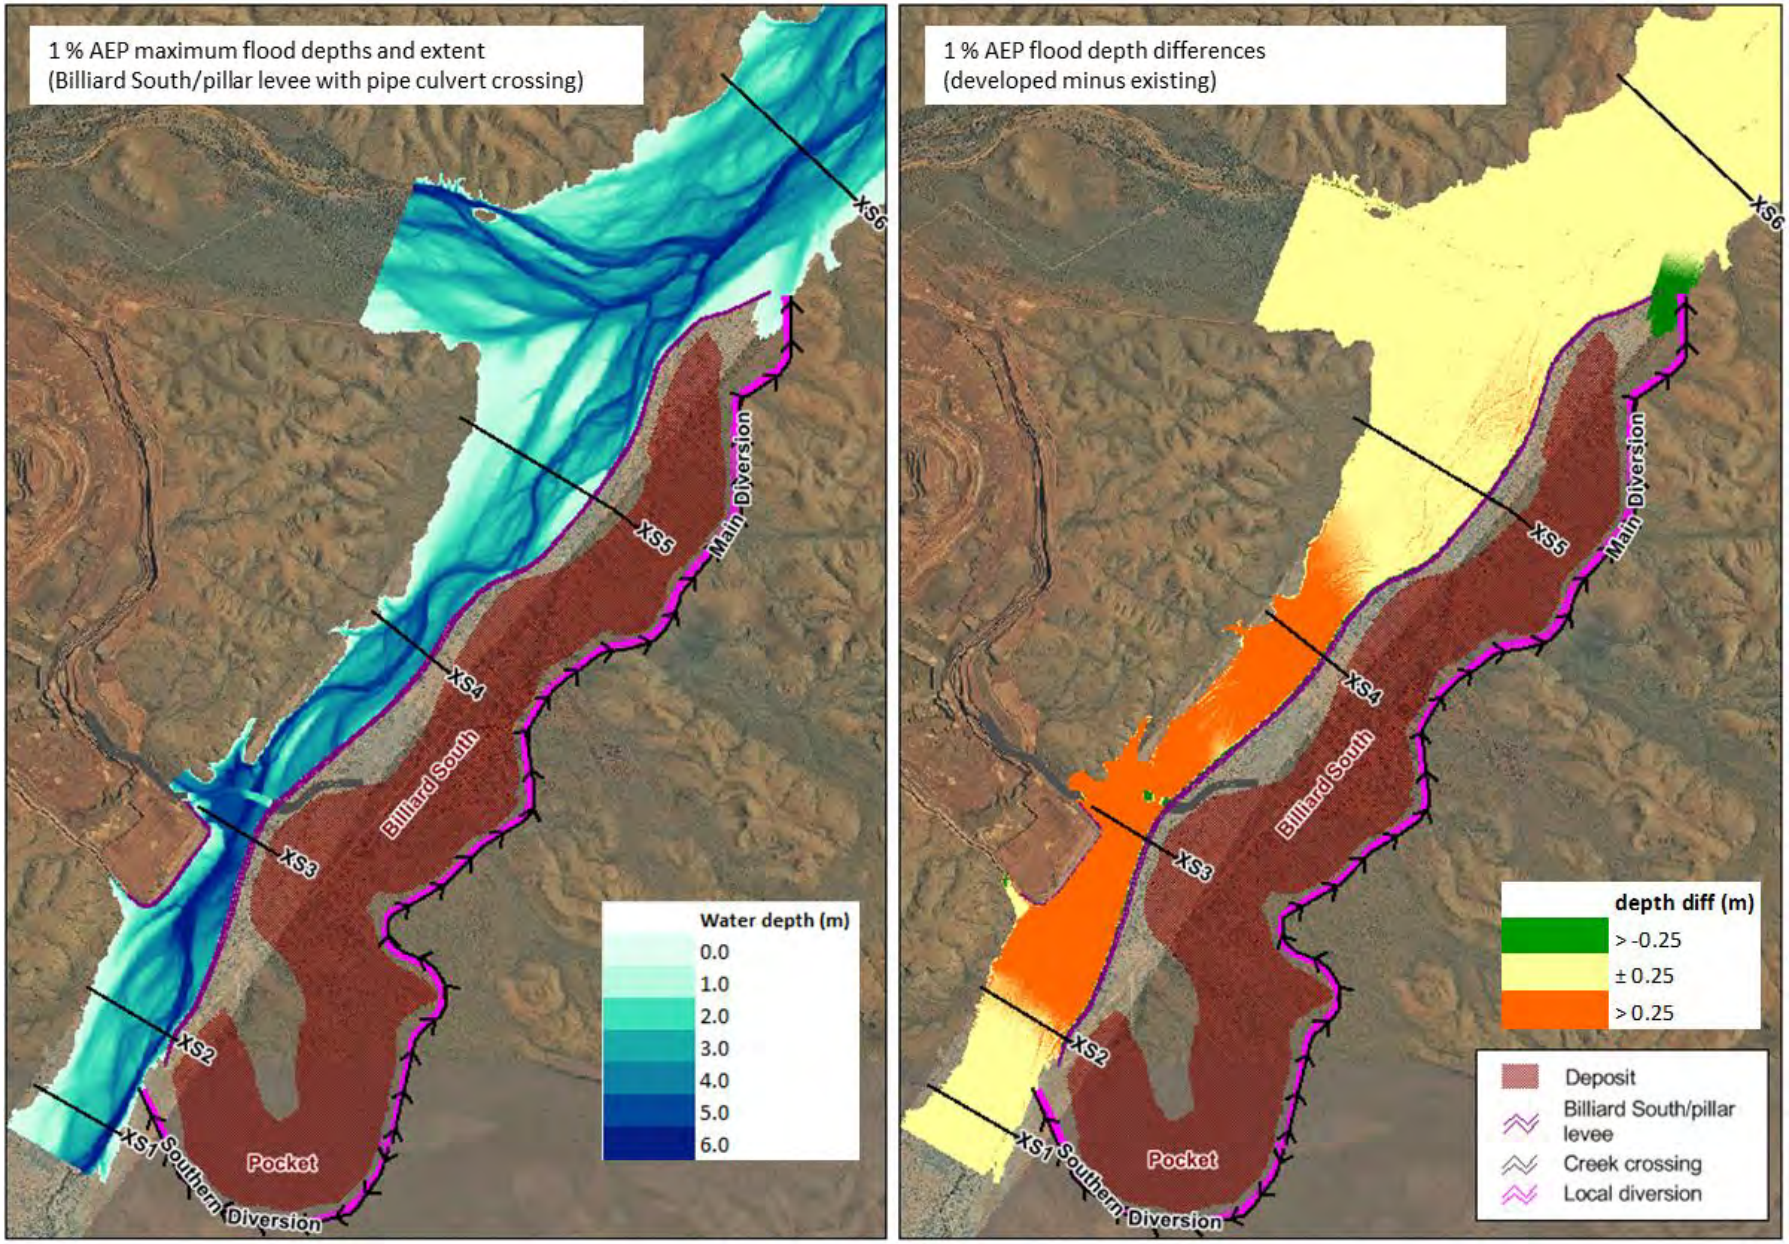

Figure 23: Maximum flood depths and flood depth differences for the 1 % AEP event.

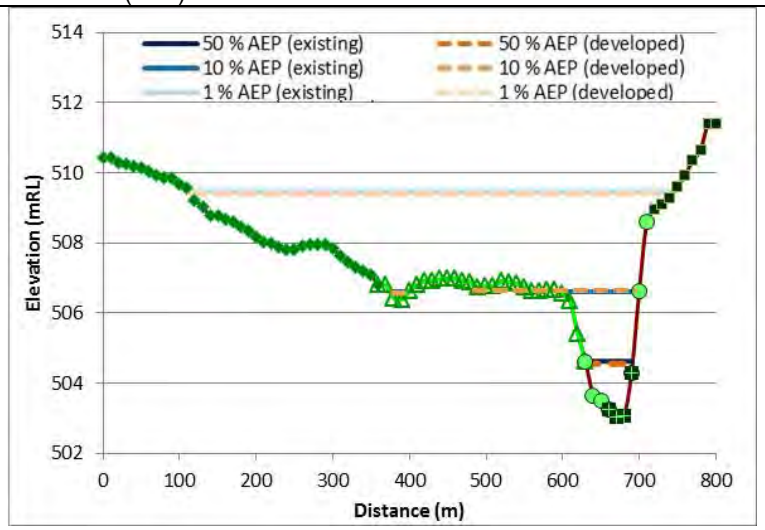
Table 6: Chosen cross section locations along Weeli Wolli Creek showing typical riparian vegetation and flood level differences for the 50 %, 10 % and 1 % AEP events between the existing and developed catchment conditions.

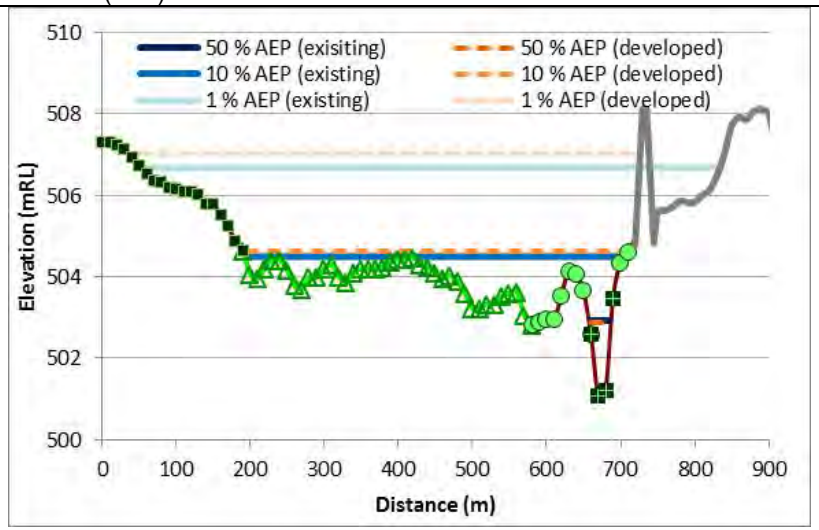
Cross section 1 (XS1)



(F2)	*Acacia pruinocarpa, A. citrinoviridis* tall open shrubland
(C4)	*Eucalyptus victrix* open woodland over *A. citrinoviridis*
(C1)	*E. camaldulensis, E. victrix* woodland over *Melaleuca argentea*
(C3)	*E. victrix* scattered trees over *A. citrinoviridis*
(P4)	*A. pruinocarpa low open woodland over Triodia wiseana* open hummock grassland

A comparison of the flood elevations for the 50 %, 10 % and 1 % AEP events under existing and developed catchment conditions indicates flood regime change at XS1 is negligible. Flood level is altered by no more than 10 cm, for both the pipe culverts and box culvert bridge crossings, at this location post-development. This suggests the flooding characteristics and flood water supply for riparian vegetation along this section of the creek will likely remain unchanged during operation.

Cross section 2 (XS2)



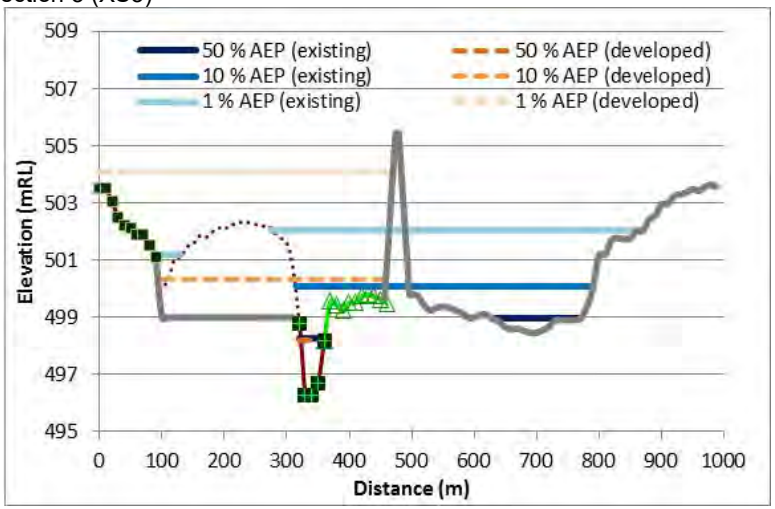
(C4)	*Eucalyptus victrix* open woodland over *A. citrinoviridis*
(C1)	*E. camaldulensis, E. victrix* woodland over *Melaleuca argentea*
(C3)	*E. victrix* scattered trees over *A. citrinoviridis*
(P4)	*A. pruinocarpa low open woodland over Triodia wiseana* open hummock grassland
	Potential disturbed areas

XS2 identifies the upstream end of the Billiard South levee, which alignment, as shown in grey in the cross section, is positioned on the right-hand bank of the creek.

Hydraulic modelling indicates the 50 % AEP flow along the low flow channel of the creek will remain more or less unchanged under this option thus creek water supply for the type C3 vegetation, which occurs along the low flow channel, will likely be unaffected during mining. A minor increase in water level is observed for the 10 % AEP event but changes, based on the model results, are less than 4 % for both crossing options and therefore unlikely to cause significant impacts on riparian vegetation, in particular the type C4 species, at this location. It is expected that the woodland of *E. victrix* on the left floodplain be flooded during the 10 % AEP event under natural conditions; this flooding regime will likely remain unchanged post-development.

A greater change in flood regime is observed for the 1 % AEP event, where the developed water level is raised 0.3 to 0.4 m higher than the pre-development level. This may result in more of the type P4 vegetation being inundated during this event.

Cross section 3 (XS3)



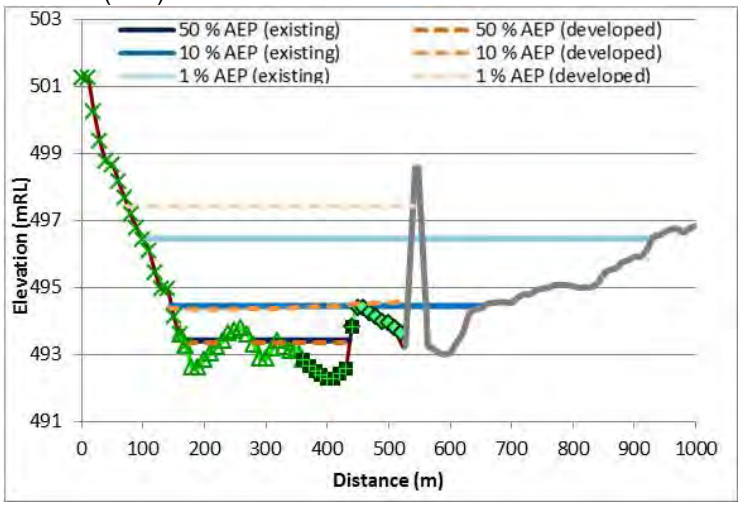
(P4)	*A. pruinocarpa low open woodland over Triodia wiseana* open hummock grassland
(C3)	*E. victrix* scattered trees over *A. citrinoviridis*
(C4)	*E. victrix* open woodland over *A. citrinoviridis*
	Potential disturbed areas

XS3 marked the location where the creek will be most significantly affected during mining. Potential disturbed areas, as identified in grey in the cross section, include the levee and the pit beyond in the east and the excavated area immediately upstream of the crossing in the west. The floodplain is also most constricted at this location, whereby the area of conveyance is reduced by half under this levee option.

Low flow conditions along the creek will likely be unaffected during mining under this option hence water supply by creek flows for riparian vegetation that occurs within or aligns the bank of the low flow channel will remain unchanged post-development.

Model results suggest small increase in flood level (less than 0.25 m) for the 10 % AEP event while flood elevation is raised by more than 2 m during the 1 % AEP storm for both the pipe culverts and box culvert bridge crossing options. This is a result of severe flow constriction and obstruction caused by the levee and road crossing immediately downstream. Consequently, all the type P4 vegetation that fringes the left-hand floodplain will be inundated during the 1 % AEP event instead of the 0.5 % AEP flood during operation.

Cross section 4 (XS4)



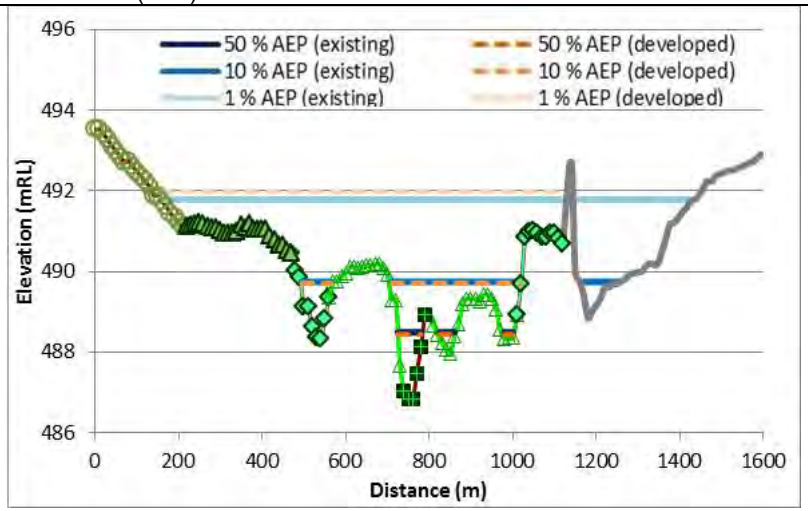
(H1)	*Eucalyptus leucophloia* scattered low trees over *Hakea chordophylla*, *Acacia inaequilatera*
(C4)	*E. victrix* open woodland over *A. citrinoviridis*
(C3)	*E. victrix* scattered trees over *A. citrinoviridis*
(P3)	*A. pruinocarpa low open woodland over A. citrinoviridis, A. inaequilatera*
	Potential disturbed areas

Similarly the greyed out area in XS4 illustrates the position of the proposed levee and pit on the eastern floodplain of the creek.

As shown in the plot above, the levee does not interfere with the 50 % AEP flood extent hence regime change for these smaller events is likely to be minimal during operation. Similarly, model results indicate impacts to flows for the 10 % AEP event is small. This suggests vegetation species (mainly type C3 and C4) that would normally receive water from creek flows during these events pre-development will likely be unaffected under developed conditions.

Flood level is shown to increase by approximately 1 m at this location during the 1 % AEP storm, which exceeds the pre-development flood level for the 0.5 % AEP event. As shown above, the 1 % AEP flood extent is extended further to the west, causing vegetation that will only receive water during rarer events of 0.5 % AEP or greater pre-development be flooded during the 1 % AEP storm under developed conditions.

Cross section 5 (XS5)

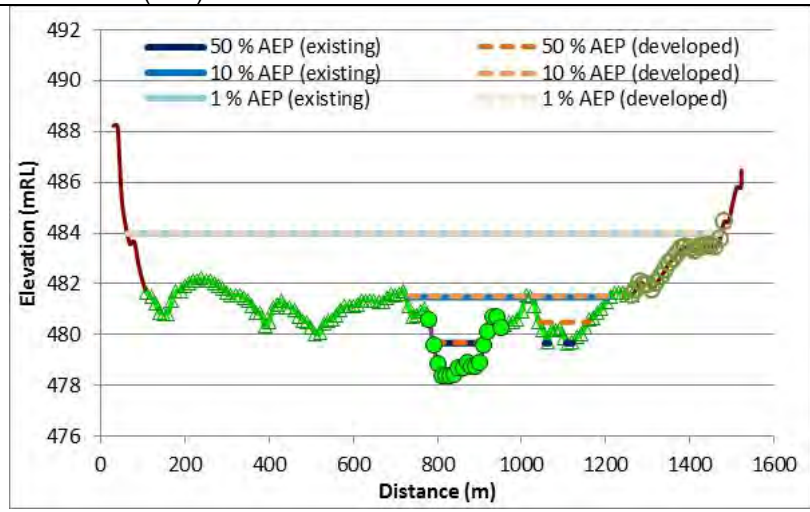


(P5) ○	*Eucalyptus leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia bivenosa, A. ancistrocarpa* open shrubland
(P6) △	*A. aptaneura* low open forest over *Eremophila forrestii* open shrubland
(P3) ◇	*A. pruinocarpa low open woodland over A. citrinoviridis, A. inaequilatera*
(C4) △	*E. victrix* open woodland over *A. citrinoviridis*
(C3) ▦	*E. victrix* scattered trees over *A. citrinoviridis*
∿	Potential disturbed areas

Similar to XS4, the levee at this location does not interact with the 50 % AEP flood along Weeli Wolli Creek hence changes to flow characteristics for these smaller events are likely to be small during mining. Flood level change for the 10 % AEP event is also negligible, where water level is altered by no more than several centimetres for both the pipe culverts and box culvert bridge crossing options. This suggests the flooding characteristics and creek water supply for riparian vegetation at this location will likely remain unchanged post-development during events of low and medium magnitudes.

Model results indicate a minor increase in flood level, approximately 0.2 m, for the 1 % AEP event under developed conditions. This may result in a greater portion of the type P5 vegetation being inundated during this event, but impacts, as shown in the plot above, are likely to be minor.

Cross section 6 (XS6)



(C4) △	*Eucalyptus victrix* open woodland over *Acacia. citrinoviridis*
(C1) ●	*E. camaldulensis, E. victrix* woodland over *Melaleuca argentea*
(P5) ○	*E. leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *A. bivenosa, A. ancistrocarpa* open shrubland

XS6 illustrates the section of Weeli Wolli Creek immediately downstream of the operation. Hydraulic modelling indicates flood regime change caused by the proposed surface water infrastructures along Weeli Wolli Creek is unlikely to propagate downstream beyond the vicinity of the operation. However surface water runoff contributing to the high flow channel in the east may increase during smaller events of 50 % AEP or less due to increased contribution of runoff from the main diversion, temporarily raising the water level at this location. This means a larger extent of the C4 vegetation on the floodplain will be inundated during low flows if the diversion is activated by local catchment runoff from the east. However, changes to the flood regime is expected to decrease with AEP when the high flow channel is activated by Weeli Wolli Creek and when the influence of creek flows exceeds that of runoff contributing from the drain.

Based on the model results, it can be seen that the overall impacts on the flooding regime and creek water supply for riparian vegetation at XS6 and beyond are small during operation.

9.3 Flow velocities

Modifications to flow velocities are also a consequence of flow constrictions and obstructions caused by the levees and/or crossings along Weeli Wolli Creek. This change to the regime may affect the geomorphological conditions of the creek by increasing the erosion potential of sections where velocity increases or encouraging sediment deposition where ponding occurs and velocity drops. This shift in velocity distribution may also alter areas of vegetation growth where sections of increased velocity may experience increased vegetation loss while ponding areas, in particular behind the road crossing, may become suitable habitat for tree growth.

The degree and extent of change to the flow velocity were assessed by comparing the velocity distribution during the 50 %, 10 % and 1 % AEP floods under pre-development and operational catchment conditions. Model results are presented in the form of velocity difference maps, which illustrate the changes in three shades of colour: the yellow shade indicates less than ± 0.5 m/s change in velocity; the red shade indicates an increase in velocity (> 0.5 m/s increase); and the blue shade shows a decrease (> 0.5 m/s decrease). If changes are within 0.5 m/s, there are unlikely significant changes to the mobilisation of sediments specific to that velocity range (Table 4). However, if changes are more than ± 0.5 m/s, there is the potential for an increase or decrease in sediment mobilisation, which signifies a more noticeable change in geomorphological characteristics of the creek.

Model results (maximum velocity distribution and velocity differences) for the 50 %, 10 % and 1 % AEP storms are illustrated in Figure 24, Figure 25 and Figure 26.

As shown in Figure 24, changes to velocity along the main channel of Weeli Wolli Creek are minimal during the 50 % AEP event. Maximum velocity remained at approximately 2 m/s, the pre-development level for the same event. However, velocity is shown to decrease between XS3 and XS4 along the high flow channel due to termination of runoff from the east while increases at XS6 as a result of increased contribution of runoff from the main diversion. Flows exiting the diversion drain will have higher velocities than natural, but, based on the model results, not exceeding 1.5 m/s for the 50 % AEP event hence unlikely to cause significant erosion or scour along the creek bed. It is important to note that velocities at the outlets of the diversions will increase with AEP thus energy dissipation structures are required to minimise scour along the creek immediately downstream. Overall, it can be concluded that the flood infrastructures have minor impacts on the velocity distribution and subsequently the sediment conditions along Weeli Wolli Creek during events of low flows.

For the 10 % AEP event (Figure 25), notable changes are observed around the creek crossing where velocities are increased over the floodway and decreased when ponding occurs upstream of the road embankment. These changes are to be expected as the road disrupts surface water flows along the creek and potential changes to the existing geomorphological regime may occur in vicinity of the crossing. However, based on the model results, these changes are localised and unlikely to extend 1 km upstream and downstream of the road, thus impacts to the wider creek area are likely to be small. Velocity is shown to increase, against the levee, immediately downstream of XS4 where the floodplain is most constricted. This area will experience increased erosion during a flood and the impacted area will expand as the magnitude of the storm increases.

Severe changes to the flow velocities and as a result the geomorphological characteristics of the creek can be observed upstream and downstream of the creek crossing during the 1 % AEP flood (Figure 26). The impact zone, as shown in the difference map, extends approximately 1.7 km upstream and 850 m downstream of the road. Velocities generally increase as a result of flow constriction and obstruction caused by the levee and crossing but the critical location is along the low flow channel adjacent to the outcrop where velocity approaches 6 m/s. If a flood event of this magnitude occurs, the morphology of the creek will change along this section if no management is in place to control the velocities. Furthermore, some heavy rock armouring will be required along the road crossing to minimise the risk of failure, which would result in a severe consequence to the riverine environment of Weeli Wolli Creek. Velocity is shown to increase across the whole breadth of the creek, downstream of XS4. Pre-development flow velocity ranges from 2 to 3 m/s along this section of the creek, which is increased to 3 to 4 m/s under developed conditions. Increased erosion and scour is expected along this section, which may result in higher vegetation loss during events of this magnitude.

Overall, significant changes to flow velocities and sediment conditions along the creek are confined to section adjacent to the operation. However, appropriate erosion protections around major infrastructures are required to minimise long term impacts on the morphology and sediment characteristics of the creek.

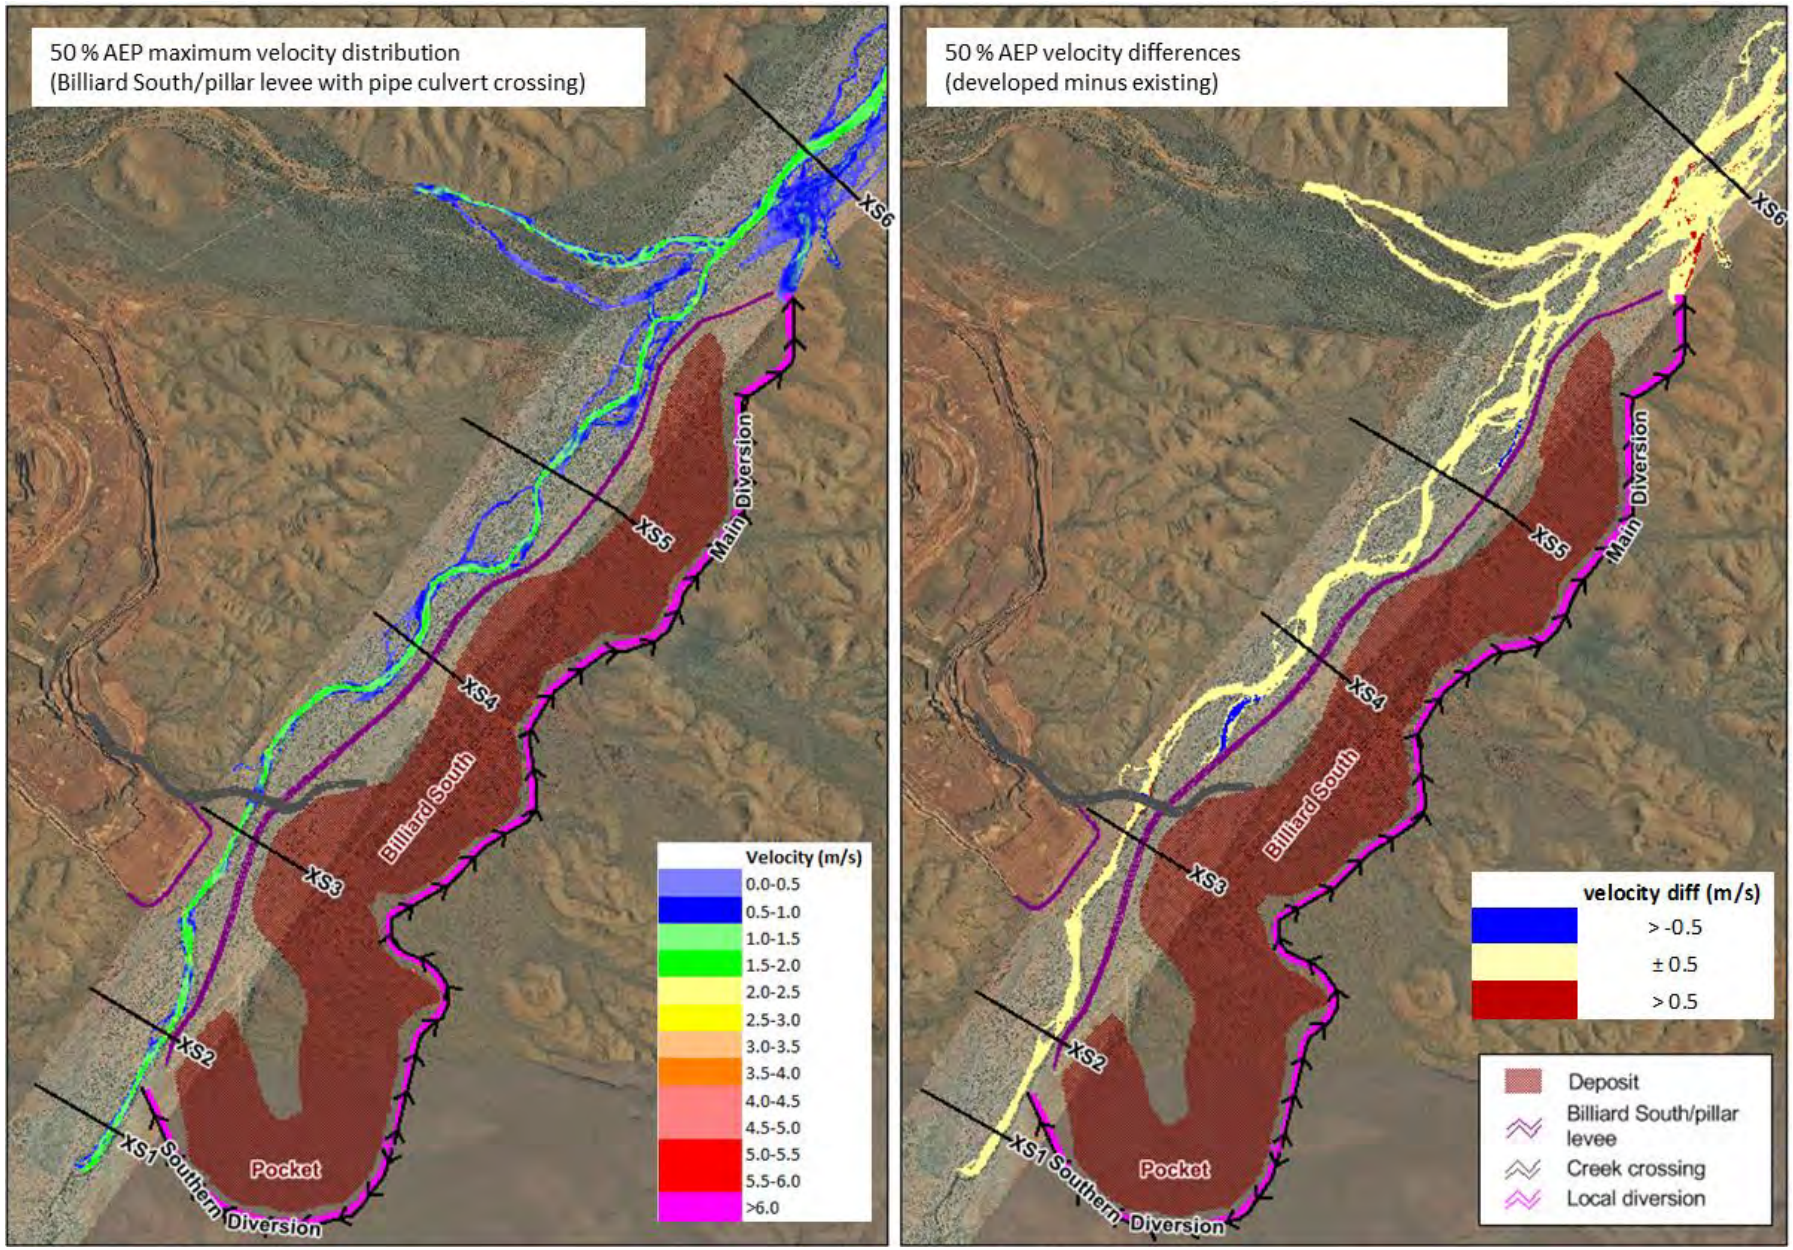


Figure 24: Maximum velocity distribution and velocity differences for the 50 % AEP event.

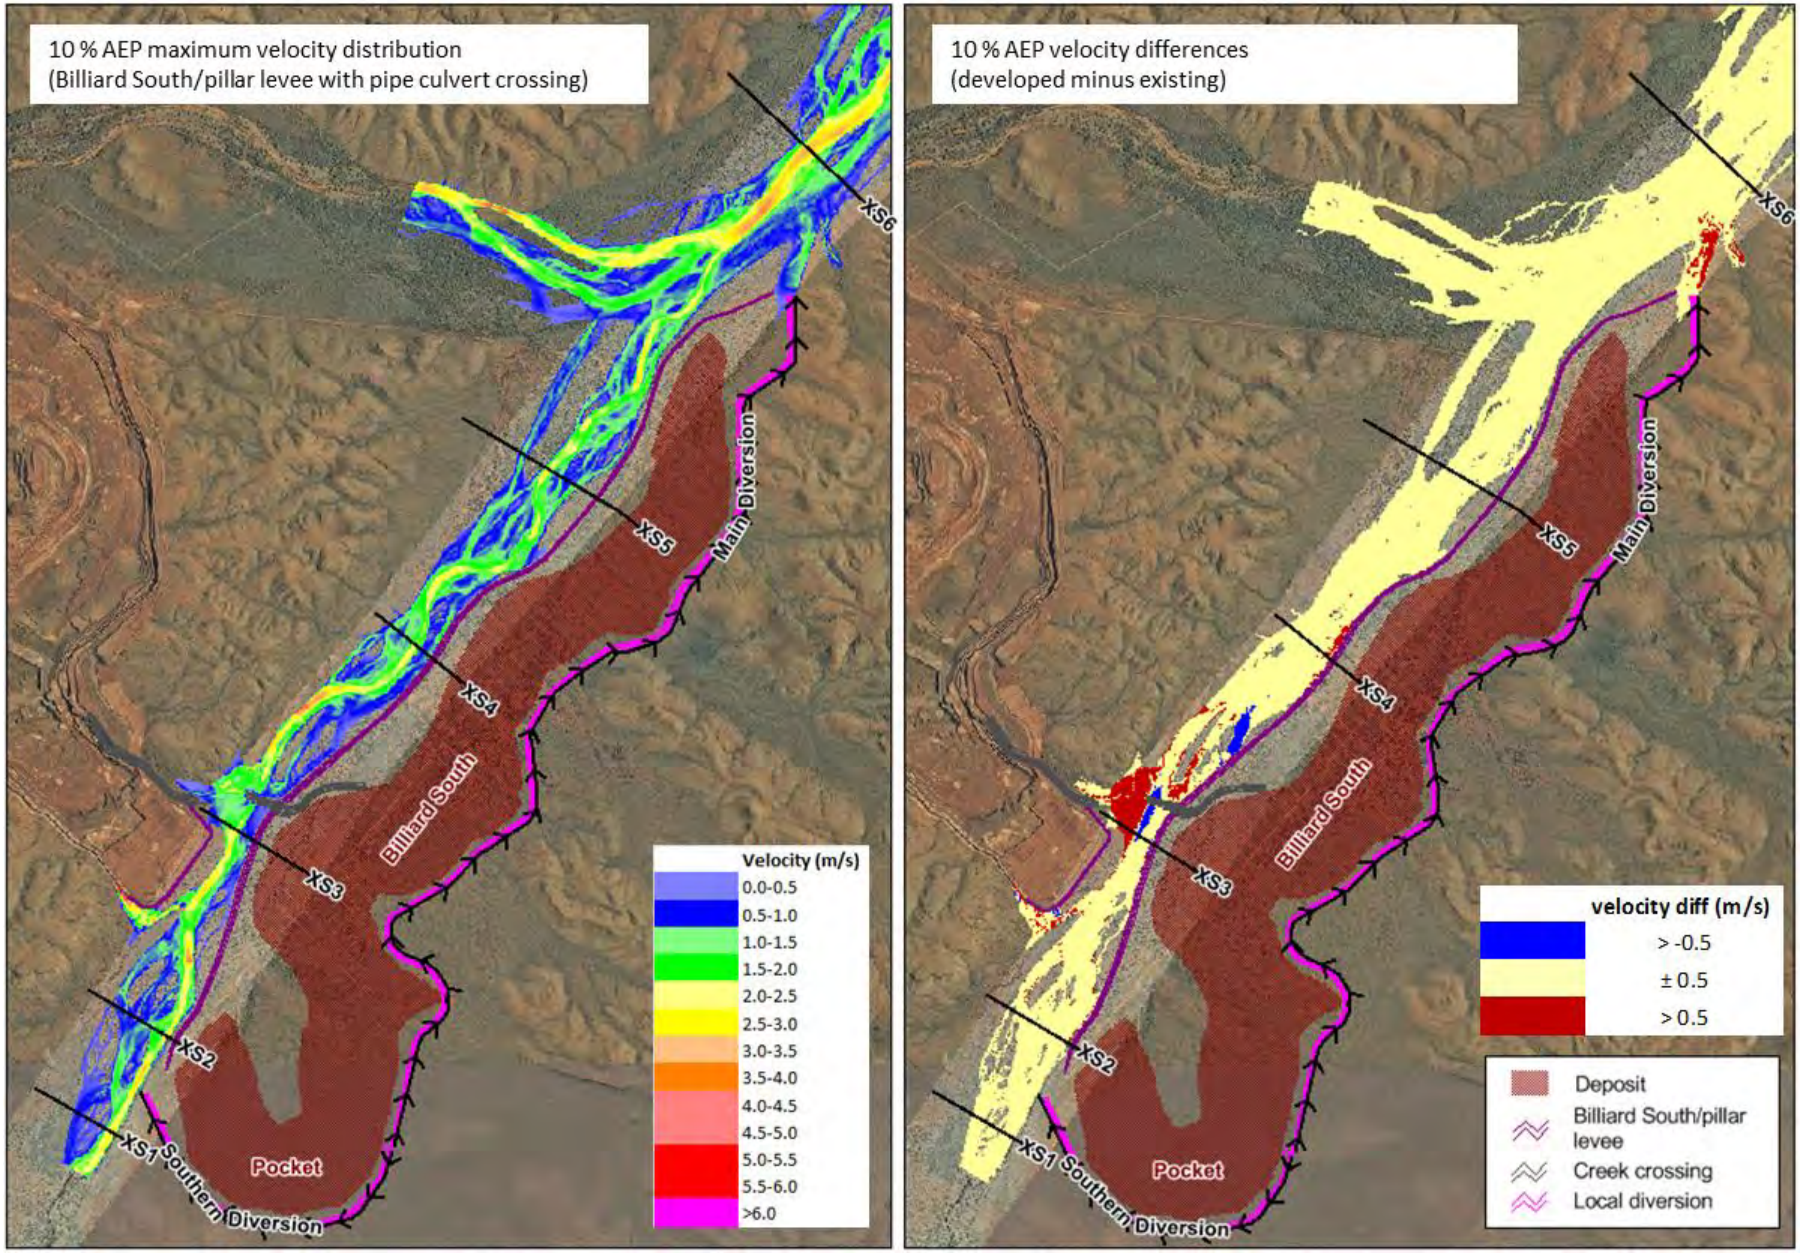

Figure 25: Maximum velocity distribution and velocity differences for the 10 % AEP event.

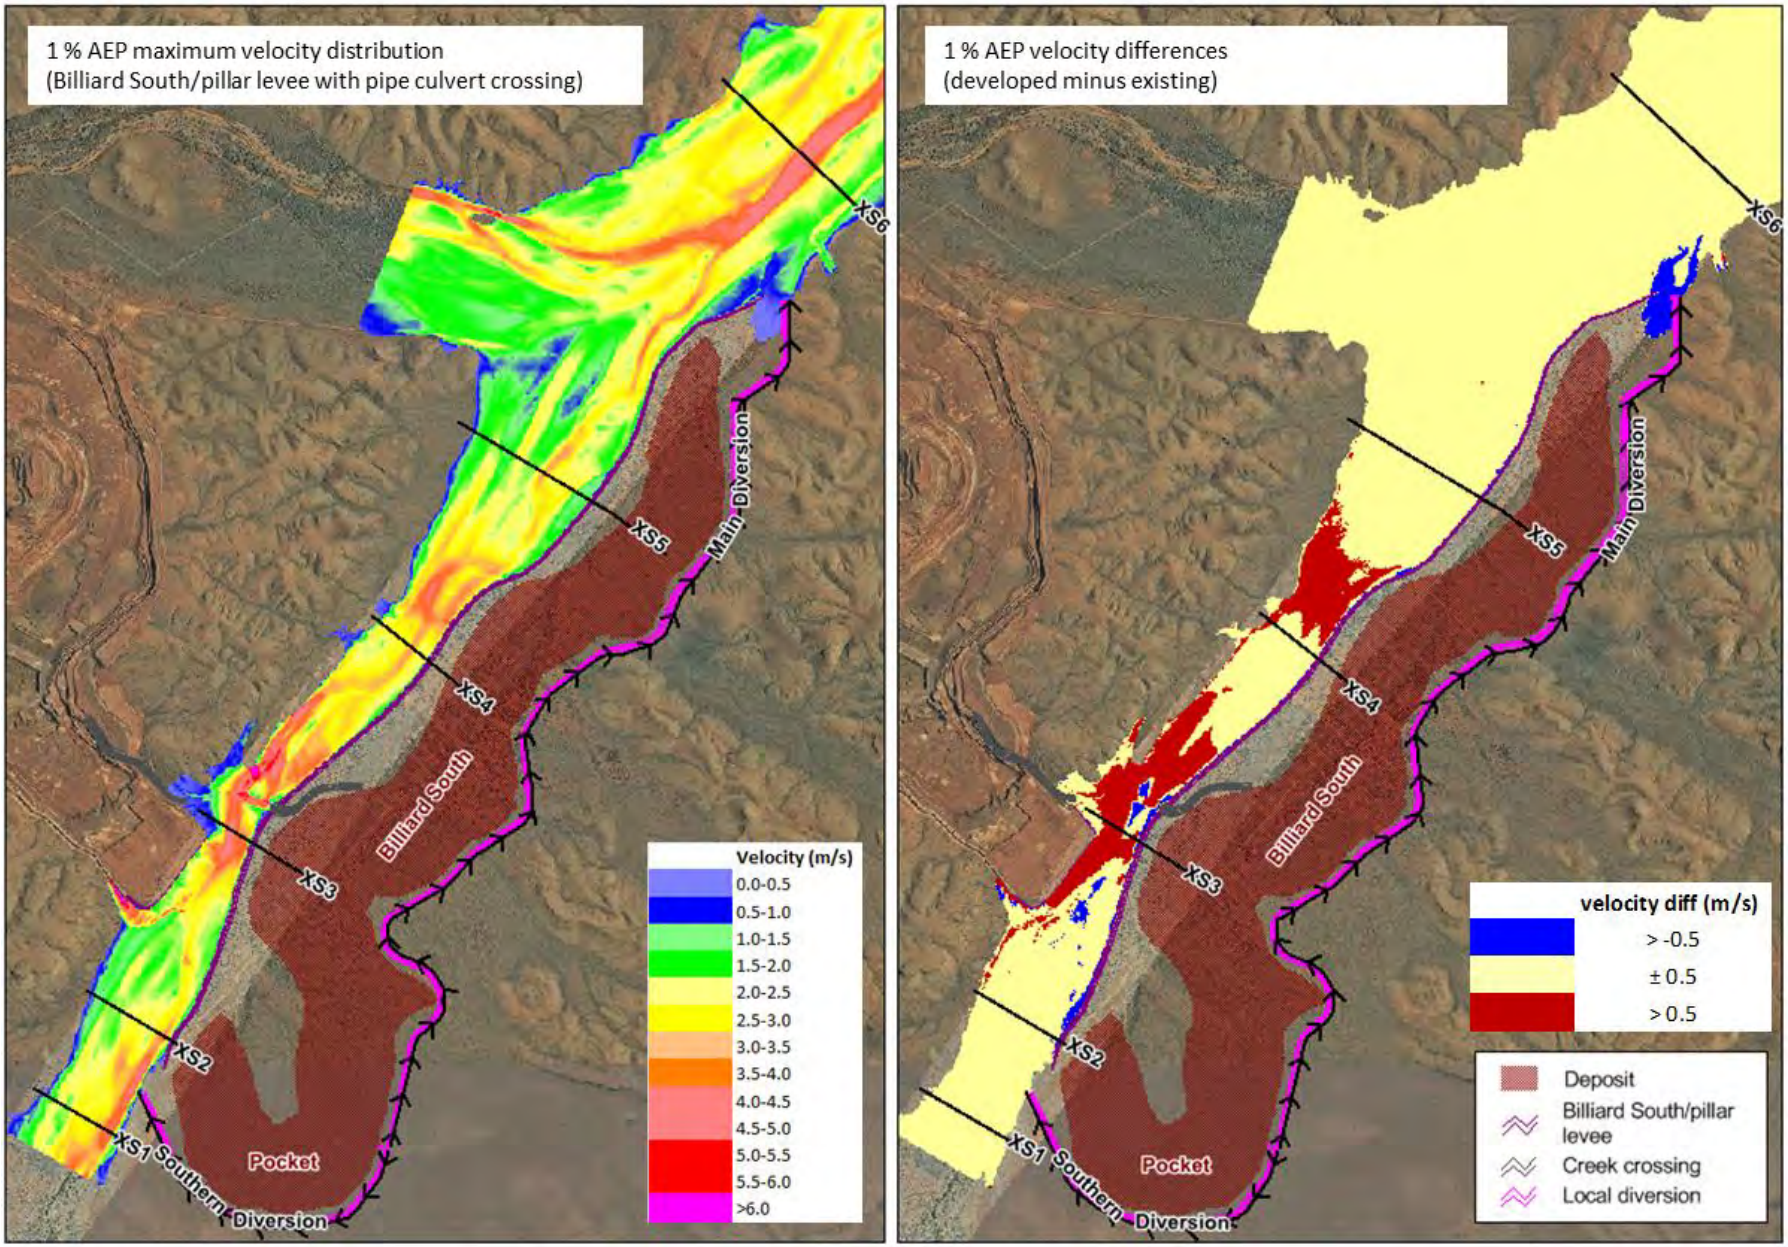

Figure 26: Maximum velocity distribution and velocity differences for the 1 % AEP event.

Conclusion

An ecohydrological assessment was carried out to identify the likely changes to surface water flow regime of Weeli Wolli Creek and the subsequent impacts on riparian vegetation as a result of development of Pocket and Billiard South within the Yandicoogina mine. Mining of these deposits will require rigorous approach of surface water management, which includes the construction of flood protection levees, local diversions and road crossing along Weeli Wolli Creek. These infrastructures will constrict and impede surface water flows and consequently alter the surface water flow conditions, such as the flood level and velocities, along the creek.

2D hydraulic modelling was carried out to determine the likely flow characteristics of Weeli Wolli Creek during mining when these infrastructures are in place. It can be concluded that:

- Minor increases in peak flow rates may be expected downstream of the operation during mining due to concentrated runoff contribution from the main diversion drain. However, impacts to the overall flood regime will decrease with AEP as the influence of surface water flows from Weeli Wolli Creek exceeds that from the diversion.
- Disruption to the existing surface water flows (water level and velocity) along Weeli Wolli Creek is small during events of low flows. A greater change, however, may be triggered by modification to local runoff from the eastern catchments causing water level/velocity to decrease or increase along the creek.
- Notable changes in flood level occur along the section of the creek between XS3 and XS4, in particular around the creek crossing, during the 10 % AEP event. Water elevation is raised by approximately 1 m behind the road, with the effects of backwater propagated 300 m upstream. Beyond the area of influence, changes are minimal.
- Impacts caused by infrastructures during the 1 % AEP flood are more significant due to greater constriction and obstruction of flows, in particular along the section between JSE and Billiard South. Greater effects of backwater are generated by the crossing, with the water level increased by 3 m above the pre-development level and the backwater propagated 2 km upstream. However the changes are confined to the creek section adjacent to the proposed operation and unlikely to extend beyond the impact zone.
- Significant changes in flow velocities occur in vicinity of the creek crossing where velocities are increased over the floodway and decreased when ponding occurs upstream of the road embankment. Flow velocities also increase along the creek section where the floodplain is most constricted. Changes are significant during the 1 % AEP event, with velocity reaching 6 m/s along the low flow channel immediately downstream of the crossing.
- Flooding characteristics and creek water supply for riparian vegetation during events of low and medium flows will likely remain unchanged during operation. For larger events, flood level will increase more prominently and the floodplain extends further to the west, thus larger area of vegetation, in particular those fringing the floodplain will be inundated during events of a lower AEP post-development.
- Changes to the flow velocities will likely influence the geomorphological conditions of the creek, especially in vicinity of the crossing. Increased erosion is expected in

areas where velocity increases and higher rate of sediment deposition will take place in areas where ponding occurs.

Based on the study outcomes, it was determined that the overall impact to surface water flow regime along Weeli Wolli Creek is restricted to the section adjacent to the proposed mine, while impact to the wider creek area is small during operation. However, appropriate management and monitoring are recommended to minimise long term impacts on the morphology and flow regime of the creek.

Executive Summary

Development of the Billiard South iron ore deposit, located within Rio Tinto's Yandicoogina operation upstream of the confluence of Marillana Creek and Weeli Wolli Creek, will encroach on the existing floodplain. Mining will be constrained by the natural flood extent unless flood protection levees are constructed. A conceptual flood protection levee alignment has been proposed to permit safe mining of the Billiard South deposit.

Weeli Wolli Creek is a significant Pilbara creek system subject to large, infrequent flood events. These large floods are significant events for the geomorphology of the creek. An understanding of the fluvial processes in Weeli Wolli Creek is important for managing potential impacts of the proposed development. This geomorphological study report is intended to increase understanding in support of Rio Tinto's environmental approval process.

This report covers the following items:

- Description of the existing geomorphological regime of Weeli Wolli Creek in the study area;
- Assessment of the potential impact of the proposed levee associated with development of the Billiard South iron ore deposits on the existing geomorphological regime of Weeli Wolli Creek; and
- Identification of key geomorphological issues for Weeli Wolli Creek related to haul road design, potential development of iron ore deposits at Billiard North, and Yandicoogina mine closure plans.

The current flow regime of Weeli Wolli Creek has been altered from the naturally ephemeral, pre-mining regime due to sustained discharges from upstream dewatering activities. Weeli Wolli Creek primarily has a single, sinuous low-flow channel situated within a high-flow channel characterised by gravel bars and connected to an anabranching system of flood runners activated by larger flows. The floodplain has multiple levels that are engaged at varying flow frequencies. The lowest levels are the most active area, and are associated with gravelly deposits, whereas the higher, less frequently engaged levels are characterised by silty surface sediment deposits and are vegetated with spinifex. Comparisons of historical aerial photographs show that the low-flow channel has become more pronounced due to flow supplementation but there is little evidence of change in channel location over the past four decades. Some localised migration has occurred by processes of lateral erosion and accretion, with this seen as within the normal bounds of the natural processes.

In the Billiard South levee scenario, the proposed levee would encroach on part of the existing floodplain and anabranch system. The constrictions created by the proposed levee encroachment on the floodplain has significant hydraulic effects and geomorphological implications. In broad terms, the levee would lead to additional sedimentation in the backwater zone upstream of the constriction, an increase in sediment mobilisation through the constriction, and deposition of scoured material downstream of the constriction as the stream power returns to its natural level. Key issues include risk of levee failure (particularly at pressure points where the creek or floodplain flows impinge against the levee), potential destabilisation of the creek channel and floodplain in the project area, vegetation loss, increased debris loads, risk of headward erosion extending upstream of the study area and increased sediment export to downstream reaches.

Local tributaries from the catchment area to the east of the South Billiard deposits will be routed around the levee and join Weeli Wolli Creek further downstream. This is not expected to significantly impact on the geomorphology of Weeli Wolli Creek, as these local tributaries drain a small proportion of the total catchment area and would be relatively minor contributors of flow and sediment.

The hydraulic modelling of the levee scenario does not include the impacts of a haul road across the floodplain and channel. Assessment of preliminary haul road designs indicates significant risk of exacerbating the hydraulic and geomorphological impacts of the levee, which need to be addressed by careful haul road design assessed to the same hydraulic and geomorphological standards as the levee scenario.

Although this study focuses on Billiard South, mine planning for the Junction South East (JSE) and Billiard North deposits is relevant to the closure design for Billiard South. JSE is outside of the Weeli Wolli Creek floodplain and is not further considered here. The Billiard North deposit extensively overlaps the Weeli Wolli Creek floodplain and its development may potentially have significant geomorphological impacts upstream and downstream as well as within the project area. These risks have not been assessed quantitatively in this report.

Rio Tinto has recognised that closure challenges for Yandicoogina are largely associated with water management. Although this report focuses on the Billiard South Deposit during operations, closure scenarios are also relevant and are addressed briefly in this report. The currently preferred closure scenarios involve the creation of permanent pit lakes that will impact the downstream flow frequency, floodplain connectivity and sediment transport regime. In the Billiard South area, a key risk for the rehabilitated landforms will be the avulsion of Weeli Wolli Creek into the former mine. It will be important to ensure that the rehabilitated landforms and surface water management features are designed to minimise this risk.

1 Introduction

1.1 Scope and objectives

Weeli Wolli Creek drains the Hamersley Range in the Eastern Pilbara region of Western Australia. It is a tributary stream in the Fortescue River catchment and discharges into the Fortescue Marshes. This report discusses the geomorphology of Weeli Wolli Creek in the vicinity of the Billiard South iron ore deposit near Yandicoogina. The study area is situated in the vicinity and upstream of the confluence of Weeli Wolli Creek and Marillana Creek (Figure 1-1).

The objectives of this report are to:

- Describe the existing geomorphological regime of Weeli Wolli Creek in the study area;
- Assess the potential impact of the proposed levee alignment associated with development of the Billiard South iron ore deposits on the existing geomorphological regime of Weeli Wolli Creek; and
- Identify key geomorphological issues for Weeli Wolli Creek related to a haul road crossing, potential development of iron ore deposits at Billiard North, and Yandicoogina mine closure plans.

The existing geomorphological regime of Weeli Wolli Creek differs from the natural regime primarily because of flow supplementation with mine water discharged from Hope Downs and Yandicoogina's Junction South East (JSE), resulting in the presence of permanent water in this formerly ephemeral reach. Further details are described in Chapter 2.

The potential impact of the Billiard South development has been assessed by comparing the existing condition to a levee scenario defined by Rio Tinto Iron Ore (RTIO) that encroaches onto the floodplain of Weeli Wolli Creek. Further information about the existing and levee scenarios is provided in Chapter 3.

1.2 Methodology and data sources

This report is based on a site inspection of Weeli Wolli Creek and a review of existing reports and data. The site inspection was undertaken on 24-25 June 2014 by Mark Pearcey (RTIO), Scott Seymour (Aquatic Systems Management) and Krey Price (MWH). Appendix A presents the field notes and site visit route (Figures A-1 and A-2).

The description of the current geomorphology of Weeli Wolli Creek and the assessment of operational and closure scenarios are based on the site inspections and the following key reports and data sources:

- Aerial photographs (1970, 1994, annual from 2003 to 2014);
- Published 1:250,000 geological mapping (SF 50-12 Roy Hill);
- Digital Elevation Model (DEM) and floodplain cross-sections based on LiDAR data surveyed in December 2011;
- RTIO (2013) Weeli Wolli Creek Hydrology & Floodplain Assessment - Yandicoogina Billiard South Order of Magnitude Study, December 2013 (RTIO-PDE-0117748);
- RTIO (2014) Yandicoogina Closure Plan (RTIO-HSE-0208486);
- Two-dimensional TUFLOW hydraulic modelling outputs for the existing condition (2% AEP flow, 1% AEP flow and 0.5% AEP flow); and
- Stream flow data for GS 708013 Weeli Wolli Creek at Waterloo Bore and GS 708014 Weeli Wolli Creek at Tarina (http://kumina.water.wa.gov.au/waterinformation/telem/stage.cfm).

The assessment of potential impacts of the Billiard South development is based on scenarios outlined by RTIO (2013) and two-dimensional TUFLOW hydraulic modelling outputs provided by RTIO:

- 2% AEP flow – existing condition and levee condition;
- 1% AEP flow – existing condition and levee condition; and
- 0.5% AEP flow – existing condition only (levee condition not provided).

Potential implications of a haul road and bridge crossing were examined based on:

- Preliminary designs for bridge and haul road, (RTIO Plans BILL-PRJ-SKE-Y-0004_A and BILL-PRJ-SKE-Y-0005_A); and

- RTIO Water Resource Evaluation (2014) Billiard South bridge crossings – design review, July 2014 (RTIO Internal Memo).

Discussion of geomorphological issues associated with the development of the Billiard North iron ore deposits and Yandicoogina mine closure is based on:

- RTIO (2013) Weeli Wolli Creek Hydrology & Floodplain Assessment - Yandicoogina Billiard South Order of Magnitude Study, December 2013 (RTIO-PDE-0117748); and
- RTIO (2014) Yandicoogina Closure Plan (RTIO-HSE-0208486).

1.3 Report outline

The existing geomorphological regime of Weeli Wolli Creek is discussed in Chapter 2. The geological and topographic settings are outlined in Section 2.1 and key hydrologic influences are discussed in Section 2.2. Section 2.3 examines creek channel characteristics and behaviour with reference to channel/floodplain interactions (Section 2.3.1), the creek bed and banks (Section 2.3.2), sediment characteristics and regime (Section 2.3.3), and vegetation cover (Section 2.3.4).

The Billiard South development scenarios are examined in Chapter 3. The scenarios and assumptions are outlined in Section 3.1. The levee scenario is discussed in Section 3.2.

Chapter 4 discusses other related proposals, including the potential implications of a haul road crossing that links Billiard South to the existing Yandicoogina Mine (Section 4.1), key issues for the geomorphology of Weeli Wolli Creek relating to the potential development of the Billiard North iron ore deposits (Section 4.2), and Yandicoogina mine closure plans (Section 4.3).

Appendices include notes, findings, and background details from the site visit (Appendix A), results of the historical aerial photo analysis (Appendix B), hydraulic modelling results (Appendix C), and a discussion of hydraulic design implications (Appendix D).

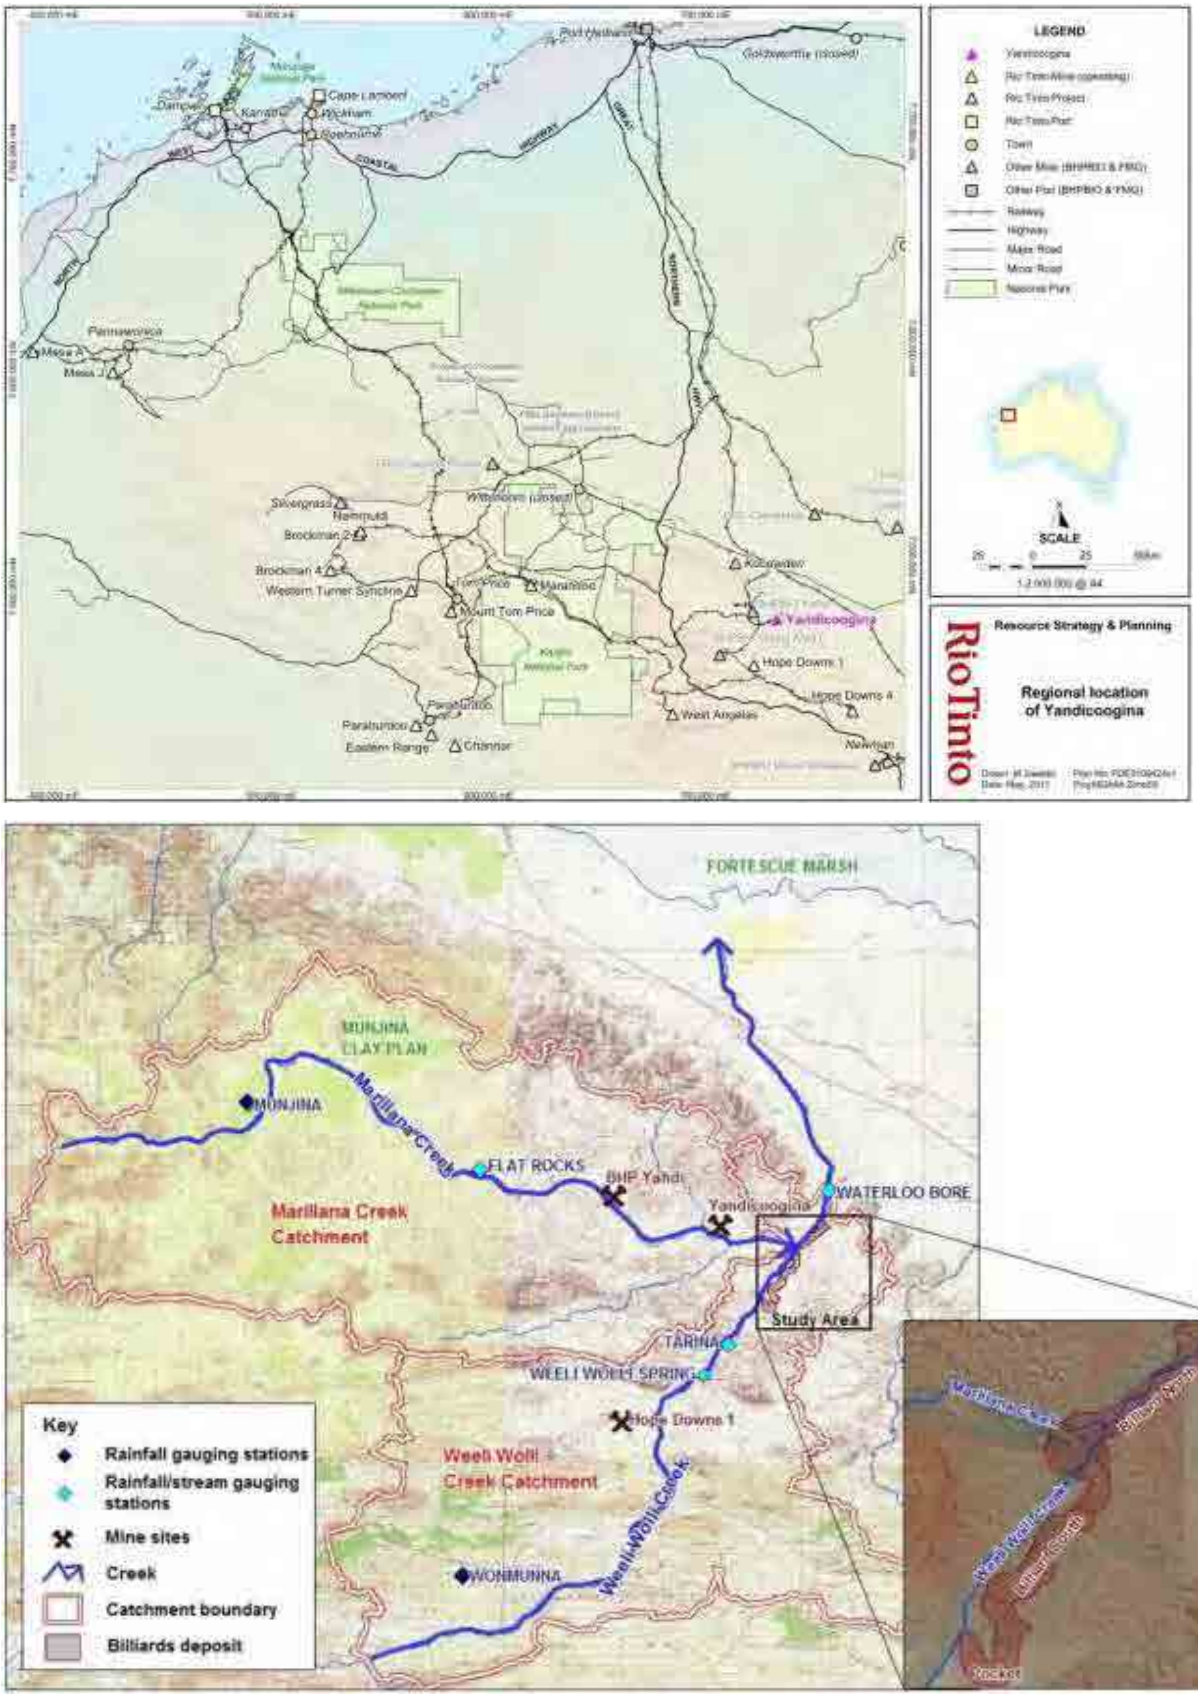

Figure 1-1: Yandicoogina Vicinity (RTIO 2014b) and Weeli Wolli Creek catchment (RTIO 2013)

2 Existing regime of Weeli Wolli Creek

This chapter describes the existing and pre-mining geomorphology of Weeli Wolli Creek in the Billiard South project area. Whilst mining operations have been ongoing in the Weeli Wolli Creek catchment for several decades, the primary differences between natural and existing regimes in the immediate project area relate to flow supplementation from JSE (adjacent to the project reach) and Hope Downs (upstream of the study area).

2.1 Geology and topography

Figure 2-1 shows a shaded digital elevation model of the study area as an overlay on the 2014 aerial photo. The relief shows the network of channels comprising Marillana Creek and Weeli Wolli Creek.

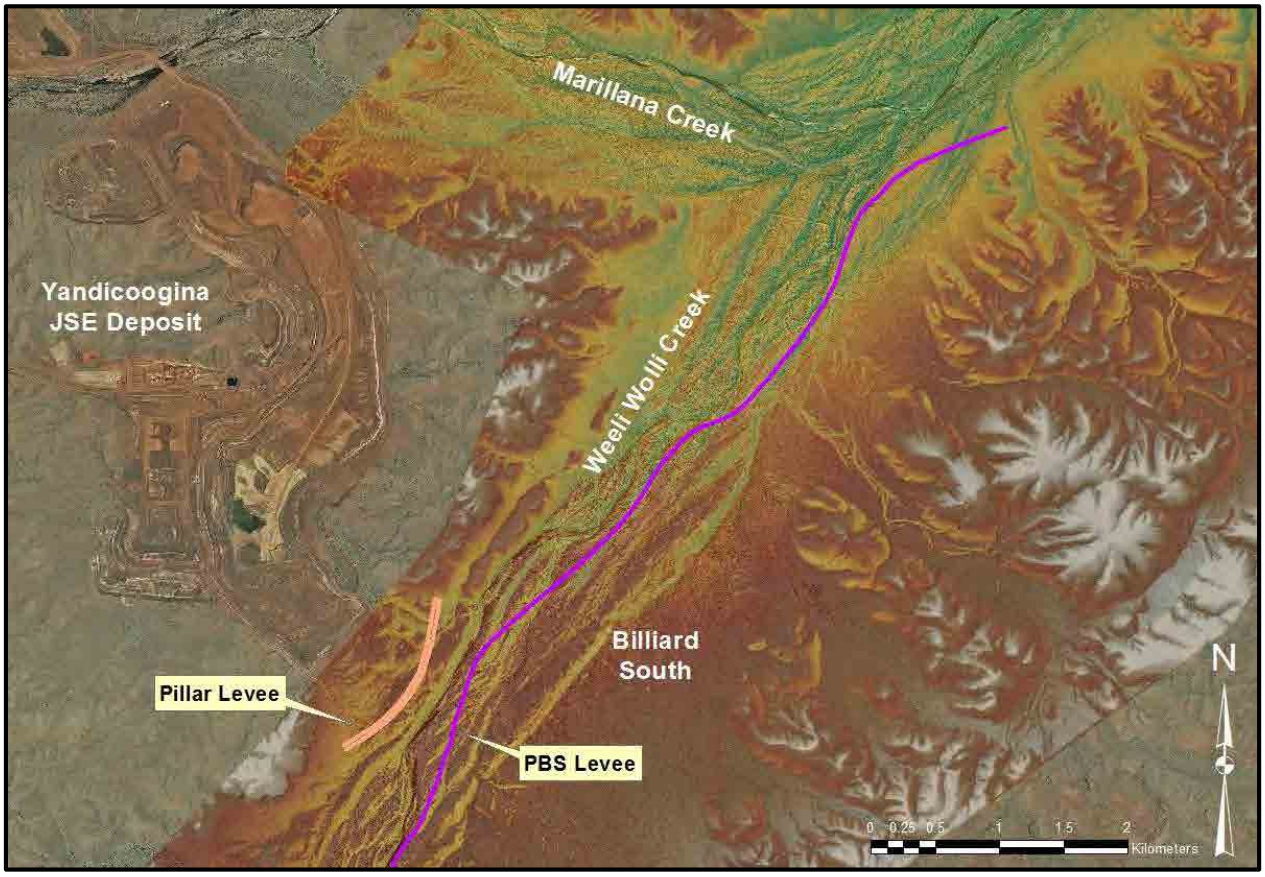

Figure 2-1: Digital Elevation Model of Study Area showing Levee Alignments

The Roy Hill 1:250,000 geological map shows that Weeli Wolli Creek in the study area flows in a generally NNE direction along a valley cut into ancient Proterozoic rocks of the Hamersley Group's Weeli Wolli Formation, consisting of banded iron-formation (commonly jaspilitic) pelite and metadolerite sills. The valley contains Cainozoic sediment deposits, including Cainozoic colluvium (partly consolidated quartz and rock fragments in silt and sand matrix; old valley fill deposits) and Cainozoic calcrete (sheet carbonate; found along major drainage lines) as well as a floodplain consisting of Quaternary alluvium. At the downstream end of the study area, Weeli Wolli Creek is joined by Marillana Creek, its largest tributary[1]. The floodplain of Weeli Wolli Creek widens at the Marillana Creek confluence.

Within the study area and throughout the catchment, there are minor localised impacts from trampling by introduced grazing animals, particularly cattle.

[1] Note: In some mapping sources, Marillana Creek is considered to be a tributary to Yandicoogina Creek; this report presents Yandicoogina Creek as a tributary entering Marillana Creek upstream of the Weeli Wolli Creek confluence.

Upstream of the study area, the various upper catchment tributaries of Weeli Wolli Creek converge in a broad basin containing Cainozoic sedimentary deposits. The creek then flows through a narrow valley carved through Proterozoic bedrock, which includes Weeli Wolli Springs and the Tarina stream flow gauging station (GS No. 708014). Weeli Wolli Creek emerges from this confined valley a few kilometres upstream of the study area

Immediately downstream of the study area, the geological and topographic setting is similar to the study area, but with a broader floodplain. Further downstream, Weeli Wolli Creek discharges onto a broad, flat deposition zone containing extensive deposits of Quaternary and Cainozoic sediments. Weeli Wolli Creek fans out into multiple distributaries as it enters this depositional basin, although a clearly defined main channel is evident. About 10 km downstream of the study area, the main valley passes through a narrower constriction confined by Proterozoic bedrock ranges on both sides, but higher level floodplain deposits diverge from the main valley upstream of this constriction to follow an alternative course toward Fortescue Marsh. Hydraulic modelling information provided by Rio Tinto indicates that this alternative course is only active in large floods. Floodplain flows cross the Mt Newman Railway in a series of culverts and bridges. The main Weeli Wolli Creek channel crosses the railway under a trestle located approximately 20 km downstream of the alluvial fan apex. Weeli Wolli Creek terminates at the Fortescue Marsh approximately 15 km downstream of the railway crossing.

2.2 Hydrology

Stream flow records for the Tarina gauging station (GS No. 708014), which is situated in the narrow valley upstream of the study area, show that the natural flow regime of Weeli Wolli Creek is summer-dominant. There is a high degree of annual variability in flows, with cyclones bringing major episodic flooding. A decadal trend in rainfall and streamflow has been noted, with 1985-1993 and 2006-present being drier than average, while 1994-2005 was wetter than average with five major cyclones passing in the vicinity of the Weeli Wolli Creek catchment (RTIO 2013).

The flow regime of Weeli Wolli Creek is naturally ephemeral; however, since 2007, flows in Weeli Wolli Creek have been supplemented by the discharge of surplus mine water (approximately 110 ML/d) from Hope Downs (RTIO 2013). There are also pumped inflows to Weeli Wolli Creek from the Yandicoogina mine of approximately 38 ML/d. Supplementation has increased total flows in the creek, reduced the degree of annual variability, and changed the flow regime from ephemeral to having a sustained base flow and permanent pools. The wetting front extends beyond the downstream end of the study area, generally occurring between 4 and 5 km downstream of the confluence of Weeli Wolli Creek and Marillana Creek (RTIO 2013) before all surface flows have drained into the deeper gravel lenses in the floodplain alluvium.

There is a high degree of natural connectivity between surface water and groundwater in Weeli Wolli Creek. Weeli Wolli and Marillana Creeks are important sources of groundwater (Inverarity et al 2012[2]). Water is retained in alluvial aquifers when the creeks cease to flow, supporting riparian vegetation (Inverarity et al 2012). In the case of Weeli Wolli Creek, the supplemented flow persists as a sustained surface base flow through the study area, but further downstream the creek reverts to its natural ephemeral character as the supplemented base flow is lost from the creek due to seepage into the alluvium and gravel seams. The older trees along Weeli Wolli Creek and its anabranches are using this shallow groundwater as their main water source.

The Marillana Creek catchment receives a slightly higher average annual rainfall than the Weeli Wolli Creek catchment (408 mm/a compared with 382 mm/a) (RTIO 2013). Rainfall and streamflow are spatially variable, and the proportional contribution of Weeli Wolli Creek and Marillana Creek to any given flood event is also variable. For example, in the flood of February 1995, the flood flows originated primarily from Marillana Creek catchment rather than Weeli Wolli catchment, whereas in other floods there has been a more significant contribution from Weeli Wolli Creek (RTIO 2013). The flood peaks in both streams, even if similar in magnitude, are generally not simultaneous; for example, a cyclone or tropical low may cross the Marillana Creek catchment well before reaching the upper Weeli Wolli Creek catchment. This hydrological variability creates complex and variable hydraulic conditions, which are reflected in the complex geomorphology of the confluence zone. The design floods used by RTIO in the TUFLOW modelling are based on uniform application of the design rainfall across the entire Marillana and Weeli Wolli catchments (RTIO 2013).

[2] Inverarity, N., Dogramaci, S. and Rea, I. (2012) Combined numerical and analytical modelling as a means to assess closure options for open-pit mines, Pilbara Region. International Mine Water Association Annual Conference, 2012.

2.3 Channel characteristics and behaviour

2.3.1 Channel / Floodplain interaction

Weeli Wolli Creek primarily has a single main river channel under low flow conditions. The channel pattern is generally sinuous. The main stream channel consists of a high flow channel characterised by gravel bars, with a smaller low flow channel situated within it (Figure 2-2).

The low flow channel is connected to an anabranching system of flood runners, which are activated by larger flows (Figure 2-3), and the floodplain is also engaged in large floods (Figure 2-4). The floodplain has multiple levels, associated with varying flow frequencies. The lowest levels are the most active area, and are associated with gravelly deposits, whereas the higher, less frequently engaged levels are characterised by silty surface sediments.

Comparisons of aerial photographs taken in 1970 and 2014 show a wet and clearly defined low flow channel in 2014, compared with an anabranching system of dry channels in 1970. The 2014 low flow channel generally follows the alignment of the 1970 channel system, with some localised migration by processes of lateral erosion and accretion (Appendix B). However, it cannot be conclusively determined whether the same channel was dominant in its entirety in 1970 as in 2014.

Hydraulic conditions in Weeli Wolli Creek and floodplain have been simulated by RTIO in a two-dimensional TUFLOW hydraulic model. Flow conditions for the 2%, 1% and 0.5% AEP were provided. Outputs from these model runs (Appendix C) show that the floodplain is extensively engaged in the 2% AEP flow, but some of the higher benches are only inundated in larger events. Hydraulic loadings (as indicated by flow velocities and shear stress) are highest along the main channel and are also high along parts of the major anabranches.

Figure 2-2: Narrow low flow channel bordered by wide gravel bars

Note: The gravel bars at this site include well-worn river gravels as well as some more angular material that appears to have been more recently won from bank erosion impinging on adjacent foothills.

Figure 2-3: Example of a mid-level anabranch of Weeli Wolli Creek

Note: The lower level anabranches display evidence of more active fluvial processes, with exposed gravel and pebble deposits in the bed.

Figure 2-4: Weeli Wolli Creek floodplain

Note: The surface sediments consist of silty material with extensive growth of spinifex.

2.3.2 Bed and banks

The low flow channel has pools (Figure 2-5) separated by gravel-bar controls (Figure 2-6). Gravel bars provide riffle-run habitat. Under low flow conditions, part of the Weeli Wolli Creek flow appears to seep through the controls. Historical aerial photographs from 1970, prior to flow supplementation, show a dry bed with no permanent pools.

Field observations indicate that the material exposed in the creek banks consists largely of alluvium, and is subject to erosion by natural meander processes. As noted in Section 2.3.1, comparison of historical (1970) and recent (2014) aerial photographs shows only a few localised shifts in channel position, indicating slow overall meander migration rates over this period. The two-dimensional hydraulic modelling outputs show areas of locally high velocity and shear stress occur in the creek channel during large floods. The limited degree of meander migration over the past 44 years reflects episodic meander migration processes and the infrequent incidence of large floods associated with significant channel change, as is common in arid and semi-arid zone streams, rather than a stable channel. Weeli Wolli Creek remains at risk of significant erosion in major floods.

Localised outcrops of calcrete were observed during the site inspection, particularly at Site 4 and Site 14, (Figure A-2) which abut areas of Cainozoic calcrete mapped on the 1:250,000 Roy Hill geological sheet (e.g. Figure 2-7). However, no evidence was observed of any widespread calcrete or hard bedrock controls, i.e. large or extensive outcrops that would significantly limit bed or bank erosion. This means that in a major flood, particularly if hydraulic loadings are increased (for example, due to confinement by the levees), bed and bank scour would occur at rates governed by the erodibility of the bed and bank sediments, rather than being constrained by hard bedrock or calcrete outcrops. Hence, Weeli Wolli Creek is susceptible to significant geomorphological change in response to change or disturbance.

Figure 2-5: Example of a pool, a key element in the characteristic pool and gravel bar morphology of Weeli Wolli Creek

Note: Under natural conditions, prior to flow supplementation, the pools were generally dry, although the same bedforms would have been present.

Figure 2-6: Example of a gravel-bar control, which provides riffle-run habitat

Figure 2-7: Calcrete outcrop (arrowed) at Site 14 (downstream of Grey's Crossing)

Note: This area coincides with the edge the of Cainozoic calcrete deposit mapped on the Roy Hill 1:250,000 geological map.

2.3.3 Sediment characteristics and regime

Weeli Wolli Creek is a gravel-bed stream. A general feature is the presence of large gravel bars in the main channel (Figure 2-2) and the more active anabranches (Figure 2-8), with finer material, particularly silt, in the less active anabranches (Figure 2-3), and on the floodplain benches where velocities are lower (Figure 2-4).

Figure 2-8: Gravel bars in an anabranch near Site 7

The predominant Wentworth size class on the gravel bars is pebble/gravel size (2 mm to 64 mm), with some larger particles up to cobble size (64 mm to 256 mm), as well as sand-sized material (62.5 µm to 2 mm) (Figure 2-9). There is considerable variability in sediment size within the creek channel, reflecting local variations in hydraulic conditions.

In the upstream part of the study area, the bed sediments include a mixture of materials that are angular with sharp edges, suggesting fresh supply from a proximal local source, as well as more rounded (i.e. less sharp) materials, indicative of a greater degree of fluvial reworking. Further downstream the bed materials are predominantly well-rounded. The rock particles generally have low sphericity (i.e. particles tend to be oblong or flat rather than spherical), reflecting the properties of the rock formations from which they were sourced.

Sediment transport processes are episodic, with most bedload transport occurring during flood events, when significant scour and fill may occur, particularly in the vicinity of localised flow obstructions such as trees (Figure 2-10). Given the channel configuration, the velocity and stream power associated with the supplemented baseflow (approximately 150 ML/d) are below the entrainment thresholds required to mobilise and transport bedload in Weeli Wolli Creek. No bedload transport was observed during the June 2014 site inspection, when flows of 169-189 ML/d were recorded at the Tarina gauging station.

Figure 2-9: Typical gravel bar in Weeli Wolli Creek

Figure 2-10: Exposure of tree roots on gravel bars provides evidence of scour-and-fill processes

2.3.4 Vegetation cover

There is a dense band of riparian trees and shrubs along the low flow channel of Weeli Wolli Creek, with scattered trees and shrubs across the high flow channel and floodplain. There is bare gravel within the high flow channel and in major flood runners. On the floodplain surface, there is finer sediment with extensive groundcover of spinifex, reflecting more benign hydraulic conditions.

A key feature of Weeli Wolli Creek is the strong recruitment of river red gums along the edge of the low flow channel over the past 7 years of supplemented flows (Figure 2-11), with at least 3 distinct age class cohorts of saplings evident. The persistently wet substrate resulting from supplemented flows into which the new trees could recruit has created favourable conditions for the establishment of the young red gums, possibly working in combination with wet seasons flows setting off seeding behaviour. The absence of major floods over this period (as indicated by the streamflow sequence shown in Figure 6.2 of RTIO 2013) would also have contributed by minimising the disturbance of the seedlings by scour. These new trees increase the flow resistance (hydraulic roughness) and decrease the erodibility of the areas they vegetate.

Patchy growths of Typha species were observed in some pools (Figure 2-12), but otherwise little aquatic macrophyte cover was observed in the low flow channel, despite the persistent flows and extensive pools. The presence of typha appeared to be associated with a lack of shading and the presence of permanent water. Typha is unlikely to have been present in this reach of Weeli Wolli Creek in its natural ephemeral condition, although suitable habitat would have been present further upstream at Weeli Wolli Springs.

Extensive growths of algae were observed to present in the pool areas within the study area.

Some large woody material is present in Weeli Wolli Creek, including the main channel, anabranches and floodplain (Figure 2-13). The large woody material appears to have been transported downstream during flood events. This is supported by hydraulic modelling results supplied by RTIO, which indicate deep and locally fast flows during large flood events.

Figure 2-11: Young cohort of red gum saplings

Note: Saplings have colonised the margins of the low flow channel in apparent response to the supplemented flows.

Figure 2-12: Typha sp. colonisation of sediments in large pool at Site 11

Figure 2-13: Large woody material in Weeli Wolli Creek channel and floodplain, Site 2

3 Billiard South development scenarios

3.1 Scenario descriptions and assumptions

The Billiard South iron ore deposit runs parallel to Weeli Wolli Creek and intersects the Weeli Wolli Creek floodplain (Figure 1-1 inset). The operational scenario is examined as a basis for assessing the potential implications of the Billiard South development on the geomorphology of Weeli Wolli Creek. The operational scenario allows for the development of the Billiard South iron ore deposit. In this scenario, mining operations extend onto the Weeli Wolli Creek floodplain, with a flood levee and minimum buffer separating the Billiard South mine from Weeli Wolli Creek and its flood flows.

Local drainage from the catchment area to the east of the Billiard South deposits and outside the levee will be routed around the levee and join Weeli Wolli Creek further downstream. This will affect the timing of some of the contributing flow; however, relative to the main channel flow, the overall flow frequency and floodplain connectivity downstream of the proposed levee is not anticipated to be significantly affected during operations. These local tributaries drain a small proportion of the total catchment area and would be relatively minor contributors of flow and sediment.

Heavy and light vehicle roads would be required to connect the Billiard South development to the service area and processing plant within the existing Yandicoogina mine. At least one crossing of Weeli Wolli Creek and its floodplain would be required. No provision for a road crossing is simulated in the 2D hydraulic modelling that was reviewed for this report; therefore, the road crossing is not incorporated in the geomorphological analysis of the Billiard South development scenarios in Sections 3.2 and 3.3; however, a general discussion of geomorphological considerations relating to such a road crossing is included in Section 4.1, because such a crossing could potentially have significant geomorphological impacts.

The geotechnical properties below the levee alignment are currently unknown. RTIO (2013) noted this as a knowledge gap and recommended that geotechnical investigations be carried out to characterise geotechnical properties of the foundation soil profile and provide baseline information for slope stability and seepage analysis of the levee structure. Similarly, no information was reviewed covering implications of groundwater drawdown from mine dewatering or effects related to the shallow alluvial aquifers that interact with surface flows and support riparian vegetation. The assessment of geomorphological implications of the Billiard South development scenarios in this report (Sections 3.2 and 3.3) has been undertaken primarily based on hydraulic considerations, coupled with analysis of geomorphological conditions and processes outlined above.

To distinguish between other proposed levees in report figures, the levee along the east bank of Weeli Wolli Creek that is the focus of this report is referred to as the Pocket and Billiard South (PBS) Levee, In addition to the PBS Levee, RTIO (2013) discusses two other levee proposals for the Weeli Wolli Creek floodplain: the Pillar Levee and Fortescue Metals Group (FMG) levees. The Pillar Levee option entails the construction of a new levee to protect expansion of the JSE mine, which would be situated immediately opposite the Pocket and PBS levee, further confining the Weeli Wolli Creek floodplain (RTIO 2013). The Pillar Levee would further constrict the flow and further increase hydraulic loadings (RTIO 2013), which would be expected to generally increase geomorphological impacts; however, geomorphological assessment of the Pillar Levee option is beyond the scope of this report.

The FMG levees would be situated approximately 10 km downstream of the study area. RTIO (2013) simulated these levees in the 2D TUFLOW hydraulic model. The results show significant local increases in flood inundation depth in the vicinity of FMG levees; however, the impacts of the FMG levees do not extend as far upstream as the Billiard South project area. Hence, the FMG levees are not considered further in this report.

The assessment of the geomorphological implications of the Billiard South development options was undertaken for the operating life of the mine, with the levees remaining in place and separating the mine from the creek and floodplain. Mine closure scenarios are discussed in broad terms in Section 4.3.

3.2 PBS Levee

The PBS levee leads to a significant reduction in the width of the Weeli Wolli Creek floodplain, particularly in the middle section of the study area. This leads to the direct loss of a substantial part of the floodplain and the truncation of several anabranches, including a major anabranch system (Figure 3-1). Appendix C shows hydraulic output for the existing condition and the levee scenario. Figures C-1 to

C-20 show the entire extent of the proposed levees, while Figures C-21 to C-30 focus on the area with the maximum constriction near the JSE Deposit.

The compression of the floodplain leads to increased hydraulic loadings, as indicated by increases in velocity and shear, particularly in the more confined parts of the floodplain (Figures C-13 and C-14). Geomorphological implications of these hydraulic changes include:

- Potential destabilisation of the creek channel, including increased bank erosion, increased rates of meander migration, increased mobility of bed sediment, channel widening, bend cut-offs and bed deepening (including erosion of bed controls). Figure 3-3 and Figure 3-4 show that velocity and shear will be highest in the middle section of the study area, putting this part of the creek at highest risk of destabilisation.
- Increased rates of meander migration that could lead to the migration of pressure points where the creek channel impinges against the levee (Figure 3-2), extending the length of the area requiring protective reinforcement.
- Erosion of bed controls (which from the site inspection appear to be gravel controls that are not visibly underpinned by calcrete or bedrock) that could lead to the upstream transmission of an erosion head for several kilometres until stopped by a bedrock control.
- A change in channel morphology towards a wider, more braided channel form within and downstream of the study area resulting from increased sediment load due to increased local erosion within the study area and potentially increased sediment inputs from upstream sources if headward erosion occurs.
- Increased hydraulic loadings on the remaining floodplain (significant parts will be cut off by the levee) are indicated by the hydraulic modelling (Figure 3-3 and Figure 3-4), particularly in the middle section of the study area. This is likely to lead to more dynamic geomorphological processes, including floodplain scour and stripping, sand and gravel splay deposition (i.e. deposition of fan-like lobes of coarse sediments onto the floodplain), and increased risk of shifts in channel position by meander cutoffs and avulsion.
- Increased sediment export to downstream reaches.
- Vegetation loss, including old mature trees, would be expected in the area of increased energy, due to direct hydraulic loadings as well as undermining by bank erosion and scour of adjacent soil and sediments. Vegetation loss due to direct hydraulic loadings could be expected in areas where shear exceed 50 n/m^2; however, local turbulence and indirect effects via scour of banks and substrate could result in vegetation loss in areas with lower shear. The middle section of the study area where hydraulic loadings will be largest (Figure 3-3 and Figure 3-4) will be at greatest risk. Debris loads of large woody material would increase.

The hydraulic effects of the levee result in a significant risk of levee failure, particularly at pressure points where the creek or floodplain flows impinge against the levee (Figure 3-2). Levee failure would have major consequences for the Billiard South mining operation. Although the levee design and armour rock sizing is beyond the scope of this study, the geomorphic implications of levee failure warrant some discussion of armour requirements. RTIO (2013) recognised this risk and noted the need for protective reinforcement works along the levee. The current levee alignment is conceptual and armour design has not been completed; however, it is assumed that levee armouring and toe scour control will be required to a sufficient height above and depth below the toe of the levee. Bed control in the form of structures such as cross-channel bed armouring may also be required. Consideration should also be given to the installation of structures (e.g. groynes) to deflect fast, deep, and turbulent flows away from the toe of the levee.

Although the 2D hydraulic model scenario for the levee scenario did not include a haul road, the model results indicate severe hydraulic conditions that are likely to destabilise a haul road and any foundations for structural elements placed within the constricted reach. RTIO's (2014) review of the preliminary design for a haul road shows significant stability problems even at the 2% AEP flow, which is considerable smaller than the 0.5 % AEP design flow for the levee (see Section 4.1).

Backwater effects at the upstream end of the study area (upstream of the confined section), may lead to an undersized levee and locally reduced hydraulic loadings (Figures C-13 and C-14). This may promote

increased deposition, unless the creek is destabilised by headward erosion originating in the area of high hydraulic loadings.

If constructed in conjunction with the proposed haul road crossing, the geomorphological impacts of the crossing (described in Section 4.1) would apply to this scenario.

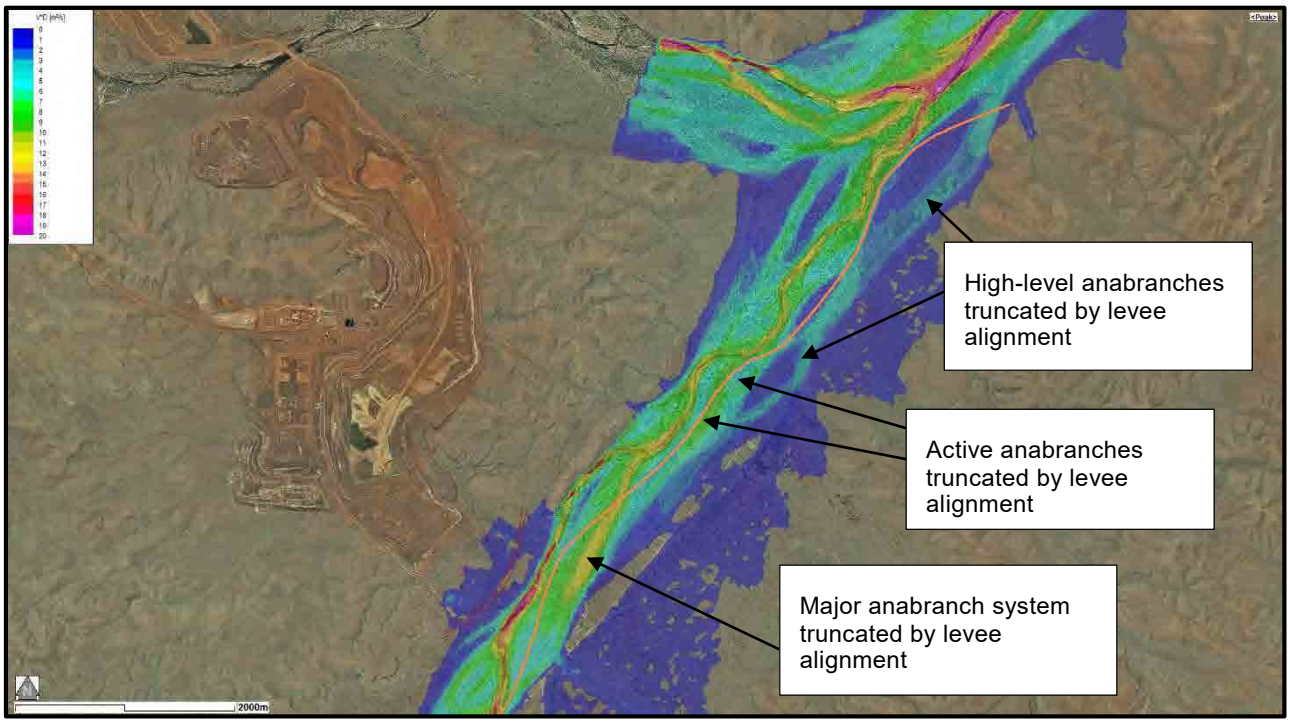

Figure 3-1: Map of flow depth times velocity for the 0.5% AEP flow

Note: Flow areas to the east of the levee will be disconnected from Weeli Wolli Creek by the levee.

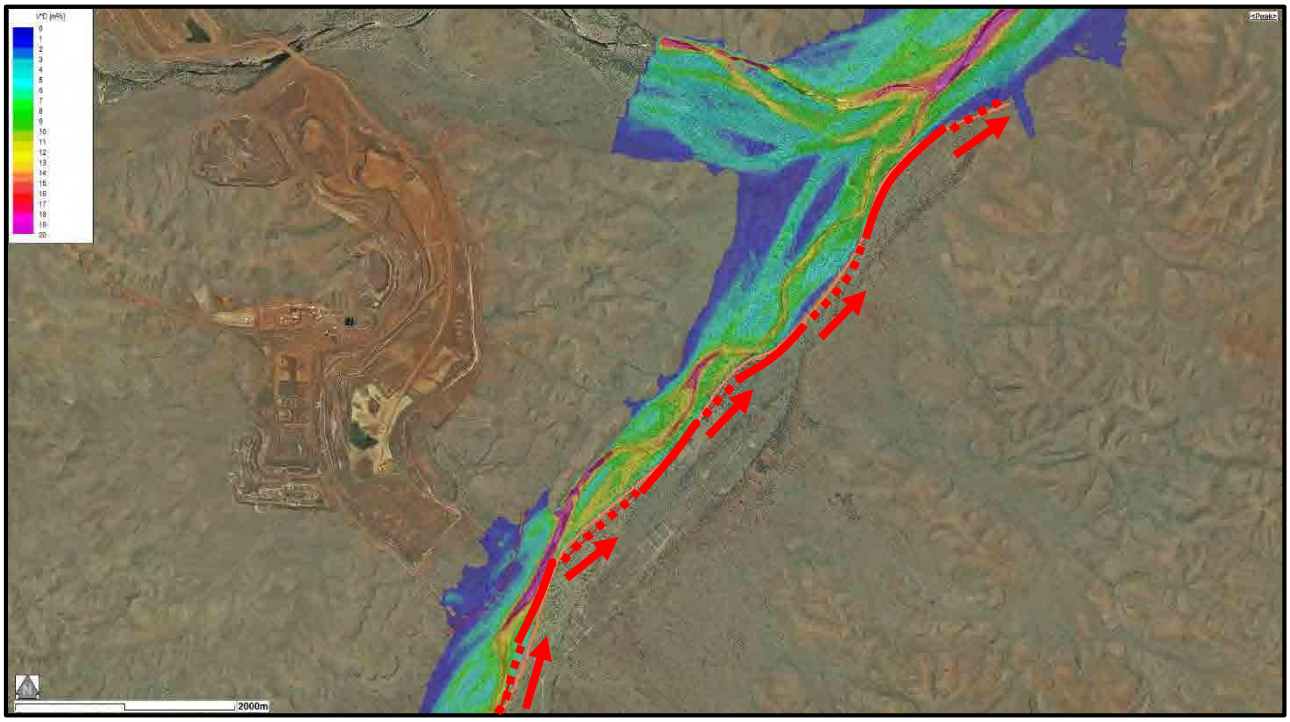

Figure 3-2: Map of flow depth times velocity for the 1% AEP flow levee scenario

Note: Key pressure points at risk from bank erosion from the main channel are indicated by solid red lines, and areas at risk from anabranch or floodplain flows are highlighted by dashed red lines. Arrows indicate the likely downstream migration of pressure points where the main channel impinges on the levee.

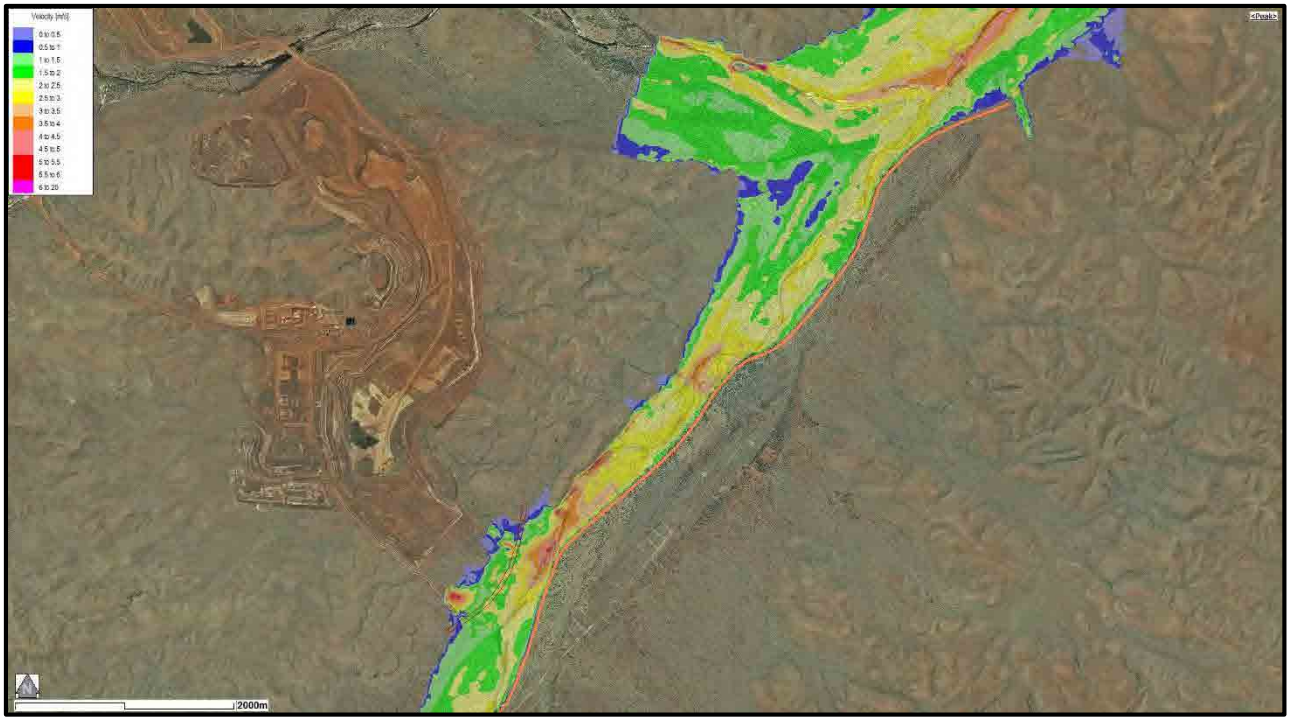

Figure 3-3: Map of velocity for the 1% AEP flow levee scenario

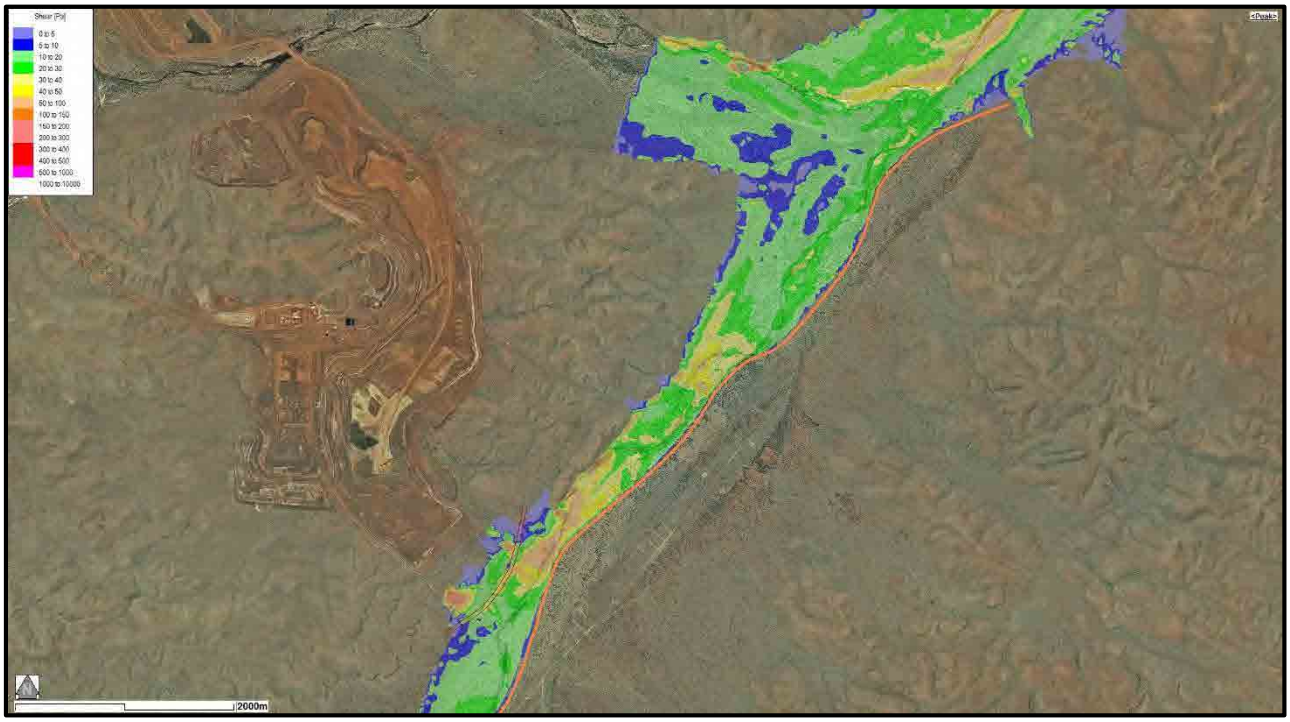

Figure 3-4: Map of shear for the 1% AEP flow levee scenario

Appendix D includes typical thresholds for various bank stabilisation materials. RTIO has incorporated guidance from U.S. Army Corps of Engineers (Fischenich, 2001) into a standard palette that is shown in the figure legends for velocity and shear (Figures C-11 to C-30). A description of the categories corresponding to each velocity and shear range is shown in Table D-1. As indicated by the hydraulic results in the constricted area (Figure C-29), localised velocities approach the threshold for 600mm D_{50} armour rock. The rock must be properly graded (i.e. D_{10} = 250mm, D_{50} = 600mm, D_{90} = 900mm) to ensure interlocking, and the rock armouring would need to be at least 2 x D_{50} deep.

Appendix D also includes Main Roads WA guidance (Tables D-2 and D-3) for armour rock sizing. As shown in the tables, Main Roads WA recommends a velocity-based approach. The ability of hydraulic forces to mobilise a particular rock size is also highly dependent on the depth, however, shear stress is a more reliable predictor of erosive potential. Velocity times depth is also commonly used to assess erosive potential or flood hazard. Figure D-1 shows the standard flood hazard mapping categories using the classification system embedded in WaterRide software. Areas of high depth times velocity indicate stronger, deeper flows; as shown in Figure D-1, the main channel is entirely in the extreme hazard classification.

Figures D-2 through D-6 show an indicative comparison of channel hydraulics for the existing condition and levee scenario in profile and section view. These figures are based on 1-dimensional modelling and should be viewed to interpret general trends rather than reflecting the results at specific cross sections.

4 Additional scenarios

Whilst this study focuses on the levee scenario, additional considerations are presented related to the proposed haul road crossing, the development of Billiard North, and Yandicoogina mine closure scenarios.

4.1 Haul road crossing

The construction of a haul road crossing across Weeli Wolli Creek and its floodplain to connect Billiard South to the existing mine at Yandicoogina has potentially significant hydraulic and geomorphological implications. The preliminary haul road alignment is shown in Figure 4-1.

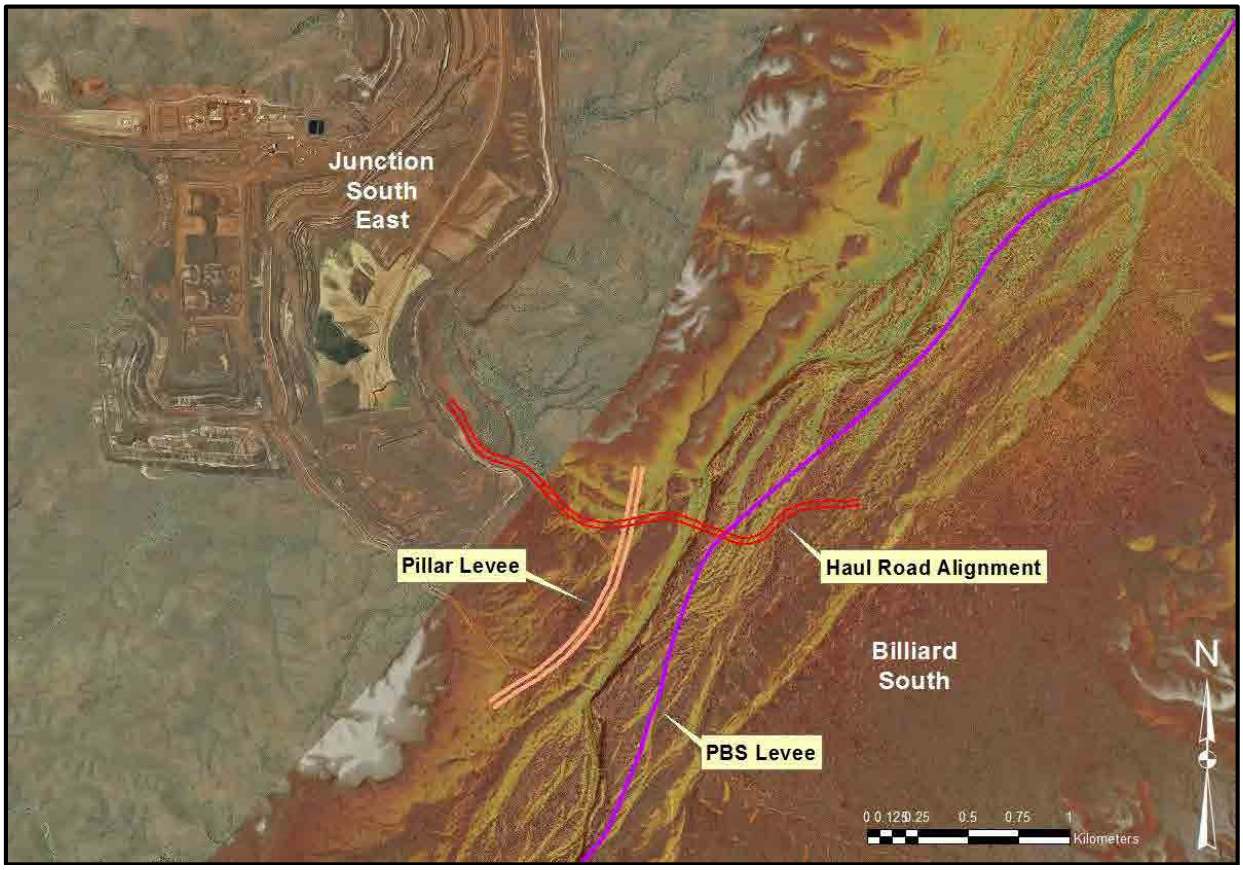

Figure 4-1: Haul Road Alignment (RTIO 2014b)

An internal RTIO hydraulic review indicated that the initial design had inadequate hydraulic capacity (RTIO 2014). Furthermore, the original design was found to be problematic in terms of hydraulic and environmental impacts (RTIO 2014). Further refinement to the design is ongoing; hence the discussion of geomorphological issues relating to a haul road crossing here are general in nature rather than referring to a specific crossing design. RTIO reported localised velocities in excess of 5 m/s for preliminary designs, which exceeds the bounds of many rip rap sizing charts and requires structural protection methods (such as those intended for spillway designs) that can accommodate supercritical flows and resist cavitation with concrete lining designs or energy dissipation structures that create a hydraulic jump.

The issues identified in this assessment relate to the geomorphological character of Weeli Wolli Creek. The creek and its flood runners consist of a gravel and cobble bed stream with large gravel bar deposits. These deposits, which are lightly vegetated with grasses, are fairly loose and subject to surficial reworking under most events into new banks and mounds. Finer fractions are subject to winnowing from the deposits and will be moved further. The floodplain surface is silty and vegetated with spinifex.

Debris load – Weeli Wolli Creek carries a debris load that includes natural timber from fallen trees. Increased vegetation growth in response to flow supplementation has increased the availability of organic material to contribute to flood debris. In addition, increased erosion in the development scenarios would generate further debris. This makes it highly likely that a culvert-type crossing as shown

in the preliminary designs would easily become partially or fully blocked during a flood. Therefore, it is important that blockage analysis be incorporated into the hydraulic assessment of the haul road design, especially for a culvert-type crossing. Debris traps, transitional inlet designs, or other design features may reduce the amount of debris build-up.

Crossing location – The confinement of flow by the PBS and Pillar Levees will lead to severe hydraulic conditions where the flow confinement is greatest, as shown by the 2D hydraulic modelling output. RTIO (2014) noted this problem in regard to the crossing location, where severe hydraulic conditions make any crossing problematic. Further hydraulic assessment would be necessary to determine the performance of the design under larger flows with potential sedimentation, scour, and culvert blockages.

Flow impedance and confinement – The degree of flow impedance and confinement by the crossing should be minimised. Both of the preliminary crossing designs indicate significant impedance of flows, resulting from filling of the floodplain and confinement of flows into a culvert-style crossing at the creek and a secondary higher level floodway. This can be expected to lead to ponding, increased flood heights and reduced velocities upstream of the crossing (promoting increased deposition) and increased velocities across the formation and downstream of the crossing (promoting scour, including the formation of scour holes in the creek bed or floodplain surface, and potentially under the culverts). There is high potential for bed foundation failure of the main opening /culverts through scouring. If hydraulic forces across the road or floodway are high and reach critical or supercritical conditions, the road or floodway embankment are most likely to fail. Energy dissipation structures may be warranted for this case but as a standalone measure are unlikely to mitigate failure. Hydraulic loadings would be exacerbated if energy gradient is steepened by downstream scour, or if the culvert crossing is blocked by debris, diverting additional flow over the formation. Sudden failure of the floodway or embankment could lead to significant floodplain scour and potentially to channel avulsion. There is also potential for the hydraulic impacts resulting from flow impedance and confinement by the crossing to threaten the integrity of the levee (via elevated flood levels, increased velocities and turbulence from flow eddies), potentially resulting in levee failure.

The following design criteria would help minimise impedance and confinement of flow:

- Minimum loss of floodplain cross section and flood channel;
- Establish the haul road at the floodplain surface;
- Open spans rather than culverts over the main channel and large openings on flood runners;
- No further compression of floodplain with haul road ramps over levees.

Foundations – Weeli Wolli Creek in the study area flows through unconsolidated gravelly alluvium. The depth to bedrock or other consolidated material that would provide a stable foundation is unknown. Geotechnical investigations should be undertaken to determine suitable foundations for the structural components of the proposed crossing.

The hydraulic standard for designing the haul road should be the same as for the levee, namely the 0.5% AEP flow. This is due to the potential for hydraulic changes resulting from the haul road to destabilise the creek channel and the levee, including the risk of levee failure. If the crossing is designed to meet the above criteria, it may become submerged at or above the bankfull discharge stage (of the primary channel).

4.2 Billiard North development

Although this study focuses on Billiard South, mine planning for the JSE and Billiard North deposits is relevant to the closure design for Billiard South. Under the current mine plan, overburden waste from Billiard South will be used to backfill the JSE pits, and waste from Billiard North will potentially be used to backfill Billiard South. Mining of the Billiard North Deposit is not expected to commence until around 2027, and any proposed use of material from Billiard North is subject to further environmental approvals for applications that may be submitted in the meantime.

JSE is outside of the Weeli Wolli Creek floodplain and is not further considered here.

The Billiard North deposit extensively overlaps the Weeli Wolli Creek floodplain. Development of this deposit is likely to require substantial constriction or diversion of Weeli Wolli Creek and disconnection of large areas of floodplain. The Marillana Creek confluence area may potentially require relocation as well and may involve a series of diversions implemented at various stages of the mine plan. Such extensive changes bring many significant geomorphological risks, including loss of channel and floodplain habitat; channel, floodplain and infrastructure stability issues associated with floodplain compression (as

discussed above for Billiard South in Chapter 3 and Section 4.1); scour and sedimentation issues that extend beyond tenement boundaries; and risks associated with failure of stream diversions (including habitat and stability issues).

As well as affecting the project area, there may be upstream and downstream impacts. Flow constriction in the Billiard North project area may have upstream backwater effects that result in additional deposition upstream. Erosion originating in the Billiard North project area could migrate upstream by headward processes, leading to extensive destabilisation of the creek system near Greys Crossing.

Channelising the creek to enable Billiard North establishment and operation may result in a higher energy environment than the natural system. If the diversion channel is designed to remain stable and prevent scour or aggradation, the reach would act as a pass-through for sediment transport, and material that might otherwise have deposited in this reach will be transported further downstream than under the existing conditions. The discharge of the confined flow could lead to a zone of instability downstream of the confined or diverted channel, where the creek adjusts to the downstream change in hydraulic conditions (similar to an alluvial fan). Increased sediment mobilisation within and upstream of the project area could result in increased sediment export to downstream reaches.

Overall, the potential development of the Billiard North deposits appears to have high geomorphological risks; a separate detailed evaluation beyond the scope of this study is recommended.

4.3 Closure scenarios

The stated goals of the April 2014 Yandicoogina Closure Plan related to surface water include:

- maintenance of the Weeli Wolli Creek system;
- creating stable landforms;
- ensuring rehabilitated landforms are stable and designed to manage floodwater appropriately;
- ensuring water systems support existing riparian vegetation and are compatible with the natural system dynamics;
- establishing ecosystems with similar biodiversity and cultural heritage values as surrounding reference sites;
- maintaining environmental and cultural heritage values associated with creek flows and function;
- retaining environmental values of Fortescue Marsh;
- ensure water quality within pit lakes support natural ecosystems and are appropriate for use;
- minimise impacts to surface water flow paths, volumes and levels.

Appendix D of the Yandicoogina Closure Plan (RTIO 2014) outlines six options for closure:

1. No backfill (all voids become lakes);
2. Backfill to pre-mining water table (material would be mined from adjacent hills to achieve this scenario);
3. Maintaining creek flows (with lakes, including a large on-stream lake on Weeli Wolli Creek extending downstream from the Marillana Creek confluence);
4. Multiple small, deep lakes (Weeli Wolli Creek captured);
5. One permanent lake (large lake captures Weeli Wolli Creek); and
6. Continuous channel (large lake in palaeo valley, all creeks captured).

At present, Option #3 is preferred by RTIO as representing the optimal balance of known constraints. Figure 4-2 shows the final post-closure landforms.

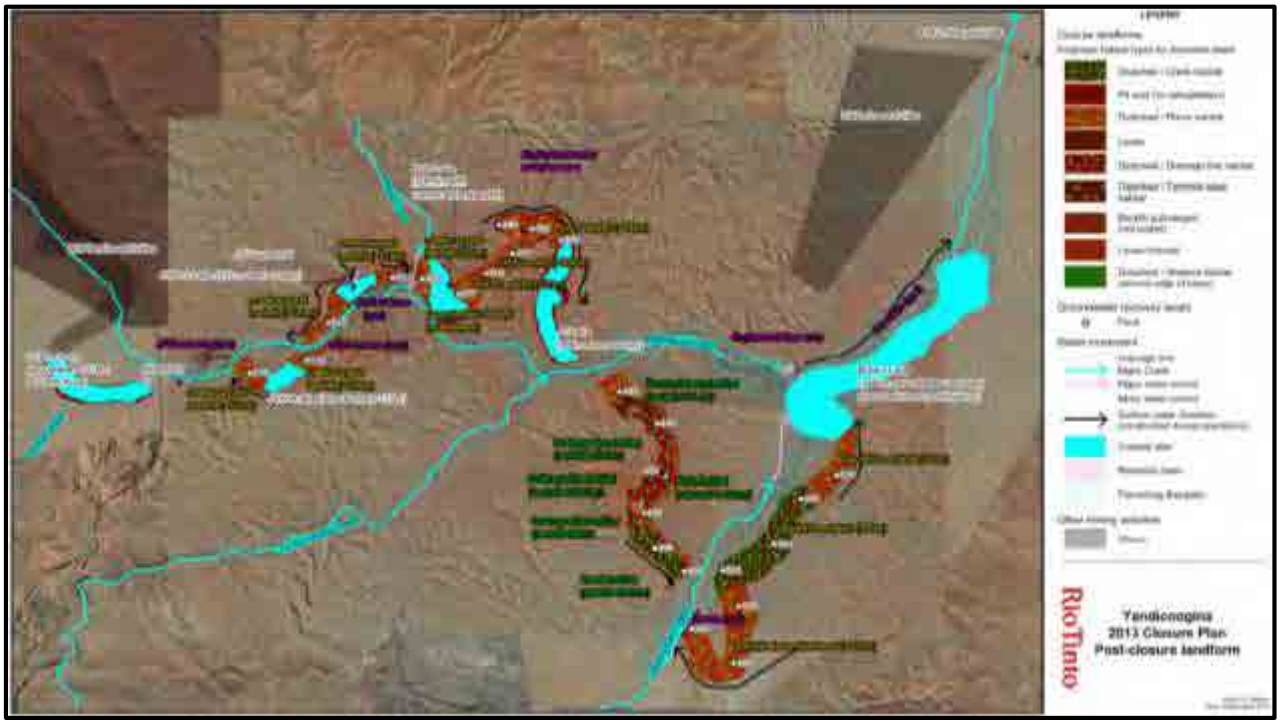

Figure 4-2: Post-closure landforms (RTIO 2014a)

An additional scenario is being considered in the event that the development of the Billiard North Deposit is not approved. This scenario includes a permanent lake or series of lakes within the Billiard South Deposit area rather than the Billiard North lake shown in Figure 4.2. It is recognised that both scenarios (approval and non-approval) must be considered until the outcome of the Billiard North approval is known.

Although Marillana Creek is shown as being diverted around the permanent lake in Figure 4-2, levee functionality is highly dependent on regular maintenance, and any engineered structure that is abandoned without maintenance will thus have a finite design life. Levee failure can result from cracking, animal burrowing or undermining, overtopping, vegetation growth (decomposition or overturning), localised erosion, geotechnical failure, or a number of other mechanisms. A single failure point will cause an entire levee to be ineffective. As such, closure scenarios that leave a pit within a floodplain should account for the potential of creek capture. Any engineered structures left in place or constructed at closure will provide additional protection but are not expected to be permanent structures that remain functional in perpetuity. Ongoing monitoring and maintenance would be required to ensure the continued integrity of the structures.

If utilised as part of the diversion plan, critical components of future levee design phases include assessment of durability, predicted long-term performance without maintenance, and erodibility if overtopped. For flow that is re-established across backfill, critical features of the pit backfill design include the infiltration rate relative to the pre-mining condition, re-establishment of drainage paths and active channel migration over the backfill, erodibility of the backfill material when inundated by floodplain flows, and settlement that might result in permanent standing water.

As shown in Figure 4-2, a permanent lake would be established in the Billiard North area. This scenario would have long-term impacts on the sediment and surface water conveyed to the downstream reach. Extreme flood flows may fill the lake and create through-flow conditions; however, the entire bed load would be retained in the void, increasing the erosive potential of the exiting flows. Downstream flow frequency and floodplain connectivity would be significantly affected as peak flows are attenuated by the storage capacity available in the void. Further studies will be required to predict environmental impacts to downstream receptors, particularly in terms of surface water delivery to the Fortescue Marsh.

From a geomorphological viewpoint, a key risk for the rehabilitated landforms at Billiard South will be the avulsion of Weeli Wolli Creek into the former mine. This risk would apply if the mine is filled and revegetated to recreate habitat that functions similarly to the pre-mining areas (as is proposed if the Billiard North development proceeds, providing material for backfill of the Billiard South mine). This risk would also apply if Billiard South is rehabilitated to one or more off-stream lakes. The risk of avulsion

could be mitigated through careful design incorporating rigorous hydraulic and geomorphological requirements. It will be important to ensure that ground surface levels and hydraulic conditions in the rehabilitated landforms are designed to minimise this risk.

If Billiard South is rehabilitated to an in-stream lake (as may occur if Billiard North does not proceed), there would be impacts resulting from disruption of sediment transport, as discussed above for Option 3.

Table A-1: Site Visit Notes

Weeli Wolli Creek Geomorphic Condition Assessment				
Sites Inspected	**27/28 June 2014**			
General notes	Conditions dry - no antecedent rain - base flow from Hope Downs and Yandi JSE evident			Weeli Wolli Creek is flows in a generally NNE direction through the Hamersley Range in a series of valleys carved into ancient bedrock. In the study area, it has a gravel, sand and cobble bed. Generally ephemeral but base flows have been supplemented by mine dewatering from Hope Downs and Yandi JSE downstream to North east of the Marillana Creek Junction. A feature of the immediate wetted perimeter in the supplemented reach was the strong recruitment of river red gums with 3 distinct year age classes over the last 7-8 years – possibly due to wet seasons setting off seeding behaviours and also a wet substrate into which the new trees could recruit. These new trees increase the roughness coefficient. A general feature was the presence of large gravel banks in the low flow channel plus multiple flood runners and gravel banks and active high flow channels, with finer material up on the floodplain benches above, where velocities were lower amongst the spinifex

Site number	Site description	Lat	Long	Conditions description
1	Lower Weeli Wolli near head of marshes U/s Railway and east of Munjina - Roy Hill Road	731514	7500912	Large deeply incised channel 45m wide by 8m deep - well rounded gravel and cobble beds with wave bedforms - up to 2 m down edges of toe of banks - with deep fine to coarse silt overlays - silt drapes on banks. No silt levees on upper bank - indicating limited overtopping - some tree losses on banks - no instream macrophytes. Highly dynamic - ephemeral - subject to major flood flows only. Gravels and cobbles reworked from banks ?? limited d/s transport of gravels, pebbles and cobbles - Next channel east not active - good vegetation cover - shrubs & small trees - 2nd east is active - 40 m wide and fine to medium silt over gravels and small rock - dryland
2	Upper end of study reach upstream of proposed levee system for Billiard Sth	731 984	747 1089	Confined stream section - primary channel 15-20 m 5m deep. Floodplain 210 m wide - Multiple flood runners - some with gravels and coarse sands - tree damage by floods - shifting gravel beds with cobbles up to 180mm - well rounded and worked but freshly won and fractured material evident from bank winning against foothills. Large trash load - small tree and Phragmites debris. Multiple gravel dumps in main active channel - steep batters - Manning's 0.065?? Base flow 110ML/day with pools held by gravel bars and small runs

3	Near start of levees and compression point - ref section 11514.42	732 724	747 2283	Floodplain 600 m wide - mainly on left bank (LB) - multiple channels on right bank (RB).
3a	major channel deviation ref section 9396	732 802	747 2479	Large outcrop of calcrete in RB deflecting flow to LB side at water level and above - wide floodplain on LB with 2 major flood runners - rock sizing from med sand to 150 mm cobbles - 20 – 100 mm dominant
4	Us/ Pillar (ref section 8769)	732 921	747 2645	Straight angle section from calcrete redirection - long pool u/s. Multiple channels RB - step off from prior floodplain with active runner in RB - steep LB – reduced limited floodplain
5	Near Pillar Levee (U/s ref section 8308)	732 986	747 3498	Large RB silt/gravel levee - prior floodplain to RB - old runners on LB - (prior floodplain). Main channel well formed with pools and gravel bar controls. Rock sizing - coarse sand to 150 mm cobbles
6	Junction of inputs from JC - us of proposed haul road (ref section 8308) - HIGH conflict zone	733 561	747 4470	Confined section stream over against LB in well-defined channel - Strong levee /gravel dump RB with old flood runner on RB side - An old prior floodplain - Rock sizing 20 – 100 mm - with small gravel and coarse sand - a lot of broken rock fragments – newly won material from left bank
7	Straight section up against hill 1300 m D/s haul Road u/s of section 6901	733 727	747 4692	Large active floodplain RB with runners but fine silts - Prior floodplain step to active floodplain - multiple runners to main channel against the RB - main channel 20 m only a lot of veg damage - lots of recruitment of new trees - rock sizing small. Gravel dumps to 3 m high. Pools all gravel bar controlled
7a	u/s bend d/s end from straight against LB hill (u/s ref section 6901)	733 680	747 4725	Pools with Gravel Bar controls - semi imbrication on channel runners - large RB floodplain - only one runner - Prior floodplain step - lots of fine silt on upper floodplain
8	Start of meandering section u/s of section 6184	734 326	747 5049	First meander bend d/s of confined valley - broad shallow channel - multiple runners with lots of gravel - Multiple gravel mounds - grain size coarse sand to large cobbles to 150 mm. - Floodplain 400 m wide - silt levee RB - with prior floodplain behind - fine silts

9	levee conflict zone	735 325	747 5952	Channel on RB with only one runner to prior FP?? - Large sed/gravel levee adj to main channel - main channel section 200 m wide - lots of gravel banks and pools - 5m deep. Other flood runners on LB - rock sizing variable less fines - 20 - 120 mm. Meander active against RB – increased levels of Typha- less shading?
10	Looking for potential break away to RB around old sand island Ref section 6901u/s	735 655	7475562	LB minor catchment's floodway breaks to main channel over road - high subject to some minor break away on 0.001% event?? - road up on ancient silt mound - drops away to west. Broad overland flow path recrosses track prior to silt Island DS [no photos]
11	U/s of Grey Crossing	736 292	747 7258	Large pools with typha - little sign of large sediment transfer d/s - one main channel 40 m wide by 3 m deep - but multiple channels in FP to LB with gravel bars to 2 m high. Also wide higher level terrace to LB - 500 m wide – with old inactive channels - full of veg - Large regeneration of recruiting trees due to continual wetness in main active channels. Gravel banks d/s 2 m high. Step up from active floodplain 3-4 m river terrace
12	Greys Crossing Main floodplain and channel u/s Yandi Road Crossing	736 292	747 7429	Large pools with Typha - little sign of active large particulate sediment transfer d/s - one main channel 40 m w by 3 m deep - but multiple channel in FP to LB with gravel bars to 2 m high - channel. Also wide higher level terrace to LB - <500 m wide - old inactive channels - full of veg - Large regeneration of recruiting trees due to continual wetness in active channel . Gravel banks d/s 2 m high. Step up from active floodplain 3-4 m to higher River terrace
13	D/s Greys Crossing - large pools drying - dead algae	736 351	747 7621	Wide gravel bed stream within shallow Floodplain - many flood runners - fine sediments. 2m +high gravel banks and lots of debris. Lower water levels ?? Due to losses to deeper gravel beds - flows low. Calcrete in RB - LB 3 m high vs. 1.5 in RB - hence runners in LB FP Gravel/pebble/Cobble size 20- 120 mm - some large rocks at crossing – bought in for crossing construction- high LWD debris and vegetative trash loads
14	d/s Marillana Junction	737 265	747 8580	Very wide gravel bed stream with large shallow pools within broad shallow active channel - many flood runners - fine sediments on RB. 2m +high Gravel banks and lots of debris. Lower water levels ?? Due to losses to deeper gravel beds - flows low. Calcrete in RB - LB 3 m high vs. 1.5 in RB - hence runners in LB FP Cobble size 20- 120 mm - some large rocks - high debris loads. Overall floodplain nearly 950 m wide with an older terrace step on LB

15	At Valley choke 9.2km d/s of Greys Crossing	740 295	748 5191	Broad deep cobble bed - limited fines - all 20 mm upwards to flat cobbles 150 diameter -- areas of imbrication - some gravel beds 2- 3 m high - dramatic photo of dynamic shifts - roots in tree up 1.8 m above the bed - Floodplain and stream 340 m wide - main channel incised 2 m - multiple runners separated by gravel banks - some steep bow fronts indicating cascading movement - of 20- 50 mm size material - a lot of winnowing going on indicated by size sorting and a general lack of finer material

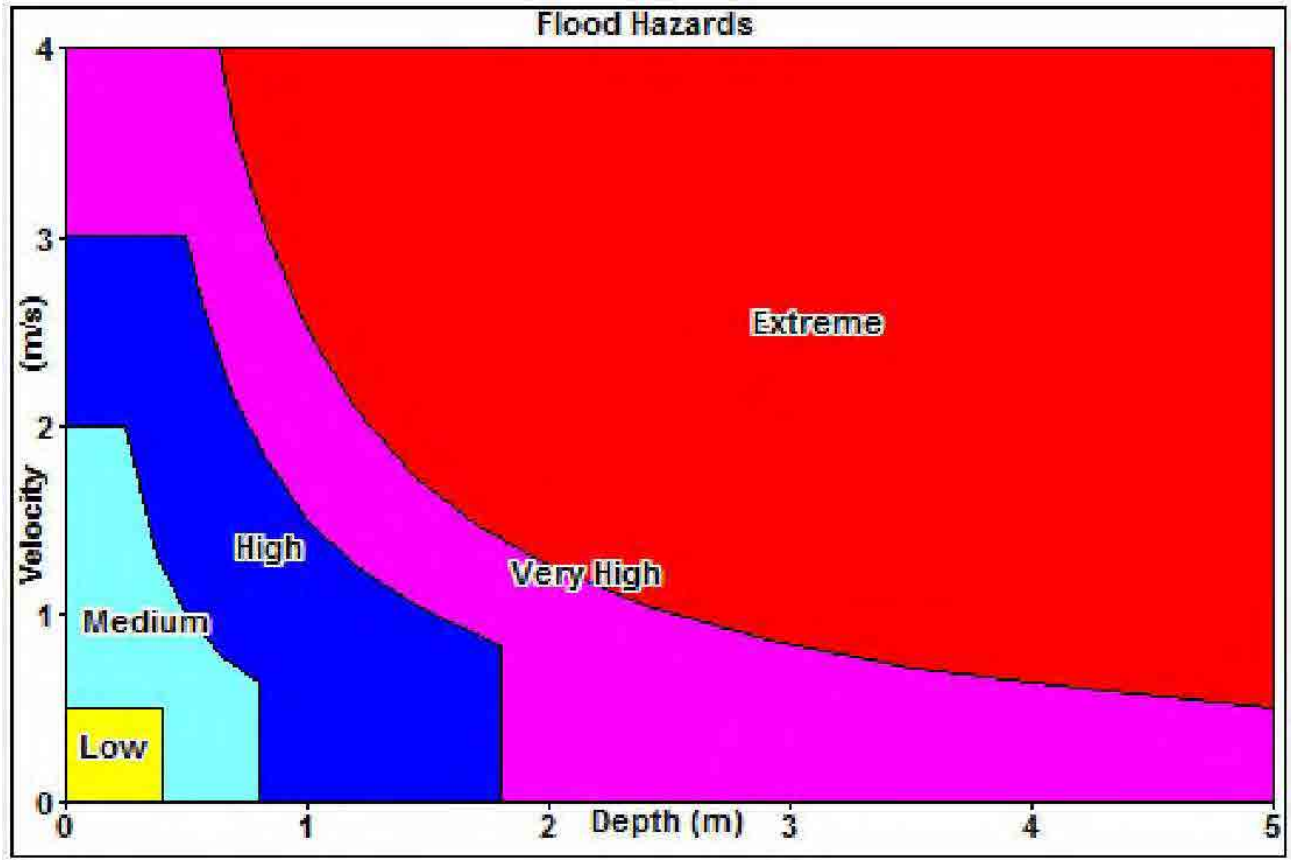
Appendix D Hydraulic Design Implications

Table D-1 Equivalent material thresholds corresponding to hydraulic results figure legend

Legend Colour	Shear stress (Pa)	Category
	0-5	Threshold for silts and fine sands
	5-10	Threshold for loams, clays and fine gravels
	10-20	Threshold for gravels up to 25mm
	20-30	Threshold for gravels up to 50mm
	30-40	Threshold for gravels with d50 = 50mm, shale and short native grass
	40-50	Threshold for long native grass
	50-100	Threshold for riprap/gravels with d50 ~100mm
	100-150	Threshold for riprap/gravels with d50 = 150mm
	150-200	Threshold for riprap/gravels with d50 = 225mm
	200-300	Threshold for riprap with d50 = 300mm
	300-400	Threshold for riprap with d50 = 450mm
	400-500	Threshold for gabions and riprap with d50 = 600mm
	500-1000	Threshold for concrete

Legend Colour	Shear stress (Pa)	Category
	0.0-0.5	Acceptable for most areas
	0.5-1.0	Threshold for silts, fine sands and fine gravels
	1.0-1.5	Threshold for clays and gravels up to 25mm
	1.5-2.0	Threshold for gravels up to 50mm
	2.0-2.5	Threshold for gravels up to 150mm
	2.5-3.0	Threshold for light riprap
	3.0-3.5	Threshold for riprap with d50 = 150-225mm
	3.5-4.0	Threshold for gravels and riprap with d50 = 300mm
	4.0-5.0	Threshold for gravels and riprap with d50 = 450mm
	5.0-6.0	Threshold for riprap with d50 = 600mm, gabions and concrete
	>6.0	Exceeds most material thresholds



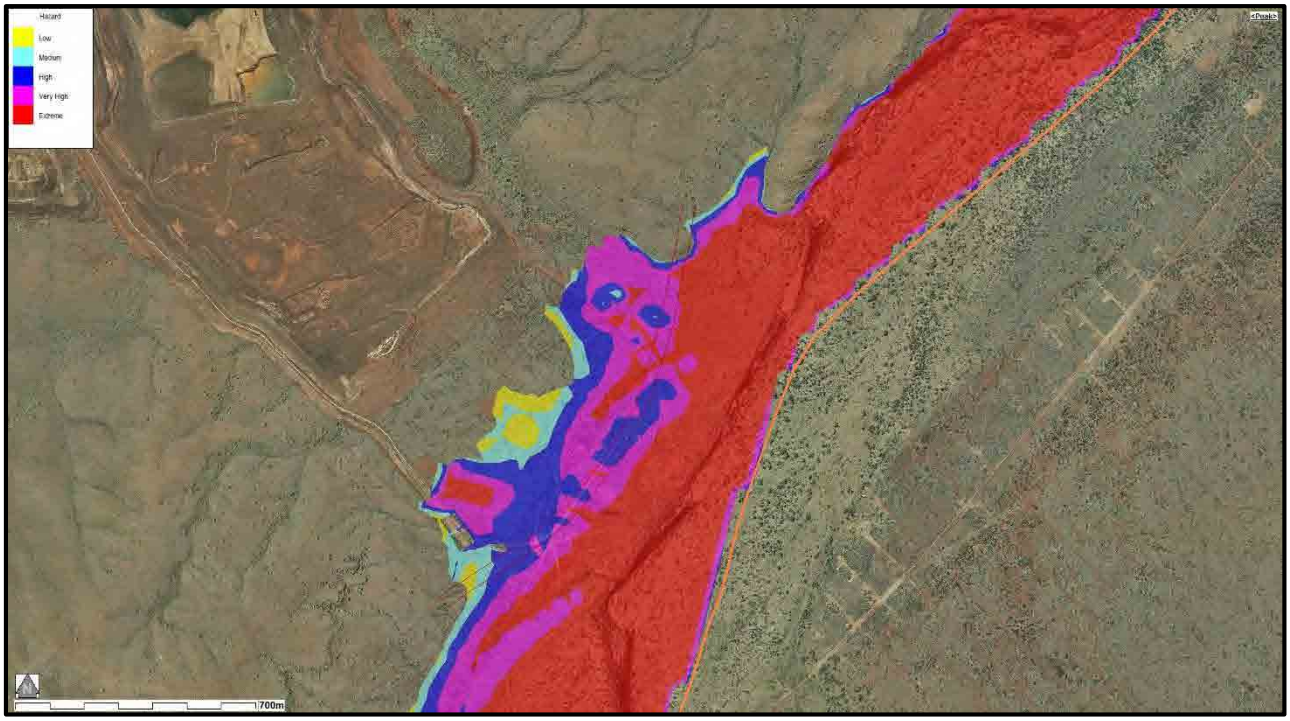


Figure D-1 WaterRide Hazard Mapping for constricted reach (1% AEP)

General rock sizing notes for levee armour and grade control rock:

Average channel velocities along the proposed levee are generally between 1.5 and 2.5 metres per second. According to Main Roads armour rock guidance (Tables D-2 and D-3), these velocities can be accommodated with Facing Rock, provided the rock is placed to sufficient depth with a properly engineered bedding layer. However, monitoring and maintenance would be required to ensure that scour does cause impinging localised flows with higher velocities to be directed toward the levee. Maximum velocities are generally at least 50% greater than average channel velocities, and the presence of bends can force higher energy flow directly against the levee.

In accordance with Main Roads WA guidelines, levees and abutments generally require armouring to resist shear stresses and other hydraulic forces where channel velocities exceed 2 m/s, with size and thickness of rock protection determined based on AustRoads Waterway Design, 2013 (p51). Main Roads design criteria are based on velocity only and do not account for the depth of flow, which affects the actual shear stress required to mobilise a particular particle size. A conservative approach may be warranted if the impacts of failure are deemed to be critical. In general, floods peaks in the Weeli Wolli Creek system are of relatively short duration, and sustained water depths against the levee are not likely; however, a seepage barrier (geosynthetic clay, for example) can extend the life of the structure. A key trench would increase the flow path length and prevent piping along the interface between levee fill and insitu materials.

Where levees terminate, armour rock should be keyed in to prevent erosion as flows spread out. Additional rock placement may be specified to account for loss and wastage. Rock armouring should be keyed in to the predicted scour depth below existing ground surface. Rock should meet minimum specific gravity requirements. Rock strength should typically meet “very high” or “extremely high” strength as defined in AS1726. Any stone placed as armour rock protection may break down over time. Some overdesign may be warranted to account for rock degradation, particularly if hardness, strength, and durability parameters are below standard recommendations. Tables D-2 and D-3 summarise the rock sizing requirements as presented in AustRoads design guides (2013). Strength requirements are shown in Table D-4.

Table D-2 Permissible velocities for standard rock classes (AustRoads 2013, MRWA 2006)

Velocity (m/s)	Class of rock protection (tonne)	Section thickness, *T* (m)
< 2	None	–
2.0–2.6	Facing	0.50
2.6–2.9	Light	0.75
2.9–3.9	¼	1.00
3.9–4.5	½	1.25
4.5–5.1	1.0	1.60
5.1–5.7	2.0	2.00
5.7–6.4	4.0	2.50
> 6.4	Special	–

Table D-3 Rock Protection Requirements (Table 3.12, AustRoads 2013)

Rock Class	Rock Size Diameter (m) *	Approximate Rock Mass (kg)	Minimum Percentage of Rock Larger than Rock Size in the Second Column	Typical Use (Examples Only)
Type A	0.20 0.10 0.075		0 50 90	Catchpit Surrounds
Type B1	0.30 0.20 0.10		0 50 90	Culvert Outlets
Type B (Facing)	0.40 0.30 0.15	100 35 2.5	0 50 90	Culvert Outlets
Light	0.55 0.40 0.20	250 100 10	0 50 90	Floodway Batters

1.0 Summary

Rio Tinto Pty Ltd's (Rio Tinto) Yandicoogina (Yandi) iron ore project is located approximately 75 km northwest of Newman, in the Pilbara region of Western Australia. Rio Tinto is currently undertaking a 'Pre-feasibility Study' for development of two channel-iron deposits at Yandi Billiards, called Pocket and Billiards South. Numerous biological surveys have been completed in the Yandi locality, and although some of these overlap Yandi Billiards, they do not provide full coverage of this area.

Biota Environmental Sciences (Biota) was commissioned in 2014 to undertake a vegetation and flora survey at Yandi Billiards (hereafter referred to as the study area) in order to address gaps in knowledge and expand the existing dataset for flora and vegetation. This survey was conducted over two seasons to comply with the requirements of a Level 2 vegetation and flora assessment. This report documents the combined results of both field surveys (Phase 1, completed in March 2014; and Phase 2, completed in July 2014).

A desktop review of biological information relevant to the study area was undertaken prior to the survey. A total of 121 quadrats and 28 relevés have been sampled in the study area to date. Of these, 46 quadrats and eight relevés were established during the Phase 1 survey and three quadrats were established during the Phase 2 survey in order to sample previously unsurveyed areas and to provide replicated sampling for particular vegetation types. Resampling of established quadrats was also undertaken during both the Phase 1 and Phase 2 surveys. Overall, 68 quadrats in the study area have been resampled over two seasons (with at least one phase of sampling in favourable conditions for plant growth). Mapping of dominant vegetation types was also undertaken in previously unsurveyed areas and in areas of broad-scale historical mapping. The field survey also included targeted searches for the Threatened species, *Lepidium catapycnon*, and for Priority flora that were identified by the desktop review as having the potential to occur in the study area.

A total of 23 vegetation types have been described for the study area. These vegetation types were associated with four broad landscape categories: major creeklines and tributaries; minor creeklines, floodplains and valleys; hills, ridges and breakaways; and plains. Most of the vegetation was in Good to Very Good condition, however the creekline and floodplain vegetation ranged from Good to Very Poor condition due to weed invasion and disturbance from cattle.

None of the vegetation types observed in the study area represent Threatened Ecological Communities (TECs) or Priority Ecological Communities (PECs). Vegetation similar to that recorded for the study area is well represented in the broader locality. One vegetation type (C1) is considered to represent an ecosystem at risk, and two other vegetation types (C2 and C3) represent good condition riparian vegetation. These vegetation types are all associated with Marillana Creek and Weeli Wolli Creek, which are two of the major ephemeral creek systems of the locality.

A total of 455 native vascular flora taxa from 147 genera and 47 families have been recorded from the study area to date. This species richness is high but still within the range expected for an area of this size in this locality.

One Threatened flora species, *Lepidium catapycnon*, was recorded from two locations in the study area during previous field surveys (Hamersley Iron 2006, Biota 2009a). These populations were not found during the Phase 1 survey, nor were any additional populations located during targeted searches. Further searches were undertaken during the Phase 2 field survey, and *L. catapycnon* was recorded from 26 locations separated into three distinct populations: the existing population originally located by Biota (2009a) and two new populations. The location of the historical record made by Hamersley Iron (2006) was searched in both Phase 1 and Phase 2, however no plants were observed. A total of 777 individuals were counted in the study area during Phase 2. Two of the

L. catapycnon populations are partly located within the preliminary proposed waste dump locations, with a total of 389 individuals (50% of the individuals recorded in 2014) located within the current project footprint.

Additional habitat suitable for *Lepidium catapycnon* occurs in the study area, not all of which has been searched. All hills and slopes of the study area could comprise suitable habitat for *L. catapycnon*, especially areas that have been burnt recently or have rocky ironstone shale slopes, however vegetation type H1 remains the most prospective unit for this species. While it is possible that additional populations of *L. catapycnon* occur in the study area, there is a low likelihood of new populations being located in areas where targeted searches have been undertaken.

Two Priority flora species were recorded in the study area:

- The Priority 3 *Sida* sp. Barlee Range (S. van Leeuwen 1642) was recorded from a free face supporting vegetation type H5 at two locations in close proximity: three individuals were recorded from the southern boundary of the study area, while two individuals were recorded approximately 10 m south of the study area. Both of these records are outside the proposed project footprint.
- The Priority 4 *Goodenia nuda* was recorded from nine locations within vegetation types P6, P2 and P3, comprising 76 individuals. Four of these locations occur in the proposed project footprint. Given that *Goodenia nuda* is a small herb, and that additional suitable habitat is present in the study area, additional populations of this species may occur.

Based on the results of the field survey, as well as the known distribution of conservation significant species and the types of habitats present in the study area, a further three Priority flora species may potentially occur in the study area:

- *Stylidium weeliwolli* (Priority 2) is a small annual herb that could occur in Weeli Wolli Creek or Marillana Creek.
- *Rostellularia adscendens* var. *latifolia (*Priority 3) is also a herb and has a wide range of habitat preferences, although it is most commonly recorded in drainage areas.
- *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) (Priority 3) is a tussock grass that could occur as scattered individuals, particularly on the floodplains surrounding the major creeks.

Eighteen introduced flora species (weeds) were recorded from the study area. **Argemone ochroleuca* (Mexican Poppy) is the only species listed as a Declared Pest for WA. **Cenchrus ciliaris* (Buffel Grass) was the most prolific weed observed in the study area. This species formed dense populations along sections of creek banks and floodplains, frequently in association with **Cenchrus setiger* (Birdwood Grass). Both **Cenchrus* species are serious environmental weeds.

2.0 Introduction

2.1 Project Background

Rio Tinto currently operates the Yandi iron ore mine as part of its Pilbara Iron operations. Yandi is located approximately 75 km northwest of Newman in the Pilbara region of Western Australia (Figure 2.1). The original Yandi mine, Junction Central, started construction in 1997 with the first shipment of ore occurring in 1999. The Yandi operations are approved under Ministerial Statement 914 (MS914).

Rio Tinto is currently undertaking a 'Pre-feasibility Study' for development of two channel-iron deposits at Yandi Billiards, called Pocket and Billiards South (PBS), located approximately 7 km east of the existing Yandi mine.

It is anticipated that the future development of Yandi Billiards may be formally assessed under the WA *Environmental Protection (EP) Act 1986* and potentially the Commonwealth *Environment Protection and Biodiversity Conservation (EPBC) Act 1999*. Numerous biological surveys have been completed in the Yandi locality, and although some of these overlap Yandi Billiards, they do not provide full coverage of this area (as defined in MS914; see Figure 2.1).

A desktop review of the surveys completed in the Yandi Billiards area was recently conducted (Biota 2013) to determine any further work required to bring the level of information for the area to a level suitable for environmental impact assessment (EIA) under Part IV of the WA *EP Act 1986*. Biota was subsequently commissioned to undertake a vegetation and flora survey in the Yandi Billiards area to address the recommendations of this report. The Yandi Billiards survey area is approximately 8,640 ha in size and is hereafter referred to as the 'study area'.

2.2 Scope and Objectives of this Study

The objective of this study was to conduct a Level 2 seasonal vegetation and flora survey in the study area, based on the recommendations of the desktop review (Biota 2013), in order to expand the existing flora and vegetation dataset for the area. This vegetation and flora assessment was undertaken in accordance with:

- the Environmental Protection Authority (EPA) Position Statement No. 3 "Terrestrial Biological Surveys as an Element of Biodiversity Protection" (EPA 2002); and
- the EPA Guidance Statement No. 51 "Terrestrial Flora and Vegetation Surveys for Environmental Impact Assessment in Western Australia"(EPA 2004).

This report details the combined methods, results and key findings of the first phase (Phase 1: 'wet season') and second phase (Phase 2: 'dry season') vegetation and flora surveys undertaken in the study area in March and July 2014, respectively. The results of the first phase of sampling in the study area were previously presented in an interim report (Biota 2014a). Information presented in the current report has been reviewed and updated as necessary, based on the combined results of the two field surveys.

As part of the Phase 1 survey, the following tasks were required to be completed:

- review and discuss the existing information for the study area, including a summary of the relevant findings of the desktop review (Biota 2013);
- describe, photograph and map the dominant vegetation types in previously unsurveyed areas of the study area, and revise and refine the existing broad-scale historical vegetation mapping as necessary;
- establish floristic survey quadrats in previously unsurveyed areas and areas of existing broad-scale historical mapping;

- establish additional floristic survey quadrats in previously mapped areas for vegetation types that required additional sampling replication to meet Level 2 requirements;
- resample approximately 60% of the existing historical quadrats in the study area;
- identify any vegetation types of conservation significance, including TECs and PECs (see Appendix 1);
- conduct targeted searches for the Threatened flora species, *Lepidium catapycnon,* and Priority flora species that may occur in the study area (see Appendix 1);
- record any introduced (weed) species and conduct vegetation condition mapping for the study area; and
- combine the Phase 1 survey results with existing data to compile a list of vascular flora species for the study area.

As part of the Phase 2 survey, the following tasks were required to be completed:

- resample approximately 60% of the floristic survey quadrats established during the first phase of sampling;
- establish any additional floristic survey quadrats in previously mapped areas for vegetation types that required additional sampling replication to meet Level 2 requirements;
- refine and update the vegetation boundaries and descriptions, where necessary;
- conduct additional searches for the Threatened flora species, *Lepidium catapycnon,* and Priority flora species that may occur in the study area;
- record any additional introduced (weed) species and update vegetation condition mapping where necessary; and
- combine existing data and results from the current survey to compile a vascular flora species inventory for the study area.

3.0 Methodology

To meet the objectives of the study and provide an assessment of the biological values of the study area, a desktop review was completed (see Section 3.1), followed by a field survey (see Section 3.2).

3.1 Desktop Review

Prior to the field survey, Biota was commissioned to undertake a desktop review of the study area with the specific aim of assessing the survey effort completed to date, identifying data gaps, and providing recommendations on additional biological surveys required to support a formal EIA of the study area. This review considered regional information, previous biological surveys in the locality, and the results of various database searches, as discussed in the sections below. The results of the desktop review were used to identify gaps in knowledge (see Section 4.10), which were then addressed in the design of the current field survey.

3.1.1 Literature Review

Published and unpublished reports relevant to the study area were examined. Several regional-scale reports and datasets were reviewed, including the summary of bioregional data (Kendrick 2003a), land systems mapping (Van Vreeswyk et al. 2004) and vegetation description and mapping by Beard (1975a, 1975b).

Additionally, a number of vegetation and flora surveys undertaken previously in the vicinity of the study area were reviewed (see Section 4.7).

3.1.2 Database Searches

Three databases were searched for records of flora and vegetation of conservation significance[1] that had been previously recorded or could potentially occur within or in the vicinity of the study area:

- The NatureMap[2] database: NatureMap is a joint project of the Western Australian Museum (WAM) and the WA Department of Parks and Wildlife (DPaW), which was formerly known as the Department of Environment and Conservation (DEC). This database represents the most comprehensive source of information on the distribution of Western Australia's flora and fauna, comprising records from DPaW's Fauna Survey Returns Database, Threatened Fauna Database Threatened Flora database and the WA Herbarium Specimen Database; the WAM Specimen Database; and BirdLife Australia's Atlas of Australian Birds.
- The Commonwealth *EPBC Act 1999* Protected Matters database.
- The Atlas of Living Australia[3], which is a joint project between academic collecting institutions, private individual collectors and community groups. The atlas contains occurrence records, environmental data, images and the conservation status of species throughout Australia.

The NatureMap and *EPBC Act 1999* Protected Matters database searches were based on an approximate central point of the study area (22° 47' 31"S, 119° 18' 26"E) surrounded by a 25 km buffer. The Atlas of Living Australia search was centred around the same coordinate (22° 47' 31"S, 119° 18' 26"E), using a 10 km buffer. All database searches were conducted on 22nd May 2013. In addition, outputs from Rio Tinto's and Biota's internal databases of rare flora records from previous surveys in the vicinity were also examined.

---

1 The framework for conservation significance ranking of communities and species in Western Australia is presented in Appendix 1.

2 http://NatureMap.dpaw.wa.gov.au

3 http://www.ala.org.au/

3.1.3 Ranking of Conservation Significant Flora

All results from the literature review and database searches were used to compile a list of conservation significant flora species that had previously been recorded from the broader locality. The likelihood that each species would occur in the study area was then assessed using the rankings and criteria provided in Table 3.1. Two rankings have been provided:

1. An initial assessment was made during the desktop review (see Section 4.9 and Appendix 2). This was based on consideration of the overall distribution of the species, the proximity of the study area to known populations and, if the species was known to be linked to particular habitats, whether suitable habitat was present in the study area based on inspection of aerial photography and/or existing information. In the case of the current study area, major and minor creeklines, stony hills and plains were apparent on aerial imagery.
2. The likelihood rankings were subsequently revised as necessary based on the findings of the field survey (see Section 6.4 and Appendix 2). Where the initial and final likelihood rankings were different, the reason was provided.

Table 3.1: Ranking system used to assign the likelihood that a species would occur in the study area.

Rank	Example Criteria
Recorded	1. The species has been previously recorded in the study area.
Likely	1. There are existing records of the species in close proximity to the study area, or from the locality; and • the species is strongly linked to a specific habitat, which is present in the study area; or • the species has more general habitat preferences, and suitable habitat is present.
May potentially occur	1. There are existing records of the species from the locality, however • the species is strongly linked to a specific habitat, of which only a small amount is present in the study area; or • the species has more general habitat preferences, but only some suitable habitat is present. 2. There is suitable habitat in the study area, but the species is recorded infrequently in the region.
Unlikely	1. The species is linked to a specific habitat, which is absent from the study area; or 2. Suitable habitat is present, however there are no existing records of the species from the locality despite reasonable previous search effort in suitable habitat; or 3. There is some suitable habitat in the study area, however the species is very infrequently recorded in the region.
Would not occur	1. The species is strongly linked to a specific habitat, which is absent from the study area; and/or 2. The species' range is very restricted and would not include the study area.

3.2 Field Survey

3.2.1 Survey Team

A two-phase survey was carried out in the study area, with the first phase timed to follow the expected period of highest rainfall in the Pilbara bioregion (i.e. after summer) and the second phase timed to follow winter rain. The timing of the two-phase field survey was selected to provide optimal conditions for the detection of all species present in the study area (see Section 3.2.2). Both phases of the field survey were undertaken by Biota botanists who have extensive experience in flora and vegetation surveys in the Pilbara, including large-scale Level 2 surveys.

Phase 1 of the field survey was undertaken between the 8th and 20th of March 2014 by five botanists (Rachel Butler, Chloe Flaherty, Pierre-Louis de Kock, Dr Shadila Venkatasamy and Scott Werner). Chloe Flaherty completed the mapping traverses during this survey, while the remaining personnel conducted the quadrat sampling. Excluding travel days, a total of 57.5 person days

were spent on this phase of sampling (no sampling occurred on the 8th of March and a half day of sampling was completed on the 20th of March).

Phase 2 of the field survey was undertaken largely between the 7th and 11th of July 2014 by four botanists (Prue Anderson, Pierre-Louis de Kock, Chloe Flaherty and Scott Werner), who all completed quadrat sampling. Additional traverses through the study area were also completed on the 14th of July. Excluding travel days, a total of 20 person days were spent on this phase of sampling.

3.2.2 Survey Timing and Conditions

The weather conditions (particularly rainfall) leading up to a field survey are important factors influencing the number and type of flora species that are recorded from an area. To indicate rainfall leading up to this survey, monthly rainfall data from the Yandi mine weather station for the months preceding the field surveys are shown in Figure 3.1. The monthly rainfall totals were compared to the long-term median monthly rainfall for the area. The latter data were sourced from the Bureau of Meteorology (BOM) Marillana weather station (number 5009), which is the closest recording station to the study area (approximately 20 km away) with long-term rainfall data (BoM 2014).

The data showed that rainfall received at Yandi during the wet season (December 2013 to February 2014) preceding the Phase 1 field survey was more than twice the median rainfall for this period (334.4 mm compared to 118.3 mm). Several large rainfall events occurred in December 2013-January 2014, and the last rainfall event prior to the Phase 1 survey occurred over the 10th-12th February (23 days before the Phase 1 survey, when 6.4 mm of rain was received). Given this, the Phase 1 survey timing was considered optimal for the collection of annual and cryptic perennial flora species.

In the three months preceding the Phase 2 survey (April-June 2014), 45 mm of rainfall was received at Yandi, which is 1.6 times the median for this period (28 mm). The last rainfall event preceding this survey was over the 24th–25th of June (12 days before the Phase 2 survey, when 4.6 mm of rain was received). The Phase 2 survey timing was therefore considered favourable for the collection of perennial flora. However, despite the above average rainfall preceding the Phase 2 survey, July is still a typically dry time of year for the Pilbara and it is possible that some annual and cryptic perennial species may not have been present.

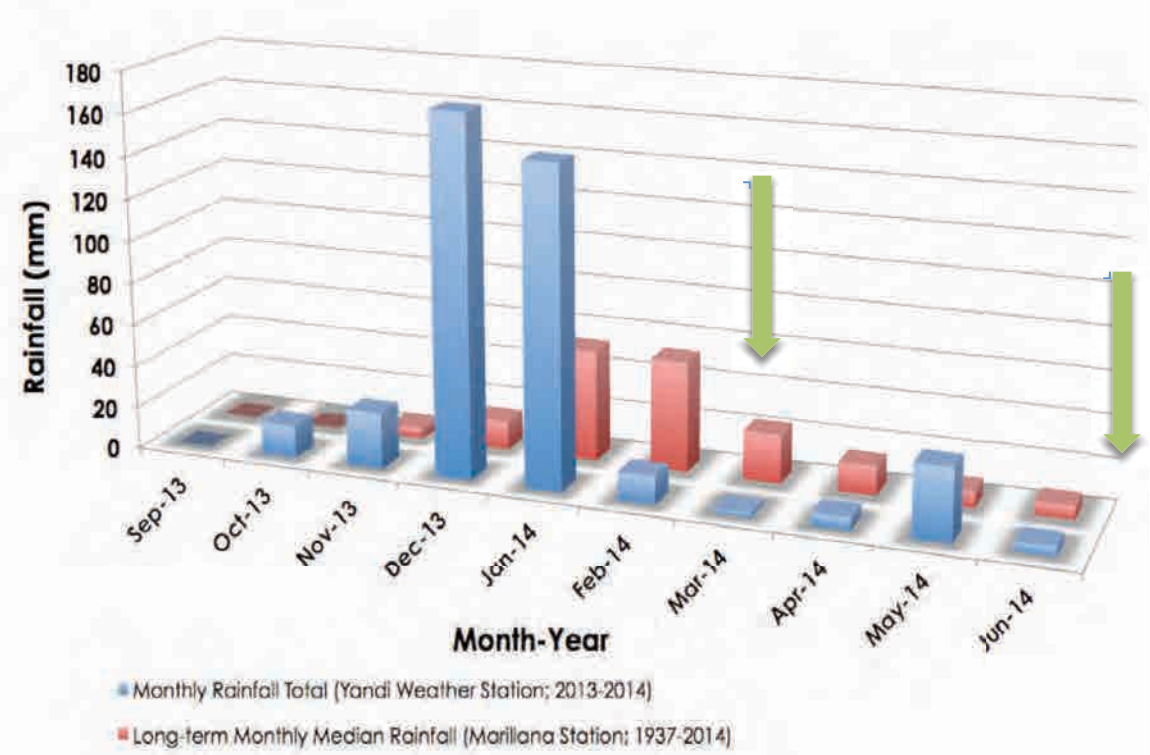

Figure 3.1: Monthly rainfall at the Yandi mine weather station for September 2013-June 2014, compared to the long-term monthly median rainfall from the Marillana recording station (BoM 2014). Arrows indicate timing of field surveys.

3.2.3 Establishment and Assessment of Flora Quadrats and Relevés

Indicative quadrat locations were selected prior to the field survey. The study area boundaries, aerial photography and previous vegetation mapping were viewed using Geographical Information System (GIS) software (QGIS). Quadrat sites were then selected such that there was replication of sampling (a minimum of two quadrats) within each mapped vegetation type, taking into account the broad habitats and vegetation types apparent from the aerial imagery. Some additional quadrats were established in previously mapped areas to improve sampling replication. Once in the field, the actual locations of the quadrats were adjusted as necessary (e.g. to be placed in an area more representative of the broader vegetation type).

Permanently marked quadrats (flora sampling sites of a fixed area) were used wherever possible. Most quadrats established were 50 m x 50 m in size, or an equivalent area (2,500 m^2). This area is recognised as providing an adequate sample of species presence for the Pilbara vegetation and is the standard quadrat size for botanical survey work in the region (Clarke 2009). Where a square quadrat was unsuitable for capturing the vegetation type (e.g. along narrow creeklines), a rectangular quadrat of equivalent area (e.g. 25 m x 100 m) was established instead. The quadrats were permanently marked using steel fence droppers on at least three corners. An optical square and measuring tapes were used to accurately position the quadrat boundaries.

In cases where quadrats could not be established (e.g. due to the small size or irregular shape of the habitat), these locations were instead surveyed as relevés, or mapping notes were taken (see Section 3.2.4). A relevé is an unbounded flora sampling site with a similar area to a standard quadrat; essentially the same information is recorded as for a quadrat, however the sampling of flora is typically not as thorough. Relevé sampling is usually undertaken if the vegetation type has a narrow linear or irregular shape (e.g. minor flowlines, narrow ridgelines, areas of cracking clay, etc.) or comprises only a small area (e.g. on rockpiles), making establishment of a standard quadrat in a single vegetation type difficult.

A total of 121 quadrats and 28 relevés have been sampled in the study area to date (Table 3.2 and Figure 3.2). These include 46 quadrats and eight relevés established during Phase 1 of the current survey, and three additional quadrats established during Phase 2.

Resampling of established quadrats was also undertaken in Phase 1 and Phase 2 of the current study. Overall, 68 quadrats in the study area have been resampled over two seasons to date (with at least one phase of sampling in favourable conditions for plant growth). These include:

- 32 existing quadrats that were established within the study area as part of other surveys in the locality, which were resampled during the Phase 1 survey;
- 30 quadrats that were established in Phase 1, which were resampled during the Phase 2 survey; and
- six quadrats that had been both established and resampled during a previous survey (Biota 2009b).

Eleven quadrats out of the 36 sampled by Biota (2009b) were established at a time when conditions for plant growth were unfavourable, and were resampled during a typically dry time of year (although the conditions during this latter survey were relatively favourable for this season). These quadrats have not been considered as being effectively resampled, as it is likely that some species may not have been present or identifiable at the time of both phases of surveys (e.g. annual daisies that would germinate mostly after late winter rains, annual grasses, etc.).

Fourteen quadrats that were sampled in the study area have since been cleared for expansion of the mine or the establishment of roads or drill tracks (see Table 3.2).

Table 3.2: Number of quadrats and relevés sampled in the study area.

Survey (Reference)	Survey Timing (Conditions for Plant Growth)	Number of Quadrats Established	Number of Quadrats Resampled	Number of Relevés Recorded	Other Comments
Yandi Billiards Vegetation and Flora Survey – Phase 2 (current survey)	July 2014 (favourable for this time of year)	3	30	0	
Yandi Billiards Vegetation and Flora Survey – Phase 1 (current survey)	March 2014 (optimal)	46	32	8	
Yandi Additional Areas Level 2 Flora and Vegetation Survey (Biota 2014b)	June 2012 (favourable for this time of year)	11	0	5	1 quadrat has subsequently been cleared.
Vegetation and Flora Survey of the Billiards Deposit, near Yandi (Biota 2009b)	June 2007 (unfavourable)	29	0	14	2 quadrats have subsequently been cleared.
	July/August 2008 (favourable for this time of year)	7	11	0	Quadrats were both established and resampled under unfavourable conditions, and are therefore not included in the overall resample total.
	June 2009 (favourable for this time of year)	0	6	0	
Flora and Vegetation Survey of the Yandi Expansion Area (Biota 2004a)	August/September 2004 (unfavourable)	13	0	1	6 quadrats have subsequently been cleared.
Flora and Vegetation Survey of the Hope Downs Rail Corridor Extension through the Hamersley Range (Biota 2004b)	April 2003 (favourable)	9	0	0	4 quadrats have subsequently been cleared.
Vegetation and Flora of the Hope Downs Rail Corridor from Port Hedland to Weeli Wolli Creek (Biota 2002)	April/May 2001 (favourable)	2	0	0	1 quadrat has subsequently been cleared.
Hope Downs Rail Corridor Biological Surveys (Halpern Glick Maunsell 2000)	November/ December 1999 (unfavourable)	1	0	0	
	Total	121	68	28	

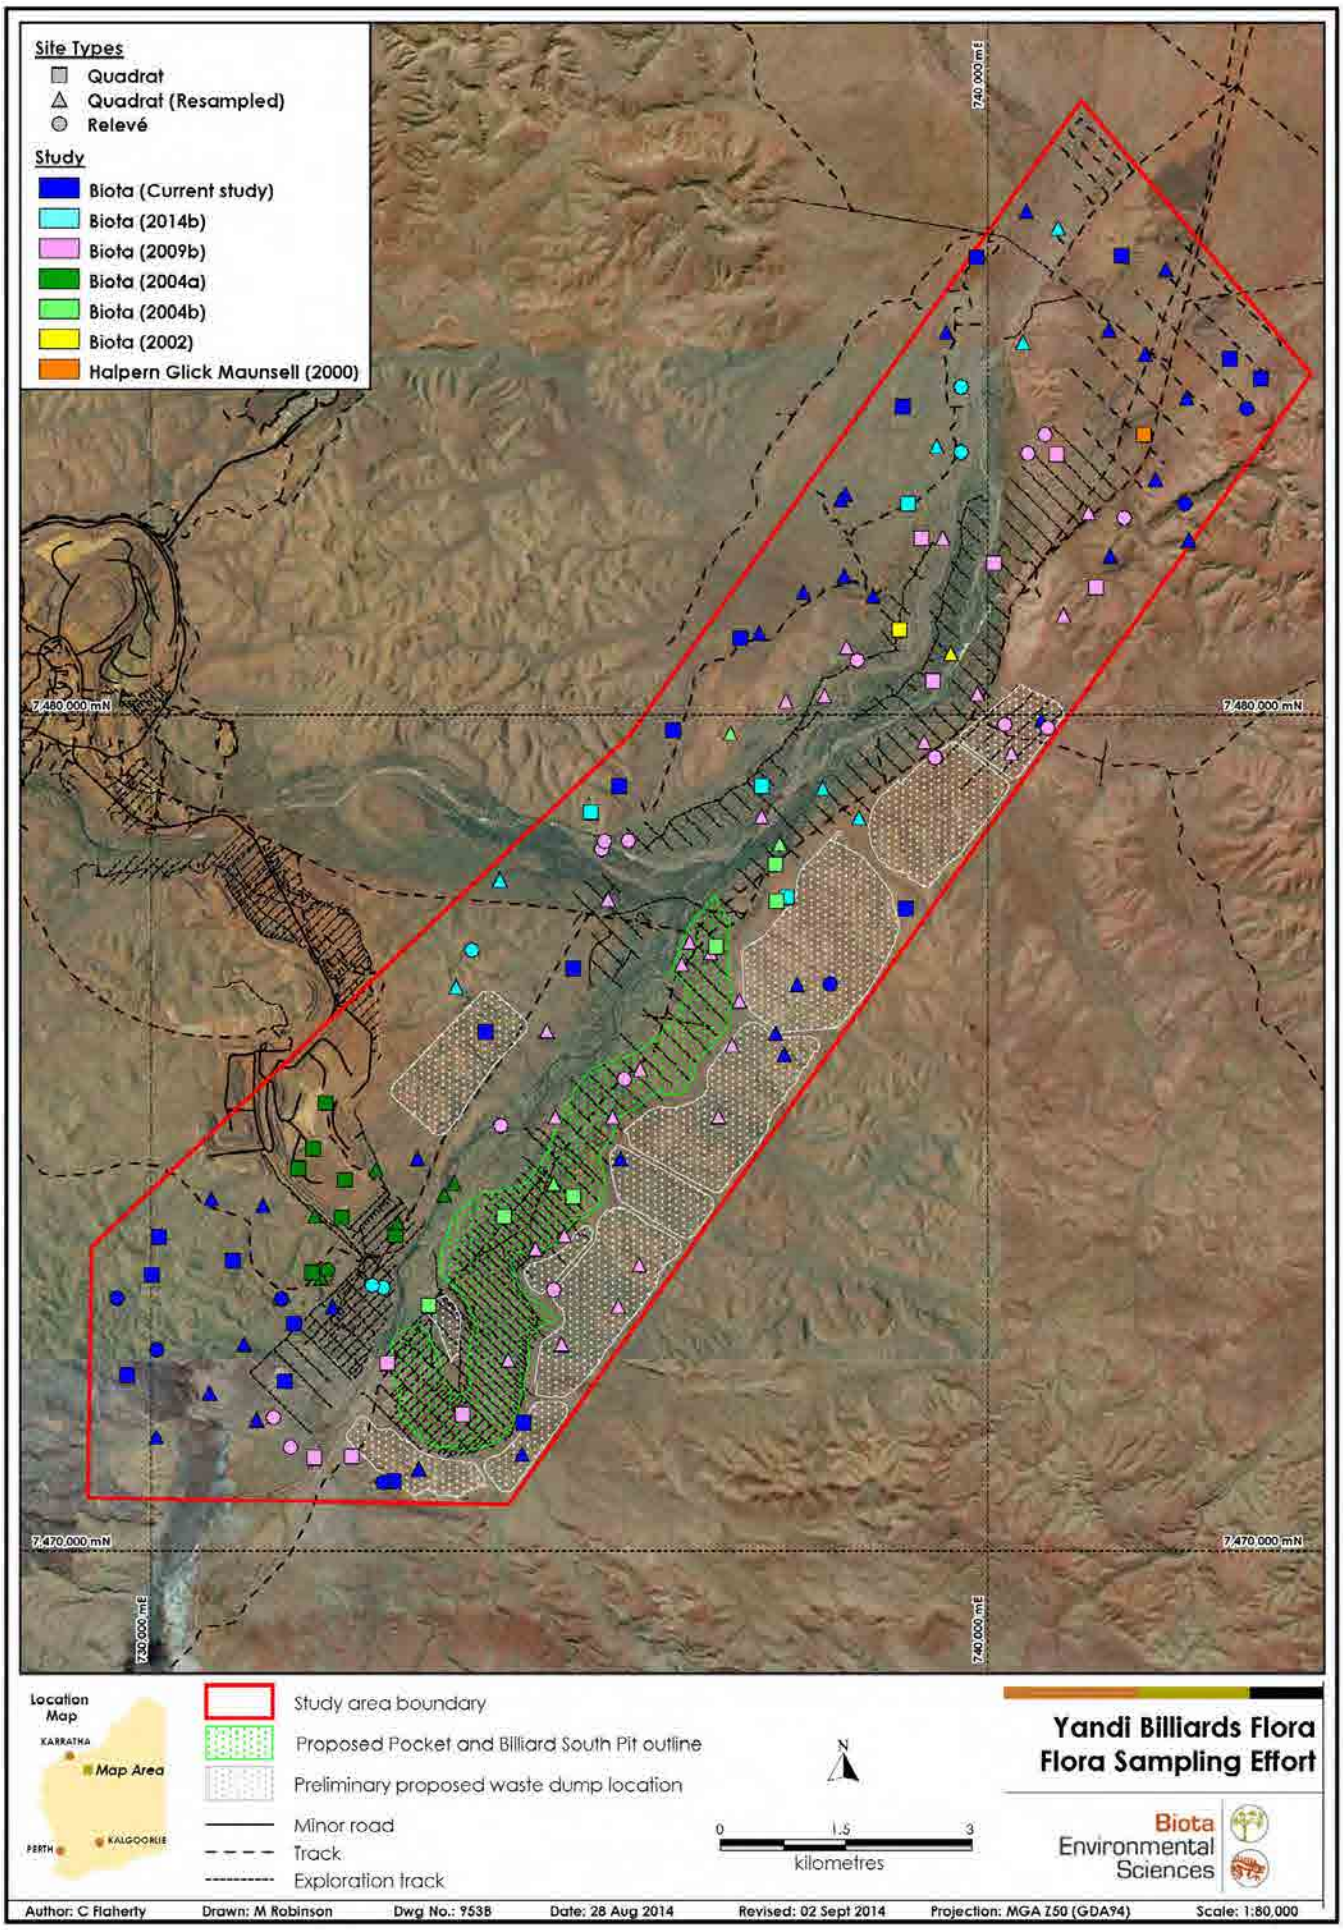

Figure 3.2: Quadrat and relevé locations in the study area.

The following information was recorded for each quadrat and relevé:

- location co-ordinates (±5 m), recorded with a hand-held Global Positioning System (GPS) using the WGS84 datum; all coordinates in this report are displayed in MGA Zone 50;
- a colour photograph of each site (usually taken from the northwest corner of the quadrat, looking southeast);
- habitat description;
- broad soil type;
- fire history (approximate time since last fire, where applicable);
- vegetation description based on the height and estimated cover value of dominant species (Aplin 1979; see Appendix 3);
- vegetation condition ranking (Trudgen 1988; see Appendix 3); and
- the estimated percent foliar cover of each flora species present within the quadrat, or in the vicinity (within a ~30 m radius) of the centre point of the relevé.

Quadrat and relevé locations are shown on the vegetation mapping in Appendix 4. Vegetation condition mapping and weed locations are provided in Appendix 5. All raw data from the sampling sites are presented in Appendix 6.

3.2.4 Vegetation Description and Mapping

Vegetation mapping was undertaken in the study area in previously unsurveyed areas and areas of broader historical mapping (see Figure 4.5), which extended over an area of 3,395 ha (39% of the study area).

Vegetation types identified from aerial photography were ground-truthed during foot traverses in the study area. The boundaries of the study area were loaded onto hand-held GPS units to ensure that the correct areas were traversed. Vegetation descriptions for each vegetation type observed in the field were recorded at all quadrats and relevés (see Section 3.2.3), and also in a series of mapping notes. Mapping notes are sampling sites conducted over an area of smaller scale than a quadrat or relevé; these notes are typically brief, with only dominant and commonly associated species being recorded. Mapping notes are taken primarily during foot traverses of an area, with the objective of detecting boundaries and changes in vegetation types. Typical information recorded at a mapping note location includes notes on the habitat, landscape and vegetation type, usually with a representative photograph and often with opportunistic specimen collections to supplement the species list. Mapping note locations are presented in Appendix 7.

Vegetation descriptions were based on the height and estimated cover value of dominant species using Aplin's (1979) modification of the vegetation classification of Specht (1970). The previous detailed vegetation mapping of the study area (Biota 2014b) was used as a guide to inform the mapping of the unsurveyed areas. Vegetation was mapped to a similar scale and, where possible, vegetation types used in previous surveys were extended or repeated.

The vegetation types were described at the sub-association level (level VI as per the National Vegetation Information System)[4]. The sub-association level includes information about the dominant growth form, height and cover for up to five species in all layers/sub-strata observed (e.g. *Eucalyptus xerothermica* scattered low trees over *Acacia citrinoviridis, Stylobasium spathulatum* tall shrubland over *Ptilotus obovatus* var*. obovatus* scattered shrubs over *Themeda triandra, Chrysopogon fallax, *Cenchrus ciliaris* very open tussock grassland).

Similar vegetation descriptions were grouped to establish the vegetation types for the study area. Vegetation descriptions that shared a suite of perennial species with a similar range of cover values were considered to be alike.

[4] http://www.environment.gov.au/erin/nvis/publications/avam/section-2-1.html

Two coding systems are presented in this report to refer to the individual vegetation types:

1. An alphabetic code was assigned to represent the dominant flora species from the tallest stratum to the lowest stratum. Each dominant species was given a unique code by using an abbreviation of the genus to capital letter(s) followed by an abbreviation of the species to lower case letter(s) (e.g. EvAciAcMgCEc denotes a vegetation type dominated by *Eucalyptus victrix, Acacia citrinoviridis, Acacia coriacea* subsp*. pendens, Melaleuca glomerata and *Cenchrus ciliaris*). This coding enables vegetation types from different studies to be quickly compared, although it can sometimes result in long and unwieldy codes.
2. To aid interpretation, each vegetation type was also assigned an alpha-numeric code as a unique precursor to the species-driven code (e.g. C3: EvAciAcMgCEc for the third creekline sub-association). This short code is used to refer more simply to the individual vegetation types.

Although some of the vegetation types were first drafted in the field, the majority of the vegetation mapping was completed in the office after the fieldwork was completed. Field data and aerial imagery were studied to determine boundaries of vegetation types, which were then mapped to an appropriate scale. The maps were created and consolidated using GIS software (QGIS and MapInfo), and point locations of sampling sites, conservation significant flora and weeds were added. All maps in this report were produced using the MapInfo package (version 11).

3.2.5 Searches for Flora of Conservation Significance and Weeds

Targeted searches were undertaken in suitable habitats for the conservation significant flora[5] that were identified through the desktop review as having the potential to occur in the study area (see Section 4.9). A map of all foot traverses conducted through the study area during Phase 1 and Phase 2 is provided in Appendix 7 as an indication of the degree of survey effort for conservation significant flora.

The Threatened species *Lepidium catapycnon* was a key search focus for the field survey, given that it is known to occur in the Yandi locality and was previously recorded from two locations in the study area (Hamersley Iron 2006, Biota 2009a). The locations of the previously recorded populations of *L. catapycnon* were checked in Phase 1 and Phase 2 of the field survey so that the populations could be confirmed and number of individuals re-counted (see Section 6.4.1). Additional targeted searches for *L. catapycnon* were undertaken in habitat determined likely to support this species, with a focus on searching potential habitat within the main project footprint. Based on known records of this species and its habitat preferences (see Section 4.9.1), areas of rocky hills and slopes in the study area were identified as potentially suitable habitat within the study area and these areas were the focus of the targeted searches. Searches for *L. catapycnon* and other conservation significant flora were also conducted during the extensive foot traverses that were required to validate the vegetation mapping, while traveling on foot between sites, and also while completing quadrats and relevés.

The locations of flora of conservation significance, unknown flora and introduced species (weeds) were recorded using a hand-held GPS (WGS84 datum, Zone 50). Where conservation significant flora species were encountered, estimates of the density or number of individuals were made in the area (in an approximate 20 m radius) and a description of the habitat and associated flora were recorded. A continuous list of vascular flora species was also recorded during the traverses, which contributed to the overall species list for the study area (see Appendix 8).

All records of conservation significant flora are provided in Section 6.4 and are displayed on the vegetation mapping in Appendix 4. All records of introduced flora are provided in Appendix 5.

[5] The framework for conservation significance ranking of species in Western Australia is provided in Appendix 1.

3.3 Specimen Identification, Nomenclature and Data Entry

Common species that were well known to the survey botanists were identified in the field. Voucher specimens of all other species were collected and assigned a unique number to facilitate tracking of data. These were pressed in the field and dried using heaters.

Specimens were identified using flora keys, consulting appropriate publications, checking voucher reference collections, and comparing the specimens to the collections held at the WA Herbarium. Biota botanists (Cassie Adam, Prue Anderson, Rachel Butler, Pierre-Louis de Kock and Chloe Flaherty) identified most specimens, the majority of which were confirmed by Biota's principal botanist (Michi Maier). A Pilbara flora expert, Malcolm Trudgen (of M.E. Trudgen and Associates), was consulted for some complex plant identifications, including but not limited to *Abutilon* and *Corchorus* species. Ryonen Butcher (WA Herbarium taxonomist) was consulted for assistance with the genus *Tephrosia*. Andrew Perkins (WA Herbarium taxonomist) provided confirmation for conservation significant specimens and some atypical specimens collected from the study area (*Corchorus tectus, Heliotropium glabellum* and *Swainsona maccullochiana*).

Nomenclature was checked against the current listing of scientific names recognised by the WA Herbarium and updated as necessary. All data were entered into a Microsoft Access Vegetation Database structure held internally at Biota. The database model employed by Biota was developed by Ted Griffin (private consultant) at the request of Malcolm Trudgen (M.E. Trudgen and Associates).

Data from sites located in the current study area that were sampled during previous surveys were reviewed, and specimen identifications were checked and amended as necessary to reflect recent taxonomic changes.

Provided material is of adequate condition and not already vouchered for the locality, specimens will be lodged with the WA Herbarium for all taxa representing flora of conservation significance, range extensions, undescribed or poorly collected taxa. Threatened and Priority Flora Report Forms will be submitted to DPaW for all Threatened and Priority flora species recorded from the study area.

3.4 Floristic Analysis

In order to examine the relationships between the floristic composition of the sampling sites in the study area compared to a selection of sites from the broader locality, cluster analyses were carried out using the PRIMER software package. The dataset comprised 212 quadrats and 17 detailed relevés from the locality, comprising:

- 81 quadrats and seven relevés assessed within the study area during Phase 1 and/or Phase 2 of the current survey;
- another 39 quadrats and five relevés from the study area that had been sampled previously (Halpern Glick Maunsell 2000, Biota 2004a, 2009b, 2010, 2014b, 2014c); and
- 92 quadrats and five relevés in the broader Yandi locality (sampled previously by Biota 2004a, 2009b, 2010, 2014b, 2014c).

A full list of the sites and their source studies is provided in Appendix 9, with each site attributed with its alpha-numeric vegetation code and broad habitat (see Section 3.2.4). Seven vegetation types that were not mapped within the study area were present within the data set. Although these are not discussed in the report, each has been assigned a vegetation code as follows to assist with data presentation:

- Ca (vegetation code C3 of Biota 2014b): *Eucalyptus victrix* scattered low trees over *Acacia bivenosa, A. ancistrocarpa, A. maitlandii* tall open shrubland over *Eriachne tenuiculmis, Themeda triandra* very open tussock grassland in a minor creekline;

- Ha (vegetation code H8 of Biota 2014b): *Acacia inaequilatera* scattered tall shrubs over *Eremophila fraseri* subsp. *fraseri* scattered shrubs over *Triodia pungens* very open hummock grassland on a hill;
- Hb (vegetation code H5 of Biota 2014c): *Grevillea pyramidalis, Eremophila fraseri* tall open shrubland over *Triodia pungens* hummock grassland on a hill slope;
- Hc (vegetation code H7 of Biota 2014c): *Corymbia hamersleyana* scattered low trees over *Gossypium robinsonii, Androcalva luteiflora, Acacia tumida* var. *pilbarensis, Grevillea wickhamii* subsp. *hispidula* shrubland over *Themeda triandra, Cymbopogon ambiguus* open tussock grassland in a gorge;
- Hd (vegetation code H3 of Biota 2014c): *Eucalyptus leucophloia* scattered low trees over *Acacia bivenosa* open shrubland over *Triodia wiseana* hummock grassland on hills;
- He (vegetation code H4 of Biota 2014c): *Eucalyptus leucophloia* scattered low trees over *Acacia pruinocarpa* tall open shrubland over *Triodia wiseana, T. pungens* open hummock grassland on hills; and
- Hf (vegetation code H6 of Biota 2014c): *Acacia monticola* tall shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), *T. wiseana* closed hummock grassland on a hill slope.

A combined species list was created from all of the sites and reviewed for errors or inconsistencies in nomenclature. Both annual and perennial vascular flora species were included. Fungi were removed, as were all weeds other than **Cenchrus ciliaris* and **C. setiger*, which were combined and treated as "**Cenchrus* spp.". Where multiple taxa were considered likely to represent the same species, these were all referred to a single taxon identification code in the dataset, and thus treated as a single entity in the subsequent analyses. Where a taxon name could refer to more than one entity across different projects (e.g. "*Euphorbia* sp."), it was excluded. Finally, singleton species (those occurring in only one site) were removed to reduce noise in the dataset, unless they were characteristic of a particular habitat (e.g. *Astrotricha hamptonii*).

Site data from multiple phases were merged to create a single set of data for each site; where cover values differed between phases, the highest cover value was accepted.

For the resulting list of species, two matrices were then generated:

- percentage foliar cover of each species at each site; and
- presence / absence of each species at each site.

Two additional matrices were generated from the above by removing annual species, which would only be recorded under optimal sampling conditions. These matrices were used to investigate potential bias in the dataset caused by sampling during different seasonal conditions for different projects.

Four analyses were subsequently performed based on:

1. Percentage foliar cover data for all species (perennials and annuals);
2. Percentage foliar cover data for perennial species only;
3. Presence / absence data for all species (perennials and annuals); and
4. Presence / absence data for perennial species only.

Percentage foliar cover values were transformed using a square root transformation. The Bray-Curtis coefficient was used to produce a similarity matrix. The cluster analysis used the group average method. The clusters were tested for significance using the similarity profile permutation test (SIMPROF). The similarity percentage test (SIMPER) was used to determine which species contributed most to the similarities between groups.

Following initial review of the floristic groups identified by these analyses, further analyses were performed with the addition of some other sites from the locality (specifically three sites in *Triodia*

schinzii hummock grasslands, and numerous sites in *Triodia longiceps* hummock grasslands) to test whether particular floristic groups were restricted to the study area.

Representative outputs are presented as both floristic dendrograms and non-metric, multi-dimensional scaling (MDS) ordination plots in Section 5.4 and Appendix 9. Due to the size of the dataset it is not provided within this document.

3.5 Limitations of this Study

Limitations of this study that should be considered are as follows:

- Whilst targeted searches for conservation significant flora were undertaken and opportunistic taxa were recorded during representative traverses through all habitats in the study area, the entire study area was not systematically searched. The list of vascular flora documented from the study area is therefore not exhaustive.
- The Phase 1 survey was undertaken in March 2014 and was optimally timed for the collection of annual flora. The Phase 2 survey was undertaken in July, which is typically a dry time of year in the Pilbara, however above average rainfall was received prior to this survey. Given the favourable rainfall conditions, most species should have been present during the field surveys, however it is possible that some annual or cryptic perennial species would have been absent during the Phase 2 survey due to the seasonal timing (see Section 3.2.2).
- Consistent with the accepted level of effort for a survey of this type and scale, fungi and non-vascular flora (algae, mosses and liverworts) were not sampled.
- One vegetation type (H5; see Section 5.0) was described from relevés rather than quadrats. Quadrats could not be established in this vegetation type due to the narrow dimensions of the habitat and the steep, rocky terrain.
- The existing disturbance footprint for the study area was the most current version available (December 2013), however clearing is ongoing for earthworks which are not part of this proposal (drill pads, drill tracks, etc.). Some areas of recent clearing within the study area were therefore not mapped.
- Quadrat data for the Pilbara region is typically patchily distributed and concentrated in development areas, and not all vegetation associations are equally well sampled. The results of the floristic analysis presented in this report reflect the dataset utilised, and analysis using different or additional sites may result in a somewhat different interpretation.

4.0 Desktop Review

4.1 IBRA Bioregion and Subregion

The study area lies within the Pilbara bioregion, one of 89 bioregions defined by the Interim Biogeographic Regionalisation for Australia (IBRA) (Department of Environment 2013). The study area occurs at the boundary between two subregions of the Pilbara:

- Hamersley (PIL3): mountainous area of Proterozoic ranges and plateaus with low Mulga (*Acacia aneura*) woodland over bunch grasses on fine textured soils, and Snappy Gum (*Eucalyptus leucophloia*) over *Triodia brizoides* on the skeletal sandy soils of the ranges (Kendrick 2003a); and
- Fortescue Plains (PIL2): alluvial plains and river frontages with salt marsh, Mulga-bunch grass and short grass communities on alluvial plains and River Gum (*Eucalyptus camaldulensis*) woodlands fringing drainage lines (Kendrick 2003b).

4.2 Conservation Reserves in the Locality of the Study Area

The IBRA provides a national system for assessing the condition of native ecosystems and their level of protection in the National Reserve System (NRS). The NRS is Australia's network of protected areas, including national parks and other Government reserves, indigenous lands, and reserves run by non-profit conservation organisations. At the time of the regional biodiversity audit conducted by the then Department of Conservation and Land Management, the Pilbara bioregion was considered to be under-represented by the NRS, with less than 10% of the bioregion protected (Kendrick 2003a, 2003b). Of the four subregions within the Pilbara bioregion, the Hamersley subregion had the highest percentage of area under some form of protection, while the Fortescue Plains subregion had the lowest (Kendrick 2003a, 2003b).

Karijini National Park (Karijini) is the closest conservation reserve to the study area. The nearest boundary of Karijini to the study area is approximately 64 km to the west. Areas surrounding the Fortescue Marsh, approximately 30 km north of the study area, are also proposed to be excluded from the Marillana Station pastoral lease in 2015 to assist with management of this important ephemeral wetland.

4.3 Surface Geology

The study area encompasses eight geological units mapped by the Geological Survey of Western Australia (1984). These units are described in Table 4.1 and displayed in Figure 4.1.

Table 4.1: Geological units occurring within the study area (Geological Survey of Western Australia 1984).

Unit Code	Geological Description	Area (ha)	Percentage of Study Area
Czc	Colluvium: partly consolidated quartz and rock fragments in silt and sand matrix; old valley-fill deposits.	2,337	27.0%
Czk	Calcrete-sheet carbonate; found along major drainage lines.	341	3.9%
Czp	Robe Pisolite: pisolitic limonite deposits developed along river channels.	4	0.05%
PLHb	Brockman Iron Formation: banded iron-formation, chert, and pelite.	637	7.4%
PLHj	Weeli Wolli Formation: banded iron-formation (commonly jaspilitic), pelite and numerous metadolerite sills.	2,350	27.2%
Qa	Alluvium: unconsolidated silt, sand, and gravel; in drainage channels and on adjacent floodplains.	2,413	27.9%
Qs	Eolian deposit-sand; in sheets and longitudinal dunes.	1	0.01%
Qw	Alluvium and colluvium: red-brown sandy and clayey soil; on low slopes and sheetwash areas.	557	6.4%

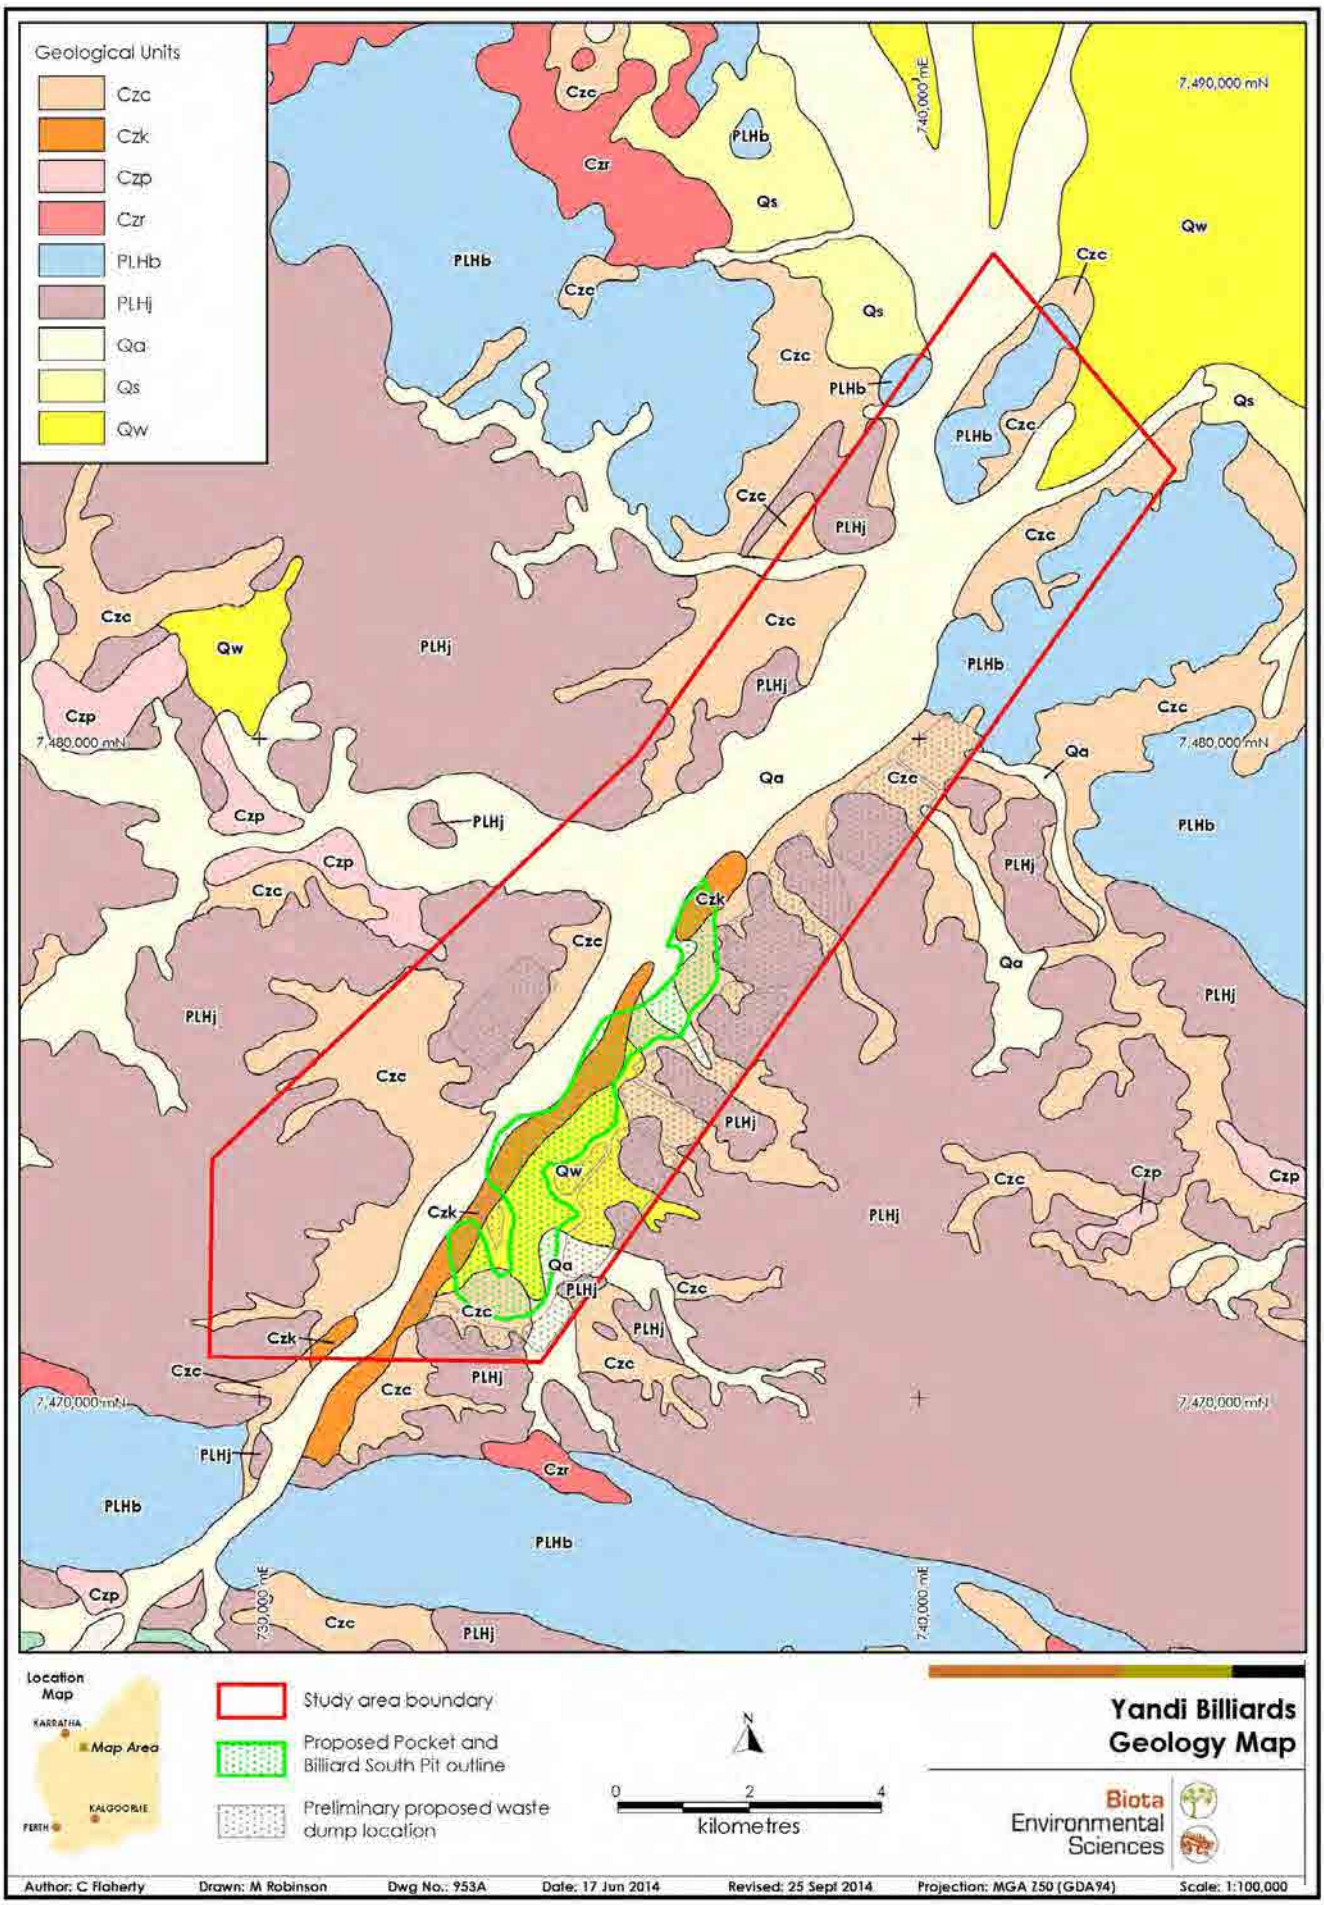

Figure 4.1: Geological units mapped in the vicinity of the study area (Geological Survey of Western Australia 1984).

4.4 Land Systems

Western Australian Rangelands Surveys have been conducted for various parts of the State as part of a program of rangeland classification, mapping and resource evaluation (Waddell et al. 2010). These surveys have been conducted in Western Australia since the 1950s, when they were commenced by the Commonwealth Scientific and Industrial Research Organisation (Speck et al. 1960), and more recently have been conducted as a collaboration between the Department of Agriculture and Food WA and Landgate. The land system approach to mapping different country types has been used in all of the regional rangeland surveys in Western Australia.

The concept of land systems was first used by Christian and Stewart (1953). They defined a land system as 'an area with a recurring pattern of topography, soils and vegetation'. These recurring patterns can be mapped using 1:50,000 scale aerial photography or other remotely sensed images (Waddell et al. 2010). It is assumed areas with a similar pattern represent the same land system. The land systems are then ground-truthed during fieldwork.

A total of 105 land systems have been identified and mapped in the Pilbara bioregion[6], with 63 land systems occurring in the Hamersley subregion and 54 occurring in the Fortescue Plains subregion. Land systems mapping covering the study area has been prepared by van Vreeswyk et al. (2004).

The study area intersects five land systems, which are summarised in Table 4.2. These land systems are widespread and extensive in terms of their area within the Pilbara bioregion. Their location in relation to the study area is shown in Figure 4.2.

4.5 Landforms and Surface Hydrology

Aerial imagery and available information indicate that the study area encompasses the northern portion of the Weeli Wolli Creek valley, where this widens from a shallow gorge to form a true valley, and its associated floodplains and hillslopes.

Drainage within the study area is dominated by Weeli Wolli Creek, which flows in a northeast direction through the Hamersley Range and ends in an alluvial fan. The alluvial fan stretches from the footslopes of the Hamersley Range scarp, across the pediment slope to the edge of the Fortescue Marsh. The confluence of Weeli Wolli Creek and Marillana Creek occurs in the centre of the study area, just behind the scarp of the Hamersley Range. There are numerous floodout areas adjacent to the creeks, and islands in the anabranching creek beds of both creek systems.

Low crests and hillslopes define the edge of the creek valley. Numerous short minor drainage lines dissect the hills, forming shallow gorges and narrow floodplains before they flow into Weeli Wolli Creek. In an area near the southern end of the eastern boundary of the study area, the creek valley widens considerably and several minor drainage lines flow through a narrow pediment zone before entering the Weeli Wolli Creek floodplain.

[6] This information was obtained by merging the Ashburton land system mapping (Payne et al. 1988) and Pilbara land system mapping (Van Vreeswyk et al. 2004) and intersecting this with the Pilbara bioregion (Environment Australia 2000) in ArcView (v. 3.2).

Table 4.2: Extent of land systems in the study area and the percentage this represents of their total extent in the Pilbara bioregion.

Land System	Description (Van Vreeswyk et al. 2004)	Total Area of Land System within the Study Area	Percentage of Study Area	Total Area of Land System in the Pilbara	Percentage of Total Land System in Study Area
Boolgeeda	Stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands. Component landforms include low hills and rises (4%), stony slopes and upper plains (20%), stony lower plains (65%), groves (1%), and narrow drainage and channels (10%). Not susceptible to degradation or soil erosion.	2,221 ha	25.8%	961,637 ha	0.2%
McKay	Hills, ridges, plateaus and breakaways of meta-sedimentary rocks supporting hard spinifex grasslands. Component landforms include hills, ridges ad plateaus remnants (60%), breakaways (2%), lower foot slopes (10%), stony plains (20%), and drainage floors (8%). Not susceptible to degradation or soil erosion.	1,455 ha	16.8%	426,145 ha	0.3%
Newman	Rugged jaspilite plateaus, ridges and mountains supporting hard spinifex grasslands. Component landforms include plateaus, ridges, mountains and hills (70%), lower slopes (20%), stony plains (5%), and narrow drainage floors with channels (5%). Not susceptible to degradation or soil erosion.	2,326 ha	26.9%	1,993,745 ha	0.1%
River	Active floodplains and major rivers supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands. Component landforms include sandy levees and sand sheets (15%), upper terraces (5%), floodplains and lower terraces (50%), stony plains (10%), and minor and major channels (20%). Susceptibility to erosion is high or very high if vegetation is removed.	2,142 ha	24.8%	497,421 ha	0.4%
Urandy	Stony plains, alluvial plains an drainage lines supporting shrubby soft spinifex grasslands. Component landforms include stony plains (58%), alluvial plains (35%), and drainage zones and channels (7%). Most of the system is not susceptible to degradation or soil erosion.	496 ha	5.7%	131,975 ha	0.4%

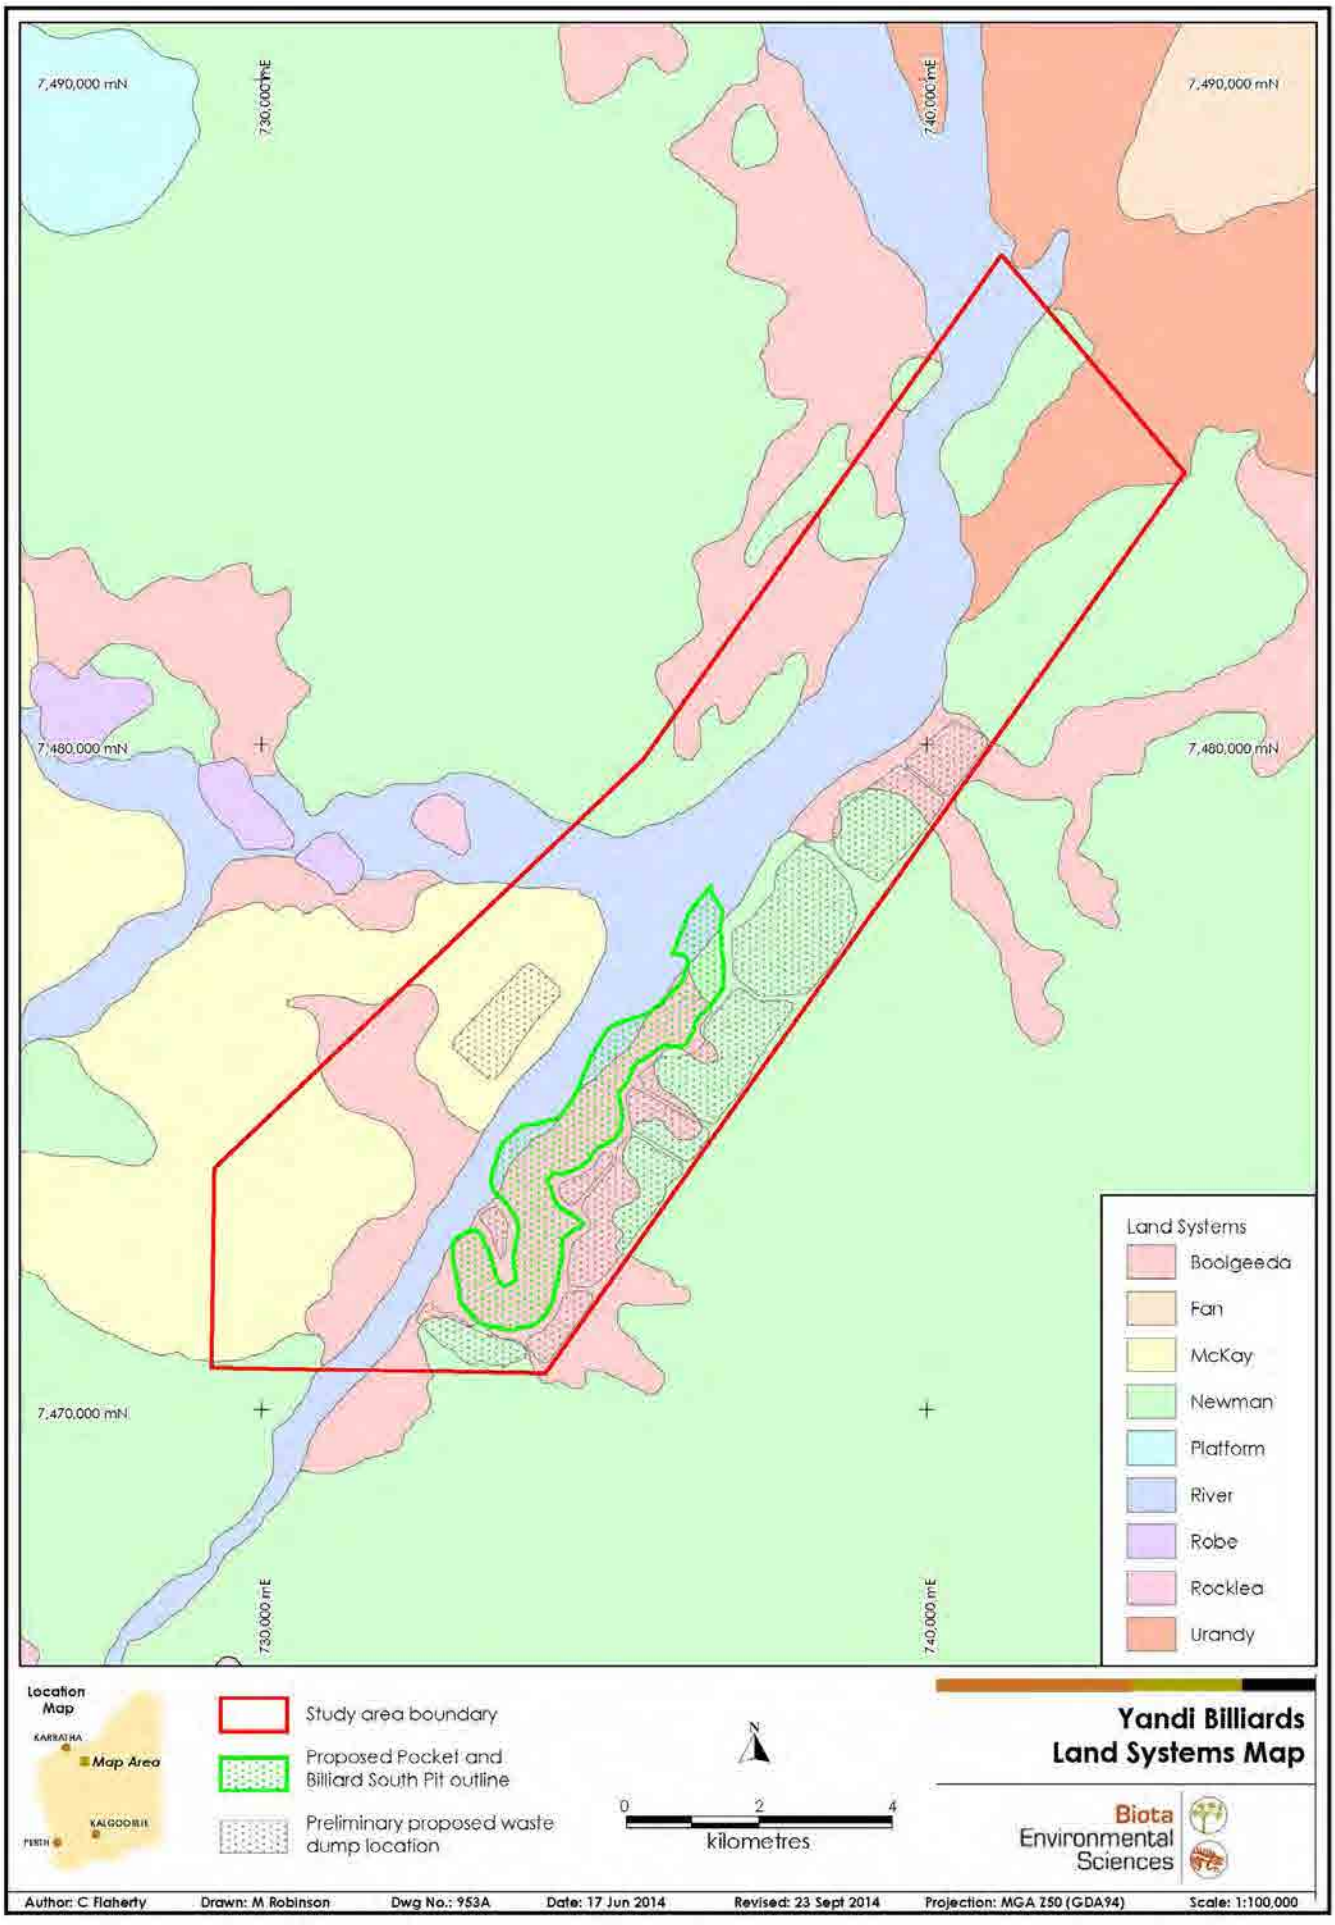

Figure 4.2: Land systems of the locality including the study area.

4.6 Beard's Vegetation Mapping

Beard (1975a, 1975b) described and mapped the vegetation of the Pilbara at a scale of 1:1,000,000. The study area is located on the Hamersley Plateau, which is within the Fortescue Botanical District of the Eremaean Botanical Province as defined by Beard. The vegetation of this province is typically open, and frequently dominated by spinifex, wattles and occasional eucalypts.

Three vegetation units mapped by Beard (1975b) occur within the study area (see Figure 4.4), two of which are essentially the same vegetation type:

- Fortescue Valley 29: Sparse low woodland; Mulga (*Acacia aneura* sens. lat.), discontinuous in scattered groups; and
- Fortescue Valley 82 and Hamersley 82: Hummock grasslands, low tree steppe; Snappy Gum (*Eucalyptus leucophloia*) over Limestone Spinifex (*Triodia wiseana*).

These vegetation units are relatively widespread in the Pilbara bioregion and largely uncleared (see Table 4.3). Given the broad nature of Beard's mapping, these units are only broadly applicable to the vegetation of the study area (see Section 5.0 for a more detailed description of the vegetation).

Table 4.3: Beard's (1975b) mapping units that occur in the study area and their extent in the Pilbara bioregion (data from Government of Western Australia 2013).

Beard's Vegetation Mapping Unit	Pre-European Extent in the Hamersley or Fortescue Subregion (as relevant)	Current Extent in the Hamersley or Fortescue Subregion (% Remaining)	Extent within the Study Area (% of Current Mapped Extent in the Hamersley or Fortescue Subregion)
Fortescue Valley 29	893,395 ha	893,222 ha (>99.9%)	4,512.1 ha (0.5%)
Fortescue Valley 82	24,192 ha	24,192 ha (>99.9%)	1,021.8 ha (4.2%)
Hamersley 82	2,177,574 ha	2,165,235 ha (99.4%)	3,105.2 ha (0.1%)

4.7 Previous Biological Surveys in the Locality

Numerous botanical surveys have been undertaken in the Yandi locality. In order to provide regional context, 12 previous botanical surveys completed in the vicinity of the study area were reviewed (see Table 4.4). In particular, the review aimed to identify species and communities of conservation significance that may occur in the study area (see Section 4.9 and Appendix 2). Eight of these surveys overlap the study area (Figure 4.3), and the key findings from these are summarised in Table 4.5.

Table 4.4: Previous flora and vegetation surveys in the Yandi locality that have been reviewed.

Survey	Reference
Flora and vegetation survey of the Northern Transport Corridor associated with the Yandicoogina Junction Project Area	Mattiske (1995a)
Flora and vegetation survey of the Southern Transport Corridor associated with the Yandicoogina Junction Project Area	Mattiske (1995b)
Hope Downs Rail Corridors biological surveys	Halpern Glick Maunsell (2000)
Tom Price – Yandi Power Line review of botanical surveys	Biota (2000)
Vegetation and flora survey of the Hope Downs Rail Corridor from Port Hedland to Weeli Wolli Creek	Biota (2002)
Flora and vegetation survey of the Yandi Expansion area	Biota (2004a)
Flora and vegetation survey of the Hope Downs Rail Corridor Extension through the Hamersley Range	Biota (2004b)

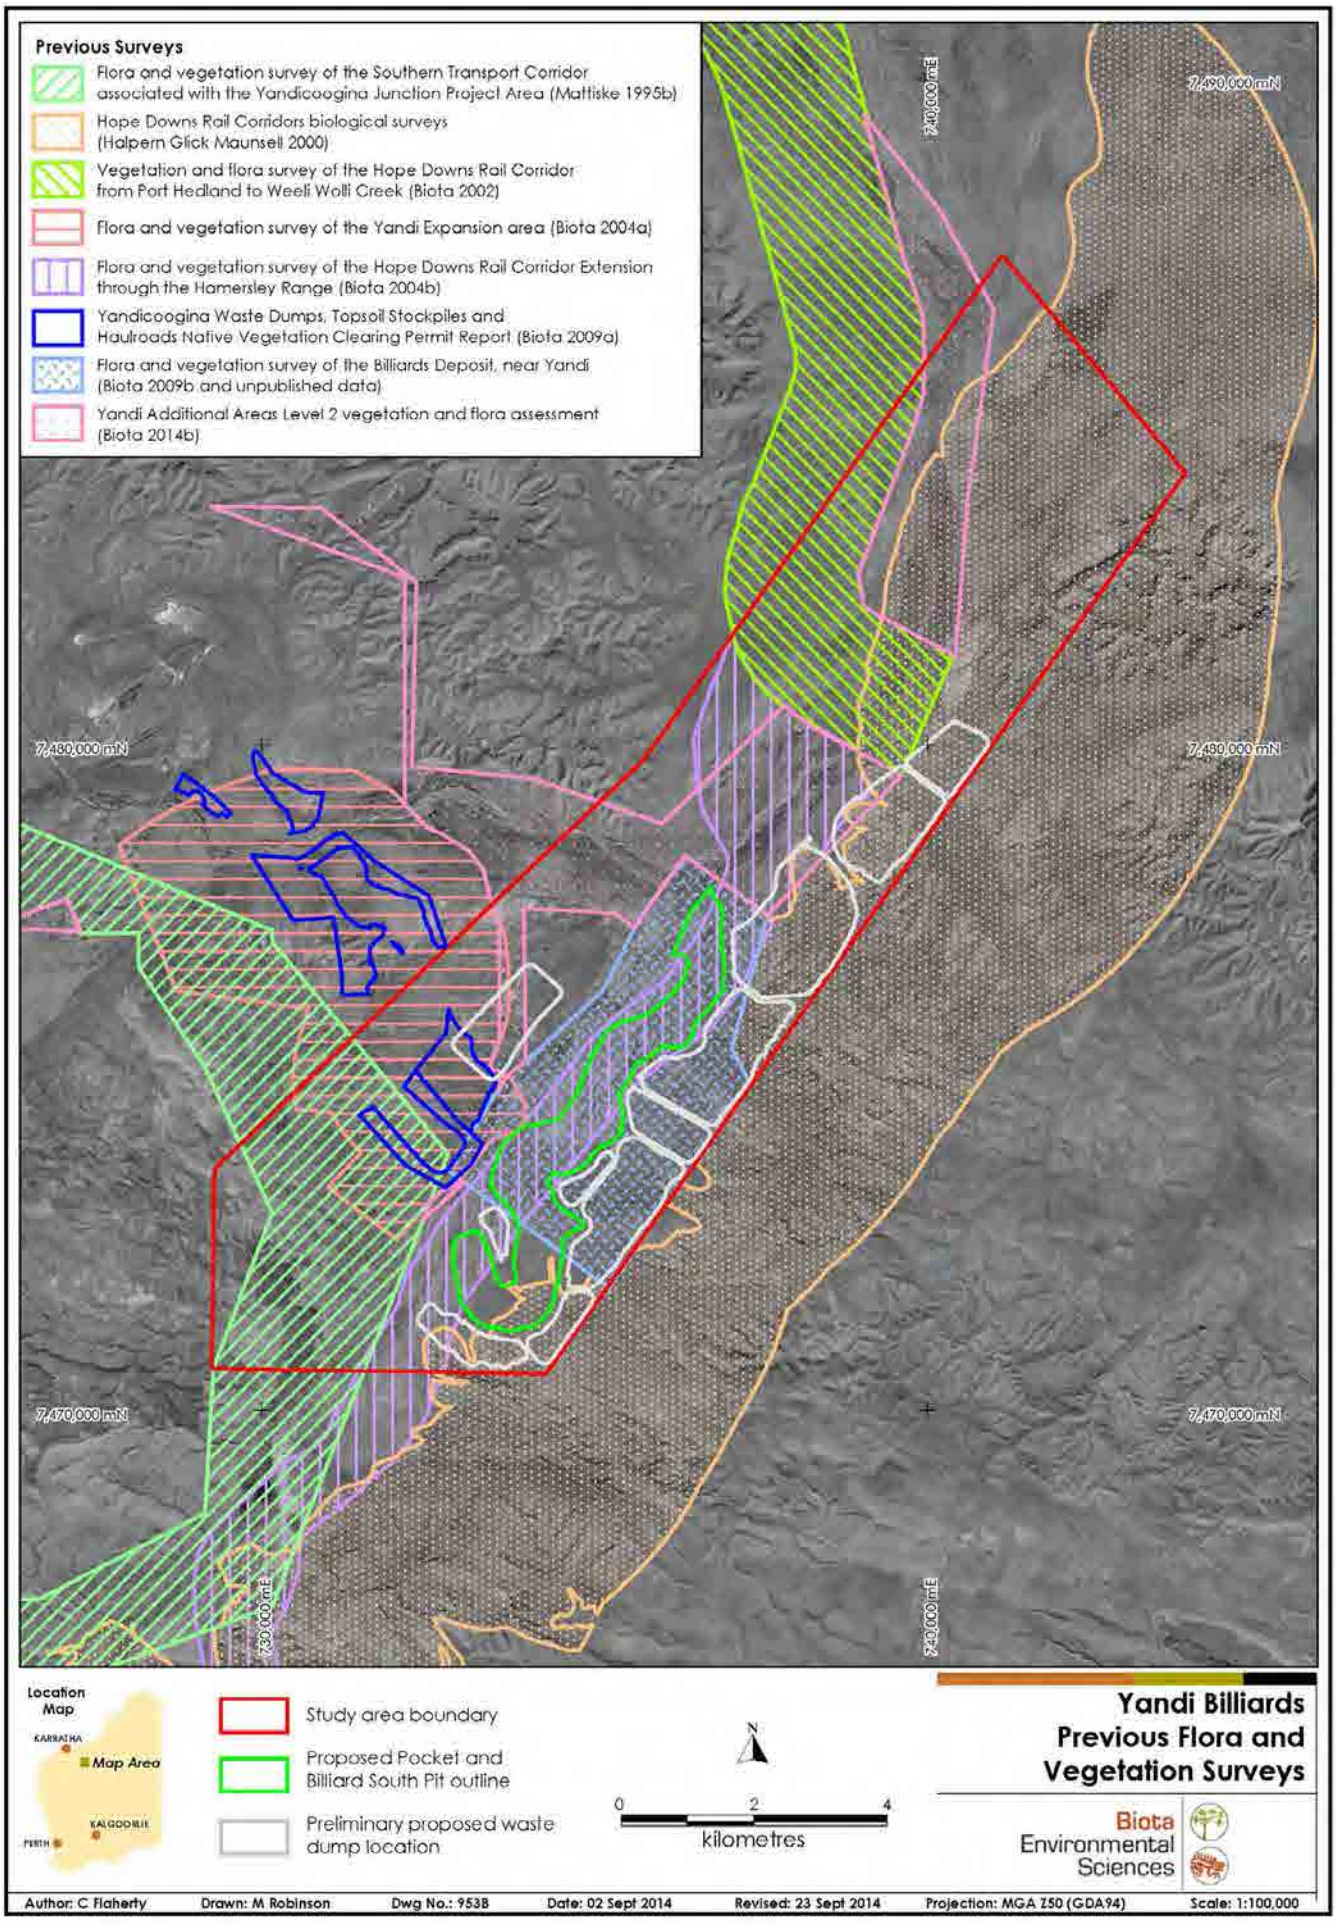

Figure 4.3: Previous flora and vegetation surveys conducted in the vicinity of the study area.

Table 4.5: Summary of previous vegetation and flora surveys that overlap the study area.

Survey (Reference)	Survey Dates	Location in Relation to Study Area	No. of Sites Recorded	No. of Flora Species Recorded		Communities and Species of Conservation Significance Identified for the Overall Survey Area	Survey / Report Limitations
				Native Vascular Flora	Introduced Flora		
Flora and vegetation survey of the Southern Transport Corridor associated with the Yandicoogina Junction Project Area (Mattiske 1995b)	January and March 1994 February 1995	Covers 1,061.4 ha of the study area.	116	392	7	• No TECs or PECs. • Three communities of local significance and four communities of regional significance. • No Threatened flora. • Five Priority flora species recorded (no longer listed). Two species of significance noted, which are currently listed as Priority flora species: *Stylidium weeliwolli* (Priority 2) and *Rhagodia* sp. Hamersley (M. Trudgen 17794) (Priority 3).	• Vegetation mapping was completed at a very broad scale. • No quadrat data was provided to support the mapping. • Climatic data for Marillana Station (the closest recording station to the study area) is not available for the survey dates. Thus, the suitability of the conditions for plant growth prior to the surveys is unknown. • Plant identifications were completed 17 years ago, over which time there have been many taxonomic changes for Pilbara flora.
Hope Downs Rail Corridors biological surveys (Halpern Glick Maunsell 2000)	16-23 October 1998 25 November - 3 December 1999	Covers 1,903.8 ha of the study area.	75	354	8	• No TECs or PECs. • Three communities of conservation significance. • No Threatened flora. • Six Priority flora species recorded (five are no longer listed; the remaining species was not recorded near Yandi and is not considered further).	• Vegetation mapping was completed at a broad scale. • Quadrats were widely spaced along the corridor. • Plant identifications were completed 13 years ago, over which time there have been many taxonomic changes for Pilbara flora.

Survey (Reference)	Survey Dates	Location in Relation to Study Area	No. of Sites Recorded	No. of Flora Species Recorded		Communities and Species of Conservation Significance Identified for the Overall Survey Area	Survey / Report Limitations
				Native Vascular Flora	Introduced Flora		
Vegetation and flora survey of the Hope Downs Rail Corridor from Port Hedland to Weeli Wolli Creek (Biota 2002)	25 April – 14 May 2001 29 May – 10 June 2001 July 2001	Covers 448.5 ha of the study area.	286	752	8	• No TECs or PECs. • Eight vegetation types of high conservation significance. • No Threatened flora. • 14 Priority flora recorded (seven are no longer listed; three were not recorded near Yandi). The remaining species are *Indigofera ixocarpa* (Priority 2), *Gymnanthera cunninghamii* (Priority 3), *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) (Priority 3) and *Goodenia nuda* (Priority 4).	• Vegetation mapping was completed at a broad scale • Quadrats were widely spaced along the corridor.
Flora and vegetation survey of the Yandi Expansion area (Biota 2004a)	30 August – 5 September 2004	Covers 884.1 ha of the study area.	39	319	13	• No TECs or PECs. • No Threatened flora. • Five Priority flora species recorded (three are no longer listed). The remaining species are *Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3) and *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) (Priority 3).	• Unfavourable climatic conditions during the survey for the identification of annual and cryptic flora species. • Quadrats were sampled once only.
Flora and vegetation survey of the Hope Downs Rail Corridor Extension through the Hamersley Range (Biota 2004b)	April 2003	Covers 1,183.1 ha of the study area.	25	361	10	• No TECs or PECs. • Four vegetation types of high conservation significance. • No Threatened flora. • Seven Priority flora (six no longer listed): the remaining species is *Goodenia* sp. East Pilbara (A.A. Mitchell PRP 727) (Priority 3).	• Vegetation mapping was completed at a broad scale. • Quadrats were widely spaced along the corridor.
Yandicoogina Waste Dumps, Topsoil Stockpiles and Haulroads Native Vegetation Clearing Permit Report (Biota 2009a)	4 – 7 September 2008	Covers 175.7 ha of the study area	NA	211	11	• No TECs or PECs. • One Threatened flora species: *Lepidium catapycnon*. • No Priority flora.	• Unfavourable climatic conditions during the survey for the identification of annual and cryptic flora species

Survey (Reference)	Survey Dates	Location in Relation to Study Area	No. of Sites Recorded	No. of Flora Species Recorded		Communities and Species of Conservation Significance Identified for the Overall Survey Area	Survey / Report Limitations
				Native Vascular Flora	Introduced Flora		
Flora and vegetation survey of the Billiards Deposit, near Yandi (Biota 2009b and unpublished data)	11 – 20 June 2007 27 July – 6 August 2008 3 – 9 June 2009	Covers 1,510.0 ha of the study area.	50	247	7	• No TECs or PECs. • One vegetation type of high conservation significance. • No Threatened flora. • No Priority flora.	• Unfavourable climatic conditions during the 2007 and 2008 surveys for the identification of annual and cryptic flora species. • Only some quadrats were resampled.
Yandi Additional Areas Level 2 vegetation and flora assessment (Biota 2014b)	12 – 18 June 2012	Covers 1,518.7 ha of the study area.	34	313	14	• No TECs or PECs. • Ecosystems at risk were identified (Weeli Wolli Creek and Marillana Creek). • No Threatened flora. • One Priority 4 flora species: *Goodenia nuda.* • One species of interest: *Eulalia* sp. (Three Rivers Station, B. Forsyth AQ6789133).	• Quadrats sampled once only.

4.8 Communities of Conservation Significance Known from the Locality

The following section describes vegetation of conservation significance known from the Yandi locality. The framework for ranking communities of conservation significance in Western Australia is presented in Appendix 1.

4.8.1 Threatened Ecological Communities

TECs are described by DPaW as "biological (flora or fauna) assemblages occurring in a particular habitat, which are under threat of modification or destruction from various processes" (DEC 2010a). TECs listed by DPaW are significant at the State level and are protected as Environmentally Sensitive Areas (ESAs) under the WA *Environmental Protection Act 1986*.

Two TECs are listed for the Pilbara bioregion: the '*Themeda* grasslands on cracking clays (Hamersley Station, Pilbara)' and the 'Ethel Gorge aquifer stygobiont community' (DPaW 2014a). Twenty-three of the 69 TECs listed in Western Australia are also nationally recognised and listed under the Commonwealth *EPBC Act 1999.* These do not include either of the two TECs listed for the Pilbara bioregion.

The Ethel Gorge stygobiont TEC is approximately 77 km southeast of the study area, while the nearest area of the *Themeda* grasslands TEC is approximately 140 km northwest. Neither TEC is therefore relevant to the study area.

4.8.2 Priority Ecological Communities

PECs include possible TECs that do not meet survey criteria or are not adequately defined (DEC 2010a). These are added to DPaW's PEC list under Priorities 1 (highest priority), 2 and 3. Ecological Communities that are: 1) adequately known; 2) are rare but not threatened, or meet criteria for Near Threatened; or 3) have been recently removed from the threatened list, are placed in Priority 4. Conservation dependent ecological communities are placed in Priority 5.

Thirty PECs are listed for the Pilbara bioregion (DPaW 2014b). No PECs are known to occur in the study area. The nearest PECs to the study area are the Priority 1 'Weeli Wolli Spring community', located approximately 7 km to the south; and two of the Priority 3 'Fortescue Valley Sand Dunes', one located approximately 5 km to the east and the other 5 km to the northwest of the study area. The Priority 1 'Fortescue Marsh' PEC is also located in the vicinity of the study area; the marsh itself is located approximately 27 km north of the study area, and is surrounded by fringing vegetation. None of these mapped occurrences of PECs would be expected to be impacted by the proposed works.

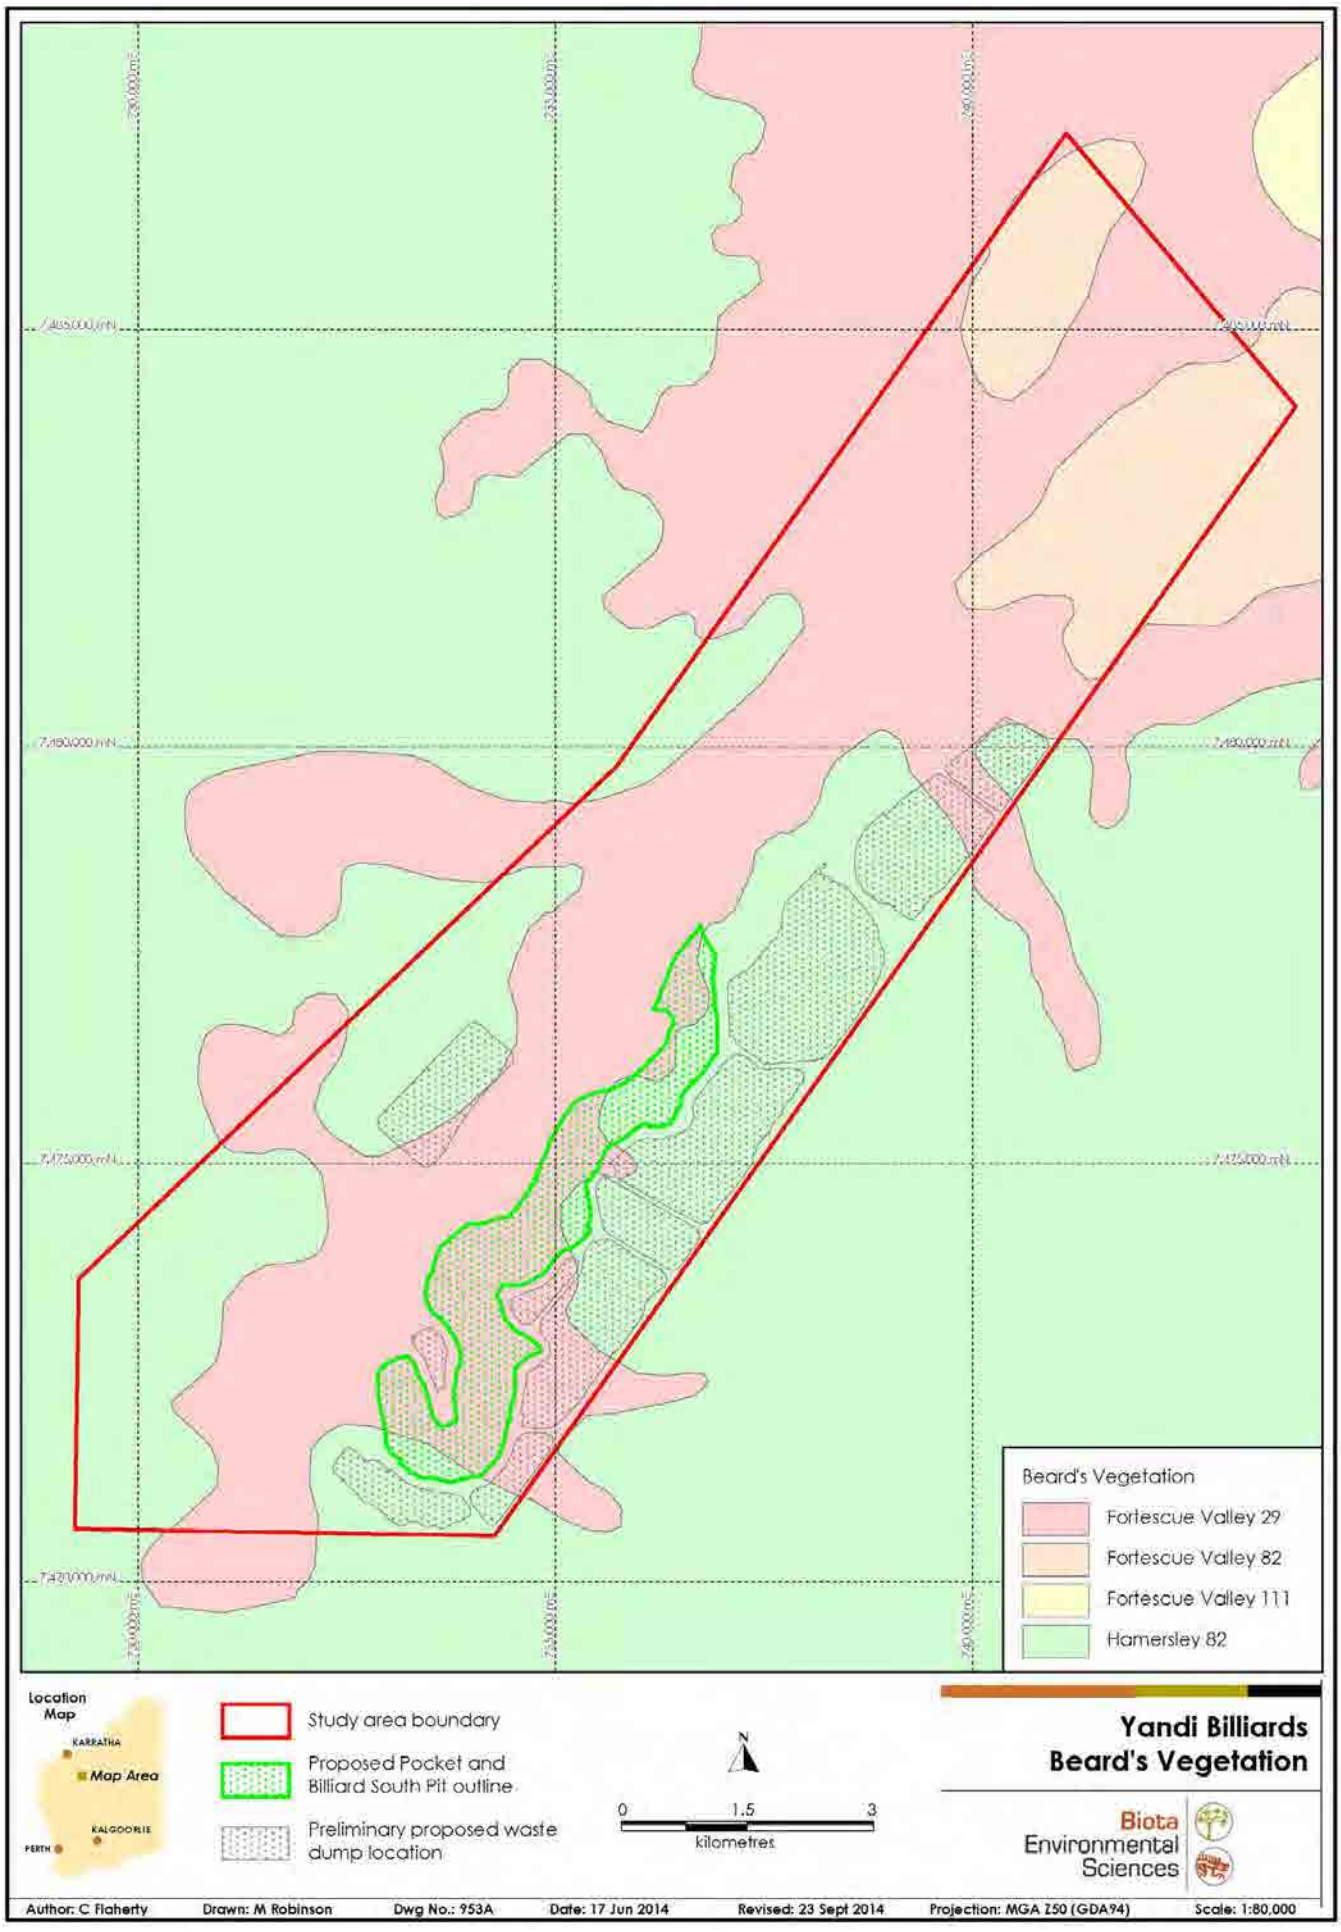

Figure 4.4: Beard's vegetation mapping for the locality including the study area.

4.9 Conservation Significant Flora Known from the Locality

4.9.1 Threatened Flora

Three Threatened flora species (*Aluta quadrata, Lepidium catapycnon* and *Thryptomene wittweri*) are known from the Pilbara bioregion. *Lepidium catapycnon* and *Thryptomene wittweri* are listed as Threatened flora under the Commonwealth *EPBC Act 1999* as well as the WA *Wildlife Conservation Act 1950*. *Aluta quadrata* has only recently been listed (State of Western Australia 2012) and is currently only recognised as Threatened under the *Wildlife Conservation Act 1950.* Each species is described briefly below:

- *Aluta quadrata* is a perennial shrub occurring mainly in rocky gullies, although it sometimes extends down along the creeklines draining the gullies, or out onto the adjacent ridge slopes and crests. This species is currently thought to be restricted to the southern flanks of the range of hills surrounding Paraburdoo, where it occurs over an east-west range of approximately 40 km. *Aluta quadrata* has not been previously recorded within 40 km of the study area. Given the restricted distribution of this species, it would not occur in the study area.
- *Lepidium catapycnon* (Hamersley Lepidium) is a woody perennial herb or low shrub occurring mainly on hillsides in skeletal soils. It typically occurs in hummock grasslands on low stony hills and occasionally stony plains, particularly in association with the Newman land system (see Section 4.4). This relatively short-lived shrub species is often recorded from areas that have been recently disturbed, apparently persisting for only a few years. *Lepidium catapycnon* has a range that extends broadly from Tom Price to Newman. It is now known from over 30 locations in the Hamersley Range, including one population in the conservation estate of the Karijini National Park (DPaW 2014c). Some of these populations comprise hundreds to over a thousand individuals (M. Maier, Biota, pers. obs.).

  Lepidium catapycnon has been previously recorded from two locations in the study area (Hamersley Iron 2006, Biota 2009a) and additional suitable habitat for this species is present. *Lepidium catapycnon* may therefore occur at other locations within the study area.

  Table 4.6: Locations of the Threatened flora species, *Lepidium catapycnon*, in the study area.

Species	Source	Number of individuals	Easting	Northing
Lepidium catapycnon	Biota (2009a)	171	733172	7475074
Lepidium catapycnon	Hamersley Iron (2006)	not provided	732596	7470785

- *Thryptomene wittweri* (Mountain Thryptomene) is a spreading, perennial shrub occurring in skeletal stony soils on breakaways and in drainage channels, typically high in the landscape on mountains of greater than 1,000 m elevation. All Pilbara records are restricted to the Mt Meharry area. *Thryptomene wittweri* would not occur in the study area as suitable habitat is not present, and its distribution does not include the study area.

4.9.2 Priority Flora

Based on the results of the database searches and literature reviews conducted for this study, a total of 12 Priority taxa and two species of interest have been recorded within 25 km of the study area. A brief description of these taxa along with an assessment of the likelihood of occurrence for each taxon in the study area is provided in Appendix 2.

Prior to the current survey, no Priority flora were known from the study area. Based on the known distributions of the Priority flora species, and comparison of their habitat preferences with the habitats that appeared to be present in the study area, five of the 12 Priority flora taxa were identified through the desktop review as:

- Likely to occur:
  - one Priority 4 taxon: *Goodenia nuda*.
- May potentially occur:
  - one Priority 2 taxon: *Stylidium weeliwolli; and*

– three Priority 3 taxa: *Rostellularia adscendens* var. *latifolia, Sida* sp. Barlee Range (S. van Leeuwen 1642) and *Themeda* sp. Hamersley Station (M.E. Trudgen 11431).

With regards to the species considered likely to occur in the study area:

- *Goodenia nuda* (Priority 4)
  Goodenia nuda is an erect to ascending, slender herb growing to 50 cm in height, with yellow flowers and narrow, pale green glaucous leaves (DPaW 2014c). This species is typically found growing near creeklines and in wet areas. It has a broad distribution; most records occur over a range of approximately 450 km through the Pilbara bioregion, with populations known from Karijini and Millstream-Chichester National Parks. There is also an outlying record from the Canning Stock Route in the Gascoyne bioregion. *Goodenia nuda* has been recorded 7.2 km northwest of the study area, next to Marillana Creek (Biota 2010). This species has also been recorded during several other surveys in the Yandi locality (Biota 2000, 2002, 2014b, 2014c), predominantly from floodplains associated with Marillana Creek (or tributaries of Marillana Creek). This species would be likely to occur in the study area, particularly in association with minor flowlines or floodplains.

With regards to the species considered to have the potential to occur in the study area:

- *Stylidium weeliwolli* (Priority 2)
  This annual herb grows to 25 cm and produces pink flowers between August and September. This species has a relatively broad range through the Pilbara and Gascoyne bioregions, extending over more than 330 km, but is only infrequently recorded. This is probably partly due to its small and delicate stature, and also a reflection of the habitats in which it occurs (seasonally damp or wet areas including root mats of *Melaleuca*, on floodplains and in seepages around granite rocks). In the Pilbara, this species occurs mainly along major watercourses. There are two records of this species from the Yandi locality: from Weeli Wolli Creek, in the vicinity of Weeli Wolli Springs (the closest record is approximately 6 km upstream of the study area); as well as from a tributary of Marillana Creek (approximately 23 km upstream of the study area). It is possible that this species occurs along the sections of Marillana Creek and Weeli Wolli Creek within the study area.

- *Rostellularia adscendens* var. *latifolia* (Priority 3)
  Rostellularia adscendens var. *latifolia* is a small herb to low shrub that occurs in a broad range of habitats, but is most frequently recorded in drainage areas and on plains (DPaW 2014c). This taxon has a broad distribution across the Pilbara (over 400 km, extending from the Brockman locality to the Oakover River), with five populations known from Karijini National Park. There is suitable habitat for this species in the study area and it has been recorded from a location 7.6 km to the northwest (Biota 2014c).

- *Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3)
  This spreading shrub grows to 0.5 m tall and produces yellow flowers in August. It typically occurs on steep slopes with red skeletal soils and exposed rock, often in gorges and gullies. This species has been recorded from rocky habitat along Marillana Creek, approximately 2.3 km northwest of the study area (Biota 2004a); the number of individuals in this population was not recorded. It is possible that this species could occur in rocky habitats within the study area.

- *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) (Priority 3)
  This tussock grass grows to 1.8 m tall and occurs on red clay pans and grass plains. It differs from the more common and widespread *Themeda triandra* by its larger size, sturdier culms and pale bluish colouring (*T. triandra* has yellowish colouring). There is a record of this species from 2.8 km northwest of the study area (Biota 2004a), which is the only record within 30 km. This species could potentially occur in the study area, particularly along the floodplains associated with Marillana or Weeli Wolli Creek.

4.9.3 Other Species of Interest

Two taxa of interest have been recorded near Yandi and may occur in the study area (see Appendix 2). These are:

- *Eulalia* sp. (Three Rivers Station, B. Forsyth AQ6789133)
  This currently undescribed species of *Eulalia* has been recorded from one location on a plain on the southern side of Marillana Creek (Biota 2014b), 900 m west of the current study area. Dr. Ken Tinley first collected this species in 2008 on Three Rivers Homestead (approximately 290 km south of the Yandi project) and the phrase name *Eulalia* sp. (Three Rivers Station) was applied (Bryan Simon, Queensland Herbarium, pers. comm. 2012). *Eulalia* sp. (Three Rivers Station) differs from the common *Eulalia* species occurring in the Pilbara (*E. aurea*) by its broader leaves, elongated rhizomes and the inflorescences remaining closed at maturity (Simon and Alfonso 2012). It is likely that this taxon has been under-collected given its similarity to *Eulalia aurea*. Currently, the phrase name is not recognised on FloraBase or Australia's Virtual Herbarium. A formal description of *Eulalia* sp. (Three Rivers Station) is being progressed by Rachel Butler (Biota) and Mr. Malcolm Trudgen (M.E. Trudgen and Associates).

- *Glycine* sp. aff. *arenaria*
  This creeper with apparent affinities to *Glycine arenaria* was collected from a single site in Marillana Creek (Biota 2014c), approximately 11 km upstream of the current study area. This taxon was identified by Malcolm Trudgen (M.E. Trudgen and Associates), who described it as uncommon in the Pilbara. To date, no specimens of *G. arenaria* have been vouchered from outside the Northern Kimberley. The voucher specimen collected by Biota (2012a) was submitted to the WA Herbarium for lodgement in February 2013, but is believed to be awaiting incorporation to the collection. Additional collections of *Glycine* have recently been made from this area; none are currently considered likely to represent *G. arenaria,* however the identifications are pending confirmation by Andrew Perkins (taxonomist at the WA Herbarium). These specimens will be submitted for lodgement if required.

4.10 Knowledge Gaps Identified for the Study Area

The following section summarises the flora and vegetation findings based on the results of the 2013 desktop review of the study area (Biota 2013).

While a comprehensive dataset existed for the Yandi Billiards study area and there was considerable data from the locality to provide context, some additional biological survey work was considered to be required to raise the level of information for the study area to a level suitable for EIA under Part IV of the *Environment Protection Act 1986*.

Key flora and vegetation knowledge gaps identified in 2013 for the Yandi Billiards study area included:

1. Approximately 9% (or 784 ha) of the study area had not been subject to vegetation mapping or flora quadrat sampling (Figure 4.5). A further 30% (or 2,611 ha) had only been subject to broad historical vegetation mapping, which required refinement and additional flora quadrat sampling (Figure 4.5). Approximately 39% of the area thus required vegetation mapping to current standards.
2. Six vegetation types from recent vegetation mapping (Biota 2004a, 2009b, 2014b), totalling 376 ha, required additional flora quadrat sampling to meet current regulator expectations (Figure 4.5).
3. A total of 49 of the 72 flora quadrats previously established in the study area were sampled during unfavourable climatic conditions for plant growth. These required resampling to meet Level 2 survey standards.
4. Targeted systematic searches for the Threatened flora species, *Lepidium catapycnon,* had not been conducted in all suitable habitats.

5. A total of 32 flora taxa recorded previously within the study area were required to be reviewed to address advances in taxonomy since their original identification.

These points are discussed in more detail in the Yandi Billiards Terrestrial Fauna, Flora and Vegetation Desktop Assessment (Biota 2013).

The current study (this report) addresses these five points to bring the baseline surveys for the study area up to a Level 2 standard.

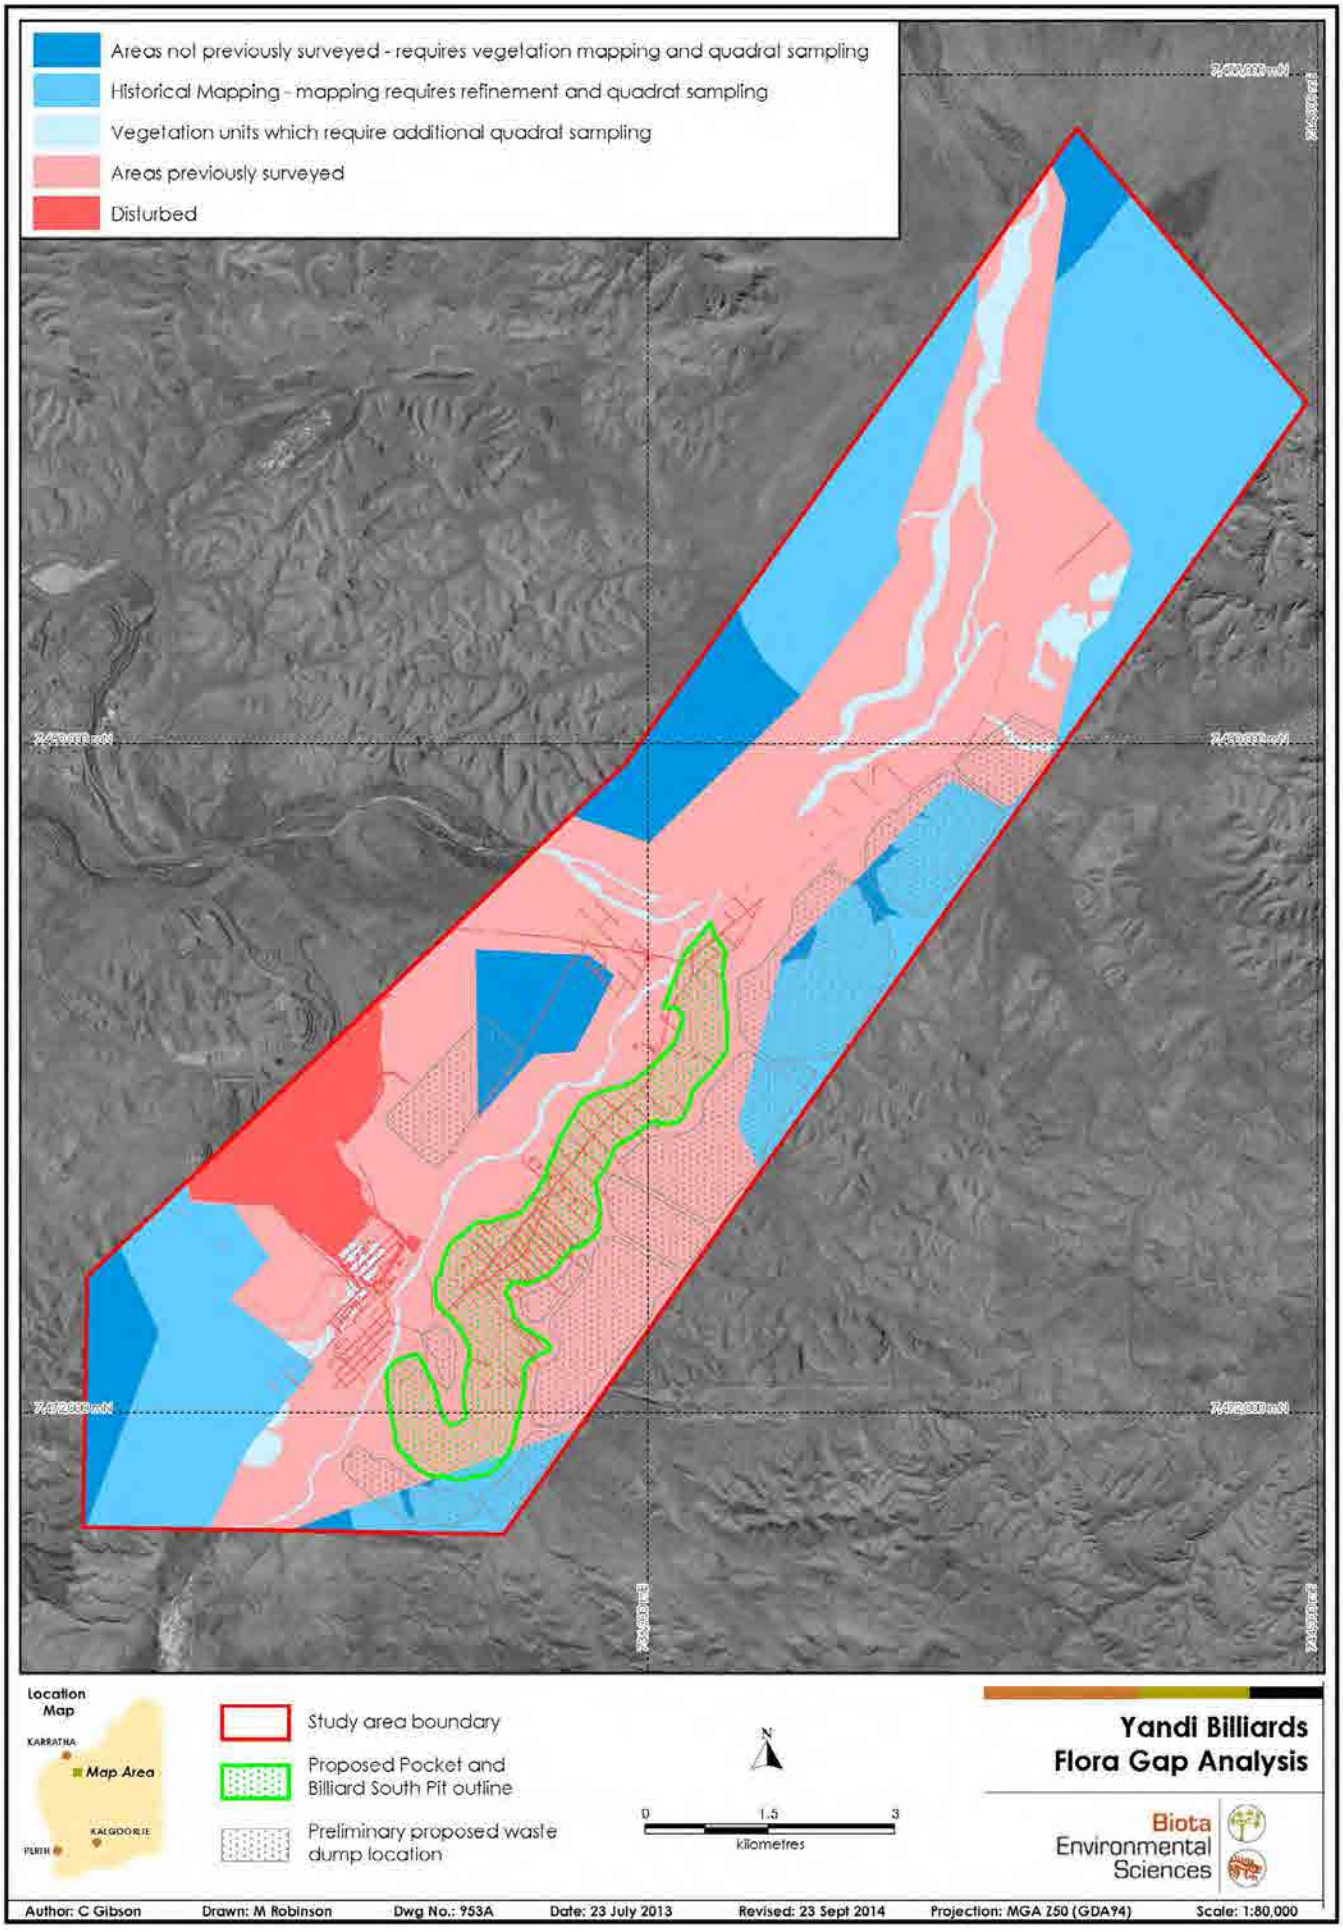

Figure 4.5: Gaps in vegetation mapping and quadrat sampling of the study area that were identified by Biota (2013).

This page intentionally blank.

5.0 Vegetation of the Study Area

5.1 Overview

A total of 495 ha (5.7%) of the study area had been cleared and was mapped as "Disturbed". Twenty-three vegetation types have been described for the study area, as summarised in Section 5.2.

These vegetation types were broadly associated with the following landforms:

- major creeklines and tributaries;
- minor creeklines, floodplains and valleys;
- hills, ridges and breakaways; and
- plains.

Soils in the study area were generally described as red-brown loams, clay loams or sandy clay loams and were covered with a loose surface layer of stones and pebbles. Soils were stonier at the margins of the valley and on the associated footslopes. Heavier soils were found in the lower parts of the valley and in the flood-out areas. Some small areas of light clay supported Mulga woodland on the plains. Soils of the creek beds were a coarse sand-pebble mix.

Table 5.1: Area of each unit mapped in the study area.

5.2 Description of the Vegetation Types

5.2.1 Vegetation of Major Creeklines and Tributaries

C1: EcEvMaMgAc	*Eucalyptus camaldulensis* subsp. *refulgens, E. victrix* woodland over *Melaleuca argentea, M. glomerata, Acacia coriacea* subsp. *pendens* low open woodland
Distribution and Comments	This riparian vegetation type occurred in the bed of Weeli Wolli Creek and Marillana Creek (Plate 5.1). Cadjeputs (*Melaleuca argentea*) occurred in patches along the creek. In wetter areas, an open sedgeland of *Cyperus vaginatus* was present, sometimes with patches of Native Bulrush (*Typha domingensis*). In drier areas, a tussock grassland stratum was typically present; this was dominated by a combination of *Eriachne tenuiculmis, Eulalia aurea* and *Themeda triandra.*
Associated Species	Trees/Tall Shrubs: *Acacia citrinoviridis, A. pyrifolia* var. *pyrifolia, Atalaya hemiglauca* and *Gossypium robinsonii.* Low Shrubs: *Corchorus crozophorifolius, Heliotropium pachyphyllum, Hybanthus aurantiacus, Indigofera monophylla, Sesbania cannabina, Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) and *Waltheria indica.* Herbs and Grasses: *Amaranthus undulatus, *Argemone ochroleuca* subsp. *ochroleuca, Cleome viscosa, Crotalaria medicaginea* var. *neglecta, Euphorbia alsiniflora, E. biconvexa, Evolvulus alsinoides* var. *villosicalyx, *Flaveria trinervia, Gomphrena cunninghamii, Ipomoea muelleri, *Malvastrum americanum, Phyllanthus maderaspatensis, Pluchea dentex, P. rubelliflora, Polycarpaea longiflora, Rhynchosia minima, *Solanum nigrum, *Sonchus oleraceus, Stemodia grossa, Trachymene oleracea* subsp. *oleracea, Typha domingensis* and *Wahlenbergia tumidifructa.*
Vegetation Condition	Good; several weed species have been recorded, however none were abundant; they typically occurred only as scattered individuals. There was some evidence of disturbance by cattle, which are widespread in the Yandi area.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	YBI30S^ and YBI23 (Biota 2009b).
Other Notes	Quadrat YBI23 was not resampled during the current survey as the creek was inundated (Plate 5.2).

Plate 5.1: Vegetation type C1 (YBI30S).

Plate 5.2: Quadrat YBI23 inundated in 2014.

C2: EvChAtuGwTErCYpERItTHt	*Eucalyptus victrix, Corymbia hamersleyana* scattered low trees over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* subsp. *hispidula* tall shrubland over *Tephrosia rosea* var. Fortescue Creeks (M.I.H. Brooker 2186) low shrubland over *Cymbopogon ambiguus, C. procerus, Eriachne tenuiculmis, Themeda triandra* very open tussock grassland
Distribution and Comments	This vegetation occurred in the study area in three moderate-sized creeklines (tributaries feeding into Weeli Wolli Creek; Plate 5.3). Patches of the tall shrub *Androcalva luteiflora* were present in places, and *Triodia pungens* sometimes occurred as a very open hummock grassland. **Cenchrus ciliaris* and **C. setiger* were present as an open tussock grassland in some places.
Associated Species	Tall Shrubs: *Acacia pyrifolia* var. *pyrifolia, Atalaya hemiglauca* and *Gossypium robinsonii.* Shrubs: *Corchorus crozophorifolius, Eremophila longifolia, Gossypium australe, Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii* and *Sida* sp. spiciform panicles (E. Leyland s.n. 14/8/90). Low Shrubs: *Crotalaria medicaginea* var. *neglecta, Hybanthus aurantiacus, Indigofera georgei, Ptilotus astrolasius* and *Waltheria indica.* Herbs and Grasses: *Amaranthus undulatus*, *Aristida holathera* var. *holathera*, *Boerhavia coccinea, *Cenchrus ciliaris*, **C. setiger, Enneapogon polyphyllus, Gomphrena cunninghamii, Goodenia stobbsiana, Paraneurachne muelleri, Polycarpaea longifolia* and *Triodia pungens.*
Vegetation Condition	Good; **Cenchrus ciliaris* and **C. setiger* often occurred as scattered tussock grasses to an open tussock grassland, and scattered individuals of **Setaria verticillata* were also recorded. Several standing dead trees, which could not be distinguished as *E. victrix* or *C. hamersleyana*, were noted in quadrat BIL31; the cause of these deaths was not apparent.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	BIL02^ and BIL31^ (current survey).
Other Notes	This vegetation was originally mapped as EvAtuGwTErCYpERItTHt (Biota 2014b). The description has been updated with the addition of *Corymbia hamersleyana* in the low tree stratum; this species occurred as a co-dominant with *Eucalyptus victrix* in some creeklines in the study area.

Plate 5.3: Vegetation type C2 (BIL02).

C3: EvAciAcMgCEc	*Eucalyptus victrix* scattered trees over *Acacia citrinoviridis, A. coriacea* subsp. *pendens, Melaleuca glomerata* tall open shrubland over **Cenchrus ciliaris* scattered tussock grasses
Distribution and Comments	This was the predominant vegetation of the creek beds of Marillana and Weeli Wolli Creek (Plate 5.4). It was observed in scoured channels that occurred in a braided pattern through the broader creekline vegetation.
Associated Species	Tall Shrubs: *Acacia pyrifolia* var. *pyrifolia* and *Atalaya hemiglauca*. Shrubs: *Corchorus crozophorifolius, Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) and *Waltheria indica*. Low Shrubs: *Crotalaria medicaginea* var. *neglecta* and *Indigofera monophylla.* Herbs and Grasses: **Argemone ochroleuca* subsp. *ochroleuca*, *Amaranthus undulatus*, *Boerhavia coccinea, Cleome viscosa, Cymbopogon procerus, Enneapogon lindleyanus, Eriachne tenuiculmis, Eulalia aurea, Gomphrena cunninghamii, Goodenia lamprosperma, Phyllanthus maderaspatensis, Pluchea rubelliflora* and *Polycarpaea longiflora.*
Vegetation Condition	Very Good; scattered individuals of several weed species were recorded, along with minor disturbance from cattle (scats and low levels of grazing).
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	YBI01^ (Biota 2009b) and BIL30^ (current survey).
Relevés in the Study Area	YBI-RRWB (Biota 2009b).

Plate 5.4: Vegetation type C3 (BIL03).

C4: EvAciAprAThCEc	*Eucalyptus victrix* open *woodland* over *Acacia citrinoviridis, A. pruinocarpa, Atalaya hemiglauca* low woodland over **Cenchrus ciliaris* tussock grassland
Distribution and Comments	This vegetation type occurred on the broad floodplains of Marillana and Weeli Wolli Creeks (Plate 5.5). It was also recorded from two moderate-sized creeklines (tributaries of Weeli Wolli Creek) at the southern end of the study area. **Cenchrus ciliaris* formed a closed tussock grassland in some sites situated on floodplains. Scattered *Triodia pungens* was often present in the understorey.
Associated Species	Trees/Tall Shrubs: *Acacia coriacea* subsp. *pendens, A. pyrifolia* var. *pyrifolia, A. sclerosperma* subsp. *sclerosperma, Corymbia hamersleyana, Gossypium robinsonii, Hakea lorea* subsp. *lorea and Stylobasium spathulatum.* Shrubs: *Corchorus crozophorifolius, Gossypium sturtianum, Ptilotus obovatus* var. *obovatus, Rhagodia eremaea, Senna artemisioides* subsp. *helmsii, Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) and *Waltheria indica.* Low Shrubs: *Hybanthus aurantiacus, Indigofera monophylla, Melhania oblongifolia* and *Ptilotus astrolasius.* Herbs, Grasses and Sedges: **Bidens bipinnata, *Cenchrus setiger, Cymbopogon procerus, Cyperus vaginatus, Dicladanthera forrestii, Enneapogon lindleyanus, E. robustissimus, Eulalia aurea, Evolvulus alsinoides* var. *decumbens, Evolvulus alsinoides* var. *villosicalyx, *Malvastrum americanum, Notoleptopus decaisnei* var. *decaisnei, Phyllanthus maderaspatensis, *Setaria verticillata, Themeda triandra* and *Triodia pungens.*
Vegetation Condition	Good to Very Poor: much of this vegetation type was extensively invaded by **Cenchrus ciliaris* (often with **C. setiger* as a co-dominant). Several other weed species were present as scattered individuals and disturbance from cattle was also recorded. Historical (mostly overgrown) drill lines were also noted in this vegetation type.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	H051 and H050^ (Biota 2002); HDA09^ (Biota 2004b); YBI02, YBI03, YBI04 and YBI08^ (Biota 2009b); YAQ12^ and YAQ21 (Biota 2014b); and YEX02^ (Biota 2004a).
Relevés in the Study Area	YBI-RBMK, YBI-RPHB and YBI-RPHA (Biota 2009b); and YAQ-CSRA (Biota 2014b).
Other Notes	Quadrat H051 has been cleared.

Plate 5.5: Vegetation type C4 (YAQ12).

5.2.2 Vegetation of Minor Creeklines, Floodplains and Valleys

F1: ChAtuGwTp	*Corymbia hamersleyana* scattered low trees to low open woodland over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* tall open shrubland over *Triodia pungens* hummock grassland
Distribution and Comments	This vegetation type occurred throughout the study area in minor creeklines on plains and in between low hills (Plate 5.6). It was also found in a broad valley in the northern end of the study area, where the vegetation was regenerating after being recently burnt (less than 3 years ago).
Associated Species	Trees: *Eucalyptus gamophylla*. Tall Shrubs: *Acacia ancistrocarpa, A. bivenosa, A. dictyophleba, A. pyrifolia* var. *pyrifolia, Androcalva luteiflora* and *Gossypium robinsonii.* Shrubs: *Gossypium australe, Senna artemisioides* subsp. *helmsii, S. artemisioides* subsp. *oligophylla, S. artemisioides* subsp. *oligophylla x* subsp. *helmsii* and *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186). Low Shrubs: *Corchorus lasiocarpus* subsp. *lasiocarpus, C. tectus, Hybanthus aurantiacus* and *Waltheria indica.* Herbs and Grasses: *Aristida holathera* var. *holathera, Bothriochloa ewartiana, *Cenchrus ciliaris, Cymbopogon ambiguus, Digitaria brownii, Eriachne mucronata, Goodenia muelleriana, Hibiscus sturtii* var. *platychlamys, Pterocaulon sphacelatum, Rhynchosia minima, Sida cardiophylla, Stemodia grossa, Themeda triandra* and *Trichodesma zeylanicum* var. *zeylanicum*.
Vegetation Condition	Very Good to Good: scattered weed species were present at some sites. **Cenchrus ciliaris* formed a very open tussock grassland in some areas.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	YBI20^, YBI25 and YBI35S^ (Biota 2009b); BIL16^ (current survey).
Relevés in the Study Area	YBI-RBME (Biota 2009b); BIL-RCFC and BIL-RSWA (current survey).

Plate 5.6: Vegetation type F1 (BIL16).

F2: AprAciCEc	*Acacia pruinocarpa, A. citrinoviridis* tall open shrubland over **Cenchrus ciliaris* tussock grassland
Distribution and Comments	This vegetation type occurred on broad floodplains fringing Weeli Wolli Creek in the north of the study area, and in broad tributaries of Weeli Wolli Creek at the southern end of the study area (Plate 5.7). *Corymbia hamersleyana* and *Eucalyptus victrix* trees were occasionally scattered in areas close to the creekline. **Cenchrus ciliaris* formed a continuous tussock grassland in the understorey, however occasional *Triodia pungens* hummocks were also present.
Associated Species	Trees: *Corymbia hamersleyana* and *Eucalyptus victrix.* Tall Shrubs: *Acacia bivenosa, A. pyrifolia* var. *pyrifolia, A. synchronicia, A. tumida* var. *pilbarensis, Androcalva luteiflora, Atalaya hemiglauca, Gossypium robinsonii* and *Hakea lorea* subsp. *lorea.* Shrubs: *Ptilotus obovatus* var. *obovatus* and *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186). Low Shrubs: *Abutilon lepidum, Corchorus lasiocarpus* subsp. *lasiocarpus, Crotalaria medicaginea* var. *neglecta* and *Hybanthus aurantiacus.* Herbs and Grasses: *Bothriochloa ewartiana, Chrysopogon fallax, Enneapogon polyphyllus, Eulalia aurea, *Flaveria trinervia, Duperreya commixta, *Malvastrum americanum, Streptoglossa decurrens* and *Themeda triandra.*
Vegetation Condition	Poor; extensively invaded by **Cenchrus ciliaris* (sometimes with **C. setiger*), and scattered other weeds of various species were also present; some disturbance from cattle (grazing and scats).
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	YEX38^ (Biota 2004a); YAQ30^ (Biota 2014b); BIL23^ and BIL24^ (current survey).
Relevés in the Study Area	YBI-RBMF and YBI-RBMH (Biota 2009b); YAQ-CSRC and YAQ-CSRD (Biota 2014b).

Plate 5.7: Vegetation type F2 (BIL24).

F3: ElChAtuAaAbGwTspp	*Eucalyptus leucophloia, Corymbia hamersleyana* low open woodland over *Acacia tumida* var. *pilbarensis*, *A. ancistrocarpa, A. bivenosa, Grevillea wickhamii* tall open scrub over mixed *Triodia* hummock grassland
Distribution and Comments	This vegetation type occurred in numerous minor creeklines amongst low hills in the south of the study area near the Junction South East (JSE) mine (Plate 5.8). These creeklines had a defined rocky bed and narrow banks. Most of the creeklines were too narrow to establish a standard flora quadrat (50 x 50 m). The composition of the shrub stratum was variable but was typically dominated by a combination of the species listed above. The dominant spinifex varied with location and usually reflected the species present in the surrounding plains; *Triodia pungens, T. basedowii* and *T. wiseana* were typical dominant species.
Associated Species	Trees: *Eucalyptus victrix* and *E. xerothermica*. Tall Shrubs: *Acacia coriacea* subsp. *pendens, A. dictyophleba, Androcalva luteiflora, Atalaya hemiglauca, Eremophila longifolia* and *Gossypium robinsonii.* Shrubs: *Acacia tenuissima, Jasminum didymum* subsp. *lineare, Ptilotus obovatus* var. *obovatus, Santalum lanceolatum, Senna artemisioides* subsp. *helmsii* and *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186). Low Shrubs: *Crotalaria medicaginea* var. *neglecta, Indigofera monophylla, Melhania oblongifolia* and *Waltheria indica.* Herbs and Grasses: *Aristida holathera* var. *holathera, Boerhavia coccinea, Bonamia erecta, *Cenchrus ciliaris, Enneapogon robustissimus, Eriachne mucronata, Eulalia aurea, Evolvulus alsinoides* var. *villosicalyx, Goodenia microptera, G. muelleriana, Indigofera colutea, Polycarpaea longiflora* and *Setaria verticillata.*
Vegetation Condition	Good; **Cenchrus ciliaris* was the dominant weed species, forming a very open tussock grassland in some creeklines. Several other weed species were present as scattered individuals.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	YEX07, YEX08^ (Biota 2004a); BIL35^ and BIL36^ (current survey).
Relevés in the Study Area	YAQ-RPLA, established in the Yandi Additional Areas survey (Biota 2014b).
Other Notes	Quadrat YEX07 has been cleared.

Plate 5.8: Vegetation type F3 (BIL35).

F4: ChAtuAaPcAtenBONeARhPAmTp	*Corymbia hamersleyana* scattered low trees over *Acacia tumida* var. *pilbarensis* tall open shrubland over *A. ancistrocarpa, Petalostylis cassioides, A. tenuissima* open shrubland over *Bonamia erecta* very open herbland over *Aristida holathera* var. *holathera, Paraneurachne muelleri* very open tussock grassland and *Triodia pungens* very open hummock grassland.
Distribution and Comments	This vegetation type occurred on a floodout located on a plain and fed by minor creeklines that flowed through low hills to the east (Plate 5.9).
Associated Species	Trees: *Eucalyptus gamophylla*. Tall Shrubs: *Acacia citrinoviridis, A. dictyophleba, A. inaequilatera, A. pruinocarpa* and *Gossypium robinsonii*. Shrubs: *Acacia pyrifolia* var. *pyrifolia, Gossypium australe, Senna artemisioides* subsp. *oligophylla* and *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186). Low Shrubs: *Corchorus tectus, Dicrastylis cordifolia, Hibiscus sturtii* var. *platychlamys, Hybanthus aurantiacus, Indigofera georgei, Ptilotus astrolasius* and *Sida cardiophylla*. Herbs and Grasses: *Boerhavia coccinea, *Cenchrus ciliaris, Eriachne aristidea, Gomphrena cunninghamii, Polymeria ambigua, Themeda triandra* and *Triodia basedowii.*
Vegetation Condition	Very Good; some scattered individuals of **Cenchrus ciliaris* and **Setaria verticillata*; minor disturbance from cattle.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	BIL11^, BIL14 and BIL46^ (current survey).

Plate 5.9: Vegetation type F4 (BIL46).

F5: ChAciAaAiSENsppTp	*Corymbia hamersleyana* scattered low trees over *Acacia citrinoviridis, A. ancistrocarpa, A. inaequilatera* tall open shrubland over *Senna* spp. open shrubland over *Triodia pungens* open hummock grassland.
Distribution and Comments	This vegetation type occurred on a small area of floodplains and floodouts in the southernmost part of the study area (Plate 5.10). The shrub stratum consisted of a mixture of *Senna* spp. including *Senna artemisioides* subsp. *helmsii, S. artemisioides* subsp. *oligophylla* and *S. glutinosa* subsp. x *luerssenii.*
Associated Species	Trees: *Acacia aptaneura*. Tall Shrubs: *Acacia bivenosa, A. pyrifolia* var. *pyrifolia, A. tumida* var. *pilbarensis, Atalaya hemiglauca, Eremophila longifolia, Gossypium robinsonii, Grevillea wickhamii, Hakea chordophylla, H. lorea* subsp. *lorea* and *Santalum lanceolatum.* Shrubs: *Corchorus crozophorifolius*, *Indigofera monophylla*, *Tephrosia* sp. Fortescue (A.A. Mitchell 606) and *Waltheria indica*. Low Shrubs: *Corchorus lasiocarpus* subsp. *lasiocarpus, C. tectus, Hybanthus aurantiacus, Isotropis atropurpurea, Pluchea ferdinandi-muelleri* and *Waltheria indica*. Herbs and Grasses: *Aristida inaequiglumis*, **Cenchrus ciliaris, Cleome viscosa, Digitaria ctenantha, Enneapogon polyphyllus, Paraneurachne muelleri, Polycarpaea corymbosa, Sida* sp. verrucose glands (F.H. Mollemans 2423), *Streptoglossa decurrens* and *Themeda triandra.*
Vegetation Condition	Good; **Cenchrus ciliaris* occurred as a very open tussock grassland in some areas, and there was some evidence of grazing by cattle.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	BIL21^, BIL47 (current survey).

Plate 5.10: Vegetation type F5 (BIL21).

5.2.3 Vegetation of Hills, Ridges and Breakaways

H1: ElHcAiGwTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Hakea chordophylla, Acacia inaequilatera, Grevillea wickhamii* tall open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland
Distribution and Comments	This vegetation type occurred throughout the study area on the crests and slopes of low stony hills (Plate 5.11). Scattered individuals of *Triodia wiseana* were also recorded at some sites and *T. brizoides* was present on some of the steeper slopes. Some areas of this vegetation type also had *Acacia adoxa* var. *adoxa* and/or *Acacia hilliana* present as scattered low shrubs to a low open shrubland. Parts of this vegetation type along the southern and eastern boundaries of the study area had been recently burnt (approximately 2 years prior; Plate 5.12). This vegetation type supported the populations of the Threatened species *Lepidium catapycnon* that were recorded from the study area (see Section 6.4.1).
Associated Species	Tall Shrubs: *Acacia bivenosa* and *A. pruinocarpa*. Shrubs: *Ptilotus rotundifolius, Senna artemisioides* subsp. *oligophylla, S. glutinosa* subsp. *glutinosa, S. glutinosa* subsp. *x luerssenii* and *S. glutinosa* subsp. *pruinosa.* Low Shrubs: *Acacia spondylophylla, Corchorus lasiocarpus* subsp. *lasiocarpus, Lepidium catapycnon* (Threatened), *Ptilotus astrolasius, Sida echinocarpa, Sida* sp. Pilbara (A.A. Mitchell PRP 1543), *Solanum lasiophyllum* and *Tribulus suberosus.* Herbs, Grasses and Sedges: *Amphipogon sericeus, Aristida holathera* var. *holathera, Eriachne mucronata, Fimbristylis dichotoma, F. simulans, Goodenia stobbsiana, G. triodiophila, Ptilotus calostachyus* and *Schizachyrium fragile.*
Vegetation Condition	Excellent.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	YBI31S^ and YBI33S^ (Biota 2009b); YEX01^, YEX06^ and YEX37 (Biota 2004a); YAQ14^, YAQ25^ and YAQ27^ (Biota 2014b); BIL05, BIL17^, BIL19, BIL20^, BIL28, BIL34^, BIL37 and BIL43.

Plate 5.11: Vegetation type H1 (BIL20).

Plate 5.12: Burnt hillslopes supporting vegetation type H1.

H2: ElAiTwTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Acacia inaequilatera* scattered tall shrubs over *Triodia wiseana*, (*T.* sp. Shovelanna Hill (S. van Leeuwen 3835)) open hummock grassland
Distribution and Comments	This vegetation type occurred throughout the study area on the crests and slopes of low to moderate-sized stony hills (Plate 5.13). Although the dominant spinifex species in this vegetation type was *Triodia wiseana, Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) was co-dominant in some places. Scattered low shrubs to a low open shrubland of *Indigofera rugosa* and/or *Acacia adoxa* var. *adoxa* was sometimes present. Minor drainage lines (too small to map) dissected this vegetation type and consisted of *Gossypium australe, Acacia pyrifolia* and *A. maitlandii* open shrublands over mixed tussock grasslands. A small area of this vegetation type along the eastern edge of the study area had been recently burnt (approximately 2 years prior; Plate 5.14).
Associated Species	Tall Shrubs: *Acacia bivenosa, A. pruinocarpa, Grevillea wickhamii* and *Hakea lorea* subsp. *lorea*. Shrubs: *Senna artemisioides* subsp. *oligophylla, S. glutinosa* subsp. *glutinosa, S. glutinosa* subsp. *x luerssenii, S. glutinosa* subsp. *pruinosa*. Low Shrubs: *Calytrix carinata, Dampiera candicans, Indigofera monophylla, Ptilotus rotundifolius, Solanum lasiophyllum, Tephrosia* sp. Fortescue (A.A. Mitchell 606) and *Tribulus suberosus.* Herbs, Grasses and Sedges: *Aristida holathera* var. *holathera, Boerhavia gardneri, Bonamia* sp. Dampier (A.A. Mitchell PRP 217), *Bulbostylis barbata, Enneapogon polyphyllus, Eriachne aristidea, Fimbristylis dichotoma, Goodenia muelleriana, G. stobbsiana, G. triodiophila, Mollugo molluginea, Ptilotus calostachyus, P. nobilis* subsp. *nobilis* and *Tephrosia* sp. NW Eremaean (S. van Leeuwen et al. PBS 0356).
Vegetation Condition	Excellent.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	HDA16, HDA24^ (Biota 2004b); YBI05^, YBI36^, YBI32S^ (Biota 2009b); YAQ19, YAQ18 (Biota 2014b); BIL03, BIL15^, BIL26, BIL27, BIL29, BIL39^, BIL40, BIL44 (current survey).
Relevés in the Study Area	BIL-RCFA (current survey).

Plate 5.13: Vegetation type H2 (BIL40).

Plate 5.14: Burnt hills supporting vegetation type H2.

H3: ElGwAarTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Grevillea wickhamii* tall open shrubland over *Acacia arida* shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) open hummock grassland
Distribution and Comments	This vegetation type occurred on the crests and slopes of low rocky hills in the northeast of the study area (Plate 5.15). The northern half of this vegetation type had been recently burnt at the time of the survey (within the last 2 years; Plate 5.16).
Associated Species	Tall Shrubs: *Acacia bivenosa* (wispy/weeping form) and *A. inaequilatera.* Shrubs: *Senna artemisioides* subsp. *oligophylla* and *S. glutinosa* subsp. *glutinosa* x subsp. *pruinosa.* Low Shrubs: *Acacia adoxa* var. *adoxa* and *Ptilotus astrolasius.* Herbs, Grasses and Sedges: *Eriachne lanata, E. pulchella, Fimbristylis dichotoma, F. simulans, Goodenia stobbsiana, Ptilotus calostachyus* and *Triodia pungens.*
Vegetation Condition	Excellent.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	BIL01^ and BIL06^ (current survey).
Relevés in the Study Area	BIL-RPCA (current survey).

Plate 5.15: Vegetation type H3 (BIL06).

Plate 5.16: Burnt hillslopes supporting vegetation type H3.

H4: ChAarTspsTw	*Corymbia hamersleyana* scattered low trees over *Acacia arida* open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), *T. wiseana* hummock grassland
Distribution and Comments	This vegetation type occurred on the crests and upper slopes of two low stony hills in the northeast of the study area (Plate 5.17).
Associated Species	Tall Shrubs: *Acacia inaequilatera, Grevillea wickhamii* and *Hakea chordophylla.* Shrubs: *Acacia pachyacra, Senna artemisioides* subsp. *oligophylla, S. glutinosa* subsp. *glutinosa, S. glutinosa* subsp. *x luerssenii* and *S. glutinosa* subsp. *pruinosa.* Low Shrubs: *Acacia adoxa* var. *adoxa, Calytrix carinata, Dampiera candicans, Ptilotus astrolasius, P. rotundifolius* and *Solanum lasiophyllum.* Herbs, Grasses and Sedges: *Amphipogon sericeus, Aristida holathera* var. *holathera, Cymbopogon obtectus, Eriachne pulchella, Fimbristylis simulans, Goodenia stobbsiana, Pterocaulon sphacelatum, Ptilotus calostachyus* and *Schizachyrium fragile.*
Vegetation Condition	Excellent.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	YBI24^ (Biota 2009b) and BIL04^ (current survey).

Plate 5.17: Vegetation type H4 (YBI24).

H5: ElCfERImTHspp	*Eucalyptus leucophloia* subsp. *leucophloia, Corymbia ferriticola* scattered low trees over *Eremophila latrobei* subsp. *filiformis, Senna* spp. scattered shrubs over *Cymbopogon ambiguus, Eriachne mucronata, Themeda* sp. Mt Barricade (M.E. Trudgen 2471), *T. triandra* open tussock grassland
Distribution and Comments	This vegetation type occurred on several narrow ridgelines with rocky free face and breakaway slopes, located in the southern half of the study area (Plate 5.18 and Plate 5.19). This vegetation type was characterised by very steep (often vertical) rocky slopes. The soil was skeletal and often occurred in pockets amongst exposed rock outcrops. This vegetation supported two populations of the Priority 3 *Sida* sp. Barlee Range (S. van Leeuwen 1642).
Associated Species	Tall Shrubs: *Clerodendrum floribundum* var. *angustifolium* and *Grevillea wickhamii*. Shrubs: *Dodonaea coriacea, Ptilotus obovatus* var. *obovatus, Rhagodia eremaea, Senna glutinosa* subsp. *glutinosa, S. glutinosa* subsp. *x luerssenii* and *Sida* sp. spiciform panicles (E. Leyland s.n. 14/8/90). Low Shrubs: *Abutilon lepidum, Maireana planifolia, Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3), *S.* sp. Excedentifolia (J.L. Egan 1925), *Hibiscus* sp. Mt Robinson (G. Byrne 3537) and *Solanum lasiophyllum.* Herbs and Grasses: *Aristida holathera* var. *holathera, Enneapogon polyphyllus, Goodenia microptera, G. muelleriana, G. stobbsiana* and *Triodia pungens.*
Vegetation Condition	Typically Excellent; one individual of **Cenchrus ciliaris* was recorded on one ridgeline.
Relevés in the Study Area	YEX-J (Biota 2004a); BIL-RCFB and BIL-RCFD (current survey).
Other Notes	As this vegetation type was too narrow for quadrat sampling, only relevés were completed.

Plate 5.18: Vegetation type H5 (BIL-RCFB).

Plate 5.19: A free face slope of vegetation type H5.

5.2.4 Vegetation of Plains

P1: ElEgAprAbAaAdTwTpTsps	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia pruinocarpa* scattered tall shrubs over *A. bivenosa, A. ancistrocarpa, A. dictyophleba* shrubland over *Triodia wiseana, T. pungens*, *T.* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland
Distribution and Comments	This vegetation type occurred over undulating, colluvial stony plains near the JSE mine, located between Weeli Wolli Creek and a range of low hills to the west (Plate 5.20). The proportion of the dominant spinifex varied considerably with location, with *Triodia wiseana* and/or *T. pungens* dominating the majority of the lower-lying areas and *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) tending to dominate the more elevated areas.
Associated Species	Tall Shrubs: *Acacia inaequilatera, A. pachyacra, A. synchronicia, Codonocarpus cotinifolius* and *Hakea chordophylla.* Shrubs: *Acacia hilliana, Eremophila fraseri* subsp. *fraseri, Senna glutinosa* subsp. *x luerssenii* and *S. glutinosa* subsp. *pruinosa.* Low Shrubs: *Acacia adoxa* var. *adoxa, Bonamia erecta, Corchorus lasiocarpus* subsp. *lasiocarpus, Hybanthus aurantiacus, Sida arenicola, S. echinocarpa* and *Solanum lasiophyllum.* Herbs and Grasses: *Aristida contorta, Cymbopogon obtectus, Goodenia microptera, G. stobbsiana, Paraneurachne muelleri, Ptilotus nobilis* subsp. *nobilis, Tephrosia* sp. NW Eremaean (S. van Leeuwen et al. PBS 0356) and *Themeda triandra.*
Vegetation Condition	Excellent.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	YEX05 (Biota 2004a); BIL38^, BIL49 (current survey).
Other Notes	Quadrat YEX05 has been cleared.

Plate 5.20: Vegetation type P1 (BIL38).

P2: ChAprAiAsclApaTp	*Corymbia hamersleyana, Acacia pruinocarpa* scattered low trees over *A. inaequilatera, A. sclerosperma* subsp. *sclerosperma, A. pachyacra* tall open shrubland over *Triodia pungens* hummock grassland
Distribution and Comments	This vegetation type occurred broadly over plains between low hills in the north of the study area, as well as on plains fringing the floodplains of both Marillana and Weeli Wolli Creeks (Plate 5.21). Shrub species varied with location; the typical dominant species are listed in the description above, however *Acacia dictyophleba* was also abundant in some places. Shrub cover tended to be higher in areas closer to the major creeks. *Triodia pungens* was the dominant spinifex species, however occasional hummocks of *T. basedowii* were also recorded.
Associated Species	Tall Shrubs: *Acacia ancistrocarpa, A. citrinoviridis, A. pyrifolia* var. *pyrifolia, Atalaya hemiglauca* and *Hakea chordophylla.* Shrubs: *Eremophila longifolia, Gossypium australe, Ptilotus obovatus* var. *obovatus, Senna artemisioides* subsp. *helmsii, S. artemisioides* subsp. *oligophylla, S. glutinosa* subsp. *x luerssenii* and *S. glutinosa* subsp. *pruinosa.* Low Shrubs: *Corchorus sidoides* subsp. *sidoides, Dicrastylis cordifolia, Dodonaea coriacea, Hibiscus sturtii* var. *platychlamys, Indigofera monophylla, Sida arsiniata, S. cardiophylla, S.* sp. verrucose glands (F.H. Mollemans 2423), *Solanum lasiophyllum* and *Tephrosia supina.* Herbs, Grasses and Sedges: *Boerhavia coccinea, Bulbostylis barbata, *Cenchrus ciliaris, Enneapogon polyphyllus, Eragrostis eriopoda, Eriachne pulchella, Mollugo molluginea, Paraneurachne muelleri* and *Tribulus astrocarpus.*
Vegetation Condition	Good; scattered individuals to a very open tussock grassland of **Cenchrus ciliaris* in places, along with scattered individuals of several other weed species.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	YBI10^ and YBI26 (Biota 2009b); YAQ16^, YAQ29 (Biota 2014b); BIL07^, BIL08, BIL09, BIL10^ (current survey).
Relevés in the Study Area	YBI-RBMC and YBI-RBMD (Biota 2009b).
Other Notes	YBI26 and YAQ29 have since been cleared.

Plate 5.21: Vegetation type P2 (BIL10).

P3: AprAciAiAsclTlo	*Acacia pruinocarpa* low open woodland over *A. citrinoviridis, A. inaequilatera, A. sclerosperma* subsp. *sclerosperma* open shrubland over *Triodia longiceps* hummock grassland
Distribution and Comments	This vegetation type occurred on plains fringing the floodplains on either side of Weeli Wolli Creek in the central section of the study area (Plate 5.22).
Associated Species	Trees: *Acacia aptaneura, A. coriacea* subsp. *pendens* and *Corymbia hamersleyana.* Tall Shrubs: *Acacia bivenosa, A. dictyophleba, A. pyrifolia* var. *pyrifolia, A. tenuissima, Atalaya hemiglauca, Eremophila longifolia, Hakea lorea* subsp. *lorea, Stylobasium spathulatum.* Shrubs: *Corchorus crozophorifolius, C. lasiocarpus* subsp. *lasiocarpus, Gossypium sturtianum, Ptilotus obovatus* var. *obovatus, Senna artemisioides* subsp. *helmsii* and *S. artemisioides* subsp. *oligophylla.* Low Shrubs: *Abutilon lepidum, Corchorus sidoides* subsp. *sidoides, Sida* sp. verrucose glands (F.H. Mollemans 2423) and *Solanum lasiophyllum.* Herbs and Grasses: *Abutilon otocarpum, Aristida holathera* var. *holathera, Boerhavia coccinea, *Cenchrus ciliaris, Cymbopogon ambiguus, Enneapogon caerulescens, Goodenia microptera, Pterocaulon sphacelatum, Sclerolaena cornishiana, Themeda triandra* and *Triodia basedowii.*
Vegetation Condition	Typically Very Good (occasionally Poor, depending on the level of weed invasion). The cover of **Cenchrus ciliaris* ranged from scattered individuals to a very open tussock grassland. One site (YBI17) was rated as Poor: a **Malvastrum americanum* open herbland was present, and several other weed species occurred there as scattered individuals.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	HDA14 (Biota 2004b); YBI11^ and YBI17^ (Biota 2009b).
Relevés in the Study Area	YBI-RBMJ (Biota 2009b).
Other Notes	HDA14 has been cleared.

Plate 5.22: Vegetation type P3 (YBI11).

P4: AprAsyAiTw	*Acacia pruinocarpa* low open woodland over *A. synchronicia, A. inaequilatera* scattered tall shrubs over *Triodia wiseana* open hummock grassland
Distribution and Comments	This vegetation type occurred on the plains at the southernmost end of the study area, fringing the floodplain on both sides of Weeli Wolli Creek (Plate 5.23).
Associated Species	Trees: *Acacia aptaneura, A. sibirica, Corymbia hamersleyana* and *Eucalyptus xerothermica.* Tall Shrubs: *Acacia bivenosa, A. pachyacra* and *A. sericophylla*. Shrubs: *Capparis spinosa* var. *nummularia, Corchorus lasiocarpus* subsp. *lasiocarpus, Eremophila forrestii* subsp. *forrestii, Gossypium australe, Ptilotus obovatus* var. *obovatus, Senna artemisioides* subsp. *helmsii, S. glutinosa* subsp. *glutinosa* and *S. glutinosa* subsp. *x luerssenii.* Low Shrubs: *Indigofera monophylla, Maireana planifolia* and *Ptilotus astrolasius.* Herbs and Grasses: *Abutilon otocarpum, *Cenchrus ciliaris, Chrysopogon fallax, Enneapogon polyphyllus, Eragrostis cumingii, E. eriopoda, Hibiscus burtonii, Sida* sp. verrucose glands (F.H. Mollemans 2423), *Paraneurachne muelleri, Polymeria ambigua, Pterocaulon sphacelatum, Streptoglossa decurrens* and *Themeda triandra.*
Vegetation Condition	Very Good to Good; scattered **Cenchrus ciliaris* were common, and some sites had other weedy herbs present as scattered individuals.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	HDA07, HDA15 (Biota 2004b); YBI19 (Biota 2009b); YEX03, YEX04^, YEX32 (Biota 2004a).
Relevés in the Study Area	YAQ-CSRB (Biota 2014b).
Other Notes	Quadrats HDA07, HDA15, YEX03, YEX32 and YBI19 have been cleared.

Plate 5.23: Vegetation type P4 (YEX04).

P5: ElEgAbAaTb	*Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia bivenosa, A. ancistrocarpa* open shrubland over *Triodia basedowii* open hummock grassland
Distribution and Comments	This vegetation type occurred on plains throughout the study area (Plate 5.24). It was particularly common on the eastern side of Weeli Wolli Creek. *Triodia basedowii* was the dominant spinifex species in this vegetation type, however occasional *T. pungens* hummocks were also recorded. (Note that *T. basedowii* was identified as *T. lanigera* in previous reporting.) A small area of this vegetation had been recently burnt (approximately 2-3 years prior to the survey).
Associated Species	Trees: *Acacia aptaneura* and *Corymbia hamersleyana*. Tall Shrubs: *Acacia dictyophleba, A. inaequilatera, A. pachyacra, A. tumida* var. *pilbarensis, Eremophila longifolia, Gossypium robinsonii, Grevillea wickhamii* subsp. *hispidula* and *Hakea chordophylla.* Shrubs: *Acacia adsurgens, Indigofera monophylla, Ptilotus obovatus* var. *obovatus, Senna artemisioides* subsp. *helmsii, S. artemisioides* subsp. *oligophylla* and *S. artemisioides* subsp. *oligophylla x* subsp. *helmsii.* Low Shrubs: *Abutilon lepidum, Bonamia erecta, Corchorus sidoides* subsp. *sidoides, C. tectus, Dicrastylis cordifolia, Ptilotus astrolasius, Scaevola parvifolia* subsp. *pilbarae, Sida cardiophylla* and *Solanum phlomoides.* Herbs, Grasses and Sedges: *Abutilon otocarpum, Aristida contorta, A. holathera* var. *holathera, Bulbostylis barbata, Cymbopogon obtectus, Enneapogon polyphyllus, Eragrostis eriopoda, Eriachne aristidea, Perotis rara, Ptilotus calostachyus, Themeda triandra, Tribulus macrocarpus, Trichodesma zeylanicum* var. *zeylanicum* and *Yakirra australiensis* var. *australiensis.*
Vegetation Condition	Excellent to Good; scattered weeds were present at some sites. **Cenchrus ciliaris* was the most common weed species and formed a very open tussock grassland in some areas. Historical drill lines (mostly overgrown) were found in this vegetation type.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	WW30 (Halpern Glick Maunsell 2000); HDA12 (Biota 2004b); YEX33 (Biota 2004a); YBI06^, YBI07^, YBI09^, YBI14, YBI16, YBI21, YBI22, YBI27^, YBI28, YBI29 and YBI34S^ (Biota 2009b); YAQ23^ (Biota 2014b); BIL18 and BIL33^ (current survey).
Relevés in the Study Area	YBI-RBMB, YBI-RBMA and YBI-RROA (Biota 2009b).
Other Notes	Quadrats HDA12 and YEX33 have been cleared.

Plate 5.24: Vegetation type P5 (BIL18).

Plate 5.25: Burnt vegetation type P5 (YAQ23).

P6: AapERfoERI/g	*Acacia aptaneura* low open forest over *Eremophila forrestii* subsp. *forrestii* open shrubland over *E. lanceolata* low open shrubland over mixed very open grassland
Distribution and Comments	This vegetation type occurred in narrow stands adjacent to the floodplains along either side of Weeli Wolli Creek (Plate 5.26). Several small patches of this vegetation also occurred on plains and hill crests in the study area. Tussock grasses typically dominated the understorey, however scattered hummock grasses were often present. This vegetation type supported the Priority 4 species, *Goodenia nuda*.
Associated Species	Trees: *Acacia ayersiana, A. catenulata, A. pruinocarpa* and *Corymbia candida*. Tall Shrubs: *Acacia citrinoviridis, A. coriacea* subsp. *pendens, Atalaya hemiglauca* and *Hakea lorea* subsp. *lorea.* Shrubs: *Gossypium australe, Ptilotus obovatus* var. *obovatus, Rhagodia eremaea, Senna artemisioides* subsp. *helmsii* and *S. artemisioides* subsp. *oligophylla.* Low Shrubs: *Abutilon fraseri, A. lepidum, A. macrum, Corchorus sidoides* subsp. *sidoides, Hybanthus aurantiacus, Maireana planifolia, M. villosa, Sida platycalyx* and *Waltheria indica.* Herbs and Grasses: *Abutilon otocarpum, Bothriochloa ewartiana, *Cenchrus ciliaris, *C. setiger, Chrysopogon fallax, Cleome viscosa, Cymbopogon ambiguus, Dactyloctenium radulans, Dichanthium sericeum* subsp. *humilius, Digitaria brownii, D. ctenantha, Dipteracanthus australasicus* subsp. *australasicus, Dysphania melanocarpa, D. rhadinostachya* subsp. *rhadinostachya, Enteropogon ramosus, Eragrostis cumingii, Evolvulus alsinoides* var. *villosicalyx, Goodenia nuda* (Priority 4), *G. prostrata, Indigofera linifolia, *Malvastrum americanum, Pterocaulon sphacelatum, Sida* sp. verrucose glands (F.H. Mollemans 2423), *Sporobolus australasicus, Trianthema pilosum, Triodia basedowii, T. longiceps, T. pungens* and *T. wiseana.*
Vegetation Condition	Good; minor disturbance from cattle (scats and grazing); presence of several weed species as scattered individuals. Existing drill lines dissected much of this vegetation type.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	HDA08^, HDA13 (Biota 2004b); YEX09 (Biota 2004a); YBI12^, YBI13, YBI15^ (Biota 2009b); BIL32^ (current survey).
Relevés in the Study Area	YBI-RBMI (Biota 2009b); BIL-RSPA (current survey).
Other Notes	Quadrat YEX09 has been cleared.

Plate 5.26: Vegetation type P6 (BIL32).

P7: ERf/g	*Eremophila fraseri* subsp. *fraseri* open shrubland over mixed very open grassland
Distribution and Comments	This vegetation type was recorded from three small areas of plain with a calcrete substrate in the south of the study area (Plate 5.27). The understorey was variable, consisting of either a mixed tussock grassland (with the dominant species comprising *Aristida contorta, Enneapogon polyphyllus, Eragrostis eriopoda, Paraneurachne muelleri*) or a *Triodia wiseana* hummock grassland.
Associated Species	Tall Shrubs: *Acacia bivenosa, A. citrinoviridis, A. synchronicia* and *Hakea lorea* subsp. *lorea.* *Shrubs:* *Corchorus lasiocarpus* subsp. *lasiocarpus, Gossypium australe, Rhagodia eremaea* and *Senna artemisioides* subsp. *helmsii.* Low Shrubs: *Abutilon lepidum, Melhania oblongifolia, Scaevola spinescens, Sclerolaena cornishiana, Sida echinocarpa* and *Solanum lasiophyllum* Herbs and Grasses: *Abutilon otocarpum, Aristida contorta, A. holathera* var. *holathera, Chrysopogon fallax, Enneapogon polyphyllus, Eragrostis eriopoda, Indigofera colutea, Paraneurachne muelleri, Sida fibulifera* sens. lat. and *S.* sp. verrucose glands (F.H. Mollemans 2423).
Vegetation Condition	Good; scattered **Cenchrus ciliaris*; signs of cattle.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	BIL25^, BIL48 (current survey).
Relevés in the Study Area	YBI-RBMG (Biota 2009b).

Plate 5.27: Vegetation type P7 (BIL25).

P8: EgAiTs	*Eucalyptus gamophylla* scattered low mallees over *Acacia inaequilatera* scattered tall shrubs over *Triodia schinzii* hummock grassland
Distribution and Comments	This vegetation type was recorded from loamy sands on gently sloping pediment slopes and colluvial plains at the base of a range of low hills in the northern section of the study area (Plate 5.28).
Associated Species	Tall Shrubs: *Acacia bivenosa* and *A. pruinocarpa*. Shrubs: *Acacia dictyophleba, A. pachyacra, A. trudgeniana*, *Santalum lanceolatum* and *Senna artemisioides* subsp. *oligophylla*. Low Shrubs: *Bonamia erecta, Corchorus tectus, Dicrastylis cordifolia, Scaevola parvifolia* subsp. *pilbarae, Senna notabilis* and *Sida cardiophylla*. Herbs and Grasses: *Abutilon otocarpum, Aristida holathera* var. *holathera, Chrysopogon fallax, Eragrostis eriopoda, Trianthema pilosum* and *Trichodesma zeylanicum* subsp. *zeylanicum*.
Vegetation Condition	Excellent.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	BIL22^ and BIL42^ (current survey).

Plate 5.28: Vegetation type (BIL22).

P9: ChEgAiAaAprPcTb	*Corymbia hamersleyana* scattered low trees over *Eucalyptus gamophylla* scattered low mallees over *Acacia inaequilatera, A. ancistrocarpa, A. pruinocarpa* tall open shrubland over *Petalostylis cassioides* open shrubland over *Triodia basedowii* open hummock grassland
Distribution and Comments	This vegetation type (Plate 5.29) occurs broadly over the plains on the western side of Weeli Wolli Creek, north of Marillana Creek. While the dominant spinifex species was *Triodia basedowii*, occasional hummocks of *T. pungens* were sometimes found in this vegetation type. (Note that *Triodia basedowii* was identified as *T. lanigera* in previous reporting.)
Associated Species	Tall Shrubs: *Acacia bivenosa, A. citrinoviridis, A. dictyophleba, A. pyrifolia* var. *pyrifolia, A. tumida* var. *pilbarensis, Gossypium robinsonii, Grevillea wickhamii, Hakea chordophylla* and *H. lorea* subsp. *lorea.* Shrubs: *Gossypium australe, Senna artemisioides* subsp. *helmsii, S. artemisioides* subsp. *oligophylla* and *S. glutinosa* subsp. *glutinosa.* Low Shrubs: *Corchorus lasiocarpus* subsp. *lasiocarpus, C. tectus, Dicrastylis cordifolia, Dodonaea coriacea, Hybanthus aurantiacus, Indigofera monophylla, Ptilotus astrolasius, Sida cardiophylla* and *S. echinocarpa.* Herbs and Grasses: *Aristida holathera* var. *holathera, Cleome viscosa, Cymbopogon obtectus, Eragrostis eriopoda, Gomphrena cunninghamii, Goodenia microptera, Mollugo molluginea, Paraneurachne muelleri* and *Triodia pungens.*
Vegetation Condition	Very Good; scattered **Cenchrus ciliaris* present. Occasional areas had a **Cenchrus ciliaris* and **C. setiger* open tussock grassland.
Quadrats in the Study Area (^ denotes the quadrat has been seasonally sampled)	BIL12^, BIL13, BIL41^ and BIL45^ (current survey).

Plate 5.29: Vegetation type P9 (BIL41).

5.3 Vegetation Condition

Vegetation condition mapping for the study area is presented in Appendix 4. The vegetation condition ranking was based on the degree of weed presence, human impact, feral animals and livestock activities, and the perceived structural integrity of the vegetation as a whole, given the impact of these disturbance factors. Appendix 3 presents the vegetation condition scale, developed by Trudgen (1988), that was used in determining the vegetation condition rankings.

A total of 5.7% of the study area was mapped as Disturbed, which is equivalent to a Completely Degraded vegetation condition (Trudgen 1988). These areas comprised current vehicle tracks, drill lines, drill pads and the JSE main mine pit. The extents of these areas were based on Rio Tinto's December 2013 disturbance footprint layer.

At the time of the field survey, additional drill lines were being cleared on the eastern side of Weeli Wolli Creek, south of the confluence with Marillana Creek. These new drill lines were not mapped as disturbed areas, as they were too new to be visible on aerial photography or captured in the Rio Tinto December 2013 disturbance footprint layer.

Fourteen quadrats that were previously sampled in the study area (between 2001 and 2012) were found to have been cleared prior to the current field survey (Table 5.2).

Table 5.2: Quadrats in the study area that have been cleared.

Vegetation Type	Quadrats that Have Been Cleared	
	Total Number	Site Name and Reference
C4: EvAciAprAThCEc	1	H051 (Biota 2002).
F3: ElChAtuAaAbGwTspp	1	YEX07 (Biota 2004a).
P1: ElEgAprAbAaAdTwTpTsps	1	YEX05 (Biota 2004a).
P2: ChAprAiAsclApaTp	2	YBI26 (Biota 2009b); YAQ29 (Biota 2014b).
P3: AprAciAiAsclTlo	1	HDA14 (Biota 2004b).
P4: AprAsyAiTw	5	HDA07, HDA15 (Biota 2004b); YEX03, YEX32 (Biota 2004a); YBI19 (Biota 2009b).
P5: ElEgAbAaTb	2	HDA12 (Biota 2004b); YEX33 (Biota 2004a).
P6: AapERfoERl/g	1	YEX09 (Biota 2004a).

The intact vegetation of the study area ranged from Excellent to Very Poor condition. The main disturbance factors in the study area were weed invasion and disturbance from livestock (cattle) including grazing, tracks, trampled vegetation and scats.

Dense weed infestations and high cattle activity were generally restricted to the creeklines and floodplains of the study area (Sections 5.2.1 and 5.2.2). **Cenchrus ciliaris* (Plate 5.30) was the most prolific weed in these habitats, sometimes occurring together with **Cenchrus setiger*. **Cenchrus* species were present as a continuous population along the edges of Weeli Wolli and Marillana Creeks and on adjacent floodplains. Where the **Cenchrus* formed a closed tussock grassland, a low number of native species was observed in the understorey.

Parts of the study area appear to have shown an increase in the infestation of **C. ciliaris* over time. In some cases this could be attributed to differing estimates of the proportion of **Cenchrus ciliaris* and **C. setiger;* the two species are indistinguishable without flowering material, which is less abundant during dry conditions. For example, an apparent increase in **C. ciliaris* at quadrat HDA09 was mirrored by a decrease in **C. setiger*, with the overall cover remaining stable. In other cases, the increase may be partly explained by variation in seasonal conditions between the two sampling phases. For example, although quadrats YEX08 and YBI10 both showed a large increase (approximately 25%) in the cover of **C. ciliaris* since they were first sampled, the first survey was undertaken during dry conditions, while the second survey was undertaken following substantial rainfall.

Given the aggressively invasive nature of these grasses, it is however probable that the abundance of **Cenchrus* species will increase over time in areas of suitable habitat, and populations may also spread to surrounding areas. Dispersal may be aided by factors such as flowing water, cattle activity, and clearing for tracks and other infrastructure; all of which are present in the study area.

Several other weed species were found in the creeklines of the study area, but these were usually present as scattered individuals only (see Section 6.6 for more information on the weeds in the study area). While most creekline and floodplain vegetation types were rated as being in Good condition, some areas were rated as Very Poor due to the high weed cover (greater than 70% cover) and evidence of extensive grazing and trampling by cattle (Plate 5.31).

Plate 5.30: **Cenchrus ciliaris*, the most prolific weed species in the study area.

Plate 5.31: Creekline vegetation in the study area with a dense **Cenchrus ciliaris* understorey grazed by cattle.

The plains of the study area (Section 5.2.4) also contained some weed species, although they were usually only present as scattered individuals. Occasionally a very open tussock grassland of **Cenchrus ciliaris* was present, usually on plains adjacent to creeklines or floodplains. Evidence of cattle was also occasionally noted on the plains. The vegetation condition of the plains therefore ranged from Good to Excellent.

The hills, ridges and breakaways of the study area (Section 5.2.3) were in Excellent condition and were mostly free from any form of disturbance. Some of the hills and slopes of the study area had been recently burnt (within 2-3 years; see Section 5.2.3). Fire is a natural process in the Pilbara region, and natural fire regimes need not affect the overall condition of vegetation (see Appendix 3).

There was a small amount of older historical clearing in the study area. Some parts of the study area contained old drill pads and tracks that were mostly overgrown (and therefore not mapped as disturbed). These areas were visible on aerial photography (2011 imagery) in vegetation types P5 and C4 (Section 5.2). As these areas were in the latter stages of regeneration, they were not mapped as Disturbed and they had only a small impact on the overall vegetation condition of these vegetation types.

5.4 Results of the Floristic Clustering Analysis

At the broadest level, sites located on stony hills (vegetation codes with an “H” prefix) tended to cluster separately on the basis of their floristic composition from sites in drainage lines (vegetation codes with a “C” prefix; see Figure 5.1). Sites on stony plains (vegetation codes with a “P” prefix) and in minor drainages and on floodplains (vegetation codes with an “F” prefix) were more variable floristically, being distributed between these two broad groupings (Figure 5.1). This is as expected, given that the topographic position of the plains landform is intermediate between the hills and drainages; and that water availability, which strongly influences the species present, declines markedly along this gradient.

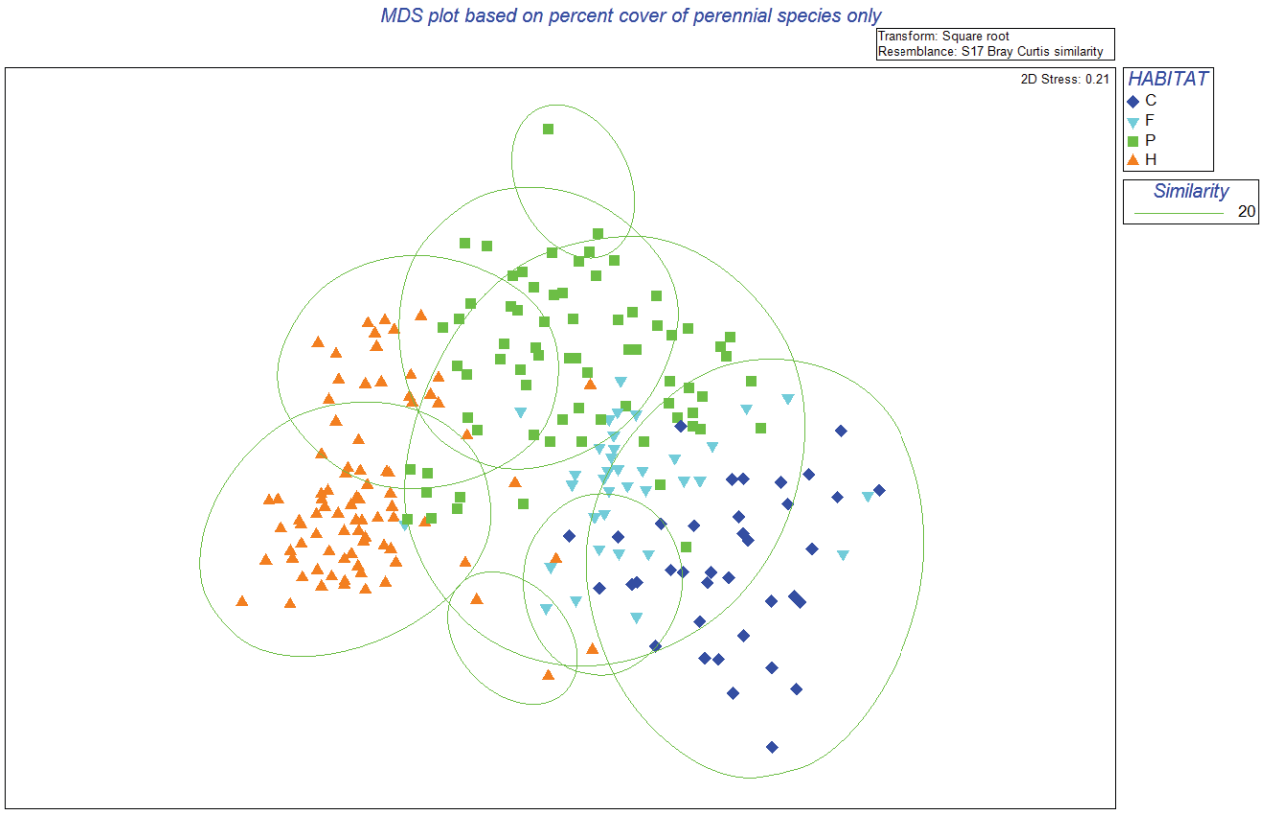

Figure 5.1: MDS plot based on percent cover data for perennial species for sites from the Yandi locality, with sites coded by broad habitat grouping.
(C = major creeklines and tributaries; F = minor creeklines, floodplains and valleys; P = plains; H = hills, ridges and breakaways.)

Sites within the study area generally grouped together with other sites that had been sampled in the locality (Figure 5.2), however some of the floristic groups identified by the analysis only contained sites from the study area. These are discussed further below.

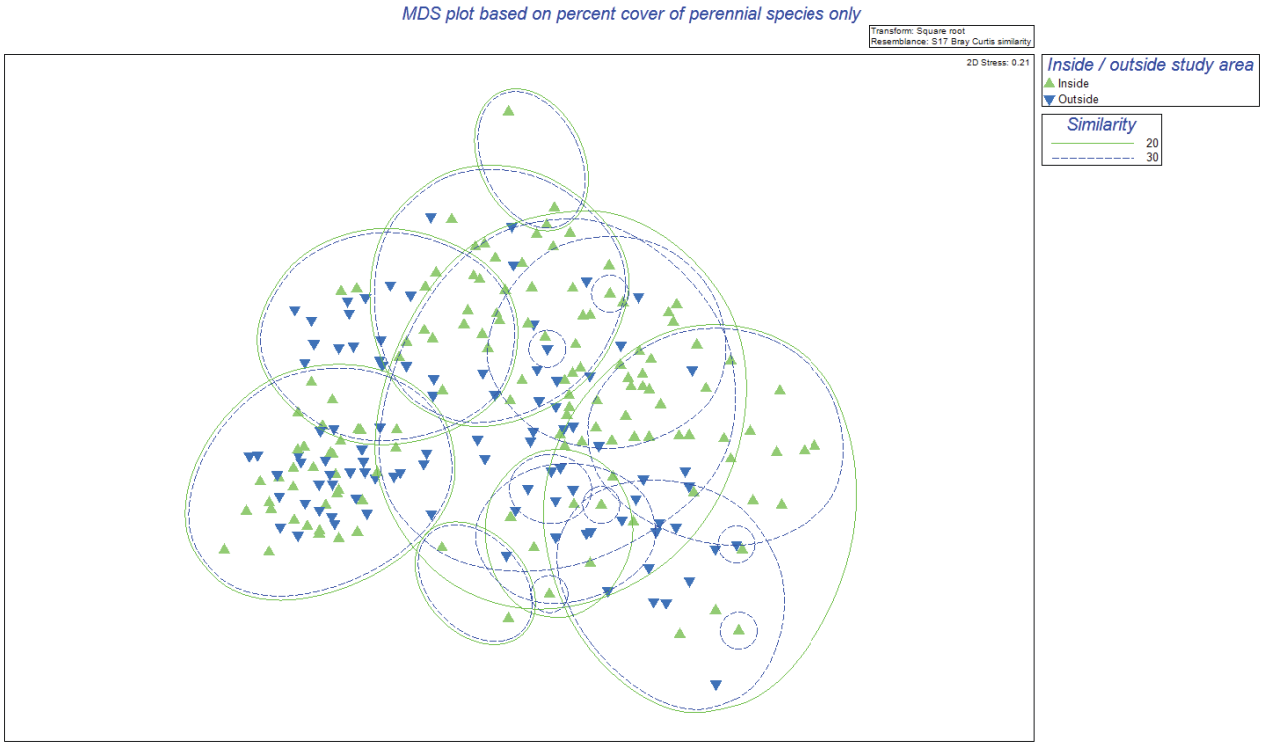

Figure 5.2: MDS plot based on percent cover data for perennial species for sites from the Yandi locality, with sites coded by their location inside or outside the study area.

The floristic analyses based on only the perennial species resulted in the closest match to the described vegetation sub-associations, as would be expected given that the latter were defined primarily on the abundance of the dominant species, which tended to be perennials. The analyses including annual species resulted in 50 floristic groups based on cover and 79 groups based on presence/absence data, including 11 and 29 groups respectively that contained only one site. Although there was still some reasonable correspondence between floristic composition and vegetation type, the groupings were less distinct, and the analyses using only the perennial species have therefore been discussed in the following section.

There was a reasonable correspondence between the floristic groups identified through the PRIMER analyses and the vegetation types described for the study, although these were not exact (see Figure 5.3). This is as expected, given that floristic composition of vegetation varies along a continuum, while the classification of sample sites into vegetation types is an attempt to impose distinct groups incorporating vegetation structure.

The analyses based on only perennial species identified 35 floristic groups from the 229 sites in the dataset when percent cover data were used, and 41 groups when presence/absence data were used (Appendix 9, Figures 1 and 2). Six floristic groups in each analysis comprised singletons (i.e. contained only one sampling site), however there was no correspondence in the particular sites that occurred as singletons in the two analyses. The analysis based on percent cover provided the most consistent interpretation, and is the primary analysis discussed further.

While there are clearly significant floristic differences between sites at lower level, the following summarised description of the floristic communities is based on a nominal 30% similarity as identified by the SIMPROF test. At this level, 16 floristic groups were identified within the data (see Figure 5.3 and Table 5.3). These groups had clear associations with the vegetation types identified for the study area, although sites from individual vegetation types were sometimes spread across more than one floristic group.

Most of the floristic groups included sites from both inside and outside the study area, and for those that did not, the pattern was typically no longer apparent when presence / absence data only were considered (compare Figures 1 and 2 in Appendix 9). However, two of the floristic groups at the 30% similarity level contained sites from the study area only (i.e. FG4, which contained the two sites sampled in vegetation type P8; and FG13, which contained sites from various vegetation types including all sites sampled in vegetation type P6). This was considered likely to be a function of the limitations of the data set, rather than an indication of a genuinely restricted distribution. To confirm this, further analyses were conducted using additional sites. Figure 3 in Appendix 9 confirms that additional sites have been sampled outside the study area in vegetation type P8. Similarly, the addition of additional sites with *Triodia longiceps* to the data set resulted in splitting apart of the original FG13 sites into three separate floristic groups at the 30% similarity level, however each of these groups now contained sites from outside the study area (Figure 4 in Appendix 9). None of the broad floristic groups identified at the 30% similarity level are therefore considered to be restricted to the study area.

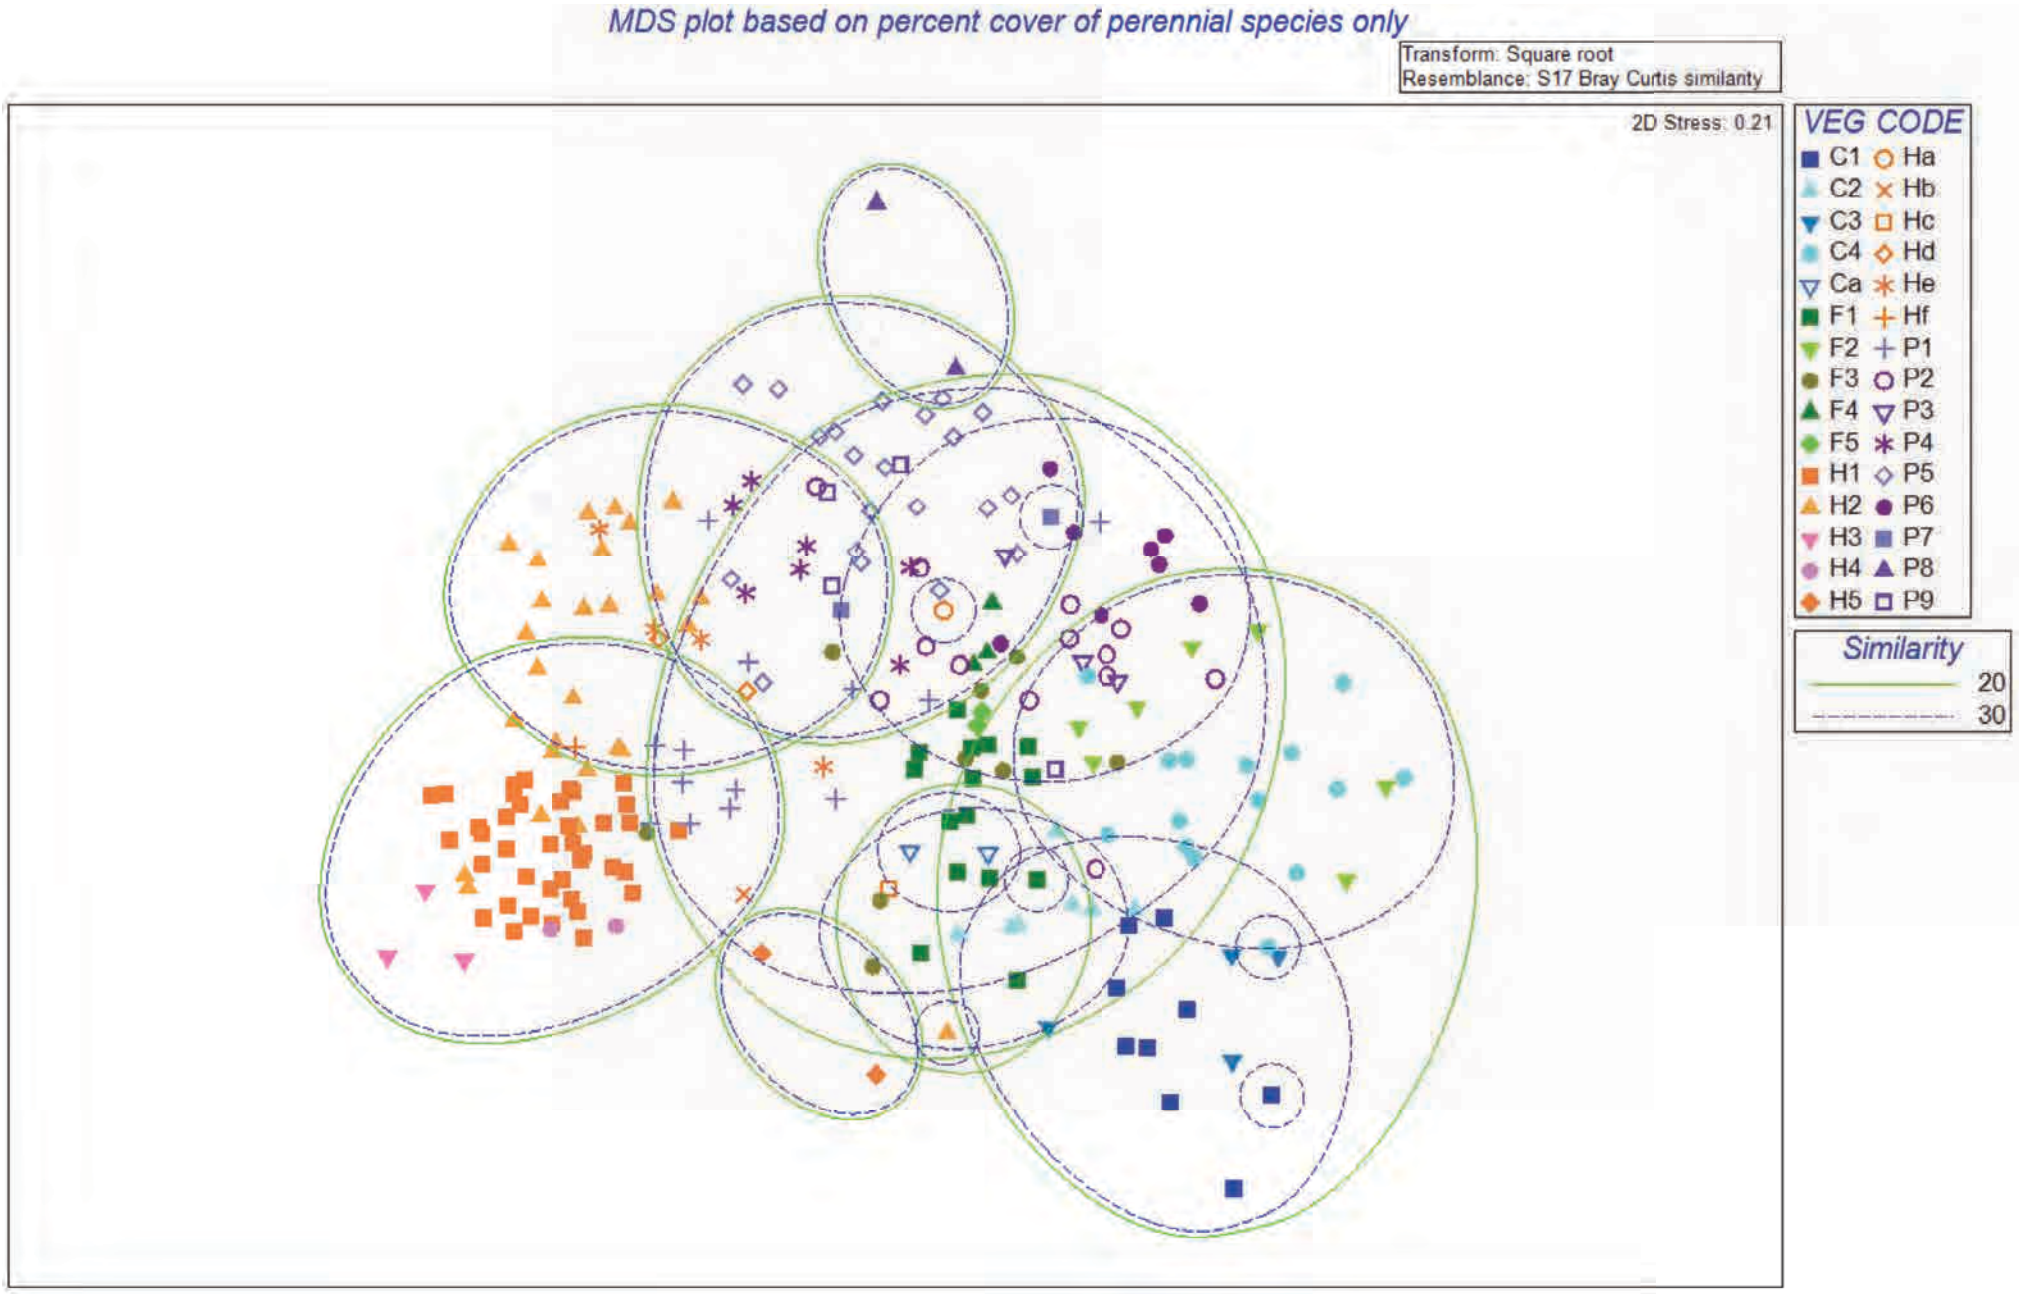

Figure 5.3: MDS plot based on percent cover of perennial species for sites from the immediate Yandi locality.

Table 5.3: Summary details for the 16 floristic groups identified at the 30% similarity level by the SIMPROF test for sites in the Yandi locality (analysis based on percent cover of perennial species only).

Floristic Group (No. of Sites in Group)	Top Four Species with Greatest Contribution to Site Similarity according to SIMPER Test (% contribution)	Vegetation Types with Sites in this Floristic Group † (Sites within Current Study Area)	Summarised Habitat and Vegetation
FG1 (n=2)	*Eriachne mucronata* (23.68%) *Corymbia ferriticola* (13.67%) *Cymbopogon ambiguus* (13.67%) *Eucalyptus leucophloia* subsp. *leucophloia* (13.67%)	H5 (BIL-RCFB, BIL-RCFD)	Vegetation of gullies.
FG2 (n=64)	*Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) (55.74%) *Eucalyptus leucophloia* subsp. *leucophloia* (5.81%) *Acacia hilliana* (4.24%) *Grevillea wickhamii* (3.79%)	F3 (nil) H1 (BIL05, BIL17, BIL20, BIL28, BIL34, BIL37, BIL43, YAQ14, YAQ19, YAQ25, YAQ27, YBI31S, YBI33S, YEX01, YEX06, YEX37) H2 (BIL03, BIL15, BIL19, BIL29, BIL39, HDA16, HDA24, YAQ18, YBI32S, YBI36) H3 (BIL01, BIL06, BIL-RPCA) H4 (BIL04, YBI24) Hf † P1 (BIL49, BIL38, YEX05)	Stony hills and plains dominated by *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grasslands.
FG3 (n=27)	*Triodia wiseana* (67.74%) *Acacia inaequilatera* (6.33%) *Paraneurachne muelleri* (1.87%) *Solanum lasiophyllum* (1.78%)	H2 (BIL26, BIL27, BIL40, BIL44, YBI05) Hd, He † P1 (nil) P4 (HDA07, HDA15, YAQ-CSRB, YBI19, YEX03) P7 (BIL43)	Stony hills and plains dominated by *Triodia wiseana* hummock grasslands.
FG4 (n=2)	*Triodia schinzii* (59.47%) *Eucalyptus gamophylla* (16.89%) *Acacia dictyophleba* (3.38%) *Acacia pachyacra* (3.38%)	P8 (BIL22, BIL42)	Plains with *Eucalyptus gamophylla* mallees over *Triodia schinzii* hummock grasslands.
FG5 (n=1)	Not calculated (only one site in floristic group); appears to be separated from neighbouring FG14 and FG15 due to the particularly high cover of *Eucalyptus victrix* (65%) and also *Cyperus vaginatus* (25%)	C1 (YBI23)	Major creek channel supporting *Eucalyptus victrix* (Coolibahs) open forest over *Melaleuca argentea* (Cadjeputs), *Acacia citrinoviridis* and *A. coriacea* subsp. pendens over *Cyperus vaginatus* open sedgeland.
FG6 (n=15)	*Eucalyptus victrix* (14.48%) *Eucalyptus camaldulensis* subsp. *refulgens* (9.28%) *Acacia coriacea* subsp. *pendens* (6.33%) *Corchorus crozophorifolius* (6.10%)	C1 (YBI30S) C2 (nil) C3 (BIL30, YBI01)	Major creeklines supporting riparian vegetation of *Eucalyptus victrix* and *E. camaldulensis* subsp. *refulgens* (River Red Gums) over *Acacia citrinoviridis*.
FG7 (n=20)	**Cenchrus* spp. (47.93%) *Acacia citrinoviridis* (21.68%) *Eucalyptus victrix* (4.58%) *Atalaya hemiglauca* (3.99%)	C4 (H050, H051, HDA09, YAQ12, YAQ21, YAQ-CSRA, YBI02, YBI03, YBI04, YEX02) F2 (BIL23, BIL24, YAQ30, YAQ-CSRC, YAQ-CSRD) P9 (BIL12)	Moderate to major creeklines and associated floodplains supporting riparian vegetation of *Eucalyptus victrix* over *Acacia citrinoviridis*, usually with **Cenchrus* spp. in the understorey.

Floristic Group (No. of Sites in Group)	Top Four Species with Greatest Contribution to Site Similarity according to SIMPER Test (% contribution)	Vegetation Types with Sites in this Floristic Group † (Sites within Current Study Area)	Summarised Habitat and Vegetation
FG8 (n=23)	*Triodia basedowii* (47.61%) *Acacia ancistrocarpa* (3.47%) *Paraneurachne muelleri* (3.24%) *Acacia pruinocarpa* (2.84%)	P5 (BIL08, BIL18, BIL33, YAQ23, YBI06, YBI07, YBI09, YBI14, YBI16, YBI21, YBI22, YBI27, YBI28, YBI29, YBI34S, YEX33) P9 (BIL13, BIL41, BIL45)	Plains dominated by *Triodia basedowii* hummock grasslands.
FG9 (n=1)	Not calculated (only one site in floristic group); appears to be separated from neighbouring FG22 and FG23 due to the relatively high cover of *Senna artemisioides* subsp. *oligophylla* (15%) and *Triodia epactia* (5%).	F1 (BIL-RSWA)	Valley supporting *Gossypium robinsonii, Senna artemisioides* subsp. *oligophylla, Atalaya hemiglauca* tall shrubland over *Triodia epactia* very open hummock grassland.
FG10 (n=1)	Not calculated (only one site in floristic group); appears to be separated from neighbouring FG22 and FG23 due to the relatively high cover of *Cymbopogon ambiguus* (15%) and *Enneapogon lindleyanus* (10%), and probably the lack of species such as *Acacia aneura* and *A. pruinocarpa.*	H2 (BIL-RCFA)	Minor creek supporting *Senna artemisioides* subsp. *oligophylla, Gossypium australe, Acacia pyrifolia* var. *pyrifolia* open shrubland over open tussock grassland dominated by *Cymbopogon ambiguus* and *Enneapogon lindleyanus*.
FG11 (n=2)	*Acacia bivenosa* (14.94%) *Eucalyptus victrix* (14.94%) *Eriachne tenuiculmis* (9.45%) *Acacia ancistrocarpa* (6.68%)	Ca †	Moderate-sized creeklines with an open forest to low open woodland of *Eucalyptus victrix* over a tall open shrubland dominated by *Acacia bivenosa, A. ancistrocarpa, A. maitlandii* over a mixed tussock grassland dominated by *Eriachne tenuiculmis.*
FG12 (n=1)	Not calculated (only one site in floristic group); the small amount of *Triodia wiseana* (0.1%) appears to separate this site from BIL48 in FG2, leading to clustering with FG25-FG27; FG24 appears to then be separated due to the relatively high cover of *Eremophila fraseri* (20%) and *Eragrostis eriopoda* (7%)	P7 (BIL25)	Plain supporting *Eremophila fraseri* subsp. *fraseri, (Acacia citrinoviridis)* tall shrubland over *Senna artemisioides* subsp. *helmsii* open shrubland over *Eragrostis eriopoda* very open tussock grassland.
FG13 (n=14)	*Acacia aneura* (22.57%) *Acacia pruinocarpa* (9.82%) **Cenchrus* spp. (5.78%) *Triodia longiceps* (4.33%)	F2 (YEX38) P3 (YBI11, YBI17) P4 (YEX04, YEX32) P5 (HDA12) P6 (BIL32, BIL-RSPA, HDA08, HDA13, YBI12, YBI13, YBI15, YEX09)	Alluvial plains supporting Mulga and *Acacia pruinocarpa* low woodlands over open hummock grasslands of mixed species, often dominated by *Triodia longiceps,* with mixed tussock grasses.
FG14 (n=1)	Not calculated (only one site in floristic group); appears to be separated due to the combination of a reasonable cover of *Eremophila fraseri* and *Triodia pungens*, together with negligible cover of *T. wiseana*	Ha †	*Acacia inaequilatera* scattered tall shrubs over *Eremophila fraseri* subsp. *fraseri* scattered shrubs over *Triodia pungens, (T. wiseana)* very open hummock grassland.

Floristic Group (No. of Sites in Group)	Top Four Species with Greatest Contribution to Site Similarity according to SIMPER Test (% contribution)	Vegetation Types with Sites in this Floristic Group † (Sites within Current Study Area)	Summarised Habitat and Vegetation
FG15 (n=9)	*Acacia tumida* var. *pilbarensis* (27.34%) *Triodia pungens* (8.06%) *Corymbia hamersleyana* (5.25%) *Grevillea wickhamii* (4.45%)	F1 (BIL-RCFC, YBI20, YBI25) F3 (YAQ-RPLA) C2 (BIL02)	Creeklines supporting scattered low trees to low open woodlands of *Corymbia hamersleyana* over tall shrublands to tall open scrub usually dominated by *Acacia tumida* var. *pilbarensis* and *Grevillea wickhamii* over a hummock grassland of *Triodia pungens.*
FG16 (n=46)	*Triodia pungens* (33.42%) *Corymbia hamersleyana* (4.99%) **Cenchrus* spp. (3.56%) *Acacia tumida* var. *pilbarensis* (2.74%)	C2 (BIL31) C4 (YBI08) F1 (BIL16, YBI35S) F3 (BIL35, BIL36, YEX07, YEX08) F4 (BIL11, BIL14, BIL46) F5 (BIL21, BIL47) Hb, He † P1 (nil) P2 (BIL07, BIL09, BIL10, YAQ16, YAQ29, YBI10, YBI26) P3 (HDA14) P5 (WW30)	Predominantly floodplains with scattered *Corymbia hamersleyana* trees over a scattered to open tall shrub layer of various *Acacia* spp., usually including *A. tumida* var. *pilbarensis*, over a hummock grassland of *Triodia pungens.*

† Vegetation type not mapped in the current study area.

5.5 Vegetation of Conservation Significance

5.5.1 TECs and PECs

None of the vegetation types represent TECs listed either under the Commonwealth *EPBC Act 1999* or the WA *Environmental Protection Act 1986* (see Section 4.8.1), nor do they represent PECs listed by DPaW (see Section 4.8.2).

5.5.2 Ecosystems At Risk

While not formally listed as TECs or PECs or protected by any legislation, a number of "other ecosystems at risk" are identified for the Hamersley and Fortescue Plains subregions of the Pilbara bioregion (see Kendrick 2003a, 2003b). These are ecosystems of some level of significance that are at risk of degradation from a variety of factors, including development, groundwater drawdown, frequent fires, grazing and weed invasion. One of these is relevant to the study area:

- 'All major ephemeral water courses' in the Hamersley subregion are listed as an ecosystem at risk by Kendrick (2003a). These water courses are described as supporting "*Eucalyptus* forests with a shrubby understorey", which are under threat of degradation from weed invasion and grazing and trampling by feral herbivores (Kendrick 2003a). Groundwater drawdown could also potentially impact such vegetation if it included phreatophytic (groundwater dependent) species such as *Melaleuca argentea* (Cadjeput) or *Eucalyptus camaldulensis* (River Red Gum).

One vegetation type (C1) described for the study area is considered to represent this ecosystem at risk (Table 5.4). This vegetation is associated with Marillana Creek and Weeli Wolli Creek, two of the major ephemeral creek systems for the locality. Two other vegetation types (C2 and C3) comprise riparian vegetation along these same major creek systems, but do not feature dense forests of Eucalypts.

Table 5.4: Vegetation types considered to be "ecosystems at risk" after Kendrick (2003a) and other riparian vegetation of major creeks.

Vegetation Code	Vegetation Description	Area (ha)	Percentage of the Study Area
'All major ephemeral water courses' Ecosystem at Risk			
C1: EcEvMaMgAc	*Eucalyptus camaldulensis* subsp. *refulgens, E. victrix* woodland over *Melaleuca argentea, M. glomerata, Acacia coriacea* subsp. *pendens* low open woodland	73.1	0.8
Other Riparian Vegetation of Major Creeks			
C2: EvChAtuGwTErCYpERItTHt	*Eucalyptus victrix, Corymbia hamersleyana* scattered low trees over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* subsp. *hispidula* tall shrubland over *Tephrosia rosea* low shrubland over *Cymbopogon ambiguus, C. procerus, Eriachne tenuiculmis, Themeda triandra* very open tussock grassland	22.6	0.3
C3: EvAciAcMgCEc	*Eucalyptus victrix* scattered trees over *Acacia citrinoviridis, A. coriacea* subsp. *pendens, Melaleuca glomerata* tall open shrubland over **Cenchrus ciliaris* scattered tussock grasses	269.3	3.1
	Total	365.0	4.2

Vegetation type C1 is currently in Good condition; although several weed species were recorded, they were generally present in only low numbers. Vegetation type C1 also supported both *Melaleuca argentea* and *Eucalyptus camaldulensis*, two species that could be affected by groundwater drawdown from the adjacent mining operations. Similar vegetation is widespread in major creek systems through the Pilbara, including the Robe River, Hardey River, Caves

Creek/Duck Creek and Marillana Creek/Weeli Wolli Creek systems. This vegetation is therefore considered significant at a local, rather than regional, scale.
Vegetation types C2 and C3 are similarly in Good to Very Good condition, with **Cenchrus* spp. present as only scattered individuals. These vegetation types were dominated by only scattered trees of *Eucalyptus victrix* and did not support the phreatophytic species present in C1, but occurred along the same major creek systems. Similar vegetation assemblages are widespread in major creek systems through the Pilbara including tributaries of the Beasley River, and in the Caves Creek/Duck Creek, Hardey River and Marillana Creek/Weeli Wolli Creek systems. This vegetation is thus again considered significant at a local, rather than regional, scale.

While vegetation type C4 also occurred in the major creeklines of the study area (mainly on the broad floodplains of Weeli Wolli and Marillana Creek), it has been extensively degraded by invasion of **Cenchrus ciliaris* (often together with **C. setiger*) in the understorey. This vegetation has therefore already been substantially impacted by the processes threatening riparian vegetation, and is not of particular conservation significance.

5.5.3 Other Conservation Values

All of the habitats in the study area are widespread in the locality, and none of the vegetation types appear to be restricted in distribution on the basis of their floristic composition (see Section 5.4).

The remaining vegetation types in the study area are considered to be of low conservation significance, being representative of the vegetation occurring in similar habitats throughout the local area. Note that this is not meant to imply that the vegetation in the study area is of no conservation value, as all intact native vegetation is inherently valuable (DEWHA 2010).

6.0 Flora of the Study Area

6.1 Overview

A total of 455 native vascular flora taxa from 154 genera and 47 families have been recorded from the study area, based on all survey effort to date. This includes one Threatened species (discussed in Section 6.4.1) and two Priority flora species (discussed in Section 6.4.2). Eighteen introduced flora species have also been recorded (see Section 6.6).

6.2 Dominant Families and Genera

The dominant families and genera (native taxa only) recorded from the study area are presented in Table 6.1. These are typical of the most well represented families and genera in the Pilbara bioregion.

Table 6.1: Dominant plant families and genera in the study area.

Family	No. of Native Taxa	Genus	No. of Native Taxa
Fabaceae	88	*Acacia*	39
Poaceae	81	*Senna*	20
Malvaceae	52	*Euphorbia*	14
Amaranthaceae	21	*Ptilotus*	13
Asteraceae	19	*Sida*	12

6.3 Species Richness – Regional Context

Species richness tends to vary on a logarithmic scale with the size of the study area. However, the array of habitats (and therefore vegetation types) present also has a large influence on the number and type of species recorded, as different habitats provide a greater variety of ecological niches that can be occupied by a greater number of different species. The shape of the survey area may also influence the number of species recorded, with long linear survey areas tending to intersect a greater variety of habitats and, depending on the length, sometimes different biogeographic regions.

Figure 6.1 shows the species richness of the study area compared to eight other study areas from the locality: Yandi Additional Areas (Biota 2014b), Koodaideri Northern Extension (Biota 2012b), Koodaideri Mining Lease (Biota 2012c), Koodaideri Southern Infrastructure Corridor (Biota 2012d), Junction South West Deposit (Biota 2010), Oxbow Deposit (Biota 2010), Billiards Deposit (Biota 2009b) and Yandi Expansion (Biota 2004a). When compared to these other study areas in the broader locality, all of which have been surveyed in recent years, the total number of native flora taxa recorded from the study area is high but within the range that would be expected for a survey area of this size.

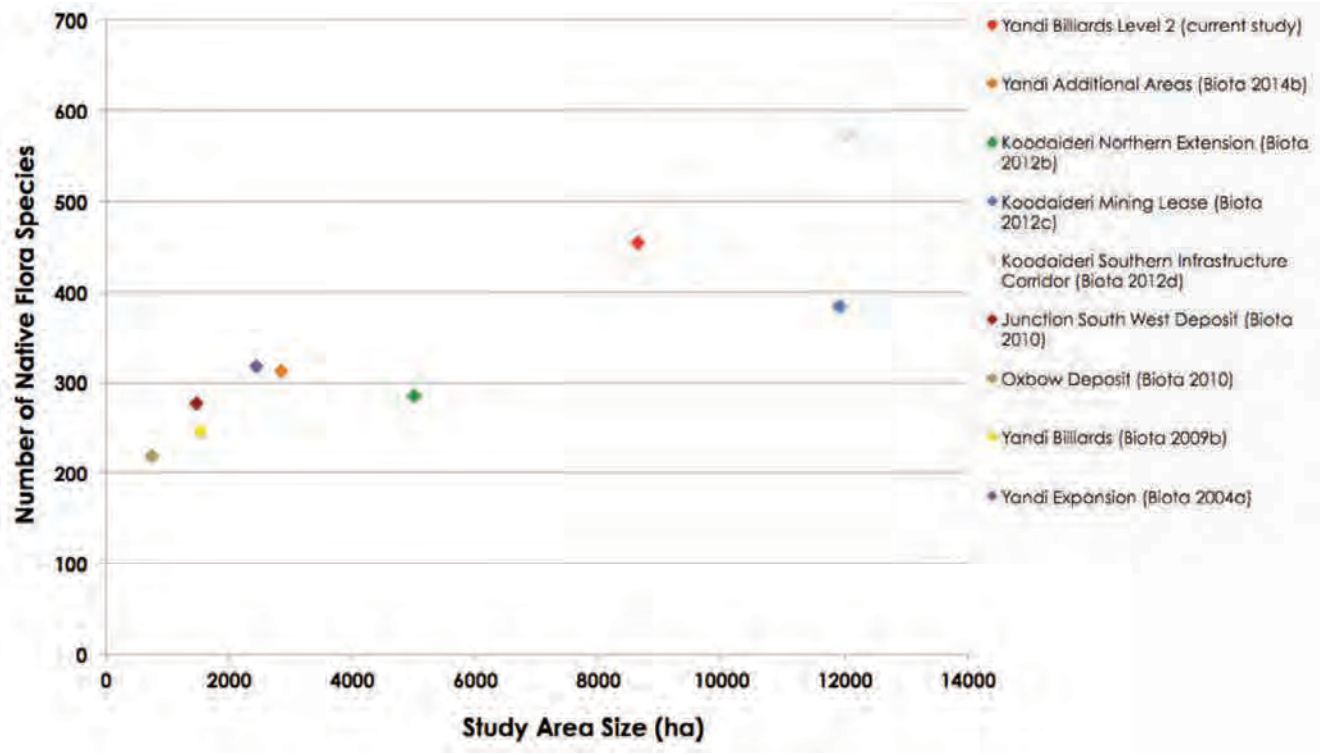

Figure 6.1: The number of native taxa recorded from the study area compared to other recent surveys in the locality.

6.4 Flora of Conservation Significance

6.4.1 Threatened Flora

One Threatened species, *Lepidium catapycnon,* listed under the Commonwealth *EPBC Act 1999* or the WA *Wildlife Conservation Act 1950,* has been recorded from the study area (see Section 4.9.1 for a description of this species).

Lepidium catapycnon was recorded from two locations in the study area during previous surveys (Hamersley Iron 2006, Biota 2009a; see Table 6.2). These are designated Populations 1 and 2 in Table 6.2 and the following text. Searches were undertaken during the Phase 1 survey at the locations of the existing records, as well as targeting areas deemed potentially suitable habitat, however no individuals of *L. catapycnon* were recorded. It was noted at the time that there was additional suitable habitat for this species in the study area and that this species may occur at other locations (Biota 2014a), therefore further targeted searches were undertaken during the Phase 2 survey.

Lepidium catapycnon was subsequently recorded during the Phase 2 survey from 26 locations comprising three separate populations[7]. Two of these represented new populations for the study area (Populations 3 and 4; see Table 6.2 and further text). Following broader searches around the record of Population 1, three individuals were found; the population size was greatly reduced compared to the original record (see below). The remaining historically recorded population, Population 2, was not found. In total, 777 individuals were counted in the study area during Phase 2, which included both mature adult and juvenile plants[8] (Plate 6.1). No individuals were flowering or fruiting at the time of the survey; all plants were in a vegetative state and appeared healthy.

[7] Plants more than 500 m from a known population are considered to be a new population (DEC 2010b).

[8] Mature adult plants are defined as those that have the potential to reproduce, while juvenile plants are defined as immature plants that have lost their cotyledons but not yet flowered (DEC 2010b). As no plants were flowering at the time of the survey, plants less than 10 cm in height were defined as juveniles.

Plate 6.1: A mature plant (left) and juvenile plant (right) of *Lepidium catapycnon* found in the study area.

All records of *Lepidium catapycnon* from the study area are provided in Table 6.2. Additionally, all records are displayed over the proposed project footprint in Figure 6.2 as well as on the vegetation mapping (Maps 4 and 5) in Appendix 4.

Table 6.2: All records of the Threatened species, *Lepidium catapycnon*, located in the study area.

† A = adult; J = juvenile.

The *Lepidium catapycnon* populations recorded in the study area (both new and historical records) are described further below:

- Population 1 (see Map 4 in Appendix 4): The 171 individuals of *L. catapycnon* previously recorded by Biota (2009a) were not found during the Phase 1 or Phase 2 surveys, however additional searches undertaken around this location in Phase 2 identified three small adult plants approximately 50 m north of the original record (Plate 6.2). These were observed growing in a shallow drainage gully amongst low undulating rocky hills, in an area mapped as the McKay land system (Van Vreeswyk et al. 2004). The associated vegetation comprised a mature community of *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Triodia wiseana* open hummock grassland, which was more broadly mapped as vegetation type H1 (see Section 5.2.3). Given the mature size of the *Triodia* hummocks, the fire age of this site was estimated to be more than five years. No dead plants were found in the area, nor were there any signs of clearing or obvious disturbance. It appears that the majority of plants in this population recorded by Biota (2009a) have died since the original record was made. It is likely that the number of individuals in this population will increase following a disturbance (particularly following a fire). This population is located adjacent to (approximately 20 m from) a preliminary proposed waste dump location (Figure 6.2).
- Population 2 (see Map 5 in Appendix 4): The site of the *L. catapycnon* record documented by Hamersley Iron (2006) was revisited and searched during both phases of the field survey. A radius of approximately 50-100 m immediately surrounding the location coordinates was searched, however no individuals were found. This area is mapped as the Newman land system (Van Vreeswyk et al. 2004). The habitat appeared to be suitable to support the species, comprising rocky slopes and a small gully below a ridgeline (Plate 6.3), which was more broadly mapped as vegetation type H1 (see Section 5.2.3). There were no obvious signs of clearing or other disturbance at the site. Some of the slopes around this location had been recently burnt (fire age of approximately two years), however there was no sign of recent fire in the small gully. As for Population 1, it appears that these plants have died since the original record was made eight years ago, and that no recruitment has occurred to renew the population. It is likely that Population 2 would re-establish following disturbance (particularly following a fire). This population does not occur within the proposed project footprint (Figure 6.2).
- Population 3 (see Map 5 in Appendix 4): A new population of *L. catapycnon* was found in the southern section of the study area (east of Weeli Wolli Creek), in an area of Newman land system (Van Vreeswyk et al. 2004). This population occurred below a free face on several steep, shale-covered slopes of a range of hills, which comprised moderate-sized rocky flat-topped hills and mesas (Plate 6.4). *Lepidium catapycnon* was recorded at 16 locations in this area[9] during targeted traverses along these slopes. Most of the plants were found growing on the east-facing upper slopes or mid-slopes, with a few records from west-facing or north-facing slopes. The associated vegetation was predominantly *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over mixed *Triodia* spp. very open hummock grassland, with the dominant *Triodia* species varying between *T. brizoides, T.* sp. Shovelanna Hill (S. van Leeuwen 3835), *T. wiseana* and *T. pungens*. This vegetation was more broadly mapped as H1 (slopes), with some areas of H5 (free faces and breakaways of ridgeline) (see Section 5.2.3). Most of the records from this population occurred in areas that had been recently burnt, with the fire age estimated at approximately two years, however some records occurred on slopes with no sign of recent fire. A total of 425 individuals were recorded from this population, comprising 283 mature plants and 142 juvenile plants. Part of this population (a total of 173 individuals (41%) from eight of the 16 location records) is located within a preliminary proposed waste dump location (Figure 6.2).
- Population 4 (see Map 5 in Appendix 4): Another new population of *L. catapycnon* was found approximately 3 km northeast of Population 3, in an area of Newman land system (Van Vreeswyk et al. 2004). This population extended along the south-facing slope of a moderate-sized rounded hill, which had a loose, ironstone shale surface (Plate 6.5). Individuals were recorded at nine locations, however the population appeared to be continuously distributed along the slope. The vegetation at this site comprised *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Triodia wiseana* open hummock grassland, which was more broadly mapped as vegetation type H1 (see Section 5.2.3). Fire age was estimated to be approximately 4-5 years and there was a considerably higher proportion of mature plants

[9] At each recorded location, all plants were counted in an approximate 20 m radius of the coordinate (see Section 3.2.5).

compared to Population 3. A total of 349 individuals were recorded from this population, comprising 309 mature plants and 40 juvenile plants. A total of 216 individuals (62%), from seven of the nine locations recorded in this population, are located within a preliminary proposed waste dump location (Figure 6.2).

Plate 6.2: *Lepidium catapycnon* Population 1: three individuals found approximately 50 m north of those originally recorded by Biota (2009a).

Plate 6.3: *Lepidium catapycnon* Population 2: habitat at site of record made by Hamersley Iron (2006). No plants were located during the current survey.

Plate 6.4: *Lepidium catapycnon* Population 3: steep, recently burnt slopes below a free face.

Plate 6.5: *Lepidium catapycnon* Population 4: south-facing slope of a moderate-sized hill.

Additional suitable habitat for *Lepidium catapycnon* occurs in the study area, not all of which has been searched. As only a portion of the suitable habitat was searched, it is possible that this species occurs at other locations in the study area. All *Lepidium catapycnon* populations in the study area occurred mainly within vegetation type H1, with some individuals occurring in areas mapped as vegetation type H5. All hills and slopes of the study area (vegetation types H1, H2, H3, H4 and H5, totalling 2,968 ha; see Appendix 4) could comprise suitable habitat for *L. catapycnon*, especially areas that have been burnt recently or have rocky ironstone shale slopes. However, vegetation type H1 (1,326 ha) remains the most prospective unit for this species. While it is possible that additional populations of *Lepidium catapycnon* occur in the study area, there is a low likelihood of new populations being located in areas where targeted searches have been undertaken. A map of the traverses through the study area is provided in Appendix 7 as an indication of the survey effort completed to date.

Lepidium catapycnon occurs over a broad range through the Pilbara, extending from northwest of Tom Price across to Newman. Over 30 populations are known, including one population in the conservation estate of the Karijini National Park, and some of these populations number in the

hundreds to over a thousand individuals (M. Maier, Biota, pers. obs.). The four populations recorded in the study area are located within the known range of the species and a total of 948 individuals have been recorded by all surveys to date (although only 777 individuals were present during the 2014 surveys). Rio Tinto database records show that *Lepidium catapycnon* has been recorded from 45 locations in the Yandi locality. These include over 3,059 individuals recorded from 25 locations within 10 km to the west of the study area, while additional populations are located within 10 km to the south of the study area. The populations within the study area would therefore not be considered to be of regional significance, and would be unlikely to be of local significance.

The preliminary proposed waste dump locations (areas where vegetation clearing would be required) intersect two of the *Lepidium catapycnon* populations (Populations 3 and 4; see above). Of the 777 individuals recorded in the study area during the 2014 surveys, 389 individuals (50%) in Populations 3 and 4 occur within the preliminary proposed waste dumps. The proposed works would therefore directly impact this species unless the preliminary waste dump design is modified to avoid these populations.

6.4.2 Priority Flora

Two Priority flora species, *Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3) and *Goodenia nuda* (Priority 4), were recorded in the study area during the field survey. Discussion of the populations in the study area is provided below, while a more general description of these species is provided in Section 4.9.2. All Priority flora records are displayed on the vegetation mapping provided in Appendix 4.

- *Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3)
  A total of five individuals of *Sida* sp. Barlee Range (S. van Leeuwen 1642) were recorded during the Phase 2 survey from two locations (Table 3). These records were in close proximity (25 m apart). The first record, of three individuals, was located on the southern boundary of the study area in vegetation type H5 (see Map 5 in Appendix 3). The second record, of two individuals, was made in the same vegetation type outside the study area, approximately 10 m south of the southern boundary. At both locations, the plants were found growing out of the side of a free face at the top of a shale-covered steep hillslope (Plate 6.6). All plants were mature, in healthy condition and flowering at the time of the survey. Both of these records occur outside of the proposed project footprint.

  Sida sp. Barlee Range (S. van Leeuwen 1642) is known from a number of locations throughout the Hamersley Range (DPaW 2014c), extending over a range of approximately 250 km from Brockman to Coondiner Creek. There has only been one previous record of this species within 10 km of the study area (Biota 2004a; see Appendix 2), however numerous additional locations have been recorded approximately 30 km northwest at Koodaideri (Biota 2012e) and there is also a record 36 km southeast at Coondiner Creek (DPaW 2014c). There is considerable suitable habitat along the range of hills to the northwest and southeast of the study area, and the lack of records of this species in the intervening areas is considered to be a reflection of a lack of survey effort rather than a genuine indication of the species' distribution. The five individuals recorded from the study area would therefore not be regionally or locally significant.

  It is possible that additional populations of this species occur in the study area but were not located during the current survey. The preferred habitat for *Sida* sp. Barlee Range (S. van Leeuwen 1642) comprises exposed rock in gullies and gorges, and vegetation type H5 (11.8 ha) is considered to represent the most prospective unit to support further populations of this species in the study area.

Table 3: Locations of *Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3) recorded inside and outside the study area during the current survey.

Location	Record Type	Date	Easting (mE)	Northing (mN)	Number of Individuals
Inside study area	Opportunistic	9-Jul-14	733697	7470558	3
Outside study area	Opportunistic	9-Jul-14	733720	7470548	2

- *Goodenia nuda* (Priority 4)
  A total of 76 individuals of *Goodenia nuda* were recorded from nine locations in the study area during the Phase 1 survey (Table 6.4; Plate 6.7). Seven of the locations were in Mulga woodlands (vegetation type P6; Section 5.2.4) on the eastern side of Weeli Wolli Creek. The two other records were from plains (vegetation types P2 and P3; Section 5.2.4) adjacent to the Marillana Creek and Weeli Wolli Creek floodplains. No additional locations of *G. nuda* were recorded during Phase 2, however the timing of this survey was less suitable to detect this species. Four records (comprising a total of 37 individuals) are located within the footprint of the proposed Pocket and Billiards South pit.

  Goodenia nuda has a broad distribution over a range of 500 km throughout the Pilbara bioregion, from Mardie Station on the coast to the eastern section of the Fortescue Valley (DPaW 2014c). This species has been recorded during several other surveys in the Yandi locality (Halpern Glick Maunsell 2000, Biota 2002, 2010, 2014b, 2014c; see Appendix 2). The records from the study area are therefore not considered to be either regionally or locally significant. Given that several populations of *G. nuda* are known from the study area (as well as from the broader Yandi locality) and that this species is a small, often inconspicuous herb, it is possible that additional populations of this species occur in the study area. Floodplains in the study area would provide the most suitable habitat for this species.

Table 6.4: Locations of *Goodenia nuda* (Priority 4) recorded in the study area.

Record Type	Date	Easting (mE)	Northing (mN)	Number of Individuals
Quadrat (YAQ16)	16-Mar-14	734166	7478025	4
Quadrat (HDA08)	16-Mar-14	734807	7474388	5
Quadrat (YBI12)	17-Mar-14	735517	7475188	1
Opportunistic	15-Mar-14	736668	7477105	8

Plate 6.6: *Sida* sp. Barlee Range (S. van Leeuwen 1642) growing out of a rocky free face in the study area.

Plate 6.7: *Goodenia nuda* inflorescence (photo not from the study area).

The three other Priority flora that were identified as having the potential to occur in the study area based on the desktop review (see Section 4.9.2 and Appendix 2) still retain this ranking, as the entire study area has not been blanket searched:

- *Stylidium weeliwolli* (Priority 2) is a small annual herb that may be present within the creek beds of Weeli Wolli and Marillana Creek. Although conditions were favourable for annual species at the time of the Phase 1 field survey, there is a possibility that individuals could have been missed due to the small size of this species. *Stylidium weeliwolli* has a broad range through the

Pilbara and Gascoyne regions (DPaW 2014c), however it is infrequently recorded. There are a number of records of this species in the Yandi locality, with the closest being 6 km upstream in Weeli Wolli Creek and 23 km upstream in a tributary of Marillana Creek (see Section 4.9.2). If *Stylidium weeliwolli* was present in the study area, it is unlikely that populations would be considered either regionally or locally significant.

- *Rostellularia adscendens* var. *latifolia* (Priority 3) is also small in size and there is the possibility that individuals could have been missed during the survey. This species may occur within the study area, particularly in creekline or floodplain habitat. *Rostellularia adscendens* var. *latifolia* is known from a number of locations with a broad distribution through the Pilbara (405 km), ranging from northwest of Tom Price to West Angelas in the south and Warrawagine in the northeast (DPaW 2014c). The study area lies within this range, and this species has been recorded at scattered locations from previous surveys in the Yandi locality (Biota 2010, 2014c). *Rostellularia adscendens* var. *latifolia* typically occurs in low numbers, when recorded. If this species was present in the study area, the populations would not be considered either regionally or locally significant.
- *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) (Priority 3) is typically associated with clayey plains, where it may form dense grasslands, however there are occasional isolated records from creeks and floodplains. This species may potentially occur in the study area, particularly on the floodplains surrounding the major creeks. However, given that it has not been recorded to date from the area, it would occur only as isolated individuals rather than dense grasslands. If this species was present in the study area, the populations would not be considered either regionally or locally significant.

6.4.3 Other Species of Interest

The currently undescribed taxon *Eulalia* sp. (Three Rivers Station, B. Forsyth AQ6789133) was recorded from three locations in the study area in a minor creekline, on a floodplain and on a plain. One of the records of this taxon was from a resampled quadrat, and it is likely that this taxon has been confused with the more common species, *E. aurea,* in past surveys. This species has a broad range extending over approximately 380 km from the Pilbara to the Gascoyne bioregion (see Section 4.9.3), and it has been recorded from other surveys in the locality including at Yandi (Biota 2014b), West Angelas (Biota 2014d) and Koodaideri (Biota 2012e). The populations in the study area are therefore unlikely to be considered either regionally or locally significant.

The taxon *Glycine* sp. aff. *arenaria* was not recorded from the study area, but may potentially occur along the sections of Marillana and Weeli Wolli Creek in the study area. Specimens of *Glycine* were collected in 2014 at the original locality near Oxbow, however none bear the 1-2 seeded pods that should be characteristic of *G. arenaria* (see Section 4.9.3). Further taxonomic work is required to determine whether the taxon from Oxbow represents *G. arenaria* or a separate species, and further resolution of the specimens collected in 2014 is being progressed through Andrew Perkins (WA Herbarium taxonomist). Given that there is currently only one record of *Glycine* sp. aff. *arenaria* from the Pilbara bioregion, if populations were present in the study area they may be considered regionally significant, depending on the outcome of the taxonomic placement. Further surveys in the Yandi locality should include targeted searches for this taxon.

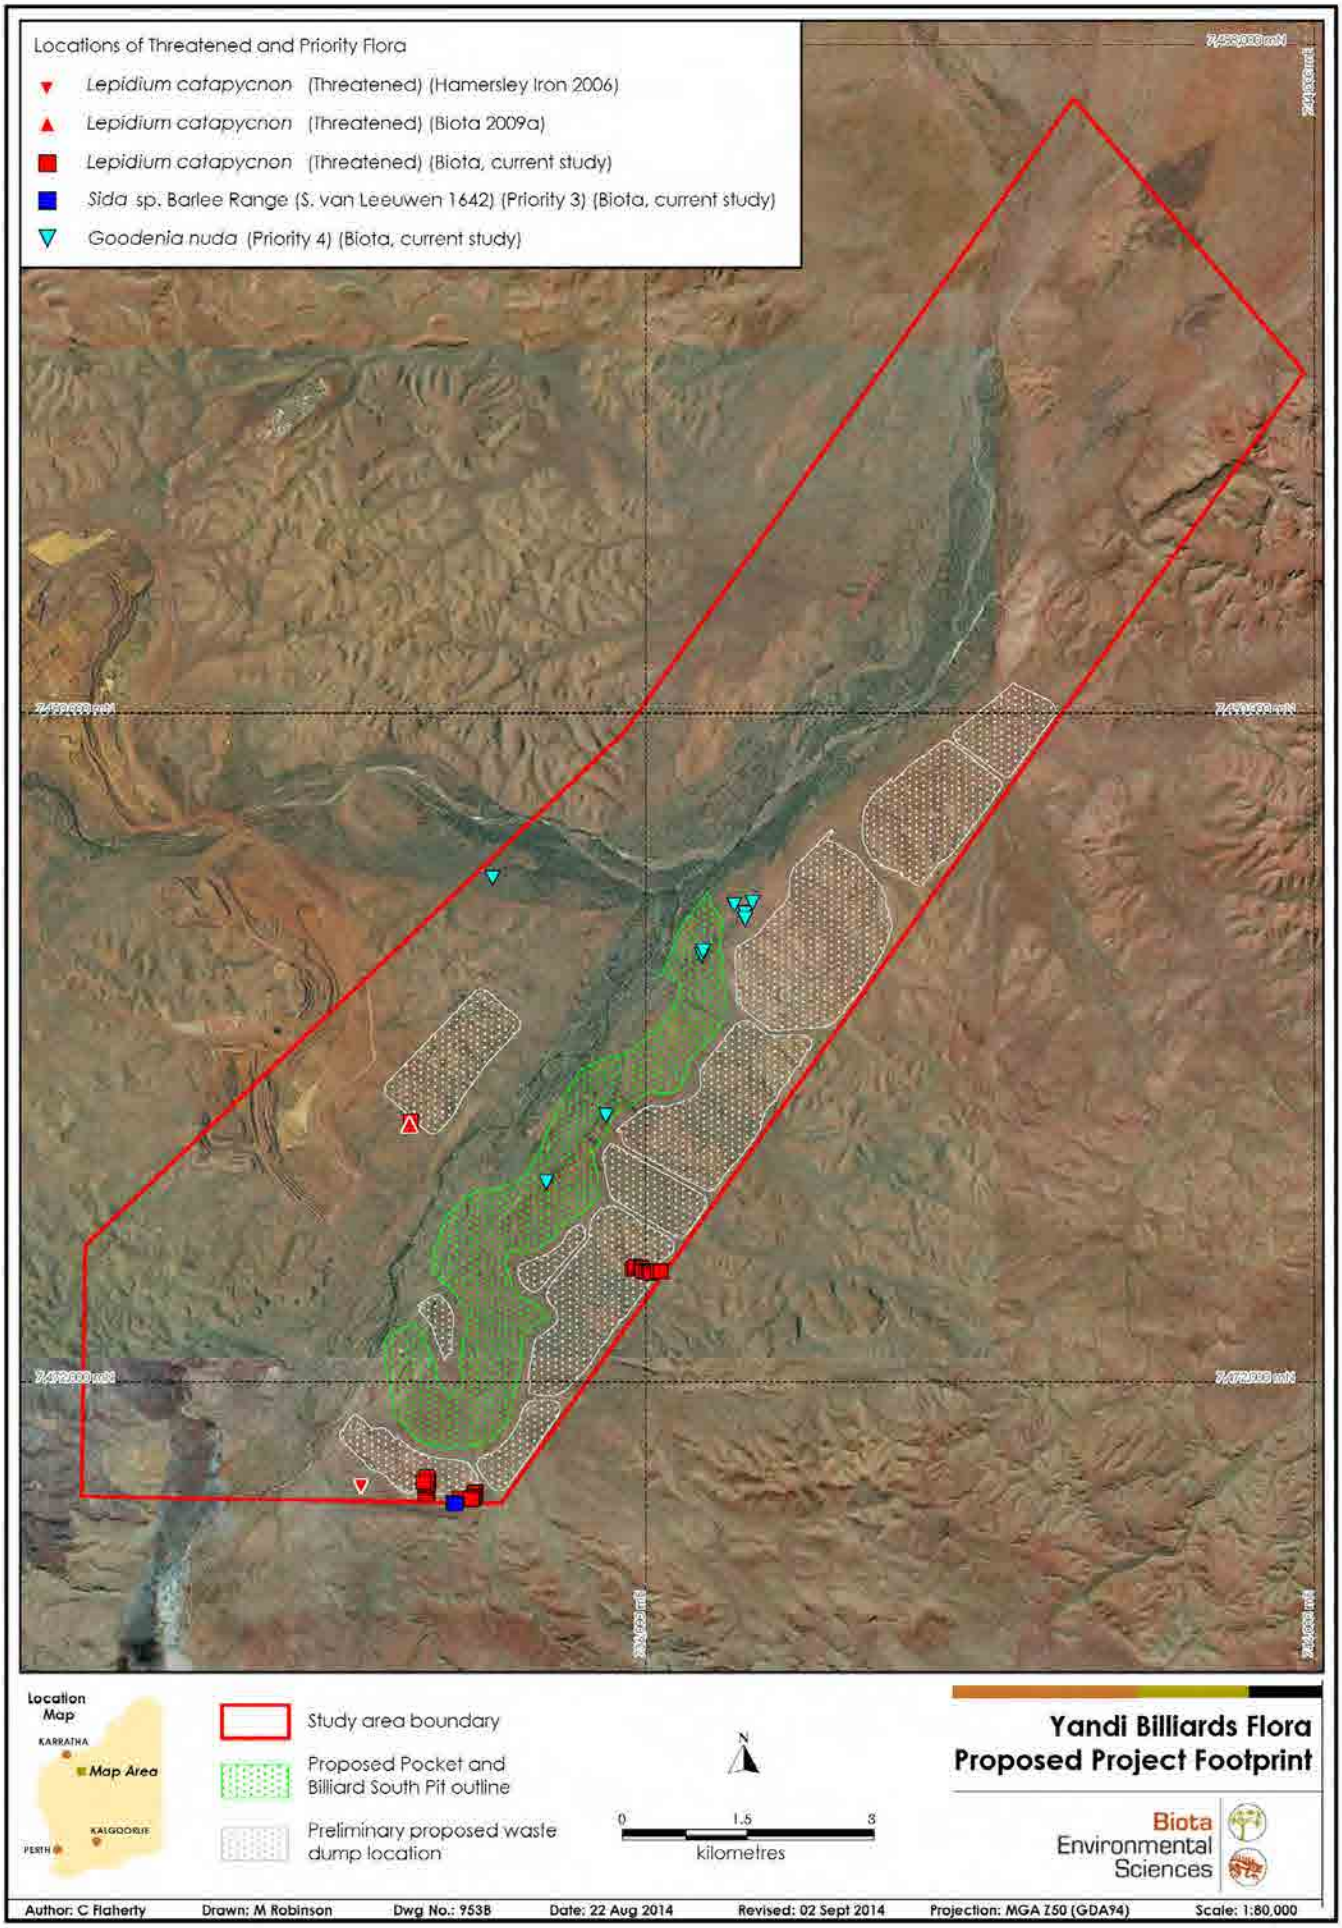

Figure 6.2: Locations of conservation significant flora in the study area shown with the proposed project footprint of the Pocket and Billiard South project.

6.5 Poorly Collected, Variable or Incompletely Resolved Taxa

Some apparent range extensions were recorded, which are considered likely to represent poorly collected taxa (*Euphorbia australis* var. *australis, Heliotropium glabellum* and *Peripleura hispidula* var. *hispidula*; see Appendix 10). In addition, some variable taxa that were distinguished with informal names in previous reporting are referred to as single entities sens. lat. ('in the broad sense') for this document (Appendix 10). One taxon recorded from the study area (*Portulaca oleracea/P. intraterranea*) has not been conclusively resolved due to a lack of taxonomic framework (see Appendix 10). None of these taxa are considered to be of conservation significance.

6.6 Introduced Flora (Weeds)

Eighteen introduced flora (weeds) have been recorded from the study area during the current and previous surveys at Yandi Billiards. Table 6.5 presents the number of records made for each weed species and the total number of locations from which each weed was recorded (the latter was to account for weeds being recorded multiple times at resampled quadrats). Weed locations are mapped and coordinates are provided in Appendix 5. Note that some of these locations have subsequently been cleared.

None of the weeds recorded are listed as Weeds of National Significance (Thorp and Lynch 2000)[10]. However, **Argemone ochroleuca* (Mexican Poppy) is listed under the WA *Biosecurity and Agriculture Management Act 2007 (BAM Act)* as a Declared Pest for the whole of WA in category C3 (management).

The draft Environmental Weed Strategy for WA developed by CALM (1999) ranked weed species according to their invasiveness, distribution and environmental impacts. Under this process **Aerva javanica*, **Acetosa vesicaria*, **Cenchrus ciliaris, *C. setiger, *Typha orientalis* and **Vachellia farnesiana* were ranked as weeds with High ecological impact, while **Datura leichhardtii, *Malvastrum americanum, *Sigesbeckia orientalis, *Sisymbrium orientale, *Solanum nigrum* and **Sonchus oleraceus* were ranked as Moderate. **Argemone ochroleuca* subsp. *ochroleuca* was ranked as Mild, and **Setaria verticillata* was ranked as Low. **Bidens bipinnata*, **Cucumis melo* subsp. *agrestis*, **Flaveria trinervia* and **Tribulus terrestris* were not rated.

DPaW currently applies an alternative ranking system to weed species within each management region, called the Weed Prioritisation Process (DPaW 2013a). None of the weed species recorded in the study area are ranked as Very High or High management priorities for the Pilbara region. However, it should be noted that for some species (e.g. **Cenchrus* spp.), this is a result of their low feasibility of control, rather than a reflection of their perceived invasiveness. **Acetosa vesicaria* is ranked by DPaW (2013a) as a Medium management priority, and all other species recorded in the study area are ranked as Low or Negligible.

[10] For the current listing of Weeds of National Significance, go to http://www.weeds.org.au/WoNS/

Table 6.5: Introduced species recorded from the study area.

Family	Species	Source and Number of Records								Total No. of Records	Total No. of Weed Locations
		Biota (2002)	Biota (2004a)	Biota (2004b)	Biota (2009b)	Biota (2014b)	Current study (Phase 1)	Current study (Phase 2)	Other

Typhaceae	**Typha orientalis*								3	3	3
Zygophyllaceae	**Tribulus terrestris*				1		9	1		11	10

Each weed species recorded in the study area is discussed briefly below:

- **Acetosa vesicaria* (Ruby Dock)
  Ruby Dock is a stout, fleshy-leaved and hollow-stemmed herb that grows up to 1 m in height and has red to pink fruit from winter to spring. It prefers sandy alluvial or ironstone soils and is commonly encountered on roadsides or in disturbed areas. It grows throughout WA with the exception of the Northern province (DPaW 2014c). This species was recorded from a creekline near the JSE mine pit by Pilbara Iron botanists (unpublished data). The remaining two records were made by GHD (2009); both of these locations have been subsequently cleared for the JSE mine footprint.

- **Aerva javanica* (Kapok)
  Kapok is a perennial herb to low shrub that typically grows up to 1.2 m tall, which has white woolly flowers from January to October (DPaW 2014c). Kapok is a widespread weed that occurs through the Pilbara and the Kimberley regions, and can form dense infestations. It is known from a variety of habitats including rocky outcrops, coastal areas, sand-dunes, creeklines and floodplains, along with disturbed areas (Hussey et al. 1997). This species reproduces by seed, which are only produced on the female plants. The small fruit are probably dispersed by animals and wind. They may also be spread by vehicles and in soil, as infestations often first appear along roadsides and near mine sites (The University of Queensland 2011). **Aerva javanica* was recorded from 16 locations in the study area, all from creekline or floodplain habitats.

- **Argemone ochroleuca* subsp. *ochroleuca* (Mexican Poppy)
  This annual daisy grows to 1 m tall and has spiny leaves. The white to pale yellow flowers are produced in February to March or July to November, and the resulting seed pods contain vast quantities of very fine seed. This species is commonly found in sandy or clay loam substrates on riverbanks, creek edges or roadsides throughout WA (DPaW 2014c). Mexican Poppy is difficult to control as it produces large quantities of seed and flooding of its habitat can spread the

seed for large distances. This species was recorded from four locations in the study area, all from major creeklines (Weeli Wolli Creek and Marillana Creek).

- **Bidens bipinnata* (Bipinnate Beggartick)
  Bipinnate Beggartick is an annual daisy, which grows to 90 cm tall and produces yellow flowers between March and September (DPaW 2014c). This species is commonly observed in association with Mulga vegetation and creeklines in the Pilbara. **Bidens bipinnata* may occur in high densities within suitable habitats and given appropriate conditions, but on its own does not appear to cause exclusion of native flora species. **Bidens bipinnata* has been recorded from 20 locations in the study area. Large populations (comprising up to 8,000 individuals) were found in Mulga woodlands. Populations were also found in floodplains and minor creeklines.

- **Cenchrus ciliaris* (Buffel Grass)
  Buffel Grass is a perennial grass introduced by pastoralists as a fodder species. It typically grows on white, red or brown sand or stony red loam and can form dense tussock grasslands along creeklines, on floodplains and in sandy, coastal areas (DPaW 2014c). **Cenchrus ciliaris* grows to 1 m tall and flowers for most the year. This species has demonstrated allelopathic capacities, whereby it releases chemicals that inhibit the growth of other plants, and it competes aggressively and effectively with native flora species (Cheam 1984a, 1984b). It reproduces by seed and short rhizomes and is thought to be dispersed primarily by wind and water, but can also be spread through movement of mammals, birds and vehicles (DPaW 2014c). **Cenchrus ciliaris* was the most prolific weed in the study area; it was recorded from 150 locations in the study area and was the dominant grass in two of the vegetation types (C4 and F2; see Section 5.2). The predominant habitat for this species comprised the creeklines and floodplains of Weeli Wolli and Marillana Creeks, where it often formed a continuous tussock grass understorey (see Section 5.3), however it was also found in lower abundance on some of the plains of the study area.

- **Cenchrus setiger* (Birdwood Grass)
  Birdwood Grass is an erect, stoloniferous grass that forms tussocks to 80 cm tall, with a compact, spike inflorescence (DPaW 2014c). Originally a fodder plant, Birdwood Grass has become a serious weed of sand dunes, rangelands, plains, stony hillsides and floodplains from Geraldton to the Kimberley (Hussey et al. 1997). This species is less common than Buffel Grass but it is a similarly serious environmental weed and often infests the same riparian habitats. This species was recorded from 49 locations in the study area, from the same habitats as **C. ciliaris*.

- **Cucumis melo* subsp. *agrestis* (Ulcardo Melon)
  Ulcardo Melon is a trailing annual herb with bristly or softly hairy leaves and yellow flowers in autumn and spring (DPaW 2014c). The mature fruit are ellipsoid, 2-5 cm in length, green to yellow in colour, and become glabrescent with age (The Royal Botanic Gardens and Domain Trust 2014). Ulcardo Melon has been recorded from a variety of habitats including grasslands on cracking clays, *Eucalyptus*, *Corymbia*, *Acacia* or *Grevillea* grassy woodlands on clay flats, and damp areas (DPaW 2014c). This species was recorded from three locations in the study area, all of which were in creekline habitats.

- **Datura leichhardtii* (Native Thornapple)
  Native Thornapple is a stout annual herb that grows to 1 m tall. It has white flowers from June to October, followed by spiny fruits (DPaW 2014c). It is widespread through the Carnarvon, Gascoyne, Little Sandy Desert and Pilbara bioregions and is often located along watercourses and drainage areas (DPaW 2014c). This species was recorded three times in the study area, from a Mulga woodland, a minor creekline and a floodplain of Weeli Wolli Creek.

- **Flaveria trinervia* (Speedy Weed)
  Speedy Weed is an annual daisy, with an inflorescence consisting of a large dense cluster of yellowish flower heads. This species is common and widespread in various habitats with sandy or loamy soils throughout the north of Western Australia, from approximately Carnarvon through to the Kimberley (DPaW 2014c). This species has been recorded from six locations along Weeli Wolli Creek.

- **Malvastrum americanum* (Spiked Malvastrum)
  Spiked Malvastrum typically occurs in Mulga vegetation, drainage lines and on floodplains, and can also be recorded on steep hill slopes and on rockpiles. It is an erect, perennial herb or

shrub to 1.3 m tall, with yellow or orange flowers from April to July (DPaW 2014c). This species has been recorded from 37 locations in the study area. It was found in Mulga woodlands, minor creeklines, and on the floodplains of Weeli Wolli and Marillana Creeks.

- **Setaria verticillata* (Whorled Pigeon Grass)
  Whorled Pigeon Grass is a loosely tufted annual grass that grows to 1.3 m tall (DPaW 2014c). This species commonly occurs in disturbed areas, on the edges of rivers and creeks and in shrublands from the Kimberley to the Pilbara (Hussey et al. 1997). Whorled Pigeon Grass has been recorded from 28 locations in the study area, most of which were associated with creeklines or floodplains.

- **Sigesbeckia orientalis* (Indian Weed)
  Indian Weed is a slender, annual herb that grows to 1 m tall and has yellow flowers all year round. It is typically found growing in loamy soils in rocky gullies, limestone ranges and creek beds (DPaW 2014c). It was recorded twice in the study area, once from a Mulga woodland and once from a floodplain of Weeli Wolli Creek.

- **Sisymbrium orientale* (Indian Hedge Mustard)
  Indian Hedge Mustard is an annual or biennial herb occurring in disturbed areas of the Eremaean and South-West provinces. It grows up to 1 m tall and has yellow flowers from autumn to spring (DPaW 2014c). This species has been recorded from a single location in Weeli Wolli Creek.

- **Solanum nigrum* (Black Berry Nightshade)
  This perennial herb or short-lived shrub grows to 1 m tall and has white flowers all year. It is distributed across most of WA from the south to the north, with the exception of the central portion (DPaW 2014c). This species has been recorded from a single location in Weeli Wolli Creek.

- **Sonchus oleraceus* (Common Sowthistle)
  Common Sowthistle is a short-lived annual herb that grows to 1.5 m tall (DPaW 2014c). This species is common and widespread in disturbed areas of WA from Wittenoom to the Nullarbor (Hussey et al. 1997). This species has been recorded from four locations in the study area on the banks and in the bed of Weeli Wolli Creek.

- **Tribulus terrestris* (Caltrop)
  Caltrop is a prostrate vine with greyish pinnate leaves and small yellow flowers. It is a widespread weed that prefers sandy soils and occurs across most of WA (DPaW 2014c). This species was recorded from 10 locations in the study area. It was found in a variety of habitats including plains, floodplains, Mulga woodlands and minor creeklines.

- **Typha orientalis* (Bulrush)
  Bulrush is a rhizomatous emergent perennial herb with brown flower spikes, which can grow to 4.5 m tall (DPaW 2014c). **Typha orientalis* is known from the southwest of WA, where it grows in winter-wet depressions, permanent wetland and irrigation channels (DPaW 2014c). There are currently no vouchered specimens of this species from the Pilbara region, however a native Bulrush species (*Typha domingensis*) that is similar in appearance is widespread. **Typha orientalis* was recorded from three locations in the study area during a weed survey by GHD (2009): two of these locations have subsequently been cleared for the JSE mine footprint, while the remaining record is located on Weeli Wolli Creek, in the south of the study area adjacent to the JSE mine. The location of the remaining **T. orientalis* record was checked during the Phase 2 survey, and while *T. domingensis* was found at this location, no **T. orientalis* was located. *Typha domingensis* has been recorded several times from Weeli Wolli Creek in the study area, and it is possible that the records of **T. orientalis* from GHD (2009) represent this taxon.

- **Vachellia farnesiana* (Mimosa Bush)
  Mimosa Bush is a spreading, thorny shrub to 4 m tall, with dark grey bark, pinnate leaves, and yellow flowers in winter. It typically grows in stony sand, clay or loam soils, or gravel (DPaW 2014c). This species is widespread from the Kimberley to near Perth, typically occurring along drainage systems and in adjacent low-lying areas (Hussey et al. 1997). Mimosa Bush has been recorded from five locations in the study area, predominantly on floodplains.

7.0 Key Findings

Key findings of this study are as follows:

- Twenty-three vegetation types have been described and mapped for the study area, none of which represent TECs or PECs (Section 5.0, Appendix 4). This number of units is considered to be within the range expected for a study area of this size in this locality, taking into account the habitats present.
- One ecosystem at risk is present in the study area: vegetation type C1 occurs along Marillana and Weeli Wolli Creeks and would represent a "major ephemeral water course" as described by Kendrick (2003a). Two additional vegetation types (C2 and C3) comprise riparian vegetation along the same major creeklines, however these units do not support dense Eucalypt forests nor obligate phreatophytic species (see Section 5.5.2). The presence of weeds (usually only as scattered individuals) and disturbance from cattle have been noted in these vegetation types, and they are mostly in Very Good to Good condition. Similar vegetation assemblages are widespread through the Pilbara in various major creek systems, and these vegetation types would therefore be of significance at the local, rather than regional, scale.
- A total of 5.7% of the study area was mapped as Disturbed or Completely Degraded. These areas consisted of cleared areas associated with the mining footprint, roads or drill lines. Fourteen quadrats that had been previously sampled in the study area have since been cleared (Section 5.3, Appendix 4).
- The condition of the remaining intact vegetation of the study area ranged from Excellent to Very Poor (Section 5.3, Appendix 5). The main disturbance factors noted were weeds and disturbance from cattle. **Cenchrus ciliaris* (Buffel Grass) was the most prolific weed in the study area and often formed dense populations in the understorey in some creekline and floodplain vegetation types (particularly C4 and F2, where it was a dominant species in the vegetation description).
- A total of 455 native vascular flora species were recorded from the study area. The total number of species recorded is high, but within the range expected for a study area of this size in this locality (Section 6.0).
- Three conservation significant flora species were recorded from the study area during the field survey; *Lepidium catapycnon* (Threatened), *Sida* sp. Barlee Range (S. van Leeuwen 1642) (Priority 3) and *Goodenia nuda* (Priority 4).
    - *Lepidium catapycnon* is now known from four populations in the study area. This species was recorded from 26 locations comprising three distinct populations in 2014; two new populations (Populations 3 and 4), and an existing population (Population 1) originally located by Biota (2009a). The location of Population 2, which was originally recorded by Hamersley Iron (2006), was searched in 2014 but no plants were found.

      A total of 777 individuals were counted in the study area in 2014. Some 171 individuals in Population 1 that were previously recorded by Biota (2009a) were no longer present, and no plants were found in Population 2.

      Of the four populations known from the study area, two (Populations 3 and 4) are partly located within preliminary proposed waste dump locations (Section 6.4.1; Figure 6.2). A total of 389 individuals (173 individuals in Population 3 and 216 individuals in Population 4) are located within the proposed clearing areas, comprising 50% of the total number of individuals recorded in 2014. While this is a relatively high proportion of the total population identified in the study area, there are a large number of records of this species from the broader locality, and some of these populations comprise hundreds to over a thousand individuals. If the preliminary proposed waste dump locations cannot be modified to reduce the number of individuals affected, clearing of the 389 individuals currently within the works area would be unlikely to affect the conservation status of this species. It should be noted that this species has been under consideration for downgrading to a Priority species since prior to 2011.

Additional suitable habitat for *Lepidium catapycnon* occurs in the study area, not all of which has been searched. All hills and slopes of the study area (vegetation types H1, H2, H3, H4 and H5; see Appendix 4) could comprise suitable habitat for *L. catapycnon*, especially areas that have been burnt recently or have rocky ironstone shale slopes, however vegetation type H1 remains the most prospective unit for this species (see Section 6.4.1). While it is possible that additional populations of *Lepidium catapycnon* occur in the study area, there is a low likelihood of new populations being located in areas where targeted searches have been undertaken (Appendix 7 shows foot traverses in the study area).

- The Priority 3 *Sida* sp. Barlee Range (S. van Leeuwen 1642) was recorded from a free face supporting vegetation type H5 at two locations in close proximity. Three individuals were recorded from the southern boundary of the study area and two individuals were recorded approximately 10 m south of the study area. Both of these records occurred outside the proposed project footprint.
- The Priority 4 *Goodenia nuda* was recorded from nine locations within vegetation types P6, P2 and P3, comprising a total of 76 individuals. Four of these records (totalling 37 individuals) occur within the footprint of the proposed Pocket and Billiards South pit. Given that suitable habitat is present and that *Goodenia nuda* is a small herb, additional populations of this species may occur in the study area.

- While no individuals have been recorded to date, three other Priority species may potentially occur in the study area: *Stylidium weeliwolli* (Priority 2) may potentially occur in the bed of Weeli Wolli or Marillana Creeks; *Themeda* sp. Hamersley Station (M.E. Trudgen 11431) (Priority 3) may occur along the floodplains of these creek systems; and *Rostellularia adscendens* var. *latifolia* (Priority 3) may potentially occur in creekline or floodplain habitat (Section 6.4.2).
- Eighteen weed species have been recorded in the study area; with the exception of **Typha orientalis*, all of these are commonly encountered in the locality (Section 6.6). **Argemone ochroleuca* (Mexican Poppy) is listed under the WA *BAM Act 2007* as a Declared Pest for the whole of WA, while **Aerva javanica*, **Acetosa vesicaria*, **Cenchrus ciliaris*, **C. setiger* and **Vachellia farnesiana* are ranked by DPaW as weeds with High ecological impact (CALM 1999). None of the weed species encountered were ranked as a Very High or High priority for management under the Weed Prioritisation Process for the Pilbara region (DPaW 2013b).

8.0 Glossary

*	Used prior to a species name to denote a weed species.
Alluvial	Loose, unconsolidated (not cemented together into a solid rock) soil or sediments, which have been eroded, reshaped by water in some form, and redeposited in a non-marine setting.
Anabranching	An anabranching river consists of multiple channels separated by vegetated (sometimes semi permanent) alluvial islands.
Annual (plant)	A plant that lives for only one year.
BAM Act 2007	The WA *Biosecurity and Agriculture Management Act 2007.*
Conservation Significant	A plant that is recognised to be rare, unusual, new or poorly sampled; may have a formally assigned conservation ranking (see Appendix 1 for more on the WA conservation framework).
Culm	The stem of a grass or sedge.
DPaW	WA Department of Parks and Wildlife (formerly the Department of Environment and Conservation (DEC)).
EPA	Environmental Protection Authority of Western Australia.
EPBC Act 1999	The Commonwealth *Environment Protection and Biodiversity Conservation Act 1999.*
Ephemeral	A plant that lives a very short time; less than one year, usually less than six months.
Floodout	An area of land, usually adjacent to a river or major drainage system, that receives water during periods of overbank flow associated with normal or extreme flood events. Can be situated at the end of the drainage line.
Flora keys	Botanical publications containing a series of questions regarding the characteristics of plants, aiding in the identification of different taxa.
Foot Traverse	Consists of walking through an area to confirm or note vegetation boundaries or to search for flora (usually sampling a narrow corridor/cross section of vegetation).
Free face	A vertical or near vertical landform element situated part way up a slope but not comprising the entire slope.
GIS	Geographic Information System.
IBRA	Interim Biogeographic Regionalisation for Australia.
NRS	National Reserve System.
NVCP	Native Vegetation Clearing Permit.
Opportunistic	A plant or animal species collected or recorded outside a formal sampling site (e.g. flora quadrats or relevés, or fauna trapping sites). Opportunistic collections are usually made during foot traverses and when travelling between sites.
PEC	Priority Ecological Community (see Appendix 1 for more on the WA conservation framework).
Perennial	A plant that lives for more than two growing seasons.
Priority flora	Flora species listed by DPaW as requiring additional information to properly evaluate their conservation significance; see Appendix 1 for more on the WA conservation framework.
sens. lat.	Abbreviation of *sensu lato* (Latin), meaning “in the broad sense”.
Stratum (plural: strata)	A horizontal level of vegetation defined by growth habit (and sometimes height); e.g. low trees, tall trees, tussock grasses, hummock grasses.
subsp.	Abbreviation of “subspecies.

Taxon (plural: taxa)	A taxonomic entity, typically at species level or below.
TEC	Threatened Ecological Community (see Appendix 1 for more on the WA conservation framework).
Threatened flora	Flora species protected by legislation, either listed under the Commonwealth *EPBC Act 1999* or the WA *Wildlife Conservation Act 1950* (flora species formerly known as Declared Rare Flora); see Appendix 1 for more on the WA conservation framework.
var.	Abbreviation of variety.

Appendix 1

Framework for Conservation Significance Ranking of Communities and Species in WA

A. Definitions, Categories and Criteria for Threatened and Priority Ecological Communities

1. General Definitions

Ecological Community
A naturally occurring biological assemblage that occurs in a particular type of habitat.

Note: The scale at which ecological communities are defined will often depend on the level of detail in the information source, therefore no particular scale is specified.

A threatened ecological community (TEC) is one which is found to fit into one of the following categories; "presumed totally destroyed", "critically endangered", "endangered" or "vulnerable".

Possible threatened ecological communities that do not meet survey criteria are added to DPaW's Priority Ecological Community Lists under Priorities 1, 2 and 3. Ecological Communities that are adequately known, are rare but not threatened, or meet criteria for Near Threatened, or that have been recently removed from the threatened list, are placed in Priority 4. These ecological communities require regular monitoring. Conservation Dependent ecological communities are placed in Priority 5.

An assemblage is a defined group of biological entities.

Habitat is defined as the areas in which an organism and/or assemblage of organisms lives. It includes the abiotic factors (eg. substrate and topography), and the biotic factors.

Occurrence: a discrete example of an ecological community, separated from other examples of the same community by more than 20 metres of a different ecological community, an artificial surface or a totally destroyed community.

By ensuring that every discrete occurrence is recognised and recorded future changes in status can be readily monitored.

Adequately Surveyed is defined as follows:
"An ecological community that has been searched for thoroughly in most likely habitats, by relevant experts."

Community structure is defined as follows:
"The spatial organisation, construction and arrangement of the biological elements comprising a biological assemblage" (eg. Eucalyptus salmonophloia woodland over scattered small shrubs over dense herbs; structure in a faunal assemblage could refer to trophic structure, eg. dominance by feeders on detritus as distinct from feeders on live plants).

Definitions of Modification and Destruction of an ecological community:

Modification: "changes to some or all of ecological processes (including abiotic processes such as hydrology), species composition and community structure as a direct or indirect result of human activities. The level of damage involved could be ameliorated naturally or by human intervention."

Destruction: "modification such that reestablishment of ecological processes, species composition and community structure within the range of variability exhibited by the original community is unlikely within the foreseeable future even with positive human intervention."

Note: Modification and destruction are difficult concepts to quantify, and their application will be determined by scientific judgement. Examples of modification and total destruction are cited below:

Modification of ecological processes: The hydrology of Toolibin Lake has been altered by clearing of the catchment such that death of some of the original flora has occurred due to dependence on fresh water. The system may be bought back to a semblance of the original state by redirecting saline runoff and pumping waters of the rising underground watertable away to restore the hydrological balance. Total destruction of downstream lakes has occurred due to hydrology being altered to the point that few of the original flora or fauna species are able to tolerate the level of salinity and/or water logging.

Modification of structure: The understorey of a plant community may be altered by weed invasion due to nutrient enrichment by addition of fertiliser. Should the additional nutrients be removed from the system the balance may be restored, and the original plant species better able to compete. Total destruction may occur if additional nutrients continue to be added to the system causing the understorey to be completely replaced by weed species, and death of overstorey species due to inability to tolerate high nutrient levels.

Modification of species composition: Pollution may cause alteration of the invertebrate species present in a freshwater lake. Removal of pollutants may allow the return of the original inhabitant species. Addition of residual highly toxic substances may cause permanent changes to water quality, and total destruction of the community.

Threatening processes are defined as follows:
"Any process or activity that threatens to destroy or significantly modify the ecological community and/or affect the continuing evolutionary processes within any ecological community."

Examples of some of the continuing threatening processes in Western Australia include: general pollution; competition, predation and change induced in ecological communities as a result of introduced animals; competition and displacement of native plants by introduced species; hydrological changes; inappropriate fire regimes; diseases resulting from introduced micro-organisms; direct human exploitation and disturbance of ecological communities.

Restoration is defined as returning an ecological community to its pre-disturbance or natural state in terms of abiotic conditions, community structure and species composition.

Rehabilitation is defined as the re-establishment of ecological attributes in a damaged ecological community although the community will remain modified.

2. Definitions and Criteria for Presumed Totally Destroyed, Critically Endangered, Endangered and Vulnerable Ecological Communities

ECOLOGICAL COMMUNITIES

Presumed Totally Destroyed (PD)
An ecological community that has been adequately searched for but for which no representative occurrences have been located. The community has been found to be totally destroyed or so extensively modified throughout its range that no occurrence of it is likely to recover its species composition and/or structure in the foreseeable future.

An ecological community will be listed as presumed totally destroyed if there are no recent records of the community being extant and either of the following applies (A or B):

A) Records within the last 50 years have not been confirmed despite thorough searches of known or likely habitats or

B) All occurrences recorded within the last 50 years have since been destroyed

Critically Endangered (CR)
An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or that was originally of limited distribution and is facing severe modification or destruction throughout its range in the immediate future, or is already severely degraded throughout its range but capable of being substantially restored or rehabilitated.

An ecological community will be listed as Critically Endangered when it has been adequately surveyed and is found to be facing an extremely high risk of total destruction in the immediate future. This will be determined on the basis of the best available information, by it meeting any one or more of the following criteria (A, B or C):

A) The estimated geographic range, and/or total area occupied, and/or number of discrete occurrences since European settlement have been reduced by at least 90% and either or both of the following apply (i or ii):

   i) geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is imminent (within approximately 10 years);

   ii) modification throughout its range is continuing such that in the immediate future (within approximately 10 years) the community is unlikely to be capable of being substantially rehabilitated.

B) Current distribution is limited, and one or more of the following apply (i, ii or iii):

   i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the immediate future (within approximately 10 years);

ii) there are very few occurrences, each of which is small and/or isolated and extremely vulnerable to known threatening processes;

iii) there may be many occurrences but total area is very small and each occurrence is small and/or isolated and extremely vulnerable to known threatening processes.

C) The ecological community exists only as highly modified occurrences that may be capable of being rehabilitated if such work begins in the immediate future (within approximately 10 years).

Endangered (EN)
An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or was originally of limited distribution and is in danger of significant modification throughout its range or severe modification or destruction over most of its range in the near future.

An ecological community will be listed as Endangered when it has been adequately surveyed and is not Critically Endangered but is facing a very high risk of total destruction in the near future. This will be determined on the basis of the best available information by it meeting any one or more of the following criteria (A, B, or C):

A) The geographic range, and/or total area occupied, and/or number of discrete occurrences have been reduced by at least 70% since European settlement and either or both of the following apply (i or ii):

i) the estimated geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is likely in the short term future (within approximately 20 years);

ii) modification throughout its range is continuing such that in the short term future (within approximately 20 years) the community is unlikely to be capable of being substantially restored or rehabilitated.

B) Current distribution is limited, and one or more of the following apply (i, ii or iii):

i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the short term future (within approximately 20 years);

ii) there are few occurrences, each of which is small and/or isolated and all or most occurrences are very vulnerable to known threatening processes;

iii) there may be many occurrences but total area is small and all or most occurrences are small and/or isolated and very vulnerable to known threatening processes.

C) The ecological community exists only as very modified occurrences that may be capable of being substantially restored or rehabilitated if such work begins in the short-term future (within approximately 20 years).

Vulnerable (VU)
An ecological community that has been adequately surveyed and is found to be declining and/or has declined in distribution and/or condition and whose ultimate security has not yet been assured and/or a community that is still widespread but is believed likely to move into a category of higher threat in the near future if threatening processes continue or begin operating throughout its range.

An ecological community will be listed as Vulnerable when it has been adequately surveyed and is not Critically Endangered or Endangered but is facing a high risk of total destruction or significant modification in the medium to long-term future. This will be determined on the basis of the best available information by it meeting any one or more of the following criteria (A, B or C):

A) The ecological community exists largely as modified occurrences that are likely to be capable of being substantially restored or rehabilitated.

B) The ecological community may already be modified and would be vulnerable to threatening processes, is restricted in area and/or range and/or is only found at a few locations.

C) The ecological community may be still widespread but is believed likely to move into a category of higher threat in the medium to long term future because of existing or impending threatening processes.

3. Definitions and Criteria for Priority Ecological Communities

PRIORITY ECOLOGICAL COMMUNITY LIST
Possible threatened ecological communities that do not meet survey criteria or that are not adequately defined are added to the Priority Ecological Community Lists under Priorities 1, 2 and 3. These three categories are ranked in order of priority for survey and/or definition of the community, and evaluation of conservation status, so that consideration can be given to their declaration as threatened ecological communities. Ecological Communities that are adequately known, and are rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list, are placed in Priority 4. These ecological communities require regular monitoring. Conservation Dependent ecological communities are placed in Priority 5.

Priority One: Poorly-known ecological communities
Ecological communities with apparently few, small occurrences, all or most not actively managed for conservation (e.g. within agricultural or pastoral lands, urban areas, active mineral leases) and for which current threats exist. Communities may be included if they are comparatively well-known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under immediate threat from known threatening processes across their range.

Priority Two: Poorly-known ecological communities
Communities that are known from few small occurrences, all or most of which are actively managed for conservation (e.g. within national parks, conservation parks, nature reserves, State forest, unallocated Crown land, water reserves, etc.) and not under imminent threat of destruction or degradation. Communities may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under threat from known threatening processes.

Priority Three: Poorly known ecological communities

(i) Communities that are known from several to many occurrences, a significant number or area of which are not under threat of habitat destruction or degradation or:

(ii) communities known from a few widespread occurrences, which are either large or within significant remaining areas of habitat in which other occurrences may occur, much of it not under imminent threat, or;

(iii) communities made up of large, and/or widespread occurrences, that may or not be represented in the reserve system, but are under threat of modification across much of their range from processes such as grazing by domestic and/or feral stock, and inappropriate fire regimes.

Communities may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and/or are not well defined, and known threatening processes exist that could affect them.

Priority Four: Ecological communities that are adequately known, rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list. These communities require regular monitoring.

(a) Rare. Ecological communities known from few occurrences that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These communities are usually represented on conservation lands.

(b) Near Threatened. Ecological communities that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable.

(c) Ecological communities that have been removed from the list of threatened communities during the past five years.

Priority Five: Conservation Dependent ecological communities
Ecological communities that are not threatened but are subject to a specific conservation program, the cessation of which would result in the community becoming threatened within five years.

Department of Parks and Wildlife

CONSERVATION CODES

for Western Australian Flora and Fauna

T: **Threatened species -** Specially protected under the *Wildlife Conservation Act 1950*, listed under Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice for Threatened Fauna and Wildlife Conservation (Rare Flora) Notice for Threatened Flora (which may also be referred to as Declared Rare Flora).

Species* which have been adequately searched for and are deemed to be in the wild either rare, in danger of extinction, or otherwise in need of special protection, and have been gazetted as such.

X: **Presumed extinct species -** Specially protected under the *Wildlife Conservation Act 1950*, listed under Schedule 2 of the Wildlife Conservation (Specially Protected Fauna) Notice for Presumed Extinct Fauna and Wildlife Conservation (Rare Flora) Notice for Presumed Extinct Flora (which may also be referred to as Declared Rare Flora).

Species* which have been adequately searched for and there is no reasonable doubt that the last individual has died, and have been gazetted as such.

IA: **Migratory birds protected under an international agreement -** Specially protected under the *Wildlife Conservation Act 1950*, listed under Schedule 3 of the Wildlife Conservation (Specially Protected Fauna) Notice.

Birds that are subject to an agreement between governments of Australia and Japan, China and The Republic of Korea relating to the protection of migratory birds and birds in danger of extinction.

S: **Other specially protected fauna -** Specially protected under the *Wildlife Conservation Act 1950*, listed under Schedule 4 of the Wildlife Conservation (Specially Protected Fauna) Notice.

Threatened Fauna and Flora are further recognised by the Department according to their level of threat using IUCN Red List criteria. For example Carnaby's Cockatoo *Calyptorynchus latirostris* is specially protected under the *Wildlife Conservation Act 1950* as a threatened species with a ranking of endangered.

Ranking:

CR: Critically Endangered - considered to be facing an extremely high risk of extinction in the wild.

EN: Endangered – considered to be facing a very high risk of extinction in the wild.

VU: Vulnerable - considered to be facing a high risk of extinction in the wild.

A list of the current rankings can be downloaded from the Listing of species and ecological communities webpage http://dpaw.wa.gov.au/plants-and-animals/threatened-species-and-communities/84-listing-of-species-and-ecological-communities .

Species that have not yet been adequately surveyed to be listed under Schedule 1 or 2 are added to the Priority Flora and Priority Fauna Lists under Priorities 1, 2 or 3. These three categories are ranked in order of priority for survey and evaluation of conservation status so that consideration can be given to their declaration as threatened flora or fauna. Species that are adequately known, are rare but not threatened, or meet criteria for Near Threatened, or that have been recently removed from the threatened list for other than taxonomic reasons, are placed in Priority 4. These species require regular monitoring. Conservation Dependent species are placed in Priority 5.

1: Priority One: Poorly-known species

Species that are known from one or a few collections or sight records (generally less than five), all on lands not managed for conservation, e.g. agricultural or pastoral lands, urban areas, Shire, rail reserves and Main Roads WA road, gravel and soil reserves, and active mineral leases and under threat of habitat destruction or degradation. Species may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under immediate threat from known threatening processes.

2: Priority Two: Poorly-known species

Species that are known from one or a few collections or sight records, some of which are on lands not under imminent threat of habitat destruction or degradation, e.g. national parks, conservation parks, nature reserves, State forest, unallocated Crown land, water reserves, etc. Species may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under threat from known threatening processes.

3: Priority Three: Poorly-known species

Species that are known from collections or sight records from several localities not under imminent threat, or from few but widespread localities with either large population size or significant remaining areas of apparently suitable habitat, much of it not under imminent threat. Species may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and known threatening processes exist that could affect them.

4: Priority Four: Rare, Near Threatened and other species in need of monitoring

(a) Rare. Species that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These species are usually represented on conservation lands.
(b) Near Threatened. Species that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable.
(c) Species that have been removed from the list of threatened species during the past five years for reasons other than taxonomy.

5: Priority Five: Conservation Dependent species

Species that are not threatened but are subject to a specific conservation program, the cessation of which would result in the species becoming threatened within five years.

*Species includes all taxa (plural of taxon - a classificatory group of any taxonomic rank, e.g. a family, genus, species or any infraspecific category i.e. subspecies, variety or forma).

Appendix 2

Results of the Flora Desktop Review: Summary of Conservation Significant Flora Species Recorded within 25 km of the Study Area

Species	Habit and Habitat Preference (DPaW 2014c)														Likelihood of Occurrence in the Study Area	
		Nature Map	Mattiske (1995a)	Mattiske (1995b)	Biota (2000)	HGM (2000)	Biota (2002)	Biota (2004a)	Biota (2004b)	Biota (2009a)	Biota (2009b)	Biota (2010)	Biota (2014b)	Biota (2014c)	Initial Ranking Based on Desktop Review	Final Ranking Including Results of Field Survey
Threatened																
Lepidium catapycnon	Low shrub on stony scree slopes	✓								✓					Recorded: two populations.	Recorded: four populations now known.
Priority 1																
Brunonia sp. Long hairs (D.E. Symon 2440)	Erect herb along creeklines	✓													Unlikely to occur: creeklines within the study area may provide suitable habitat, however this species has not been recorded by previous surveys around Yandi.	Unlikely to occur.
Priority 2																
Indigofera ixocarpa	Shrub on skeletal red soils on ironstone hill slopes						✓								Unlikely to occur; rocky slopes within the study area may provide suitable habitat, however this species has not previously been recorded by other surveys close to the study area.	Unlikely to occur.
Stylidium weeliwolli	Annual herb on major watercourses	✓		✓											May potentially occur; the sections of Weeli Wolli Creek and Marillana Creek within the study area may provide suitable habitat.	May potentially occur.
Priority 3																
Acacia subtiliformis	Slender, spindly, erect shrub; Stony calcrete plains	✓													Would not occur; no suitable calcrete habitat in the study area.	Would not occur.
Fimbristylis sieberiana	Shortly rhizomatous, tufted perennial sedge near permanent pools	✓													Unlikely to occur: the sections of Weeli Wolli Creek and Marillana Creek within the study area may provide suitable habitat, however this species has not been recorded by previous surveys close to the study area. There are records from approximately 5-6 km upstream in Weeli Wolli Creek, but these are from the permanently wet areas associated with Weeli Wolli Springs.	Unlikely to occur.

Species	Habit and Habitat Preference (DPaW 2014c)														Likelihood of Occurrence in the Study Area	
		Nature Map	Mattiske (1995a)	Mattiske (1995b)	Biota (2000)	HGM (2000)	Biota (2002)	Biota (2004a)	Biota (2004b)	Biota (2009a)	Biota (2009b)	Biota (2010)	Biota (2014b)	Biota (2014c)	Initial Ranking Based on Desktop Review	Final Ranking Including Results of Field Survey
Goodenia sp. East Pilbara (A.A. Mitchell PRP 727)	Annual to biennial herb; Low undulating plains, typically on calcrete	✓							✓						Would not occur; no suitable calcrete habitat in the study area.	Would not occur.
Gymnanthera cunninghamii	Erect woody shrub; In sandy soils surrounding permanent or semi-permanent watercourses	✓					✓								Unlikely to occur; creeklines within the study area provide suitable habitat, however this species has not previously been recorded by other surveys close to the study area.	Unlikely to occur.
Rhagodia sp. Hamersley (M. Trudgen 17794)	Shrub; Under Mulga		✓	✓											Unlikely to occur; there is only a minimal amount of Mulga shrublands in the study area.	Unlikely to occur.
Rostellularia adscendens var. *latifolia*	Herb or shrub; Creeks, rocky hills				✓									✓	May potentially occur; there is suitable habitat in the study area.	May potentially occur.
Sida sp. Barlee Range (S. van Leeuwen 1642)	Low spreading shrub; Skeletal soils on steep slopes							✓							May potentially occur; there are some areas of rocky slopes in the study area that may provide suitable habitat.	Recorded during the field survey from two locations along a rocky free face of a ridgeline.
Themeda sp. Hamersley Station (M.E. Trudgen 11431)	Annual tussock grass; Clay pan, grass plain	✓			✓		✓	✓							May potentially occur; creeklines and adjacent plains within the study area may provide suitable habitat.	May potentially occur.
Priority 4																
Goodenia nuda	Herb; Drainage areas or floodplains on clay loam to clay	✓			✓		✓					✓	✓	✓	Likely to occur; creeklines and plains within the study area would provide suitable habitat.	Recorded during the field survey from several locations in Mulga woodland and on the floodplains of Weeli Wolli Creek and Marillana Creek.

Species	Habit and Habitat Preference (DPaW 2014c)														Likelihood of Occurrence in the Study Area	
		Nature Map	Mattiske (1995a)	Mattiske (1995b)	Biota (2000)	HGM (2000)	Biota (2002)	Biota (2004a)	Biota (2004b)	Biota (2009a)	Biota (2009b)	Biota (2010)	Biota (2014b)	Biota (2014c)	Initial Ranking Based on Desktop Review	Final Ranking Including Results of Field Survey
Species of Interest																
Eulalia sp. (Three Rivers Station, B. Forsyth AQ6789133)	Perennial tussock grass; Creeks and riverbeds												✓		Likely to occur; this species has been recorded from a plain adjacent to Marillana Creek, upstream of the study area. The creeklines and adjacent plains in the study area would provide suitable habitat.	Recorded during the field survey from three locations.
Glycine sp. aff. *arenaria*	Creeper; Creeks and riverbeds													✓	May potentially occur; this species has been recorded in Marillana Creek, upstream of the study area.	May potentially occur.

Vegetation Structural Classes and Condition Scale

Vegetation Structural Classes*

Stratum	Canopy Cover (%)				
	70-100%	30-70%	10-30%	2-10%	<2%
Trees over 30 m	Tall closed forest	Tall open forest	Tall woodland	Tall open woodland	Scattered tall trees
Trees 10-30 m	Closed forest	Open forest	Woodland	Open woodland	Scattered trees
Trees under 10 m	Low closed forest	Low open forest	Low woodland	Low open woodland	Scattered low trees
Shrubs over 2 m	Tall closed scrub	Tall open scrub	Tall shrubland	Tall open shrubland	Scattered tall shrubs
Shrubs 1-2 m	Closed heath	Open heath	Shrubland	Open shrubland	Scattered shrubs
Shrubs under 1 m	Low closed heath	Low open heath	Low shrubland	Low open shrubland	Scattered low shrubs
Hummock grasses	Closed hummock grassland	Hummock grassland	Open hummock grassland	Very open hummock grassland	Scattered hummock grasses
Grasses, Sedges, Herbs	Closed tussock grassland / bunch grassland / sedgeland / herbland	Tussock grassland / bunch grassland / sedgeland / herbland	Open tussock grassland / bunch grassland / sedgeland / herbland	Very open tussock grassland / bunch grassland / sedgeland / herbland	Scattered tussock grasses / bunch grasses / sedges / herbs

* Based on Muir (1977), and Aplin's (1979) modification of the vegetation classification system of Specht (1970): Aplin T.E.H. (1979). The Flora. Chapter 3 In O'Brien, B.J. (ed.) (1979). *Environment and Science*. University of Western Australia Press; Muir B.G. (1977). Biological Survey of the Western Australian Wheatbelt. Part II: Vegetation and habitat of Bendering Reserve. *Records of the Western Australian Museum*, Suppl. No. 3; Specht R.L. (1970). Vegetation. In: *The Australian Environment*. 4th edn (Ed. G.W. Leeper). Melbourne.

Vegetation Condition Scale for use on Pilbara surveys*

E = Excellent (=Pristine of BushForever) Pristine or nearly so; no obvious signs of damage caused by the activities of European man.
VG = Very Good (= Excellent of BushForever) Some relatively slight signs of damage caused by the activities of European man. For example, some signs of damage to tree trunks caused by repeated fire, the presence of some relatively non-aggressive weeds such as **Ursinia anthemoides* or **Briza* spp., or occasional vehicle tracks.
G = Good (= Very Good of BushForever) More obvious signs of damage caused by the activities of European man, including some obvious impact on the vegetation structure such as that caused by low levels of grazing or by selective logging. Weeds as above, possibly plus some more aggressive ones such as **Ehrharta* spp.
P = Poor (= Good of BushForever) Still retains basic vegetation structure or ability to regenerate to it after very obvious impacts of activities of European man, such as grazing, partial clearing (chaining) or frequent fires. Weeds as above, probably plus some more aggressive ones such as **Ehrharta* spp.
VP = Very Poor (= Degraded of BushForever) Severely impacted by grazing, very frequent fires, clearing or a combination of these activities. Scope for some regeneration but not to a state approaching good condition without intensive management. Usually with a number of weed species including very aggressive species.
D = Completely Degraded (= Completely Degraded of BushForever) Areas that are completely or almost completely without native species in the structure of their vegetation; ie. areas that are cleared or 'parkland cleared' with their flora comprising weed or crop species with isolated native trees or shrubs.

* Based on Trudgen M.E. (1988). A Report on the Flora and Vegetation of the Port Kennedy Area. Unpublished report prepared for Bowman Bishaw and Associates, West Perth.

Vegetation of Yandi Billiards

Vegetation of Major Creeklines and Tributaries

C1: EcEvMaMgAc

Eucalyptus camaldulensis subsp. *refulgens, E. victrix* woodland over *Melaleuca argentea, M. glomerata, Acacia coriacea* subsp. *pendens* low open woodland

C2: EvChAtuGwTErCYpERItTHt

Eucalyptus victrix, Corymbia hamersleyana scattered low trees over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* tall shrubland over *Tephrosia rosea* var. Fortescue Creeks (M.I.H. Brooker 2186) low shrubland over *Cymbopogon ambiguus, C. procerus, Eriachne tenuiculmis, Themeda triandra* very open tussock grassland

C3: EvAciAcMgCEc

Eucalyptus victrix scattered trees over *Acacia citrinoviridis, A. coriacea* subsp. *pendens, Melaleuca glomerata* tall open shrubland over **Cenchrus ciliaris* scattered tussock grasses

C4: EvAciAprAThCEc

Eucalyptus victrix open *woodland* over *Acacia citrinoviridis, A. pruinocarpa, Atalaya hemiglauca* low woodland over **Cenchrus ciliaris* tussock grassland

Vegetation of Minor Creeklines, Floodplains and Valleys

F1: ChAtuGwTp

Corymbia hamersleyana scattered low trees to low open woodland over *Acacia tumida* var. *pilbarensis, Grevillea wickhamii* tall open shrubland over *Triodia pungens* hummock grassland

F2: AprAciCEc

Acacia pruinocarpa, A. citrinoviridis tall open shrubland over **Cenchrus ciliaris* tussock grassland

F3: ElChAtuAaAbGwTspp

Eucalyptus leucophloia, Corymbia hamersleyana low open woodland over *Acacia tumida* var. *pilbarensis*, *A. ancistrocarpa, A. bivenosa, Grevillea wickhamii* tall open scrub over mixed *Triodia* hummock grassland

F4: ChAtuAaPcAtenBONeARh-PAmTp

Corymbia hamersleyana scattered low trees over *Acacia tumida* var. *pilbarensis* tall open shrubland over *A. ancistrocarpa, Petalostylis cassioides, A. tenuissima* open shrubland over *Bonamia erecta* very open herbland over *Aristida holathera* var. *holathera, Paraneurachne muelleri* very open tussock grassland and *Triodia pungens* very open hummock grassland

F5: ChAciAaAiSENsppTp

Corymbia hamersleyana scattered low trees over *Acacia citrinoviridis, A. ancistrocarpa, A. inaequilatera* tall open shrubland over *Senna* spp. open shrubland over *Triodia pungens* open hummock grassland

Vegetation of Yandi Billiards

Vegetation of Hills, Ridges and Breakaways

H1: ElHcAiGwTsps

Eucalyptus leucophloia subsp. *leucophloia* scattered low trees over *Hakea chordophylla, Acacia inaequilatera, Grevillea wickhamii* tall open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland

H2: ElAiTwTsps

Eucalyptus leucophloia subsp. *leucophloia* scattered low trees over *Acacia inaequilatera* scattered tall shrubs over *Triodia wiseana*, (*T.* sp. Shovelanna Hill (S. van Leeuwen 3835)) open hummock grassland

H3: ElGwAarTsps

Eucalyptus leucophloia subsp. *leucophloia* scattered low trees over *Grevillea wickhamii* tall open shrubland over *Acacia arida* shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) open hummock grassland

H4: ChAarTspsTw

Corymbia hamersleyana scattered low trees over *Acacia arida* open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), *T. wiseana* hummock grassland

H5: ElCfERImTHspp

Eucalyptus leucophloia subsp. *leucophloia, Corymbia ferriticola* scattered low trees over *Eremophila latrobei* subsp*. filiformis,* Senna spp. scattered shrubs over *Cymbopogon ambiguus, Eriachne mucronata, Themeda* sp. Mt Barricade, *T. triandra* open tussock grassland

Vegetation of Yandi Billiards

Vegetation of Plains

P1: ElEgAprAbAaAdTwTpTsps

Eucalyptus leucophloia subsp. *leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia pruinocarpa* scattered tall shrubs over *A. bivenosa, A. ancistrocarpa, A. dictyophleba* shrubland over *Triodia wiseana, T. pungens*, *T.* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland

P2: ChAprAiAsclApaTp

Corymbia hamersleyana, Acacia pruinocarpa scattered low trees over *A. inaequilatera, A. sclerosperma* subsp. *sclerosperma, A. pachyacra* tall open shrubland over *Triodia pungens* hummock grassland

P3: AprAciAiAsclTlo

Acacia pruinocarpa low open woodland over *A. citrinoviridis, A. inaequilatera, A. sclerosperma* subsp. *sclerosperma* open shrubland over *Triodia longiceps* hummock grassland

P4: AprAsyAiTw

Acacia pruinocarpa low open woodland over *A. synchronicia, A. inaequilatera* scattered tall shrubs over *Triodia wiseana* open hummock grassland

P5: ElEgAbAaTb

Eucalyptus leucophloia subsp. *leucophloia* scattered low trees over *E. gamophylla* scattered low mallees over *Acacia bivenosa, A. ancistrocarpa* open shrubland over *Triodia basedowii* open hummock grassland

P6: AapERfoERl/g

Acacia aptaneura low open forest over *Eremophila forrestii* subsp. *forrestii* open shrubland over *E. lanceolata* low open shrubland over mixed very open grassland

P7: ERf/g

Eremophila fraseri subsp. *fraseri* open shrubland over mixed very open grassland

P8: EgAiTs

Eucalyptus gamophylla scattered low mallees over *Acacia inaequilatera* scattered tall shrubs over *Triodia schinzii* hummock grassland

P9: ChEgAiAaAprPcTb

Corymbia hamersleyana scattered low trees over *Eucalyptus gamophylla* scattered low mallees over *Acacia inaequilatera, A. ancistrocarpa, A. pruinocarpa* tall open shrubland over *Petalostylis cassioides* open shrubland over *Triodia basedowii* open hummock grassland

Appendix 6

Raw Data from Quadrats and Relevés

Yandi Billiards Level 2 BIL01

Described by Phase 1: SVSW, Phase 2: CEFSW Date Phase 1: 10-Mar-14, Phase 2: 09-Jul-14

Type Quadrat 20 x 125 m

Central Coordinate 742409 mE, 7482095 mN.

Habitat Top of hill (plateau) gently sloping W.

Soil Dark reddish brown (2.5YR 3/3) sandy clay loam with >75% cover of gravel, pebbles and cobbles.

Rock Type Ironstone.

Vegetation Phase 1: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Acacia arida* shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) open hummock grassland.
Phase 2: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Acacia arida* shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland.

Veg Condition Phase 1: Excellent. Phase 2: Excellent.

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

Notes One juvenile *Corymbia hamersleyana* outside of quadrat.

Species	Phase 1			Phase 2		
	Cover (%)	Height (cm)	Specimen	Cover (%)	Height (cm)	Specimen
Acacia arida	14	190 cm		19	210 cm	
Eriachne pulchella	0.1	10 cm				
Eucalyptus leucophloia subsp. *leucophloia*	1	580 cm		0.5	400 cm	
Fimbristylis dichotoma	0.1	15 cm	BIL01-02	0.1	15 cm	
Ptilotus calostachyus	0.1	70 cm		0.1	45 cm	
Senna artemisioides subsp. *oligophylla* x subsp. *helmsii*	0.1	40 cm	BIL01-03	0.1	35 cm	
Triodia sp. Shovelanna Hill (S. van Leeuwen 3835)	28	30 cm	BIL01-01	42	30 cm	
Triodia wiseana				0.1	40 cm	

BIL01 Phase 1

BIL01 Phase 2

Yandi Billiards Level 2		BIL02	
Described by	Phase 1: SVSW, Phase 2: CEFSW	Date	Phase 1: 12-Mar-14, Phase 2: 08-Jul-14
Type	Quadrat 20 x 125 m		
Central Coordinate	738304 mE, 7482643 mN		
Habitat	Creek bed (20 m wide) flowing E into major creek (Weeli Wolli).		
Soil	Dark reddish brown (2.5YR 3/4) skeletal sandy loam with 1-25% cover of cobbles, 26-50% cover of pebbles and 26-50% cover of gravel.		
Rock Type	Riverstone, ironstone, basalt, chert, mudstone and sandstone.		
Vegetation	Phase 1: *Eucalyptus victrix* open woodland over *Corymbia hamersleyana* low open woodland over *Acacia tumida* var. *pilbarensis, A. pyrifolia* var. *pyrifolia* tall open scrub over *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) low shrubland over **Cenchrus ciliaris, *C. setiger, Cymbopogon procerus, Themeda tri*andra open tussock grassland. Phase 2: *Eucalyptus victrix* open woodland over *Corymbia hamersleyana* low open woodland over *Acacia tumida* var. *pilbarensis, A. pyrifolia* var. *pyrifolia* tall shrubland over *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) low shrubland over *Cymbopogon procerus, *Cenchrus ciliaris, *C. setiger* open tussock grassland.		
Veg Condition	Phase 1: Good (**Cenchrus* spp.). Phase 2: Good (**Cenchrus* spp.).		
Fire Age	Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.		
Notes	Elevation: 473 m.		

Species	Phase 1			Phase 2		
	Cover (%)	Height (cm)	Specimen	Cover (%)	Height (cm)	Specimen

BIL04 Phase 1

BIL04 Phase 2

Yandi Billiards Level 2 BIL05

Described by SVSW Date 09-Mar-04

Type Quadrat 40 x 60 m

Central Coordinate 741600 mE, 7485494 mN.

Habitat NW facing upper slope of hill.

Soil 2.5YR 2.5/4 dark reddish brown sandy loam.

Rock Type Ironstone shale cobbles, pebbles and gravel overlying bedrock (90 % cover).

Vegetation *Eucalyptus leucophloia* subsp. *leucophloia* low open woodland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) closed hummock grassland.

Veg Condition Very Good (**Cenchrus ciliaris*).

Fire Age No sign of recent fire.

Notes Site set up as 40 x 60 m due to old track at crest not allowing for 50 x 50 m.

Species	Cover (%)	Height (cm)	Specimen

BIL09

Yandi Billiards Level 2 BIL10

Described by Phase 1: SVSW, Phase 2: PA/PL Date Phase 1: 09-Mar-14, Phase 2: 08-Jul-14

Type Quadrat 50 x 50 m

Central Coordinate 741890 mE, 7484313 mN.

Habitat Plain.

Soil Dark reddish brown (2.5YR 2.5/4) sandy clay.

Rock Type Ironstone.

Vegetation Phase 1: *Acacia pruinocarpa, Atalaya hemiglauca, Acacia inaequilatera, Acacia sclerosperma* subsp. *sclerosperma* tall open shrubland over *Triodia pungens* hummock grassland with **Cenchrus ciliaris, *C. setiger* very open tussock grassland.

Phase 2: *Acacia pruinocarpa, Atalaya hemiglauca, Acacia inaequilatera, Acacia sclerosperma* subsp. *sclerosperma* tall open shrubland over *Triodia pungens* open hummock grassland with **Cenchrus ciliaris, *C. setiger* very open tussock grassland.

Veg Condition Phase 1: Good (**Cenchrus* spp.). Phase 2: Good (**Cenchrus* spp.).

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

Notes Elevation: 467 m.

BIL12 Phase 2

Yandi Billiards Level 2 BIL13

Described by SVSW Date 12-Mar-14

Type Quadrat 50 x 50 m

Central Coordinate 736238 mE, 7479815 mN.

Habitat Colluvial plain between two low lying undulating hill ranges.

Soil 5YR 3/3 dark reddish brown sandy loam with cobbles (20 %), pebbles (30 %), and gravel (20 %).

Rock Type Ironstone.

Vegetation *Corymbia hamersleyana* scattered low trees over *Acacia citrinoviridis, A. inaequilatera* scattered tall shrubs over *Indigofera monophylla, Ptilotus astrolasius, Senna artemisioides* subsp. *oligophylla* low open shrubland over *Triodia basedowii* open hummock grassland.

Veg Condition Very Good (**Cenchrus ciliaris*).

Fire Age No sign of recent fire.

Notes Elevation: 500 m. Greater plain dissected by minor drainages/flowlines of *Acacia tumida, A. citrinoviridis, Gossypium robinsonii, Eucalyptus gamophylla*.

Described by PLCA Date 12-Mar-14

Type Quadrat 50 x 50 m

Central Coordinate 737046 mE, 7480911 mN.

Habitat Broad plain with some drainage.

Soil Dark reddish brown fine sandy loam with ironstone boulders, cobbles, pebbles, and gravel.

Rock Type Ironstone with ?basalt outcropping.

Vegetation *Corymbia hamersleyana* low open woodland over *Acacia tumida* var. *pilbarensis, Petalostylis cassioides, Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii* open shrubland over *Triodia basedowii, T. pungens* very open hummock grassland.

Veg Condition Very Good (**Cenchrus* spp., evidence of cattle).

Fire Age No sign of recent fire.

BIL14

Yandi Billiards Level 2 BIL15

Described by Phase 1: PLSV, Phase 2: PA/PL Date Phase 1: 18-Mar-14, Phase 2: 09-Jul-14

Type Quadrat 50 x 50 m

Central Coordinate 737722 mE, 7476773 mN.

Habitat Hill slope up to crest in a broader area of ranges to the E of major drainage.

Soil Dark reddish brown sandy loam with 1-25% cover of cobbles, 51-75% cover of pebbles and 1-25% cover of gravel.

Rock Type Ironstone.

Vegetation Phase 1: *Acacia inaequilatera* scattered tall shrubs over *Indigofera monophylla, Ptilotus astrolasius, P. rotundifolius* low open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), (*T. wiseana*) open hummock

Phase 2: *Acacia inaequilatera* scattered tall shrubs over *Indigofera monophylla, Ptilotus astrolasius, P. rotundifolius* low open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), (*T. wiseana*) open hummock

Veg Condition Phase 1: Excellent. Phase 2: Excellent.

Fire Age Phase 1: Burnt 3-5 years ago. Phase 2: Burnt 3-5 years ago.

Notes Elevation: 526 m

Soil 2.5YR 3/3 dark reddish brown sandy loam with scattered ironstone pebbles (2 %) and gravel (5 %).

Rock Type Ironstone.

Vegetation *Eucalyptus gamophylla* low open *mallee* woodland over *Acacia pachyacra, A. inaequilatera* tall open shrubland over *Acacia ancistrocarpa* open shrubland over *Triodia basedowii* hummock grassland.

Veg Condition Very Good (*Cenchrus ciliaris).

Fire Age No sign of recent fire.

Notes Elevation: 489 m. *Corymbia hamersleyana* outside of quadrat.

BIL19

Yandi Billiards Level 2 BIL20

Described by Phase 1: CASW, Phase 2: PA/PL Date Phase 1: 17-Mar-14, Phase 2: 09-Jul-14

Type Quadrat 50 x 50 m

Central Coordinate 733194 mE, 7470975 mN.

Soil Dark reddish brown sandy clay loam with 1-25% cover of boulders, 26-50% cover of cobbles, 26-50% cover of pebbles and 1-25% cover of gravel.

Rock Type Ironstone.

Rock Type BIF, shale, ironstone boulders (1 %), cobbles (40 %), pebbles (30 %) and gravel (20 %).

Vegetation Phase 1: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Hakea chordophylla* scattered tall shrubs over *Acacia hilliana* scattered low shrubs over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) open hummock grassland with *Amphipogon sericeus* scattered grasses.
Phase 2: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Hakea chordophylla* scattered tall shrubs over *Acacia hilliana* scattered low shrubs over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) open hummock grassland with *Amphipogon sericeus* scattered grasses.

Veg Condition Phase 1: Excellent. Phase 2: Excellent.

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

Notes *Heliotropium glabellum* (dead) found in small post fire patch on N boundary.

BIL23 Phase 1

BIL23 Phase 2

Yandi Billiards Level 2 BIL24

Described by Phase 1: CEFCASW, Phase 2: PLSW Date Phase 1: 19-Mar-14, Phase 2: 11-Jul-14

Type Quadrat 50 x 50 m

Central Coordinate 731105 mE, 7472466 mN.

Habitat Floodplain and bed of creek line (indistinct channel).

Soil Dark reddish brown sandy loam with 1-25% cover of gravel.

Rock Type Ironstone.

Vegetation Phase 1: *Eucalyptus victrix* scattered low trees over *Acacia citrinoviridis* (*A. pruinocarpa*) tall open scrub over *Triodia pungens* scattered hummock grasses with **Cenchrus ciliaris* open tussock grassland and *Boerhavia burbidgeana* very open herbland.
Phase 2: *Eucalyptus victrix* scattered low trees over *Acacia citrinoviridis* (*A. pruinocarpa*) tall open scrub over *Triodia pungens* scattered hummock grasses with **Cenchrus ciliaris* open tussock grassland.

Veg Condition Phase 1: Good (**Cenchrus ciliaris, *Setaria verticillata, *Aerva javanica*, cattle presence). Phase 2: Very Poor (**Cenchrus ciliaris, *Malvastrum americanum*).

Fire Age Phase 1: Very long unburnt. Phase 2: Very long unburnt.

Triodia sp. Shovelanna Hill (S. van Leeuwen 3835)	35	40 cm	BIL28-01

BIL28

Yandi Billiards Level 2 BIL29

Described by SVSW Date 12-Mar-14

Type Quadrat 50 x 50 m

Central Coordinate 735599 mE, 7479145 mN.

Habitat Gentle SSE facing transitional slope of low undulating hills. False crest/plateau situated above quadrat.

Soil 2.5 YR 3/4 dark reddish brown sandy loam (skeletal).

Rock Type Ironstone boulders (2 %), cobbles (35 %), pebbles (35 %), and gravel (20 %).

Vegetation *Eucalyptus leucophloia* subsp. *leucophloia* low open woodland over *Acacia hilliana* low open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) open hummock grassland.

Veg Condition Excellent.

Fire Age No sign of recent fire.

Notes Elevation: 522 m.

Species	Cover (%)	Height (cm)	Specimen

BIL29

Yandi Billiards Level 2 BIL30

Described by Phase 1: PLCA, Phase 2: CEFSW Date Phase 1: 09-Mar-14, Phase 2: 08-Jul-14

Type Quadrat 50 x 50 m

Central Coordinate 740462 mE, 7486024 mN.

Habitat Major drainage line running N to S.

Soil Dark reddish brown sandy clay loam with 1-25% cover of cobbles, 26-50% cover of pebbles and 26-50% cover of gravel.

Rock Type Ironstone.

Vegetation Phase 1: *Acacia citrinoviridis, Eucalyptus victrix* low open woodland over *Acacia pyrifolia* var. *pyrifolia* scattered tall shrubs over *Corchorus crozophorifolius, Indigofera monophylla, Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) open shrubland.
Phase 2: Acacia citrinoviridis, Eucalyptus victrix low open woodland over *Acacia pyrifolia* var. *pyrifolia* scattered tall shrubs over *Corchorus crozophorifolius, Indigofera monophylla, Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) open shrubland.

Veg Condition Phase 1: Very Good (**Aerva javanica, *Cenchrus spp.;* evidence of cattle). Phase 2: Very Good (**Aerva javanica, *Cenchrus spp.;* evidence of cattle).

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

Yandi Billiards Level 2 BIL32

Described by Phase 1: CEFCASW, Phase 2: PA/PL Date Phase 1: 19-Mar-14, Phase 2: 08-Jul-14

Type Quadrat 50 x 50 m

Central Coordinate 738634 mE, 7481425 mN.

Habitat Colluvial floodplain on the NW side of Weeli Wolli Creek, with very slight S sloping aspect.

Soil Dark reddish brown sandy loam with 1-25% cover of gravel.

Rock Type Ironstone.

Vegetation Phase 1: *Acacia aptaneura, A. pruinocarpa* low woodland over **Cenchrus ciliaris, *C. setiger* very open tussock grassland and *Cleome viscosa* scattered herbs.
Phase 2: Acacia aptaneura, A. pruinocarpa low woodland over *Triodia pungens* scattered hummock grasses with **Cenchrus setiger* very open tussock grassland.

Veg Condition Phase 1: Poor (**Malvastrum americanum, *Bidens bipinnata, *Setaria verticillata, *Cenchrus* spp., evidence of cattle). Phase 2: Very Poor (**Cenchrus spp., *Malvastrum americanum*).

Fire Age Phase 1: Very long unburnt. Phase 2: Very long unburnt.

Notes Phase 1: Moderate to high level of cattle tracks and scats. Phase 2: Many dead annuals.

BIL33 Phase 1

BIL33 Phase 2

Yandi Billiards Level 2 BIL34

Described by Phase 1: CASV, Phase 2: PACEF Date Phase 1: 14-Mar-14, Phase 2: 10-Jul-14

Type Quadrat 50 x 50 m

Central Coordinate 733180 mE, 7474693 mN.

Habitat Hill crest amongst low rolling hills.

Soil Dark reddish brown skeletal sandy clay loam with 1-25% cover of cobbles, 51-75% cover of pebbles, 1-25% cover of gravel and 1-25% outcropping rock.

Rock Type Ironstone.

Vegetation Phase 1: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Grevillea wickhamii* subsp. *hispidula, Acacia inaequilatera, Hakea lorea* subsp. *lorea* scattered tall shrubs over *Acacia hilliana* low open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) open hummock grassland.
Phase 2: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Grevillea wickhamii* subsp. *hispidula, Acacia inaequilatera* scattered tall shrubs over *Acacia hilliana* low open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) open hummock grassland.

Veg Condition Phase 1: Excellent. Phase 2: Excellent.

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

BIL37

Yandi Billiards Level 2 BIL38

Described by Phase 1: CEFCASW, Phase 2: PLDK Date Phase 1: 14-Mar-14, Phase 2: 11-Jul-14

Type Quadrat 50 x 50 m

Central Coordinate 732165 mE, 7472915 mN.

Habitat Colluvial plain extending close to the foot of a mesa.

Soil Dark reddish brown (2.5YR 3/4) sandy loam with 51-75% cover of cobbles, 1-25% cover of pebbles and 1-25% cover of gravel.

Rock Type Ironstone.

Vegetation Phase 1: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Acacia bivenosa* tall shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), *T. wiseana, T. pungens* open hummock grassland.

Phase 2: Eucalyptus leucophloia subsp. *leucophloia* scattered low trees over *Acacia bivenosa* tall shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), *T. wiseana, T. pungens* open hummock grassland.

Veg Condition Phase 1: Excellent. Phase 2: Excellent.

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

BIL45 Phase 2

Yandi Billiards Level 2 BIL46

Described by Phase 1: CEFCASW Phase 2: PA/PL Date Phase 1: 19-Mar-14, Phase 2: 08-Jul-14

Type Quadrat 50 x 50 m

Central Coordinate 737268 mE, 7480980 mN.

Habitat Plain/diffuse floodplain of tributary of Weeli Wolli Creek.

Soil Dark reddish brown loamy sand with 1-25% cover of cobbles, 1-25% cover of pebbles and 1-25% cover of gravel.

Rock Type Ironstone.

Vegetation Phase 1: *Acacia tumida* var. *pilbarensis,* (*A. pachyacra*) tall open shrubland over *Petalostylis cassioides, Senna artemisioides* subsp. *oligophylla* (thinly sericeous form MET 15,035), *Acacia ancistrocarpa* open shrubland over *Aristida holathera* var. *holathera, Paraneurachne muelleri* very open tussock grasses and *Bonamia erecta* very open herbland.
Phase 2: Acacia tumida var. *pilbarensis, A. pachyacra* tall open shrubland over *Petalostylis cassioides, Acacia ancistrocarpa, Senna artemisioides* subsp. *oligophylla, S. artemisioides* subsp. *oligophylla* x subsp. *helmsii* open shrubland over *Bonamia erecta, Scaevola parvifolia* subsp. *pilbarae, Corchorus tectus* low open shrubland over *Triodia pungens* scattered hummock grasses with *Aristida holathera* var. *holathera, Paraneurachne muelleri* very open tussock grassland.

Veg Condition Phase 1: Very Good (**Cenchrus* spp., cow scats and grazing). Phase 2: Good (**Cenchrus* spp.; evidence of cattle).

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

Described by	CEF	Date	14-Mar-14	Type	Relevé

Central Coordinate 731555 mE, 7473010 mN.
Habitat Rocky ridgeline adjacent to a gully.
Soil Not recorded.
Rock Type Not recorded.
Vegetation *Eucalyptus leucophloia* subsp. *leucophloia*, *Corymbia ferriticola* low open woodland over *Senna glutinosa* subsp. *glutinosa*, *Eremophila latrobei* subsp. *filiformis* open shrubland over *Themeda triandra*, *Eriachne mucronata* (typical form), *Cymbopogon ambiguus* open tussock grassland with *Triodia pungens* scattered hummock grasses.
Veg Condition Very Good (**Cenchrus ciliaris*).
Fire Age No sign of recent fire.

BIL-RPCA

Yandi Billiards Level 2 BIL-RSPA

Described by PLSW Date 13-Mar-14 Type Relevé

Central Coordinate 730066 mE, 7472398 mN.

Habitat Southeast facing moderate hill slope amongst broader undulating hills.

Soil Dark reddish brown sandy clay loam.

Rock Type Mix of ironstone and basalt boulders (1%), cobbles (3%), pebbles (40%), and gravel (20%).

Vegetation *Acacia aptaneura*, (*A. pruinocarpa*) low woodland over *Senna artemisioides* subsp. *helmsii* scattered low shrubs over *Triodia pungens* open hummock grassland with *Digitaria ctenantha* scattered grasses.

Veg Condition Good (**Bidens bipinnata, *Cenchrus ciliaris*).

Fire Age No sign of recent fire.

Notes Elevation: 550 m. Relevé size is approximately 50 x 50 m.

Hope Downs Rail/Yandi Billiards Level 2 H050

Described by Phase 1: MM; Phase 2: PLSV Date Phase 1: 28-Apr-01 Phase 2: 18-Mar-1

Type Quadrat 50 x 50 m

Location 78.6 km SE of Auski Roadhouse, 16.5 km SSW of Marillana and 77.5 km NNW of Newman.

Central Coordinate 739564 mE, 7480732 mN.

Habitat Bank of Weeli Wolli Creek.

Soil 2.5YR 3/3 dark reddish brown sandy loam.

Rock Type Riverstone and ironstone cobbles (5%), pebbles (20%), and gravel (60%).

Vegetation Phase 1: *Eucalyptus victrix* woodland over *Acacia citrinoviridis* low woodland over *Acacia coriacea* subsp. *pendens* tall open shrubland over *Ptilotus obovatus* low open shrubland over **Cenchrus ciliaris, Enneapogon robustissimus* open tussock grassland with *Triodia pungens*, *T. longiceps* very open hummock grassland.
Phase 2: *Eucalyptus victrix* low open woodland over *Acacia citrinoviridis*, *A. coriacea* subsp. *pendens* low open forest over *Corchorus crozophorifolius*, *Ptilotus obovatus* low open shrubland over *Cenchrus ciliaris*, *Enneapogon lindleyanus*, *E. robustissimus* very open tussock grassland over *Triodia pungens, T. longiceps* scattered hummock grasses.

Veg Condition Phase 1: Good; presence of weeds (*Cenchrus ciliaris, *C. setiger). Phase 2: Good (**Cenchrus ciliaris*, **Malvastrum americanum, *Setaria verticillata*).

Fire Age Phase 1: Burnt 1-2 yrs ago. Phase 2: No sign of recent fire.

H050 Phase 1 (no photo)

H050 Phase 2

Hope Downs Rail H051

Described by MM Date 27-Apr-01 Type Quadrat 50 x 50 m

Location 77.9 km SE of Auski Roadhouse, 16.6 km SSW of Marillana and 78.1 km NNW of Newman.

Central Coordinate 738944 mE, 7481012 mN.

Habitat Floodplain.

Soil Red clay loam, hardpan surface.

Rock Type Not recorded.

Vegetation *Eucalyptus victrix* scattered low trees over *Acacia citrinoviridis* tall open shrubland over **Cenchrus ciliaris* tussock grassland.

Veg Condition Very Poor; presence of weeds (**Cenchrus ciliaris, *C. setiger*).

Fire Age Burnt 1-2 years ago.

Notes Would have been high shrubland many years ago, and probably *Triodia epactia* hummock grassland before invaded by **Cenchrus ciliaris*.

HDA07

HDA and HDD/ Yandi Billiards Level 2 HDA08

Described by Phase 1: MM Phase 2: PLSV Date Phase 1: 24-Apr-03 Phase 2: 16-Mar-14

Type Quadrat 50 x 50 m

Location 24.4 km SSW of Marillana and 74.8 km NW of Newman and 78.6 km SE of Auski Roadhouse

Central Coordinate 734807 mE, 7474388 mN.

Habitat Clayey Mulga floodplain, fringing southern side of Weeli Wolli Creek.

Soil Dark reddish brown light clay.

Rock Type Nil.

Vegetation Phase 1: *Acacia aptaneura* low open forest over *Senna artemisioides* subsp. *helmsii* scattered shrubs over *Abutilon otocarpum, Pterocaulon sphacelatum* low open shrubland over *Aristida contorta,* (*Enneapogon polyphyllus*) open annual grassland with *Goodenia prostrata*, *Cleome viscosa* very open herbland.
Phase 2: *Acacia aptaneura x ayersiana*, (*Acacia pruinocarpa*) low woodland over *Eremophila forrestii* subsp. *forrestii*, *Senna artemisioides* subsp. *helmsii* scattered shrubs over *Aristida pruinosa, *Cenchrus ciliaris, *C. setiger* very open tussock grassland.

Veg Condition Phase 1: Good; signs of cattle, presence of weeds (**Malvastrum americanum*) and probably subject to repeated fires.
Phase 2: Good (**Cenchrus* spp., **Malvastrum americanum, *Setaria verticillata*, **Bidens bipinnata*).

Fire Age Phase 1: Burnt 1-2 years ago. Phase 2: Not recorded.

Notes Composition of dominant shrubs seems to have shifted in the 10 years between sampling (*A. aptaneura* to *A. aptaneura x ayersiana*).

HDA08 Phase 1

HDA08 Phase 2

HAD and HDD/Yandi Billiards Level 2 HDA09

Described by Phase 1: Phase 2: CFSV Date Phase 1: 24-Apr-03 Phase 2: 12-Mar-14

Type Quadrat 50 x 50 m

Location 19.5 km SSW of Marillana and 76.7 km NNW of Newman and 78.2 km SE of Auski Roadhouse.

Central Coordinate 737517 mE, 7478460 mN.

Habitat Floodplain / broad creek bank; fringing the southern side of Weeli Wolli Creek.

Soil 2.5YR 3/3 dark reddish brown clay loam with hard-set surface.

Rock Type Ironstone gravel (1%).

Vegetation Phase 1: *Eucalyptus victrix, Corymbia hamersleyana* low open woodland over *Acacia citrinoviridis,* (*Atalaya hemiglauca, Acacia coriacea* subsp. *pendens*, *Acacia sclerosperma* subsp. *sclerosperma*) tall closed scrub with **Cenchrus ciliaris*, (**C. setiger*) closed tussock grassland.
Phase 2: *Eucalyptus victrix* open forest over *Acacia citrinoviridis*, *Corymbia hamersleyana, Acacia coriacea* subsp. *pendens*, *Atalaya hemiglauca* low open forest over *Acacia sclerosperma* subsp. *sclerosperma*, *Hakea lorea* subsp. *lorea* tall open shrubland over **Cenchrus setiger, *C. ciliaris* closed tussock grassland.

Veg Condition Phase 1: Poor: signs of cattle (heavy grazing pressure), presence of weeds (**Cenchrus ciliaris, *C. setiger*) and probably repeated fires.
Phase 2: Very Poor (**Cenchrus* spp.).

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

Notes Phase 2: Most ground cover species absent due to 95% **Cenchrus* spp.

Described by	KBM	Date	24-Apr-03	Type	Quadrat 50 x 50 m
Location	24.4 km SSW of Marillana and 74.5 km NW of Newman and 78.9 km SE of Auski Roadhouse.				
Central Coordinate	735047 mE, 7474228 mN.				
Habitat	Broad plain, fringing southern side of Weeli Wolli Creek.				
Soil	Red clay loam with hardpan.				
Rock Type	Ironstone and mixed (colluvial).				
Vegetation	*Acacia aneura* var. *longicarpa*, *A. pruinocarpa* tall open shrubland over *Eremophila forrestii* subsp. *forrestii, Solanum lasiophyllum* scattered low shrubs over *Aristida contorta*, (*Perotis rara, Enneapogon polyphyllus*) open tussock grassland with *Triodia basedowii* scattered hummock grasses with *Ptilotus nobilis* subsp. *nobilis, P. helipteroides* very open herbland.				
Veg Condition	Excellent.				
Fire Age	Burnt 1-2 years ago.				
Notes	Co-ordinates for corner 1 of quadrat were not recorded.

HDA and HDD			HDA13		
Described by	MM	Date	25-Apr-03	Type	Quadrat 50 x 50 m
Location	21 km SSW of Marillana and 76 km NW of Newman and 78.3 km SE of Auski Roadhouse.				
Central Coordinate	736755 mE, 7477227 mN.				
Habitat	Clayey plain, a branch of the floodplain fringing Weeli Wolli Creek.				
Soil	Red-brown clay loam with scatters of ironstone pebbles and stones on				
Rock Type	Not recorded.				
Vegetation	*Corymbia hamersleyana* scattered low trees over *Acacia aptaneura*, (*A. pruinocarpa, A. citrinoviridis*) tall open scrub over *Enneapogon polyphyllus* open tussock grassland with *Triodia longiceps* very open hummock grassland with *Cleome viscosa* scattered herbs.				
Veg Condition	Good; signs of cattle (heavy grazing), presence of weeds and probably subject to repeated fires.				
Fire Age	No sign of recent fire.				
Notes	Quadrat not positioned along proposed rail centerline; established in nearby Mulga woodland instead.				
	Co-ordinates for corner 1 of quadrat were not recorded.

Type Quadrat 50 x 50 m

Location 25.8 km SW of Marillana, 77.5 km SE of Auski Roadhouse and 75.6 km NW of Newman.

Central Coordinate 732943 mE, 7473923 mN.

Habitat Broad plain, located between Weeli Wolli Creek (to east) and hills (to west).

Soil Dark reddish brown silty clay.

Rock Type Scattered ironstone cobbles (1%), pebbles (3%), and gravel (3%).

Vegetation Phase 1: *Corymbia hamersleyana, Eucalyptus xerothermica*, *Acacia aptaneura* x incurvaneura low open woodland over *Acacia bivenosa* (*A. pruinocarpa, Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii*) shrubland over *Eremophila forrestii* subsp. *forrestii*, *Pterocaulon sphacelatum* low open shrubland over *Themeda triandra*, *Paraneurachne muelleri* open tussock grassland with *Triodia wiseana, T. pungens* open hummock grassland with *Sporobolus australasicus* scattered herbs.
Phase 2: *Acacia aptaneura, Corymbia hamersleyana, Eucalyptus xerothermica* low woodland over *Acacia sibirica, A. pruinocarpa* tall open shrubland over *Eremophila forrestii* subsp. *forrestii* scattered low shrubs over *Themeda triandra, Chrysopogon fallax, Paraneurachne muelleri* very open tussock grassland and *Triodia wiseana* very open hummock grassland.

Veg Condition Phase 1: Excellent. Phase 2: Very Good to Good (**Malvastrum americanum, *Bidens bipinnata*).

Fire Age Phase 1: Burnt <1 year ago. Phase 2: Very long unburnt.

Yandi Expansion			YEX05		
Described by	RO	Date	31-Aug-04	Type	Quadrat 50 x 50 m
Location	26.2 km SW of Marillana, 76.9 km SE of Auski Roadhouse and 76 km NW of Newman.				
Central Coordinate	732277 mE, 7473978 mN.				
Habitat	Pediment; gentle rocky slope at base of low hills.				
Soil	Red clay with lots of ironstone pebbles on soil surface; colluvial / alluvial.				
Rock Type	Ironstone.				
Vegetation	*Eucalyptus gamophylla* low open mallee woodland over *Acacia ancistrocarpa, Grevillea wickhamii* subsp. *hispidula*, *Hakea chordophylla* tall open shrubland over *Acacia tenuissima*, *Sida arenicola* open shrubland over *Goodenia stobbsiana* scattered low shrubs over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) (*T. pungens*) hummock grassland.				
Veg Condition	Excellent.				
Fire Age	No sign of recent fire.				
Notes	Noted in 2012: cleared by mine expansion.

YEX05

Yandi Expansion/Yandi Billiards Level 2 YEX06

Described by Phase 1: BRM Phase 2: SVSW Date Phase 1: 31-Aug-04 Phase 2: 14-Mar-14

Type Quadrat 50 x 50 m

Location 26.3 km SW of Marillana, 76.7 km SE of Auski Roadhouse and 76.2 km NW of Newman.

Central Coordinate 731957 mE, 7474007 mN.

Habitat Transitional slope, facing northeast.

Soil Dark reddish brown fine sandy clay loam with 40% cover of pebbles 30% cover of gravel and 20% cover of cobbles.

Rock Type Ironstone.

Vegetation Phase 1: *Eucalyptus leucophloia* scattered low trees over *Acacia hilliana*, (*A. adoxa* var. *adoxa*) low open heath over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland.
Phase 2: *Eucalyptus leucophloia* subsp. *leucophloia* low open woodland *Acacia hilliana, A. adoxa* var. *adoxa* low shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland.

Veg Condition Phase 1: Excellent. Phase 2: Very Good

Fire Age Phase 1: Very long unburnt. Phase 2: No sign of recent fire.

Notes The power line track running through the quadrat is old enough that it doesn't seem to affect the species assemblage.

YEX07

Yandi Expansion/Yandi Billiards Level 2		YEX08	
Described by	Phase 1: BRM Phase 2: CASV	Date	Phase 1: 01-Sep-04 Phase 2: 15-Mar-14
Type	Quadrat 25 x 105 m		
Location	25.5 km SW of Marillana, 77 km SE of Auski Roadhouse and 76.1 km NW of Newman.		
Central Coordinate	732686 mE, 7474553 mN.		
Habitat	Banks of minor drainage line (<10 m wide) flowing east to Weeli Wolli Creek.		
Soil	2.5YR 3/3 dark reddish brown sandy clay loam.		
Rock Type	Ironstone cobbles (7%), pebbles (2%), and gravel (1%).		
Vegetation	Phase 1: *Eucalyptus victrix, E. xerothermica, Corymbia hamersleyana* low open woodland over *Acacia dictyophleba, Eremophila longifolia, A. pyrifolia, Gossypium robinsonii, Petalostylis labicheoides* tall open scrub over *Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii*, *Androcalva luteiflora* low open shrubland over **Cenchrus ciliaris*, *Themeda triandra*, (*Paraneurachne muelleri*) closed tussock grassland with *Triodia pungens* very open hummock grassland with *Euphorbia* australis var. *subtomentosa* scattered herbs. Phase 2: *Corymbia hamersleyana, Eucalyptus victrix* open woodland over *Eucalyptus xerothermica* scattered low trees over *Eremophila longifolia, Acacia dictyophleba* tall open scrub over **Cenchrus ciliaris, Themeda triandra* closed tussock grassland.		
Veg Condition	Phase 1: Very Good - Good; presence of weeds (**Cenchrus ciliaris*). Phase 2: Poor (**Cenchrus ciliaris, *Malvastrum americanum*)		
Fire Age	Phase 1: Very long unburnt. Phase 2: No sign of recent fire.		

Species	Phase 1			Phase 2

YEX08 Phase 1

YEX08 Phase 2

Yandi Expansion			YEX09		
Described by	RO	Date	01-Sep-04	Type	Quadrat 50 x 50 m

Location: 25.2 km SW of Marillana, 75.9 km SE of Auski Roadhouse and 77.2 km NW of Newman.

Central Coordinate: 732084 mE, 7475352 mN.

Habitat: Alluvial clay flat between minor drainage line (east) and hills (west).

Soil: Red clay loam with small ironstone pebbles on soil surface; alluvial.

Rock Type: Ironstone.

Vegetation: *Acacia aptaneura, A. ayersiana, A. pruinocarpa, Codonocarpus cotinifolius* low open forest over *Eremophila forrestii* subsp. *forrestii*, *Eremophila longifolia*, *Senna artemisioides* subsp. *helmsii, Acacia tenuissima* shrubland over *Pterocaulon sphacelatum* scattered low shrubs over *Aristida contorta, A. Inaequiglumis, Enneapogon polyphyllus, Cymbopogon ambiguus* tussock grassland with *Triodia basedowii, T. pungens* scattered hummock grasses.

Veg Condition: Excellent.

Fire Age: No sign of recent fire.

Notes: Noted in 2012: cleared by mine expansion.

Yandi Expansion YEX37

Described by BRM Date 04-Sep-04 Type Quadrat 40 x 60 m

Location 26.9 km SW of Marillana, 77.1 km SE of Auski Roadhouse and 75.7 km NW of Newman.

Central Coordinate 731920 mE, 7473324 mN.

Habitat Crest of hill.

Soil Red-brown sand with pebbles and stones.

Rock Type Ironstone.

Vegetation *Acacia aptaneura* low open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) hummock grassland.

Veg Condition Excellent.

Fire Age No sign of recent fire.

Species	Cover (%)	Height	Specimen

YEX37

Yandi Expansion/Yandi Billiards Level 2 YEX38

Described by Phase 1: RO Phase 2: PLSW Date Phase 1: 04-Sep-04 Phase 2: 15-Mar-14

Type Quadrat 50 x 50 m

Location 25.1 km SW of Marillana, 77.7 km SE of Auski Roadhouse and 75.5 km NW of Newman.

Central Coordinate 733626 mE, 7474399 mN.

Habitat Floodplain fringing river channel (Weeli Wolli Creek).

Soil Dark reddish brown sandy clay loam.

Rock Type Ironstone.

Vegetation Phase 1: *Corymbia hamersleyana, Acacia pruinocarpa* low open woodland over *A. citrinoviridis, Atalaya hemiglauca* tall open shrubland over *Ptilotus obovatus*, *Rhagodia eremaea* low open shrubland over **Cenchrus ciliaris, Themeda triandra* tussock grassland with *Triodia longiceps* hummock grassland.
Phase 2: *Corymbia hamersleyana* low open woodland over *Acacia bivenosa* (*A. pruinocarpa, Gossypium robinsonii, A. citrinoviridis*) tall shrubland over *Gossypium sturtianum* var. *sturtianum* scattered shrubs over **Cenchrus ciliaris* tussock grassland.

Veg Condition Phase 1: Very Poor; presence of weeds (infestation of **Cenchrus ciliaris*, **Flaveria trinervia*, **Malvastrum americanum*).
Phase 2: Good (**Cenchrus* spp., **Malvastrum americanum*, cow disturbance).

Fire Age Phase 1: Very long unburnt. Phase 2: Very long unburnt.

Described by Phase 1: RW/PH Phase 2: SVSW Date Phase 1: 15-Jun-07 Phase 2: 11-Mar-14

Type Quadrat 50 x 50 m

Location 15.4 km SSW of Marillana, 77.7 km ESE of Auski Roadhouse and 78.8 km NNW of Newman.

Central Coordinate 739465 mE, 7482118 mN.

Habitat Braided creek bed (Weeli Wolli Creek).

Soil 5YR 3/3 dark reddish brown skeletal sand.

Rock Type Ironstone, basalt, sandstone, chert, dolerite, shale cobbles (5%), pebbles (60%), and gravel (30%).

Vegetation Phase 1: *Eucalyptus victrix* woodland over *Cleome viscosa*, *Heliotropium pachyphyllum, Pluchea rubelliflora, Phyllanthus maderaspatensis* herbland.
Phase 2: *Eucalyptus victrix* woodland over *Acacia citrinoviridis* scattered tall shrubs.

Veg Condition Phase 1: Very Good; presence of weeds (**Cenchrus ciliaris, *Argemone ochroleuca* subsp. *ochroleuca*, **Setaria verticillata*).
Phase 2: Very Good (cow scats throughout).

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

Notes Phase 2: A lot of dead shrubs and herbs due to lack of water.

YBI05 Phase 1 (no photo)

YBI05 Phase 2

Yandi Billiards & Junction SW/Yandi Billiards Level 2 YBI06
Described by Phase 1: RB/B Phase 2: PLCA Date Phase 1: 15-Jun-07 Phase 2: 11-Mar-14
Type Quadrat 50 x 50 m
Location 17.1 km SSW of Marillana, 77.5 km SE of Auski Roadhouse and 78.2 km NNW of Newman
Central Coordinate 738312 mE, 7480809 mN.
Habitat Flat alluvial plain; west of river floodplain (Weeli Wolli Creek).
Soil Dark reddish brown sandy clay loam.
Rock Type Ironstone.
Vegetation Phase 1: *Acacia pruinocarpa* scattered tall shrubs over *Triodia basedowii* hummock grassland.
Phase 2: *Acacia inaequilatera, A. pruinocarpa, A. ancistrocarpa* tall open shrubland over *Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii* scattered low shrubs over *Triodia basedowii* (*T. pungens*) hummock grassland with **Cenchrus ciliaris, *C. setiger* very open tussock grassland.
Veg Condition Phase 1: Good; presence of weeds (**Cenchrus ciliaris*). Phase 2: Good (**Cenchrus* spp.).
Fire Age Phase 1: No sign of recent fire. Phase 2: Very long unburnt.

YBI06 Phase 1

YBI06 Phase 2

Yandi Billiards & Junction SW/Yandi Billiards Level 2 YBI07

Described by Phase 1: RW/PH Phase 2: PLSV Date Phase 1: 15-Jun-07 Phase 2: 18-Mar-14

Type Resampled quadrat 50 x 50 m

Location 17.2 km SSW of Marillana, 76.1 km NNW of Newman and 79.9 km SE of Auski Roadhouse.

Central Coordinate 740286 mE, 7479541 mN.

Habitat Broad plain surrounded by low hills.

Soil Dark reddish brown fine sandy loam.

Rock Type Ironstone.

Vegetation Phase 1: *Acacia ancistrocarpa*, *A. pachyacra*, *Indigofera georgei* shrubland over *Senna artemisioides* subsp. *oligophylla* (thinly sericeous form MET 15,035) scattered low shrubs over *Triodia basedowii* hummock grassland with *Aristida holathera* var. *holathera*, *Paraneurachne muelleri*, *Eriachne aristidea* open tussock grassland.
Phase 2: *Acacia ancistrocarpa* (*A. pachyacra, A. tumida* var. *pilbarensis*) tall open shrubland over *Solanum elatius* open shrubland over *Senna artemisioides* subsp. *oligophylla*, *Bonamia erecta* low open shrubland over *Triodia basedowii* hummock grassland.

Veg Condition Phase 1: Excellent. Phase 2: Very Good (**Cenchrus ciliaris*).

Fire Age Phase 1: Burnt 3-5 years ago Phase 2: Not recorded.

YBI08 Phase 1 (no photo)

YBI08 Phase 2

Yandi Billiards & Junction SW/Yandi Billiards Level 2 YBI09

Described by Phase 1: RB/B Phase 2: PLSV Date Phase 1: 15-Jun-07 Phase 2: 20-Mar-14

Type Resampled quadrat 50 x 50 m

Location 17.6 km SSW of Marillana, 76.8 km NNW of Newman and 78.9 km SE of Auski Roadhouse.

Central Coordinate 739242 mE, 7479676 mN.

Habitat Flat alluvial plain; adjacent to river floodplain (eastern side of Weeli Wolli Creek).

Soil Dark reddish brown fine sandy loam.

Rock Type Ironstone cobbles (5%), and gravel (5%).

Vegetation Phase 1: *Corymbia hamersleyana* low open woodland over *Acacia sclerosperma* subsp. *sclerosperma* tall open shrubland over *Senna artemisioides* subsp. *oligophylla* (thinly sericeous form MET 15,035) low scattered shrubs over *Triodia basedowii*, (*T. pungens*) hummock grassland with *Aristida holathera* var. *holathera, Eragrostis eriopoda, *Cenchrus ciliaris* open tussock grassland. Phase 2: *Corymbia hamersleyana* low open woodland over *Acacia sclerosperma* subsp. *sclerosperma*, (*A. inaequilatera, A. aptaneura* x, *Hakea lorea* subsp. *lorea*) tall open shrubland over *Eremophila longiflora* scattered shrubs over *Senna artemisioides* subsp. *oligophylla*, *Ptilotus obovatus* scattered low shrubs over *Triodia basedowii* (*T. pungens*) open hummock grassland and **Cenchrus ciliaris* very open tussock grassland.

Veg Condition Phase 1: Good; presence of weeds (**Cenchrus ciliaris, *C. setiger, *Malvastrum americanum*). Phase 2: Good (**Cenchrus ciliaris, *Bidens bipinnata*).

Fire Age Phase 1: No sign of recent fire. Phase 2: Very long unburnt.

Notes Phase 1: Higher percentage of *Corymbia hamersleyana* in quadrat than in general vegetation unit, where it is typically scattered (to 2% cover).

Yandi Billiards & Junction SW/Yandi Billiards Level 2		YBI10
Described by	Phase 1: RW/PH Phase 2: CASW	Phase 1: 16-Jun-07 Phase 2: 15-Mar-14
Type	Quadrat 50 x 50 m	
Location	21.2 km SW of Marillana, 77 km SE of Auski Roadhouse and 77.2 km NW of Newman.	
Central Coordinate	735461 mE, 7477797 mN.	
Habitat	Broad colluvial floodplain of river (Marillana Creek).	
Soil	2.5YR 3/3 dark reddish brown loamy sand.	
Rock Type	Ironstone cobbles (2%), pebbles (2%), and gravel (1%).	
Vegetation	Phase 1: *Acacia pruinocarpa*, (*A. citrinoviridis*) low open forest over *Acacia sclerosperma* subsp. *sclerosperma*, (*Atalaya hemiglauca*) tall open scrub over *Triodia pungens* open hummock grassland with **Cenchrus ciliaris* scattered tussock grasses. Phase 2: *Acacia pruinocarpa, A. citrinoviridis*, *A. sclerosperma* subsp. *sclerosperma*, *Atalaya hemiglauca* open scrub over *Triodia pungens* very open hummock grassland and **Cenchrus ciliaris, *C. setiger* open tussock grassland.	
Veg Condition	Phase 1: Good; presence of weeds (**Cenchrus ciliaris, *Malvastrum americanum*). Phase 2: Poor (**Cenchrus* spp., **Setaria verticillata, *Tribulus terrestris*)	
Fire Age	Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

YBI10 Phase 1

YBI10 Phase 2 (no photo)

Yandi Billiards & Junction SW/Yandi Billiards Level 2 Site YBI11

Described by	Phase 1: RB/RO; Phase 2:RO/PC; Phase 3: PLSW.
Date	Phase 1:15-Jun-07; Phase 2:03-Aug-08 ;Phase 3: 15-Mar-14.
Type	Quadrat 50 x 50 m
Location	21.1 km SSW of Marillana, 76.3 km NW of Newman and 78.1 km SE of Auski Roadhouse.
Central Coordinate	736437 mE, 7477279 mN.
Habitat	Gently sloping alluvial plain between river (Weeli Wolli Creek) and drainage area to the east; sloping to the west.
Soil	Dark reddish-brown fine sandy clay-loam; alluvial.
Rock Type	Calcareous with small amount of ironstone pebbles (10%).
Vegetation	Phase 1: *Acacia pruinocarpa* low open woodland over *Acacia citrinoviridis*, *A. inaequilatera*, *A. sclerosperma* subsp. *sclerosperma* tall open shrubland over *Senna artemisioides* subsp. *oligophylla* open shrubland over *Triodia longiceps*, (*T. basedowii*) hummock grassland with **Cenchrus ciliaris*, *Aristida holathera* var. *holathera*, *Enneapogon caerulescens*, *Eragrostis eriopoda* very open tussock grassland over *Rhynchosia minima* scattered herbs. Phase 2: *Acacia pruinocarpa* low open woodland over *Acacia citrinoviridis*, *A. inaequilatera, A. sclerosperma* subsp. *sclerosperma* tall open shrubland over *Senna artemisioides* subsp. *oligophylla* open shrubland over *Triodia longiceps*, (*T. basedowii, T. wiseana*) hummock grassland with **Cenchrus ciliaris*, *Aristida holathera* var. *holathera*, *Enneapogon caerulescens, Eragrostis eriopoda* very open tussock grassland over *Rhynchosia minima* scattered herbs. Phase 3: *Corymbia hamersleyana* scattered low trees over *Acacia pruinocarpa, A. sclerosperma* subsp. *sclerosperma*, *A. aptaneura, A. citrinoviridis, A. tenuissima* tall shrubland over *Corchorus sidoides* subsp. *sidoides* scattered low shrubs over *Triodia longiceps*, (*T. basedowii*) hummock grassland over **Cenchrus ciliaris, Paraneurachne muelleri, Eragrostis eriopoda* scattered tussock grasses.
Veg Condition	Phase 1/Phase 2: Good; presence of weeds (**Cenchrus ciliaris*). Phase 3: Very Good (**Cenchrus ciliaris*).
Fire Age	Phase 1: No sign of recent fire. Phase 2: Not recorded Phase 3: No sign of recent fire.
Notes	This quadrat was sampled a third time as both Phase 1 and Phase 2 occurred at times considered unfavourable for plant growth.

YBl11 Phase 3

Yandi Billiards Level 2	YBI12
Described by	Phase 1: RB/RO Phase 2: RO/PC Phase 3: PLSV Date Phase 1: 16-Jun-07 Phase 2: 03-Aug-08 Phase 3: 17-Mar-14
Type	Quadrat 50 x 50 m
Location	23.4 km SSW of Marillana, 75.1 km NW of Newman and 78.6 km SE of Auski Roadhouse
Central Coordinate	735518 mE, 7475188 mN.
Habitat	Flat alluvial clay plain, associated with drainage area to the east of Weeli Wolli Creek; plain is bordered by hills to the east.
Soil	Dark reddish brown light clay; alluvial.
Rock Type	Some quartz present (very small amounts); probably ironstone underneath.
Vegetation	Phase 1: *Acacia aptaneura*. (*Acacia catenulata*, *Acacia pruinocarpa*) low open forest over *Eremophila forrestii* subsp. *forrestii, E. lanceolata*, *Pterocaulon sphacelatum, Gossypium australe*, *Senna artemisioides* subsp. *helmsii* low open shrubland over *Aristida contorta, Enneapogon polyphyllus, Aristida inaequiglumis* very open tussock grassland with **Malvastrum americanum*, *Evolvulus alsinoides* var. *villosicalyx* scattered herbs Phase 2: *Acacia* aptaneura, (*Acacia pruinocarpa*) low open forest over *Eremophila lanceolata, E. forrestii* subsp. *forrestii, Pterocaulon sphacelatum, Gossypium australe* low open shrubland over *Aristida contorta, Enneapogon polyphyllus*, *Aristida inaequiglumis* very open tussock grassland over **Malvastrum americanum, Evolvulus alsinoides* var. *villosicalyx* scattered herbs. Phase 3: *Acacia aptaneura, A. pruinocarpa* low open forest over *A. aptaneura x ayersiana* tall open shrubland over *Eremophila forrestii* subsp. *forrestii*, *Senna artemisioides* subsp. *helmsii* (*Gossypium australe*) open shrubland over **Malvastrum americanum*, *Abutilon macrum, A. fraseri* scattered low shrubs over *Themeda triandra, Aristida pruinosa, *Cenchrus ciliaris, *C. setiger, Paspalidium clementii* very open tussock grassland and *Bidens bipinnata* very open herbland.
Veg Condition	Phase 1: Good; presence of weeds (**Cenchrus ciliaris, *Malvastrum americanum*) and signs of cattle (scats and grazing). Phase 2: Good; presence of weeds (**Cenchrus ciliaris, *Malvastrum americanum*) and signs of cattle (scats and grazing). Phase 3: Good (**Bidens bipinnata, *Malvastrum americanum, *Cenchrus* spp, other weeds, cattle scats).
Fire Age	Phase 1: No sign of recent fire. Phase 2: No sign of recent fire. Phase 3: Very long unburnt.
Notes	This quadrat was sampled a third time as both Phase 1 and Phase 2 occurred at times considered unfavourable for plant growth.

YBI12 Phase 3

Yandi Billiards & Junction SW		YBI13	
Described by	Phase 1: RW/PH Phase 2: JA/RB	Date	Phase 1: 16-Jun-07 Phase 2: 03-Aug-08
Type	Quadrat 50 x 50 m		
Location	21.4 km SSW of Marillana, 76.1 km NW of Newman and 78.2 km SE of Auski Roadhouse.		
Central Coordinate	736342 mE, 7477013 mN.		
Habitat	Gently sloping alluvial plain between river (Weeli Wolli Creek) and drainage area to the east.		
Soil	Red-brown sandy clay.		
Rock Type	Not recorded.		
Vegetation	Phase 1: *Acacia aptaneura*, (*Corymbia hamersleyana*) low open forest over *Senna artemisioides* subsp. *helmsii*, *Eremophila jucunda* subsp. *pulcherrima* open shrubland over *Triodia longiceps* hummock grassland with **Cenchrus ciliaris* very open tussock grassland. Phase 2: *Acacia* apt*aneura*, (*Corymbia hamersleyana*) low open forest over *Senna artemisioides* subsp. *helmsii*, *Eremophila forrestii* subsp. *forrestii* open shrubland over *Triodia longiceps* hummock grassland with **Cenchrus ciliaris* very open tussock grassland.		
Veg Condition	Phase 1: Good; presence of weeds (**Cenchrus ciliaris*) and signs of cattle (scats and grazing). Phase 2: presence of weeds (**Cenchrus ciliaris*) and signs of cattle grazing, track).		
Fire Age	Phase 1: No sign of recent fire. Phase 2: No sign of recent fire		
Notes	This quadrat is not considered to be seasonally sampled as both phases of sampling were undertaken at times considered to be unfavourable for plant growth

YBI13 Phase 1

YBI13 Phase 2 (no photo)

Yandi Billiards & Junction SW YBI14

Described by Phase 1: BB Phase 2: JA/RB Date Phase 1: 16-Jun-07 Phase 2: 03-Aug-08

Type Quadrat 50 x 50 m

Location 22.7 km SSW of Marillana, 75.3 km NW of Newman and 78.5 km SE of Auski Roadhouse.

Central Coordinate 735845 mE, 7475759 mN.

Habitat Broad plain between river (Weeli Wolli Creek) and low hills to the east; plain has very gentle slope to west.

Soil Red-brown loamy sand.

Rock Type Ironstone.

Vegetation Phase 1: *Petalostylis cassioides* scattered tall shrubs over *Senna artemisioides* subsp. *oligophylla* (thinly sericeous form MET 15,035) shrubland over *Solanum sturtianum* scattered low shrubs over *Aristida holathera* var. *holathera*, (*Paraneurachne muelleri*) open tussock grassland with *Triodia basedowii* open hummock grassland.
Phase 2: *Petalostylis cassioides* scattered tall shrubs over *Senna artemisioides* subsp. *oligophylla* (thinly sericeous form MET 15,035) shrubland over *Solanum sturtianum* low scattered shrubland over *Aristida holathera* var. *holathera*, (*Paraneurachne muelleri*) open tussock grassland with *Triodia basedowii* open hummock grassland.

Veg Condition Phase1: Excellent. Phase 2: Very Good; signs of cattle.

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

Notes Phase 1: Poor seasonal conditions for recording quadrat, annuals were degraded/deteriorated.
Phase 2: Same conditions; very dry; many shrubs have died. This quadrat is not considered to be seasonally sampled as both phases of sampling were undertaken at times considered to be unfavourable for plant growth

YBl14 Phase 2

Yandi Billiards & Junction SW/Yandi Billiards Level 2 YBI15

Described by	Phase 1: RW/PH Phase 2: JA/RB Phase 3: PLSW Date Phase 1: 17-Jun-07 Phase 2: 03-Aug-08 Phase 3: 16-Mar-14
Type	Quadrat 50 x 50 m
Location	21.1 km SSW of Marillana, 76 km NW of Newman and 78.3 km SE of Auski Roadhouse.
Central Coordinate	736687 mE, 7477149 mN.
Habitat	Drainage area through broad plain, to the east of a river (Weeli Wolli Creek).
Soil	Red-brown sandy clay.
Rock Type	Nil.
Vegetation	Phase 1: *Acacia aptaneura*, *Corymbia candida*, (*A. pruinocarpa*, *Hakea lorea* subsp. *lorea*) low open forest over *Acacia citrinoviridis*, *Atalaya hemiglauca* tall open shrubland over *Eulalia aurea, Enneapogon polyphyllus* very open tussock grassland with **Malvastrum americanum* scattered herbs. Phase 2: *Acacia aptaneura*, *Corymbia candida*, (*A. pruinocarpa, Hakea lorea* subsp. *lorea*) low open forest over *Acacia citrinoviridis, Atalaya hemiglauca* tall open shrubland over *Enneapogon polyphyllus* very open tussock grassland with **Malvastrum americanum* scattered herbs. Phase 3: *Acacia aptaneura,* (*Corymbia candida, Acacia pruinocarpa, A. citrinoviridis, Atalaya hemiglauca, Hakea lorea* subsp. *lorea*) low open forest over *Triodia longiceps* scattered hummock grasses with *Bothriochloa ewartiana *Cenchrus setiger, *C. ciliaris* very open tussock grassland.
Veg Condition	Phase 1: Good; presence of weeds (**Cenchrus ciliaris*, **C. setiger*, **Malvastrum americanum*, **Setaria verticillata*). Phase 2: Good; presence of weeds (**Cenchrus ciliaris, *C. setiger, *Malvastrum americanum, *Setaria verticillata*). Phase 3: Good (**Cenchrus* spp, **Malvastrum americanum, *Bidens bipinnata, *Setaria verticillata*, cattle activity).
Fire Age	Phase 1: No sign of recent fire. Phase 2: No sign of recent fire. Phase 3: No sign of recent fire.
Notes	Phase 2: Extremely dry conditions, many annuals too poor to determine or collect. Phase 3: This quadrat was sampled a third time as both Phase 1 and Phase 2 occurred at times considered unfavourable for plant growth.

YBl15 Phase 1

YBl15 Phase 2

YBl15 Phase 3

Yandi Billiards & Junction SW YBI16

Described by Phase 1: RB/RO Phase 2: RO/PC Date Phase 1: 17-Jun-07 Phase 2: 04-Aug-14

Type Quadrat 50 x 50 m

Location 25.2 km SSW of Marillana, 74.3 km NW of Newman and 78.9 km SE of Auski Roadhouse.

Central Coordinate 734590 mE, 7473606 mN.

Habitat Broad plain; very gently sloping to the west.

Soil Red-brown sandy loam.

Rock Type Ironstone.

Vegetation Phase 1: *Eucalyptus gamophylla* low open mallee woodland over *Acacia ancistrocarpa, A. bivenosa* tall open shrubland over *Keraudrenia velutina* subsp. *elliptica* scattered shrubs over *Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii* scattered low shrubs over *Triodia basedowii* closed hummock grassland with *Digitaria brownii* scattered tussock grasses.
Phase 2: *Eucalyptus gamophylla* low open mallee woodland over *Acacia ancistrocarpa, A. bivenosa* tall open shrubland over *Keraudrenia velutina* subsp. *elliptica* scattered shrubs over *Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii* scattered low shrubs over *Triodia basedowii* hummock grassland with *Digitaria brownii* scattered tussock grasses.

Veg Condition Phase 1: Excellent. Phase 2: Excellent.

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.

Notes Elevation at southeast corner is 503 m. This quadrat is not considered to be seasonally sampled as both phases of sampling were undertaken at times considered to be unfavourable for plant growth

YBI16 Phase 1

YBI16 Phase 2

Yandi Billiards & Junction SW/Yandi Billiards Level 2 YBI17

Described by Phase 1: BB Phase 2: RO/PC Phase 3: CEFCASW Date Phase 1: 17-Jun-07 Phase 2: 04-Aug-14 Phase 3: 17-Mar-14

Type Quadrat 50 x 50 m

Location 23.7 km SSW of Marillana, 75.4 km NW of Newman and 78.1 km SE of Auski Roadhouse.

Central Coordinate 734832 mE, 7475182 mN.

Habitat Flat plain just east of river floodplain (Weeli Wolli Creek).

Soil Dark reddish brown silty clay with 5% cover of pebbles.

Rock Type Not recorded.

Vegetation Phase 1: *Acacia bivenosa, A. citrinoviridis, Acacia pyrifolia* var. *pyrifolia* tall open shrubland over *Acacia pruinocarpa* scattered shrubs over *Triodia longiceps* closed hummock grassland with **Cenchrus ciliaris* very open tussock grassland.
Phase 2: *Acacia bivenosa, A. pyrifolia* var. *pyrifolia*, *Hakea lorea* subsp. *lorea*, *Acacia citrinoviridis* tall open shrubland over *A. pruinocarpa* scattered shrubs over *Ptilotus obovatus*, *Pterocaulon sphacelatum* low open shrubland over *Triodia longiceps* closed hummock grassland with **Cenchrus ciliaris* very open tussock grassland.
Phase 3: *Acacia bivenosa, A. pyrifolia* var. *pyrifolia* open shrubland over *Sida fibulifera* scattered low shrubs over *Triodia longiceps* very open hummock grassland with **Cenchrus ciliaris* very open tussock grassland and **Malvastrum americanum* open herbland.

Veg Condition Phase 1: Good; presence of weeds (**Cenchrus ciliaris, *C. setiger, *Bidens bipinnata, *Malvastrum americanum*).
Phase 2: Good; signs of cattle (grazing) and presence of weeds (**Cenchrus ciliaris, *C. setiger, *Bidens bipinnata, *Malvastrum americanum*).
Phase 3: Poor (**Cenchrus* spp., **Malvastrum americanum, *Aerva javanica, *Flaveria trinervia, *Bidens bipinnata*; cow scats; very close to cleared drill lines).

Fire Age Phase 1: No sign of recent fire. Phase 2: No sign of recent fire. Phase 3: Burnt 3-5 years ago.

Notes Phase 1: *Triodia longiceps* hummocks are very large. This vegetation unit is continuous for another 60 m to the northwest, before the plain surrounding the river becomes infested with **Cenchrus ciliaris*.
Phase 3: This quadrat was sampled a third time as both Phase 1 and Phase 2 occurred at times considered unfavourable for plant growth.
Site has been burnt since the first and second phase of sampling. *Triodia* hummocks are still large but many of the tall shrubs (*Hakea lorea, Acacia citrinoviridis* etc.) are resprouting from the base.
Could not find *Corymbia hamersleyana*; possibly killed by fire.

Yandi Billiards & Junction SW YBI18

Described by RW/PH Date 18-Jun-07 Type Quadrat 50 x 50 m

Location 28.5 km SSW of Marillana, 73.7 km NW of Newman and 78.9 km SE of Auski Roadhouse.

Central Coordinate 732396 mE, 7471125 mN.

Habitat Slope of a low stony hill; slope faces northwest.

Soil Red-brown sandy loam.

Rock Type Ironstone.

Vegetation *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Acacia inaequilatera* tall open shrubland over *Acacia spondylophylla* shrubland over *Acacia hilliana* scattered low shrubs over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), T. wiseana hummock grassland.

Veg Condition Excellent.

Fire Age No sign of recent fire.

YBI19

Yandi Billiards & Junction SW/ Yandi Billiards Level 2 YBI20

Described by	Phase 1: RW/PH Phase 2: RO/PC Phase 3: PLSV Date Phase 1: 07-Jun-07 Phase 2: 04-Aug-14 Phase 3: 17-Mar-14
Type	Quadrat 12.5 x 200 m
Location	26.5 km SSW of Marillana, 73.5 km NW of Newman and 79.5 km SE of Auski Roadhouse.
Central Coordinate	734268 mE, 7472275 mN.
Habitat	Bed of moderate-sized creekline (feeds into Weeli Wolli Creek).
Soil	Red-brown river sand between alluvial cobbles and pebbles.
Rock Type	Alluvial material; Ironstone, Basalt, Chert.
Vegetation	Phase 1: *Eucalyptus victrix, Corymbia hamersleyana* woodland over *Acacia tumida* var. *pilbarensis*, *Grevillea wickhamii* tall shrubland over *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) scattered low shrubs over *Aristida contorta, Aristida holathera* var. *holathera*, *Cymbopogon ambiguus* very open tussock grassland. Phase 2: *Eucalyptus victrix, Corymbia hamersleyana* woodland over *Acacia tumida* var. *pilbarensis*, *Grevillea wickhamii* tall shrubland over *Tephrosia rosea* var. Fortescue creeks (M.I.H. Brooker 2186) scattered low shrubs over *Aristida contorta, Aristida holathera* var. *holathera* very open tussock grassland. Phase 3: *Eucalyptus victrix* open woodland over *Corymbia hamersleyana* low open woodland over *Acacia tumida* var. *pilbarensis*, (*Grevillea wickhamii* subsp. *hispidula, A. pyrifolia* var. *pyrifolia*) tall shrubland over *Cymbopogon ambiguus, *Cenchrus ciliaris* very open tussock grassland.
Veg Condition	Phase 1: Good; presence of weeds (**Cenchrus ciliaris*). Phase 2: Not recorded. Phase 3: Good (**Cenchrus ciliaris*).
Fire Age	Phase 1: No sign of recent fire. Phase 2: No sign of recent fire. Phase 3: No sign of recent fire.
Notes	Phase 1: Quadrat shape modified to fit creekbed habitat; 200 m tape was positioned along the edge of the creekline, and the 9 m - 12.5 m wide creekbed was then surveyed along this length.

Yandi Billiards & Junction SW		YBI22	
Described by	Phase 1: RB/B Phase 2: JA/RB	Date	Phase 1: 18-Jun-07 Phase 2: 04-Aug-08
Type	Quadrat 33 x 63 m		
Location	26 km SSW of Marillana, 73.2 km NW of Newman and 79.9 km SE of Auski Roadhouse		
Central Coordinate	734904 mE, 7472469 mN.		
Habitat	Lower slope of colluvial spur; edge of shallow depression included.		
Soil	Not recorded.		
Rock Type	Ironstone.		
Vegetation	Phase 1 *Eucalyptus gamophylla* low open mallee woodland over *Indigofera monophylla* scattered low shrubs over *Triodia basedowii* hummock grassland with *Aristida holathera* var. *holathera*, *Amphipogon sericeus, Eragrostis eriopoda, Paraneurachne muelleri* very open tussock grassland. Phase 2: *Eucalyptus gamophylla* low open mallee woodland over *Triodia basedowii* hummock grassland with *Aristida holathera* var. *holathera*, *Amphipogon sericeus, Eragrostis eriopoda* very open tussock grassland.		
Veg Condition	Phase 1: Excellent. Phase 2: Good; presence of weeds (**Cenchrus ciliaris*).		
Fire Age	Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.		
Notes	Phase 1 Poor quadrat location, difficult to locate in single vegetation type. Area comprises narrow colluvial spurs interspersed with very shallow flowlines/depressions; Eucalyptus gamophylla is mostly in the depressions. Irregular shape to quadrat. Phase 2: Very dry conditions. This quadrat is not considered to be seasonally sampled as both phases of sampling were undertaken at times considered to be unfavourable for plant growth

YBI22 Phase 2

Yandi Billiards & Junction SW — Site YBI23

Described by RW/PH — Date 18-Jun-07 — Type Quadrat12.5 x 200 m

Location 28.7 km SSW of Marillana, 74 km NW of Newman and 78.6 km SE of Auski Roadhouse.

Central Coordinate 731950 mE, 7471111 mN.

Habitat Banks of river channel (Weeli Wolli Creek).

Soil Red-brown silty loam.

Rock Type Riverstone.

Vegetation *Eucalyptus victrix* open forest over *Melaleuca argentea* low open woodland over *Acacia citrinoviridis, A. coriacea* subsp. *pendens* tall open shrubland over *Sesbania cannabina* scattered shrubs over *Stemodia grossa*, *Pluchea rubelliflora* herbland with *Cyperus vaginatus* open sedgeland.

Veg Condition Good; presence of weeds (**Cenchrus ciliaris, *Malvastrum americanum, *Setaria verticillata*) and signs of cattle (tracks, grazing and scats).

Fire Age No sign of recent fire.

Notes Quadrat shape modified to fit the creekbank vegetation of Weeli Wolli Creek; both sides of the creek were surveyed.

YBI26

Yandi Billiards & Junction SW/Yandi Billiards Level 2 YBI27

Described by	Phase 1: RB/B Phase 2: PLSV	Date	Phase 1: 19-Jun-07 Phase 2: 14-Mar-14
Type	Quadrat 50 x 50 m		
Location	14.2 km SSW of Marillana, 78.2 km NNW of Newman and 79 km ESE of Auski Roadhouse.		
Central Coordinate	741208 mE, 7482416 mN.		
Habitat	Lower slope of colluvial rise between base of ridge (to east) and river floodplain (Weeli Wolli Creek, to west); sloping gently to the northwest.		
Soil	Dark reddish brown fine sandy loam with 1% cover of pebbles and 1% cover of gravel.		
Rock Type	Ironstone.		
Vegetation	Phase 1: *Acacia pachyacra* scattered tall shrubs over *Sida cardiophylla, Corchorus tectus* low open shrubland over *Aristida holathera* var. *holathera, Eragrostis eriopoda* tussock grassland with *Triodia basedowii* open hummock grassland. Phase 2: *Acacia ancistrocarpa, Grevillea wickhamii* subsp. *hispidula* scattered tall shrubs over *Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii* scattered low shrubs over *Triodia basedowii* hummock grassland.		
Veg Condition	Phase 1: Excellent. Phase 2: Excellent.		
Fire Age	Phase 1: Burnt 3-5 years ago. Phase 2: No sign of recent fire.		
Notes	Phase 1: Poor seasonal conditions for sampling; annuals were in poor condition. Phase 2: A number of species that were recorded in the previous phase of sampling were not recorded. The vegetation appears to have changed from a post-fire successional community to mature/climax community.

YBI28 Phase 2

Yandi Billiards & Junction SW YBI29

Described by Phase 1: PH/RB Phase 2: JA/RB Date Phase 1: 20-Jun-07 Phase 2: 04-Aug-08

Type Quadrat 50 x 50 m

Location 22.9 km SW of Marillana, 76.4 km NW of Newman and 77.4 km SE of Auski Roadhouse.

Central Coordinate 734732 mE, 7476214 mN.

Habitat Broad plain, west of river (Weeli Wolli Creek); sloping gently to east.

Soil Red-brown sandy loam.

Rock Type Ironstone.

Vegetation Phase 1: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Codonocarpus cotinifolius* open shrubland over *Acacia bivenosa*, *Senna glutinosa* subsp. x *luerssenii* low open shrubland over *Triodia basedowii,* (*T. wiseana*) open hummock grassland with *Aristida holathera* var. *holathera*, *Amphipogon sericeus*, *Eragrostis eriopoda* open tussock grassland.
Phase 2: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Codonocarpus cotinifolius* open shrubland over *Acacia bivenosa*, *Senna glutinosa* subsp. x *luerssenii* low open shrubland over (*Triodia basedowii, T. wiseana*) open hummock grassland with *Aristida holathera* var. *holathera*, *Eragrostis eriopoda* open tussock grassland.

Veg Condition Phase 1: Excellent. Phase 2: Excellent.

Fire Age Phase 1: Burnt 1-2 years ago. Phase 2: Burnt 3-5 years ago.

Notes Phase 2: Poor seasonal conditions for sampling. This quadrat is not considered to be seasonally sampled as both phases of sampling were undertaken at times considered to be unfavourable for plant growth

YBl33S Phase 2

Yandi Billiards & Junction SW		YBI34S	
Described by	Phase 1: RO/PC Phase 2: PA/RB	Date	Phase 1: 05-Aug-08 Phase 2: 04-Jun-09
Type	Quadrat 50 x 50 m		
Location	21.4 km SSW of Marillana, 75.3 km NW of Newman and 79 km SE of Auski Roadhouse.		
Central Coordinate	737033 mE, 7476575 mN.		
Habitat	Broad plain located at foot of surrounding hills.		
Soil	Red-brown loam with medium to high clay content; colluvial and alluvial deposition.		
Rock Type	Ironstone.		
Vegetation	Phase 1: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Eucalyptus gamophylla* scattered low mallee tress over *Acacia bivenosa*, *Petalostylis cassioides* open shrubland over *Acacia tenuissima*, *A. adsurgens* low open shrubland over *Triodia basedowii*, (*T. wiseana, T. pungens, T.* sp. Shovelanna Hill (S. van Leeuwen 3835)) hummock grassland over *Paraneurachne muelleri* scattered tussock grasses. Phase 2: *Eucalyptus gamophylla* scattered low mallees over *Acacia bivenosa*, *A. ancistrocarpa* tall open shrubland over *Petalostylis cassioides* scattered low shrubs over *Triodia basedowii*, (*T. pungens, T. wiseana*) open hummock grassland.		
Veg Condition	Phase 1: Excellent. Phase 2: Very Good; presence of weeds (**Setaria verticillata*).		
Fire Age	Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.		

Species	Phase 1			Phase 2		
	Cover (%)	Height	Specimen	Cover (%)	Height	Specimen
Acacia adoxa var. *adoxa*	0.5	65 cm		0.1	100 cm	YBIS34S-28

YBI34S Phase 1

YBI34S Phase 2

Yandi Billiards & Junction SW		YBI35S	
Described by	Phase 1: RB/RO Phase 2: RW/PC	Date	Phase 1: 05-Aug-08 Phase 2: 04-Jun-09
Type	Quadrat 50 x 50 m		
Location	22.8 km SSW of Marillana, 74.3 km NW of Newman and 79.6 km SE of Auski Roadhouse.		
Central Coordinate	736781 mE, 7475190 mN.		
Habitat	Floodplain adjacent to minor creekline; at base of low foothills.		
Soil	Red sandy loam. Creek is loamy.		
Rock Type	Banded Ironstone Formation; stony on higher ground.		
Vegetation	Phase 1: *Corymbia hamersleyana* low open woodland over *Acacia pyrifolia* var. *pyrifolia*, *A. tumida* var. *pilbarensis*, *A. pachyacra* tall shrubland over *Senna artemisioides* subsp. *helmsii*, *Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii*, *Indigofera georgei* open shrubland over *Petalostylis cassioides* low scattered shrubs over *Triodia pungens* hummock grassland. Phase 2: *Corymbia hamersleyana* low open woodland over *Acacia pyrifolia* var. *pyrifolia, Grevillea wickhamii* tall shrubland over *Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii* scattered low shrubs over *Triodia pungens*, (*T. basedowii*) open hummock grassland.		
Veg Condition	Phase 1: Excellent. Phase 2: Very Good; presence of weeds (**Cenchrus ciliaris*).		
Fire Age	Phase 1: No sign of recent fire. Phase 2: No sign of recent fire.		
Notes	Phase 1: Drainage line vegetation on southern edge of quadrat is the same as rest of vegetation in the quadrat, except there are more tall shrubs (higher density) and the substrate is sandy loam and less rocky.		

Species	Phase 1			Phase 2

YBI35S Phase 1

YBI35S Phase 2

Yandi Billiards & Junction SW /Yandi Billiards Level 2 YBI36

Described by Phase 1: PH/RB Phase 2: PLDK Date Phase 1: 19-Jun-07 Phase 2: 12-Mar-14

Type Quadrat 50 x 50 m

Location 18 km SW of Marillana, 77.3 km SE of Auski Roadhouse and 78.1 km NNW of Newman.

Central Coordinate 737586 mE, 7480165mN.

Habitat Slope of colluvial spur; east-facing.

Soil Red-brown sandy loam with 10% cover of boulders 10% cover of cobbles and 80% cover of pebbles.

Rock Type Ironstone.

Vegetation Phase 1: *Eucalyptus leucophloia* subsp. *leucophloia* low open woodland over *Acacia pruinocarpa, A. bivenosa* tall open shrubland over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), (*T. wiseana*) closed hummock grassland.
Phase 2: *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Acacia pruinocarpa* tall open shrubland over *Acacia bivenosa* (wispy/weeping form) scattered shrubs over *Goodenia stobbsiana* scattered low shrubs over *Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835), (*T. wiseana*) open hummock grassland.

Veg Condition Phase 1: Excellent. Phase 2: Excellent.

Fire Age Phase 1: No sign of recent fire. Phase 2: Burnt 3-5 years ago.

Species	Phase 1			Phase 2

YAQ14 Phase 1

YAQ14 Phase 2 (no Photo)

Yandi Additional Quadrats/Yandi Billiards Level 2 YAQ16

Described by Phase 1: PLSW Phase 2: PLSW Date Phase 1: 15-Jun-12 Phase 2: 16-Mar-14

Type Quadrat 50 x 50 m

Location 21.8 km SW of Marillana, 75.8 km SE of Auski Roadhouse and 78.2 km NW of Newman.

Central Coordinate 734166 mE, 7478025 mN.

Habitat Flat plain, immediately south of floodplain fringing major creek (Marillana Creek).

Soil Dark reddish brown sandy loam (with some clay).

Rock Type Ironstone pebbles (5%) and gravel (2%).

Vegetation Phase 1: *Corymbia hamersleyana* low open woodland over *Acacia dictyophleba*, *A. pruinocarpa*, (*A. sclerosperma* subsp. *sclerosperma*) tall open shrubland over *Scaevola spinescens* scattered shrubs over *Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii* scattered low shrubs over *Triodia pungens* open hummock grassland with *Themeda triandra* scattered tussock grasses.
Phase 2: *Corymbia hamersleyana* low open woodland over *Acacia dictyophleba, A. pruinocarpa, A. sclerosperma* subsp. *sclerosperma*, *Atalaya hemiglauca* tall open shrubland over *Scaevola spinescens, Senna artemisioides* subsp. *oligophylla* x subsp. *helmsii* open shrubland over *Triodia pungens* hummock grassland and *Eulalia* sp. (Three Rivers Station, B.Forsyth AQ6789133), **Cenchrus ciliaris*, *Themeda triandra* scattered tussock grasses.

Veg Condition Phase 1: Good; presence of weeds (**Cenchrus ciliaris*, **Malvastrum americanum*). Phase 2: Good (**Cenchrus ciliaris, *Bidens bipinnata, *Malvastrum americanum*).

Fire Age Phase 1: Very long unburnt. Phase 2: No sign of recent fire.

Yandi Additional Quadrats YAQ29

Described by PLSW Date 17-Jun-12 Type Quadrat 50 x 50 m

Location 15.3 km SW of Marillana, 77.2 km ESE of Auski Roadhouse and 79.4 km NNW of Newman.

Central Coordinate 739045 mE, 7482529 mN.

Habitat Floodplain.

Soil Red-brown clay loam with some cover of cobbles and rocks.

Rock Type Not recorded.

Vegetation *Corymbia hamersleyana* low scattered trees over *Acacia pruinocarpa*, *Grevillea wickhamii* subsp. *hispidula*, *A. inaequilatera* tall open shrubland over Corc*horus tectus, Ptilotus astrolasius* scattered low shrubs over *Triodia pungens* very open hummock grassland.

Veg Condition Good; occasional **Cenchrus ciliaris*; fencing wire present in quadrat.

Fire Age Burnt 3-5 years ago.

Notes Elevation 474 m ASL. *Eucalyptus gamophylla* is present outside quadrat.

Appendix 8

List of Flora Taxa Recorded in the Study Area

Vascular flora species (ordered by family)

Acanthaceae

Dicladanthera forrestii
Dipteracanthus australasicus subsp. *australasicus*

Aizoaceae

Trianthema glossostigmum
Trianthema pilosum
Zaleya galericulata subsp. *galericulata*

Amaranthaceae

Achyranthes aspera
**Aerva javanica*
Alternanthera angustifolia
Alternanthera denticulata
Alternanthera nana
Amaranthus cuspidifolius
Amaranthus undulatus
Gomphrena affinis subsp. *pilbarensis*
Gomphrena cunninghamii
Ptilotus aervoides
Ptilotus astrolasius
Ptilotus auriculifolius
Ptilotus calostachyus
Ptilotus clementii
Ptilotus fusiformis
Ptilotus gaudichaudii subsp. *gaudichaudii*
Ptilotus helipteroides
Ptilotus nobilis subsp. *nobilis*
Ptilotus obovatus var. *obovatus*
Ptilotus polystachyus
Ptilotus roei
Ptilotus rotundifolius

Apocynaceae

Rhyncharrhena linearis
Tylophora flexuosa

Araliaceae

Trachymene oleracea subsp. *oleracea*

Asteraceae

**Bidens bipinnata*
Blumea tenella
Calotis plumulifera
Centipeda minima subsp. *macrocephala*
Chrysocephalum apiculatum
Chrysocephalum gilesii
Chrysocephalum pterochaetum
**Flaveria trinervia*
Helichrysum luteoalbum
Ixiochlamys cuneifolia
Peripleura arida
Peripleura hispidula var. *hispidula*
Pluchea dentex
Pluchea dunlopii
Pluchea ferdinandi-muelleri

Pluchea rubelliflora
Pterocaulon sphacelatum
Rhodanthe floribunda
**Sigesbeckia orientalis*
**Sonchus oleraceus*
Streptoglossa bubakii
Streptoglossa decurrens
Streptoglossa odora

Boraginaceae

Heliotropium chrysocarpum
Heliotropium cunninghamii
Heliotropium glabellum
Heliotropium heteranthum
Heliotropium inexplicitum
Heliotropium pachyphyllum
Heliotropium tanythrix
Heliotropium tenuifolium
Trichodesma zeylanicum var. *zeylanicum*

Brassicaceae

Lepidium catapycnon (Threatened)
Lepidium oxytrichum
Lepidium pedicellosum
Lepidium phlebopetalum
Lepidium pholidogynum
**Sisymbrium orientale*

Campanulaceae

Lobelia arnhemiaca
Wahlenbergia tumidifructa

Capparaceae

Capparis lasiantha
Capparis spinosa var. *nummularia*

Caryophyllaceae

Polycarpaea corymbosa var. *corymbosa*
Polycarpaea holtzei
Polycarpaea longiflora

Chenopodiaceae

Dysphania cristata
Dysphania kalpari
Dysphania melanocarpa forma *melanocarpa*
Dysphania plantaginella
Dysphania rhadinostachya (sterile; subsp. not determined)
Dysphania rhadinostachya subsp. *inflata*
Dysphania rhadinostachya subsp. *rhadinostachya*
Dysphania sp. (juvenile; insufficient material to determine species)
Enchylaena tomentosa var. *tomentosa*
Maireana planifolia
Maireana planifolia x *villosa*
Maireana villosa
Rhagodia eremaea
Salsola australis
Sclerolaena cornishiana
Sclerolaena eriacantha

Cleomaceae

Cleome viscosa

Convolvulaceae

Bonamia erecta
Bonamia pannosa
Bonamia sp. Dampier (A.A. Mitchell PRP 217)
Convolvulus clementii
Duperreya commixta
Evolvulus alsinoides (sterile; var. not determined)
Evolvulus alsinoides var. *decumbens*
Evolvulus alsinoides var. *villosicalyx*
Ipomoea muelleri
Ipomoea polymorpha
Operculina aequisepala
Polymeria ambigua

Cucurbitaceae

**Cucumis melo* subsp. *agrestis*
Cucumis variabilis

Cyperaceae

Bulbostylis barbata
Bulbostylis turbinata
Cyperus cunninghamii subsp. *cunninghamii*
Cyperus difformis
Cyperus iria
Cyperus ixiocarpus
Cyperus squarrosus
Cyperus vaginatus
Eleocharis atropurpurea
Fimbristylis dichotoma
Fimbristylis microcarya
Fimbristylis simulans
Schoenoplectus subulatus

Euphorbiaceae

Euphorbia alsiniflora
Euphorbia australis (specimen lost)
Euphorbia australis var. *australis*
Euphorbia australis var. *erythrantha*
Euphorbia australis var. *hispidula*
Euphorbia australis var. *subtomentosa*
Euphorbia biconvexa
Euphorbia sp. (*biconvexa/coghlanii/trigonosperma*; sterile)
Euphorbia boophthona
Euphorbia coghlanii
Euphorbia drummondii
Euphorbia tannensis subsp. *eremophila*
Euphorbia trigonosperma
Euphorbia sp. (insufficient material to determine species)

Fabaceae

Acacia adoxa var. *adoxa*
Acacia adsurgens
Acacia ancistrocarpa
Acacia ancistrocarpa x *arida*

Acacia aptaneura
Acacia aptaneura x
Acacia aptaneura x *ayersiana*
Acacia aptaneura x *incurvaneura*
Acacia aptaneura x *macraneura*
Acacia arida
Acacia arida x *hilliana*
Acacia ayersiana
Acacia bivenosa
Acacia bivenosa (wispy/weeping form)
Acacia catenulata
Acacia citrinoviridis
Acacia coriacea subsp. *pendens*
Acacia dictyophleba
Acacia elachantha
Acacia hilliana
Acacia inaequilatera
Acacia kempeana
Acacia maitlandii
Acacia monticola
Acacia pachyacra
Acacia pruinocarpa
Acacia pyrifolia (var. not determined)
Acacia pyrifolia var. *morrisonii*
Acacia pyrifolia var. *pyrifolia*
Acacia sclerosperma hybrid
Acacia sclerosperma subsp. *sclerosperma*
Acacia sericophylla
Acacia sibirica
Acacia spondylophylla
Acacia synchronicia
Acacia tenuissima
Acacia tetragonophylla
Acacia trudgeniana
Acacia tumida var. *pilbarensis*
Alysicarpus muelleri
Crotalaria medicaginea var. *neglecta*
Crotalaria novae-hollandiae subsp. *novae-hollandiae*
Cullen lachnostachys
Cullen leucochaites
Cullen martinii
Glycine canescens
Gompholobium oreophilum
Indigofera colutea
Indigofera georgei
Indigofera linifolia
Indigofera linnaei
Indigofera monophylla
Indigofera rugosa
Isotropis atropurpurea
Petalostylis cassioides
Petalostylis labicheoides

Rhynchosia minima
Senna artemisioides subsp. *helmsii*
Senna artemisioides subsp. *oligophylla*
Senna artemisioides subsp. *oligophylla* (thinly sericeous form MET 15,035)
Senna artemisioides subsp. *oligophylla* (thinly sericeous form MET 15,035) x subsp. *helmsii*
Senna artemisioides subsp. *oligophylla* x *S. glutinosa* subsp. *glutinosa*
Senna artemisioides subsp. *oligophylla* x subsp. *helmsii*
Senna artemisioides subsp. x *artemisioides*
Senna ferraria
Senna glutinosa subsp. *glutinosa*
Senna glutinosa subsp. *glutinosa* x subsp. x *luerssenii*
Senna glutinosa subsp. *glutinosa* x subsp. *pruinosa*
Senna glutinosa subsp. *glutinosa* x *S. stricta*
Senna glutinosa subsp. x *luerssenii*
Senna glutinosa subsp. *pruinosa*
Senna glutinosa subsp. *pruinosa* x subsp. ? *glutinosa*
Senna glutinosa subsp. *pruinosa* x
Senna notabilis
Senna sericea
Senna sp. Meekatharra (E. Bailey 1-26)
Senna sp. (inadequate material to determine species)
Sesbania cannabina
Swainsona formosa
Swainsona kingii
Swainsona maccullochiana
Tephrosia oxalidea
Tephrosia rosea var. Fortescue creeks (M.I.H. Brooker 2186)
Tephrosia supina
Tephrosia sp. Bungaroo Creek (M.E. Trudgen 11601)
Tephrosia sp. Fortescue (A.A. Mitchell 606)
Tephrosia sp. Newman (A.A. Mitchell PRP 29)
Tephrosia sp. NW Eremaean (S. van Leeuwen et al. PBS 0356)
**Vachellia farnesiana*

Goodeniaceae

Dampiera candicans
Goodenia lamprosperma
Goodenia microptera
Goodenia muelleriana
Goodenia nuda (Priority 4)
Goodenia prostrata
Goodenia stellata
Goodenia stobbsiana
Goodenia triodiophila
Scaevola amblyanthera var. *centralis*
Scaevola browniana subsp. *browniana*
Scaevola parvifolia subsp. *pilbarae*
Scaevola spinescens

Gyrostemonaceae

Codonocarpus cotinifolius

Haloragaceae

Haloragis gossei (sterile specimen; var. not determined)

	Haloragis gossei var. *gossei*
Lamiaceae	
	Clerodendrum floribundum var. *angustifolium*
	Dicrastylis cordifolia
	Spartothamnella teucriiflora
Lauraceae	
	Cassytha filiformis
Loranthaceae	
	Amyema hilliana
	Diplatia grandibractea
Lythraceae	
	Ammannia baccifera
	Ammannia multiflora
Malvaceae	
	Abutilon amplum
	Abutilon cryptopetalum
	Abutilon fraseri subsp. *fraseri*
	Abutilon lepidum
	Abutilon leucopetalum
	Abutilon macrum
	Abutilon otocarpum
	Abutilon sp. Dioicum (A.A. Mitchell PRP 1618)
	Abutilon sp. Pilbara (W.R. Barker 2025)
	Abutilon sp. (insufficient material to determine species)
	Androcalva luteiflora
	Corchorus crozophorifolius
	Corchorus lasiocarpus (subsp. not determined)
	Corchorus lasiocarpus subsp. *lasiocarpus*
	Corchorus lasiocarpus subsp. *parvus*
	Corchorus sidoides (subsp. not determined)
	Corchorus sidoides subsp. *sidoides*
	Corchorus sidoides subsp. *vermicularis*
	Corchorus tectus
	Corchorus tridens
	Corchorus sp. (insufficient material to determine species)
	Gossypium australe (two forms observed)
	Gossypium robinsonii
	Gossypium sturtianum var. *sturtianum*
	Hibiscus brachychlaenus
	Hibiscus burtonii
	Hibiscus coatesii (variation was observed within this species)
	Hibiscus goldsworthii
	Hibiscus leptocladus
	Hibiscus sturtii var. *campylochlamys*
	Hibiscus sturtii var. *grandiflorus*
	Hibiscus sturtii var. *platychlamys*
	Hibiscus sp. Mt Robinson (G. Byrne 3537)
	Hibiscus sp. (insufficient material to determine species)
	Keraudrenia nephrosperma
	Keraudrenia velutina subsp. *elliptica*
	**Malvastrum americanum*
	Melhania oblongifolia

Sida arenicola
Sida arsiniata
Sida cardiophylla
Sida echinocarpa
Sida ectogama
Sida fibulifera sens. lat. (variation was observed within this species)
Sida platycalyx
Sida sp. Barlee Range (S. van Leeuwen 1642) (Priority 3)
Sida sp. Excedentifolia (J.L. Egan 1925)
Sida sp. Pilbara (A.A. Mitchell PRP 1543)
Sida sp. spiciform panicles (E. Leyland s.n. 14/8/90)
Sida sp. verrucose glands (F.H. Mollemans 2423)
Triumfetta clementii
Triumfetta maconochieana
Waltheria indica

Molluginaceae

Mollugo molluginea

Moraceae

Ficus brachypoda

Myrtaceae

Calytrix carinata
Corymbia aspera
Corymbia candida
Corymbia deserticola subsp. *deserticola*
Corymbia ferriticola
Corymbia hamersleyana
Eucalyptus camaldulensis subsp. *refulgens*
Eucalyptus gamophylla
Eucalyptus leucophloia subsp. *leucophloia*
Eucalyptus victrix
Eucalyptus xerothermica
Melaleuca argentea

Nyctaginaceae

Boerhavia burbidgeana
Boerhavia coccinea
Boerhavia gardneri
Boerhavia repleta

Oleaceae

Jasminum didymum subsp. *lineare*

Papaveraceae

**Argemone ochroleuca* subsp. *ochroleuca*

Phyllanthaceae

Notoleptopus decaisnei var. *decaisnei*
Notoleptopus decaisnei var. *orbicularis* (A.B. Craig 428)
Phyllanthus erwinii
Phyllanthus maderaspatensis

Plantaginaceae

Stemodia grossa

Poaceae

Acrachne racemosa
Amphipogon sericeus
Aristida contorta

Aristida holathera var. *holathera*
Aristida hygrometrica
Aristida inaequiglumis
Aristida ingrata
Aristida latifolia
Aristida pruinosa
Aristida sp. (insufficient material to determine species)
Bothriochloa ewartiana
Brachyachne prostrata
**Cenchrus ciliaris*
**Cenchrus setiger*
Chloris pectinata
Chrysopogon fallax
Cymbopogon ambiguus
Cymbopogon obtectus
Cymbopogon procerus
Cymbopogon sp. (sterile; insufficient material to determine species)
Dactyloctenium radulans
Dichanthium sericeum subsp. *humilius*
Digitaria brownii
Digitaria ctenantha
Enneapogon caerulescens
Enneapogon lindleyanus
Enneapogon polyphyllus
Enneapogon robustissimus
Enteropogon ramosus
Eragrostis cumingii
Eragrostis desertorum
Eragrostis dielsii
Eragrostis elongata
Eragrostis eriopoda
Eragrostis falcata
Eragrostis leptocarpa
Eragrostis pergracilis
Eragrostis setifolia
Eragrostis tenellula
Eragrostis xerophila
Eriachne aristidea
Eriachne lanata
Eriachne mucronata (form not determined)
Eriachne mucronata (arid form)
Eriachne mucronata (typical form)
Eriachne pulchella
Eriachne tenuiculmis
Eulalia aurea
Eulalia sp. (Three Rivers Station, B. Forsyth AQ6789133)
Iseilema dolichotrichum
Iseilema macratherum
Iseilema membranaceum
Iseilema vaginiflorum
Panicum effusum
Paraneurachne muelleri

	Paspalidium basicladum
	Paspalidium clementii
	Paspalidium rarum
	Perotis rara
	Schizachyrium fragile
	Setaria dielsii
	Setaria surgens
	**Setaria verticillata*
	Sorghum plumosum
	Sorghum timorense
	Sporobolus australasicus
	Themeda triandra
	Themeda sp. Mt Barricade (M.E. Trudgen 2471)
	Tragus australianus
	Triodia angusta
	Triodia basedowii (identified as *T. lanigera* in previous reporting)
	Triodia brizoides
	Triodia epactia
	Triodia longiceps
	Triodia pungens
	Triodia schinzii
	Triodia wiseana
	Triodia sp. Shovelanna Hill (S. van Leeuwen 3835)
	Tripogon loliiformis
	Triraphis mollis
	Urochloa holosericea subsp. *velutina*
	Urochloa occidentalis var. *occidentalis*
	Urochloa piligera
	Urochloa subquadripara
	Yakirra australiensis var. *australiensis*
Polygalaceae	
	Polygala glaucifolia
Polygonaceae	
	**Acetosa vesicaria* (recorded by Pilbara Iron, unpublished data; GHD 2009)
Portulacaceae	
	Calandrinia ptychosperma
	Calandrinia sp. (insufficient material to determine species)
	Portulaca filifolia
	Portulaca intraterranea
	Portulaca pilosa
	Portulaca sp. *(oleracea/intraterranea)*
Proteaceae	
	Grevillea berryana
	Grevillea pyramidalis subsp. *leucadendron*
	Grevillea wickhamii subsp. *hispidula*
	Hakea chordophylla
	Hakea lorea subsp. *lorea*
Pteridaceae	
	Cheilanthes brownii
	Cheilanthes contigua
	Cheilanthes sieberi subsp. *pseudovellea*
	Cheilanthes sieberi subsp. *sieberi*

Rubiaceae
- *Oldenlandia crouchiana*
- *Psydrax latifolia*
- *Psydrax suaveolens*
- *Spermacoce brachystema*
- *Synaptantha tillaeacea* var. *tillaeacea*

Santalaceae
- *Anthobolus leptomerioides*
- *Santalum lanceolatum*
- *Santalum spicatum*

Sapindaceae
- *Alectryon oleifolius* subsp. *oleifolius*
- *Atalaya hemiglauca*
- *Dodonaea coriacea*
- *Dodonaea lanceolata* var. *lanceolata*
- *Dodonaea petiolaris*
- *Dodonaea viscosa*

Scrophulariaceae
- *Eremophila forrestii* subsp. *forrestii*
- *Eremophila forrestii* x *latrobei*
- *Eremophila fraseri* subsp. *fraseri*
- *Eremophila jucunda* subsp. *pulcherrima*
- *Eremophila lanceolata*
- *Eremophila latrobei* subsp. *filiformis*
- *Eremophila latrobei* subsp. *latrobei*
- *Eremophila longifolia*

Solanaceae
- **Datura leichhardtii*
- *Nicotiana benthamiana*
- *Nicotiana occidentalis* subsp. *obliqua*
- *Nicotiana occidentalis* subsp. *occidentalis*
- *Nicotiana rosulata*
- *Nicotiana simulans*
- *Solanum cleistogamum*
- *Solanum elatius*
- *Solanum horridum*
- *Solanum lasiophyllum*
- **Solanum nigrum*
- *Solanum phlomoides*
- *Solanum* sp. (insufficient material to determine species)

Surianaceae
- *Stylobasium spathulatum*

Typhaceae
- *Typha domingensis*
- **Typha orientalis* (recorded by GHD 2009)

Violaceae
- *Hybanthus aurantiacus*

Zygophyllaceae
- *Tribulopis angustifolia*
- *Tribulus astrocarpus*
- *Tribulus hirsutus*
- *Tribulus macrocarpus*

Tribulus platypterus
Tribulus suberosus
**Tribulus terrestris*
Tribulus sp. (insufficient material to determine species)
Zygophyllum eichleri

Fungi species (ordered by family)	
Agaricaceae	
	Podaxis pistillaris
Polyporaceae	
	Pycnoporus coccineus

Appendix 9

Table 2: Summary details for the 36 floristic groups identified using the SIMPROF test for sites in the Yandi locality based on percent cover of perennial species only.

† Vegetation type not mapped in current study area.

Floristic Group (No. of Sites in Group)		Top Four Species with Greatest Contribution to Site Similarity according to SIMPER Test (% contribution)	Vegetation Types with Sites in this Floristic Group (Sites within Current Study Area)
17 group level	36 group level		
FG1 n=1)	FG1 (n=2)	*Eriachne mucronata* (23.68%) *Corymbia ferriticola* (13.67%) *Cymbopogon ambiguus* (13.67%) *Eucalyptus leucophloia* subsp. *leucophloia* (13.67%)	H5 (BIL-RCFB, BIL-RCFD)
FG2 (n=64)	FG2 (n=1)	Not calculated (only one site in floristic group); appears to be separated from sites in FG06 by the presence of a number of species that are absent from FG06 (including 2% cover of *Indigofera monophylla*) and the lack of *Acacia hilliana*.	H2 (BIL15)
	FG3 (n=3)	*Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) (33.61%) *Acacia inaequilatera* (7.05%) *Acacia adoxa* var. *adoxa* (5.12%) *Acacia hilliana* (5.12%)	H1 (nil)
	FG4 (n=2)	*Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) (47.73%) *Triodia wiseana* (18.04%) *Acacia bivenosa* (5.70%) *Acacia inaequilatera* (5.70%)	H1 (nil) H2 (BIL03)
	FG5 (n=6)	*Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) (40.50%) *Grevillea wickhamii* (10.66%) *Acacia ancistrocarpa* (4.44%) *Goodenia stobbsiana* (3.70%)	H1 (nil) P1 (YEX05)
	FG6 (n=4)	*Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) (47.51%) *Triodia wiseana* (29.31%) *Grevillea wickhamii* (2.61%) *Solanum lasiophyllum* (2.61%)	H2 (YBI32S) Hf † P1 (nil)
	FG7 (n=4)	*Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) (33.09%) *Triodia wiseana* (9.01%) *Eucalyptus leucophloia* subsp. *leucophloia* (8.37%) *Triodia pungens* (7.27%)	F3 (nil) H1 (nil) P1 (BIL38, BIL49)
	FG8 (n=44)	*Triodia* sp. Shovelanna Hill (S. van Leeuwen 3835) (57.89%) *Eucalyptus leucophloia* subsp. *leucophloia* (7.95%) *Acacia hilliana* (5.63%) *Goodenia stobbsiana* (3.14%)	H1 (BIL05, BIL17, BIL20, BIL28, BIL34, BIL37, BIL43, YAQ14, YAQ19, YAQ25, YAQ27, YBI31S, YBI33S, YEX01, YEX06, YEX37) H2 (BIL19, BIL29, BIL39, HDA16, HDA24, YAQ18, YBI36) H3 (BIL01, BIL06, BIL-RPCA) H4 (BIL04, YBI24)
FG3 (n=27)	FG9 (n=2)	*Triodia wiseana* (45.97%) *Acacia bivenosa* (16.25%) *Acacia pruinocarpa* (4.20%) **Cenchrus* spp. (4.20%)	P7 (BIL43) P4 (YEX03)
	FG10 (n=25)	*Triodia wiseana* (68.22%) *Acacia inaequilatera* (7.09%) *Paraneurachne muelleri* (1.67%) *Solanum lasiophyllum* (1.59%)	H2 (BIL26, BIL27, BIL40, BIL44, YBI05) Hd, He † P1 (nil) P4 (HDA07, HDA15, YAQ-CSRB, YBI19)

Floristic Group (No. of Sites in Group)		Top Four Species with Greatest Contribution to Site Similarity according to SIMPER Test (% contribution)	Vegetation Types with Sites in this Floristic Group (Sites within Current Study Area)
17 group level	36 group level		
FG4 (n=2)	FG11 (n=2)	*Triodia schinzii* (59.47%) *Eucalyptus gamophylla* (16.89%) *Acacia dictyophleba* (3.38%) *Acacia pachyacra* (3.38%)	P8 (BIL22, BIL42)
FG5 (n=1)	FG12 (n=1)	Not calculated (only one site in floristic group); appears to be separated from neighbouring FG14 and FG15 due to the particularly high cover of *Eucalyptus victrix* (65%) and also *Cyperus vaginatus* (25%)	C1 (YBI23)
FG6 (n=15)	FG13 (n=5)	*Eucalyptus victrix* (25.50%) *Acacia citrinoviridis* (13.11%) *Corchorus crozophorifolius* (7.24%) **Cenchrus* spp. (5.95%)	C1 (nil) C3 (BIL30, YBI01)
	FG14 (n=10)	*Eucalyptus camaldulensis* subsp. *refulgens* (15.11%) *Melaleuca glomerata* (8.68%) *Eucalyptus victrix* (7.58%) *Acacia coriacea* subsp. *pendens* (6.61%)	C1 (YBI30S) C2 (nil)
FG7 (n=20)	FG15 (n=20)	**Cenchrus* spp. (47.93%) *Acacia citrinoviridis* (21.68%) *Eucalyptus victrix* (4.58%) *Atalaya hemiglauca* (3.99%)	C4 (H050, H051, HDA09, YAQ12, YAQ21, YAQ-CSRA, YBI02, YBI03, YBI04, YEX02) F2 (BIL23, BIL24, YAQ30, YAQ-CSRC, YAQ-CSRD) P9 (BIL12)
FG8 (n=23)	FG16 (n=2)	*Triodia basedowii* (30.03%) *Triodia wiseana* (13.43%) *Acacia bivenosa* (9.49%) *Eucalyptus leucophloia* subsp. *leucophloia* (6.71%)	P5 (YBI29, YBI34S)
	FG17 (n=2)	*Triodia basedowii* (40.64%) *Paraneurachne muelleri* (9.71%) *Petalostylis cassioides* (9.71%) *Acacia dictyophleba* (3.07%)	P5 (YBI14, YBI28)
	FG18 (n=2)	*Triodia basedowii* (27.86%) *Acacia ancistrocarpa* (24.13%) *Paraneurachne muelleri* (16.48%) *Acacia adsurgens* (1.97%)	P5 (YBI07, YBI21)
	FG19 (n=17)	*Triodia basedowii* (49.33%) *Acacia pruinocarpa* (3.43%) *Acacia inaequilatera* (3.38%) *Acacia ancistrocarpa* (3.17%)	P5 (BIL08, BIL18, BIL33, YAQ23, YBI06, YBI09, YBI16, YBI22, YBI27, YEX33) P9 (BIL13, BIL41, BIL45)
FG9 (n=1)	FG20 (n=1)	Not calculated (only one site in floristic group); appears to be separated from neighbouring FG22 and FG23 due to the relatively high cover of *Senna artemisioides* subsp. *oligophylla* (15%) and *Triodia epactia* (5%).	F1 (BIL-RSWA)

Floristic Group (No. of Sites in Group)		Top Four Species with Greatest Contribution to Site Similarity according to SIMPER Test (% contribution)	Vegetation Types with Sites in this Floristic Group (Sites within Current Study Area)
17 group level	36 group level		
FG10 (n=1)	FG21 (n=1)	Not calculated (only one site in floristic group); appears to be separated from neighbouring FG22 and FG23 due to the relatively high cover of *Cymbopogon ambiguus* (15%) and *Enneapogon lindleyanus* (10%), and probably the lack of species such as *Acacia aneura* and *A. pruinocarpa*	H2 (BIL-RCFA)
FG11 (n=2)	FG22 (n=2)	*Acacia bivenosa* (14.94%) *Eucalyptus victrix* (14.94%) *Eriachne tenuiculmis* (9.45%) *Acacia ancistrocarpa* (6.68%)	Ca †
FG12 (n=1)	FG23 (n=1)	Not calculated (only one site in floristic group); the small amount of *Triodia wiseana* (0.1%) appears to separate this site from BIL48 in FG2, leading to clustering with FG25-FG27; FG24 appears to be separated due to the relatively high cover of *Eremophila fraseri* (20%) and *Eragrostis eriopoda* (7%)	P7 (BIL25)
FG13 (n=14)	FG24 (n=4)	*Triodia longiceps* (38.48%) **Cenchrus* spp. (11.23%) *Acacia pruinocarpa* (4.20%) *Corymbia hamersleyana* (3.51%)	F2 (YEX38) P3 (YBI11, YBI17) P6 (YBI13)
	FG25 (n=2)	*Triodia wiseana* (19.42%) *Paraneurachne muelleri* (17.91%) *Acacia "aneura"* (all Mulga taxa merged) (8.69%) *Triodia pungens* (8.69%)	P4 (YEX04, YEX32)
	FG26 (n=8)	*Acacia "aneura"* (all Mulga taxa merged) (33.81%) *Acacia pruinocarpa* (10.40%) **Cenchrus* spp. (4.20%) *Eremophila forrestii* subsp. *forrestii* (2.89%)	P5 (HDA12) P6 (BIL32, BIL-RSPA, HDA08, HDA13, YBI12, YBI15, YEX09)
FG14 (n=1)	FG27 (n=1)	Not calculated (only one site in floristic group); appears to be separated due to the combination of a reasonable cover of *Eremophila fraseri* and *Triodia pungens*, together with negligible cover of *T. wiseana*	Ha †
FG15 (n=9)	FG28 (n=9)	*Acacia tumida* var. *pilbarensis* (27.34%) *Triodia pungens* (8.06%) *Corymbia hamersleyana* (5.25%) *Grevillea wickhamii* (4.45%)	F1 (BIL-RCFC, YBI20, YBI25) F3 (YAQ-RPLA) C2 (BIL02)

Floristic Group (No. of Sites in Group)		Top Four Species with Greatest Contribution to Site Similarity according to SIMPER Test (% contribution)	Vegetation Types with Sites in this Floristic Group (Sites within Current Study Area)
17 group level	36 group level		
FG16 (n=46)	FG29 (n=3)	*Triodia pungens* (19.00%) *Eulalia aurea* (12.62%) *Paraneurachne muelleri* (12.11%) *Ptilotus astrolasius* (4.65%)	P2 (nil) P3 (HDA14)
	FG30 (n=3)	*Petalostylis cassioides* (9.95%) *Triodia basedowii* (7.06%) *Triodia pungens* (6.59%) *Acacia tumida* var. *pilbarensis* (5.57%)	F4 (BIL11, BIL14, BIL46)
	FG31 (n=7)	*Themeda triandra* (23.34%) *Triodia pungens* (12.93%) *Acacia tumida* var. *pilbarensis* (6.79%) *Corymbia hamersleyana* (5.60%)	C4 (nil) F1 (BIL16) F3 (BIL35, YEX07, YEX08) P2 (nil)
	FG32 (n=17)	*Triodia pungens* (23.84%) *Corymbia hamersleyana* (8.99%) *Acacia pyrifolia* (3.97%) **Cenchrus* spp. (2.82%)	C2 (BIL31) F1 (YBI35S) F3 (BIL36) F5 (BIL21, BIL47) P1 (nil) P2 (YAQ16, YAQ29)
	FG33 (n=2)	**Cenchrus* spp. (27.64%) *Triodia pungens* (20.23%) *Acacia citrinoviridis* (18.10%) *Acacia pruinocarpa* (13.82%)	C4 (YBI08) P2 (YBI10)
	FG34 (n=4)	*Triodia pungens* (41.46%) **Cenchrus* spp. (18.40%) *Acacia pruinocarpa* (6.91%) *Acacia sclerosperma* subsp. *sclerosperma* (5.32%)	P2 (BIL07, BIL09, BIL10, YBI26)
	FG35 (n=10)	*Triodia pungens* (64.49%) *Acacia dictyophleba* (3.29%) *Triodia wiseana* (3.10%) *Acacia inaequilatera* (2.81%)	Hb, He † P1 (nil) P2 (nil) P5 (WW30)

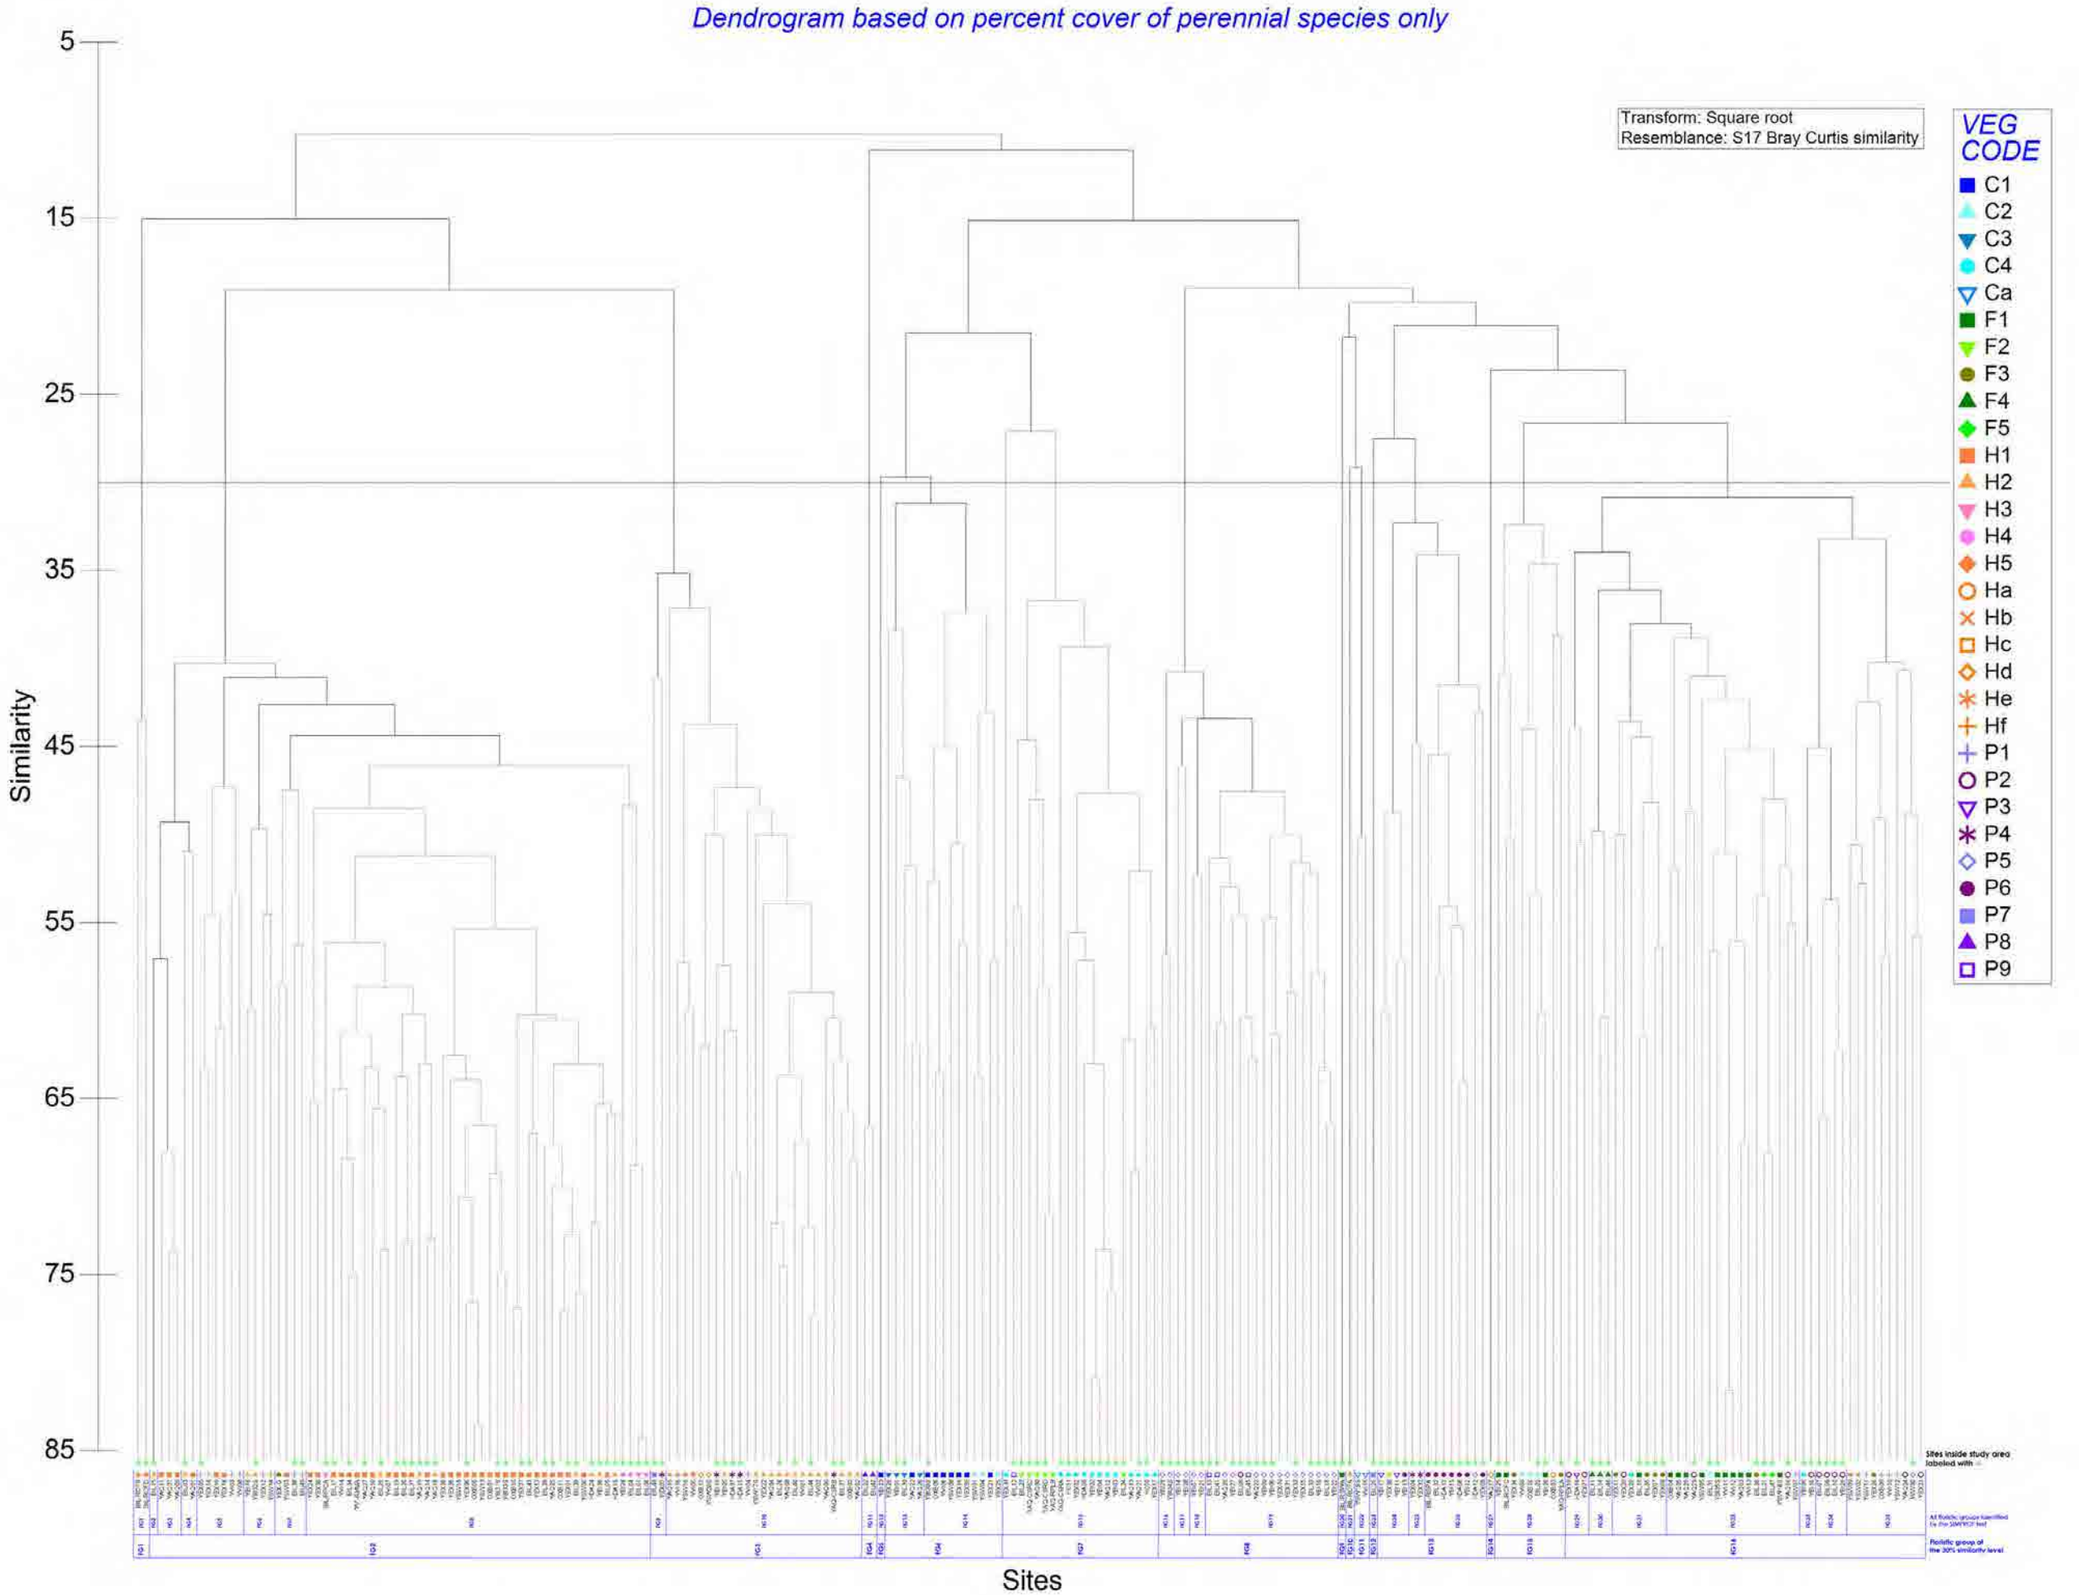

Figure 1: Dendrogram based on percent cover of perennial species in sites from the Yandi locality.
Adjacent sites connected by red lines are not significantly floristically different, as determined by the SIMPROF test.

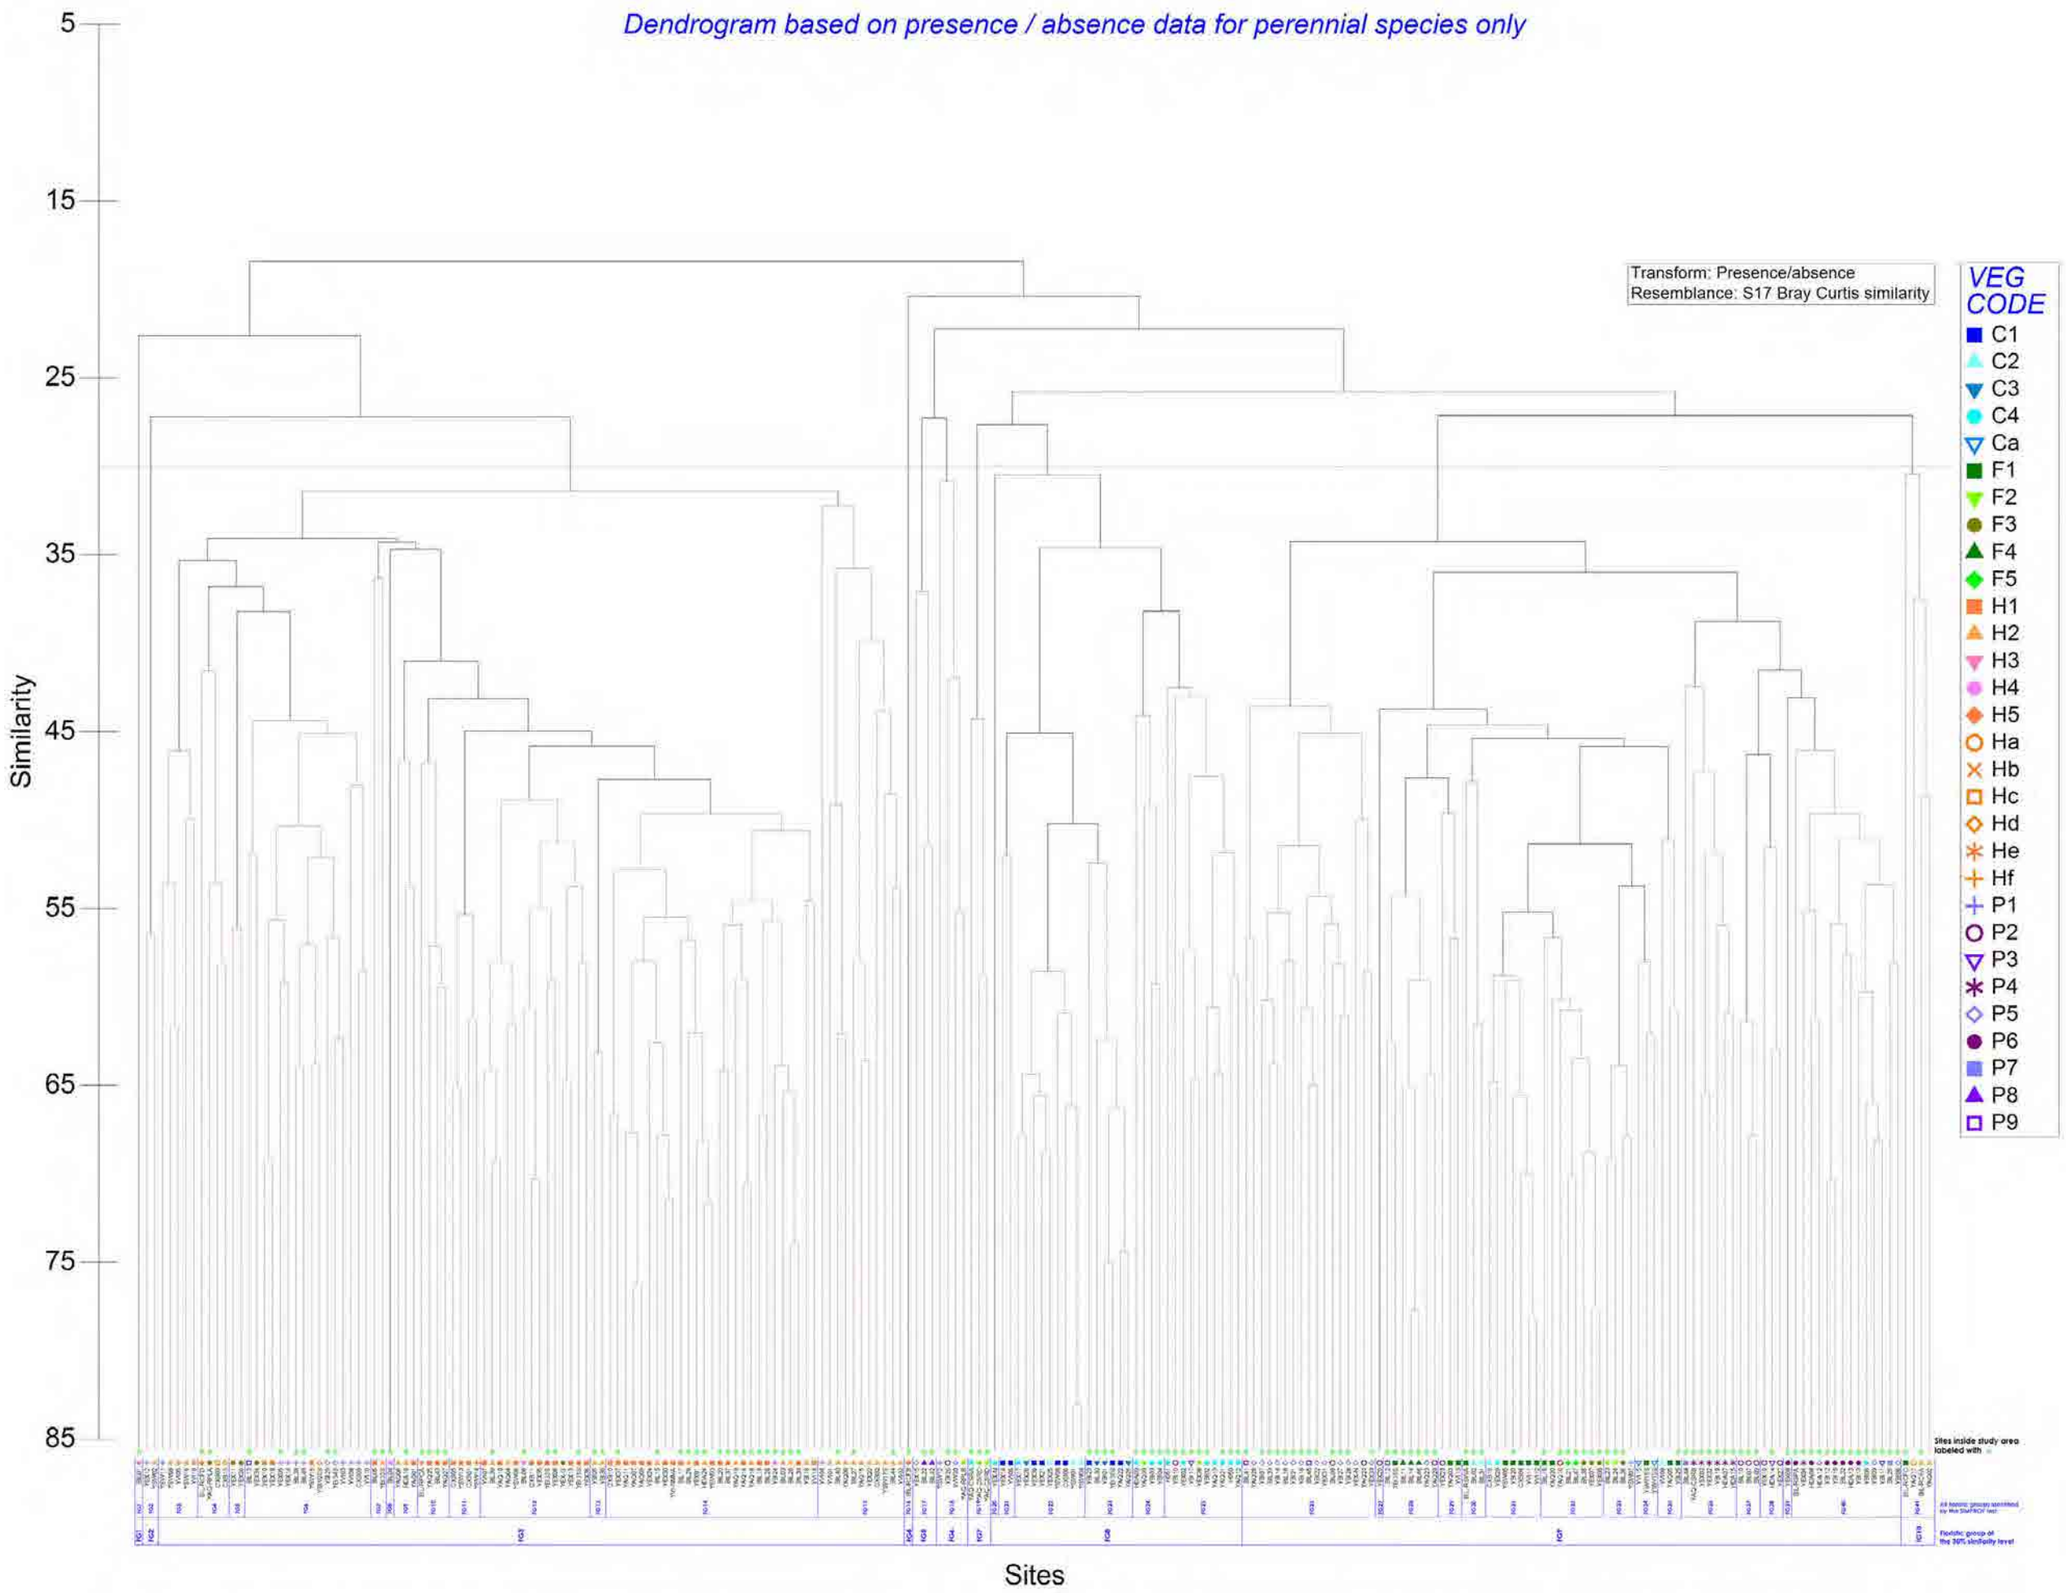

Figure 2: Dendrogram based on presence / absence of perennial species in sites from the Yandi locality.
Adjacent sites connected by red lines are not significantly floristically different, as determined by the SIMPROF test.

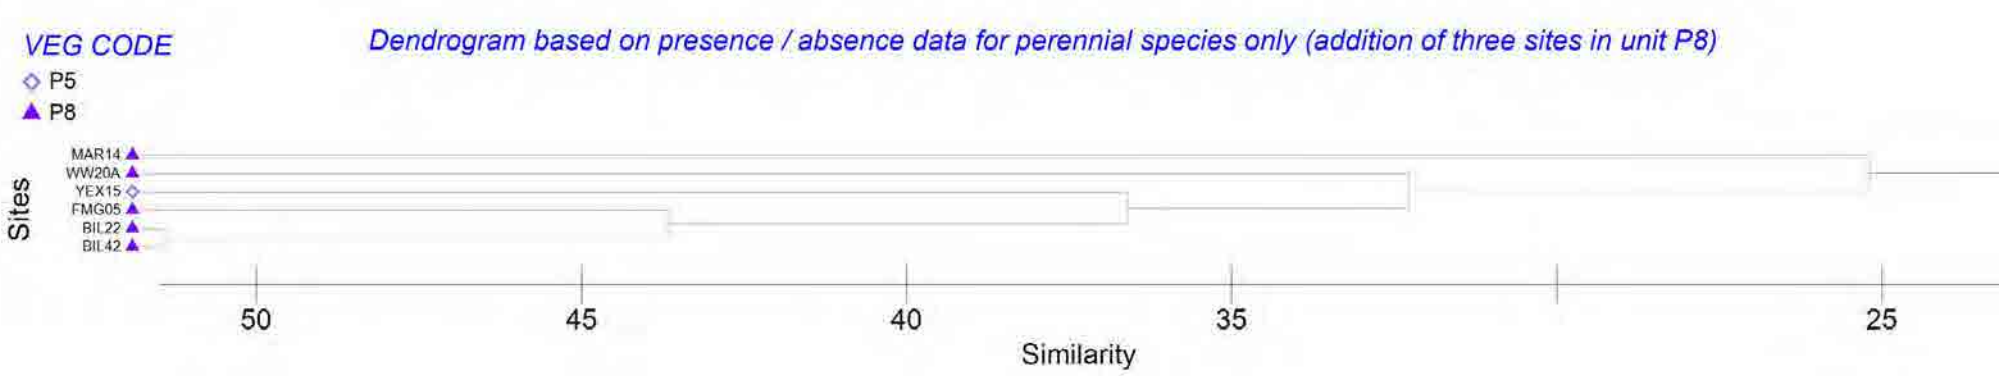

Figure 3: Extract from dendrogram showing clustering of sites from the original FG11 (BIL22 and BIL22) together with three additional sites from equivalent vegetation (unit P8) outside the study area.

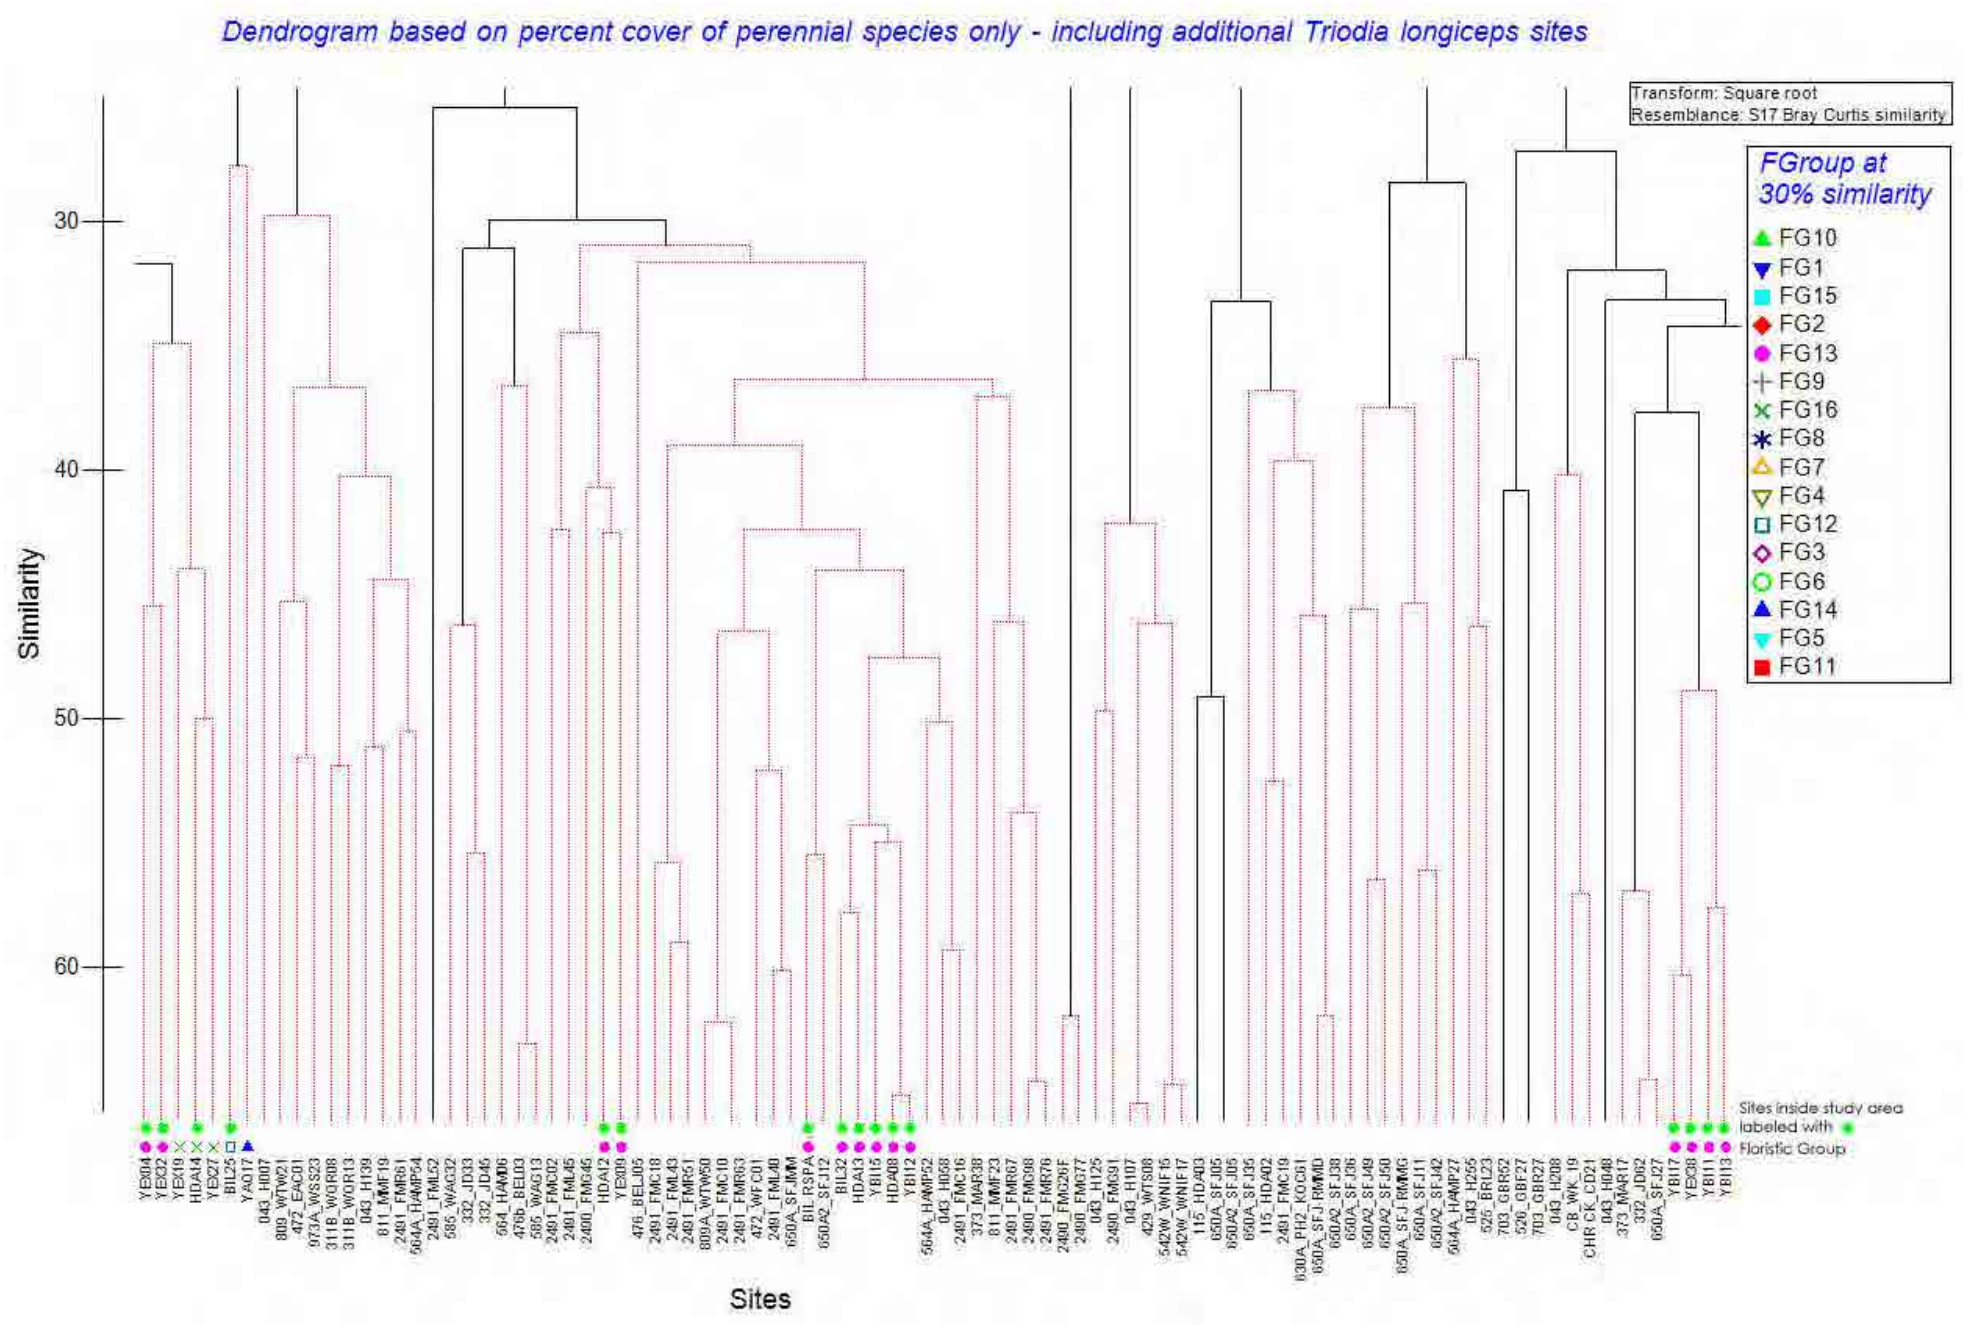

Figure 4: Extract from dendrogram showing clustering of sites from the original FG13 together with other sites from outside the study area.

Appendix 10

Poorly Collected, Variable or Incompletely Resolved Taxa

1. Poorly Collected Taxa

- *Euphorbia australis* var. *australis*
  The current vouchered specimens of this taxon are predominantly from coastal locations, with only one vouchered record from the central Pilbara. Two specimens keying to *Euphorbia australis* var. *australis* were collected from the study area. These specimens were confirmed by Andrew Perkins (a taxonomist at the WA Herbarium), and will be submitted to the WA Herbarium for lodgement.

- *Heliotropium glabellum*
  A single specimen keying to *Heliotropium glabellum* was collected from the study area during the Phase 1 survey, and four additional specimens were collected during Phase 2. Two of these specimens were confirmed by Andrew Perkins, and vouchers have subsequently been submitted to the WA Herbarium. Although this species is widespread through the Kimberley, it is uncommon in the Pilbara, with only a few voucher records from the far east of the region.

- *Peripleura hispidula* var. *hispidula*
  A single specimen keying to *Peripleura hispidula* var. *hispidula* was collected from the study area, however this taxon had not previously been considered to occur in WA. The specimen was sent to Andrew Perkins, who confirmed the identification as *P. hispidula* var. *hispidula.* This specimen will be submitted to the WA Herbarium as a voucher. Equivalent material has been recorded from other survey areas in the Pilbara, including near West Angelas (Biota 2014e), and will similarly be vouchered.

2. Variable Taxa

- *Abutilon lepidum*
  Three apparently undescribed entities in this species were identified by Malcolm Trudgen (M.E. Trudgen and Associates) in material from the study area, all of which are widespread and not believed to be of conservation significance: *Abutilon* aff. *lepidum* (1) (MET 15352), *A.* aff. lepidum (2) (MET 15970) and *A.* aff. *lepidum* (4). For the purpose of this report, they are recognised as one entity: *Abutilon lepidum* sens. lat.

- *Eriachne mucronata*
  Two forms of *Eriachne mucronata* were present in the study area: the 'typical form' (culms with sparse erect hairs), and one designated as 'arid form' (which has white woolly hairs on the culms). Both forms are widespread in the Pilbara bioregion and commonly collected. Although not formally recognised, they have been treated as separate entities for this report since they are clearly distinguishable.

- *Gossypium australe*
  Two apparently undescribed forms of *Gossypium* were recorded from the study area: *G. australe* (Burrup Peninsula form) and *G. australe* (Whim Creek form). These entities are widespread in the Pilbara. For the purpose of this report they have been recognised as a single entity: *Gossypium australe*.

- *Hibiscus coatesii*
  Considerable variation is observed within Pilbara specimens of this taxon. Two apparently undescribed entities were identified from the study area during past surveys, both of which are widespread: *Hibiscus* aff. *coatesii* (MET 16,542) and *H.* aff. *coatesii* (site 664). For the purpose of this report, they are recognised as a single entity: *Hibiscus coatesii.*

- *Indigofera monophylla*
  Several forms of *Indigofera monophylla* were identified by Malcolm Trudgen (M.E. Trudgen and Associates) amongst the specimens from the study area. All forms are considered to be widespread in the Pilbara. For the purpose of this report, the different forms of *Indigofera monophylla* have not been distinguished and they are referred to as a single entity.

- *Senna artemisioides* subsp. *oligophylla* (thinly sericeus form MET 15,035)
  This taxon is a form of *Senna artemisioides* subsp. *oligophylla* recognised by Malcolm Trudgen (M.E. Trudgen and Associates), which can be distinguished by the very appressed hairs on the leaflets. Although not formally recognised, this taxon has been included in this report because

it appears distinctly different from *S. artemisioides* subsp. *oligophylla* and is easily recognised. It also occurred in the study area as a hybrid with *Senna artemisioides* subsp. *helmsii*.

- *Sida fibulifera*
  Sida fibulifera is a very variable taxon. In past surveys, six apparently undescribed entities were identified from the study area: *Sida* aff. *fibulifera* (FMG 125-20), *S.* aff. *fibulifera* (HD12-39), *S.* aff. *fibulifera* (HD237-9), *S.* aff. *fibulifera* (oblong; MET 15 220), *S.* aff. *fibulifera* (site 1394) and *Sida* aff. *fibulifera* (prostrate A.A. Mitchell 3 572). None of these taxa are considered to be rare, and it is likely that more entities exist within this group. For the purpose of this report, all entities have been assigned to *Sida fibulifera* sens. lat.
- *Triodia basedowii*
  Following discussion with Dr Matthew Barrett (Kings Park and Botanic Garden), all specimens of *Triodia lanigera* collected from the study area during both the current survey and previous surveys have been redetermined as *T. basedowii*. A relevant specialist taxonomist will be consulted for further confirmation.

3. Incompletely Resolved Taxa

- *Portulaca oleracea/Portulaca intraterranea*
  The taxonomy of "*Portulaca oleracea*" in the Pilbara is currently unresolved. It is not clear whether specimens from this region with weakly developed tubercles on the seeds belong to *Portulaca oleracea, P. intraterranea* and/or one or more undescribed taxa (S. Dillon, WA Herbarium, pers. comm. 2012). For the purposes of this report, all specimens have been allocated to "*Portulaca oleracea/P. intraterranea*", with the exception of a single specimen that was confirmed as *P. intraterranea* by Andrew Perkins (WA Herbarium taxonomist). The latter specimen was conspicuously different to the other specimens designated as "*Portulaca oleracea/intraterranea*", having seeds with very prominent elongated tubercles with star-shaped bases.

CORPORATE CLOSURE PLANNING STATEMENT

Hamersley Iron – Yandi Pty Limited (**HIY**) is a wholly owned member of the Rio Tinto Group and part of Rio Tinto's global iron ore business. Rio Tinto's iron ore group (**Rio Tinto**) considers closure planning to be an integral part of its business. The process of preparing for closure begins in the early stages of project development, and continues throughout the life of the mine.

A team of in-house rehabilitation and closure planning specialists has been established within Rio Tinto to manage this aspect of our operations. A Rehabilitation and Closure Working Group has been established to facilitate integration of closure planning into the broader mine planning framework, and to oversee the research and improvement projects recommended in each closure plan. In this way, Rio Tinto aims to continually improve both its understanding of closure risks, and the strategies employed to mitigate them.

This plan documents the current closure knowledge base for Yandicoogina. It outlines the objectives that need to be met at closure, the strategies and plans to be employed to achieve them, and provides an indication of the criteria that will be used to assess closure success.

However, this is not a static document. Rio Tinto will continue to revisit its closure plans on a regular basis to ensure that the objectives to which it is working towards remain relevant and aligned to stakeholder expectations, and to revise its strategies and plans where appropriate to achieve improved closure outcomes.

EXECUTIVE SUMMARY

Overview

HIY's Yandicoogina channel iron deposits (**CID**) are located near the junction of Marillana Creek and Weeli Wolli Creek, approximately 90km northwest of Newman in the Pilbara region of Western Australia. The CID is a local aquifer, located adjacent to and under the current creek system. The CID is dewatered then removed using open cut, conventional drill-and-blast and load-and-haul mining methods. Waste generated through mining is deposited in temporary stockpiles adjacent to the pit, until sufficient void space becomes available for the material to be returned to the void. The mine has been operating continuously since 1998.

Scope

This closure plan has been prepared to support the Yandicoogina Iron Ore Project - Pocket and Billiard South (**PBS**) referral under Part IV of the *Environmental Protection Act* 1986 (**EP Act**). PBS will utilise infrastructure at the existing Yandicoogina operations (**Yandicoogina**). Consequently, this closure plan has been designed to address the closure requirements for Yandicoogina inclusive of the PBS decommissioning and rehabilitation requirements. This closure plan also includes reference to Oxbow East, also currently under referral under Part IV of the EP Act. Closure is assumed to include progressive rehabilitation that will occur throughout the life of the mine. The goal of mine closure at Yandicoogina is to relinquish the site to the Government.

This closure plan has been developed to meet the requirements of the joint Office of the Environmental Protection Authority / Department of Mines and Petroleum Guidelines for Preparing Mine Closure Plans (2015) [1] (**Closure Guidelines**). As such, this closure plan includes closure approaches for prospective areas that are not intended for regulatory approval at this time[2], namely Billiard North and Braid. Closure options presented for Billiard North and Braid deposits are provided solely for the purpose of facilitating discussions with key stakeholders, as part of an integrated closure plan.

Primary obligations and commitments

Yandicoogina is subject to the *Iron Ore (Yandicoogina) Agreement Act 1996* and Ministerial Statement 914 under the EP Act. It is recognised that additional obligations may arise associated with the proposal to mine PBS and Oxbow East.

Post-mining land use

The pre-mining land use of cattle grazing pastoral activities is not considered to be compatible with basic landforms that will be left as a consequence of mining, e.g. waste dumps, pit voids and pit lakes. Alternative land use options are continuing to be investigated in consultation with the local pastoral stations, local communities and Traditional Owners.

Until an alternate land use is agreed, the closure and rehabilitation strategy focuses on the following, to ensure the system remains compatible with general Pilbara land uses:

- create landforms that are stable for access by humans and native fauna;
- ensure water systems support existing riparian vegetation and are compatible with the natural system dynamics; and
- establish ecosystems with similar biodiversity and cultural heritage values as surrounding reference sites.

Closure objectives

The following closure objectives have been developed for Yandicoogina:

- rehabilitated landforms are stable and designed to manage floodwater appropriately;
- the environmental and cultural heritage values associated with creek flows and function are maintained post-closure;
- environmental values of Fortescue Marsh are not compromised;
- water quality within pit lakes support natural ecosystems and are compatible with post-mining land use;
- alluvial groundwater systems support remnant phreatophytic vegetation;
- final landforms are rehabilitated to be compatible with post-mining land use; and

[1] Department of Mines & Petroleum and Office of the Environmental Protection Authority (2015) Guidelines for Preparing Mine Closure Plans, June 2015.

[2] refer to Closure Guidelines Section 3.1, page 12, "…closure planning should start in the project feasibility stage (before project approvals)."

- public safety hazards have been addressed.

Note that these objectives do not represent the full range of closure issues that may be present at the site. Rather the objectives reflect key issues against which closure performance will be assessed by government regulators.

Indicative completion criteria have been proposed within this closure plan, however further work is required to clarify and quantify the completion criteria.

Anticipated closure outcome

Due to the limited volume of mineral waste generated by the mining operation, the legacy of below water table mining at Yandicoogina will be the creation of a series of groundwater-dependent pit lakes.

The closure approach returns mineral waste to the pit voids and preferentially places the material against pit walls that are adjacent to creeks, to stabilise the walls and prevent the creeks from collapsing into the mine voids post-closure. As a result, Marillana Creek and Weeli Wolli Creek are expected to continue to function without assistance and with no long term impact to Fortescue Marsh (located downstream of the operation).

The in pit closure landform has, subsequently, been designed to minimise the future lake surface areas. By minimising the lake area, evaporation will be minimised. This will, in turn, retard lake salinity and facilitate groundwater recovery levels to pre-disturbance[3] groundwater levels. This is expected to lead to better groundwater conditions (than other closure alternatives) within the adjacent alluvial groundwater aquifers that support groundwater dependent (phreatophytic) ecosystems.

All areas disturbed by mining activities, with the exception of the pit walls, will be rehabilitated. Away from the lakes, the disturbed land will be revegetated to provide habitat similar to the pre-mining conditions. Habitat requirements for species of biodiversity value will be integrated into the rehabilitation design, where appropriate. Surface water will be managed in a manner sympathetic to the habitat.

The lake fringes will be dynamic environments. The lake fringe will be rehabilitated to be compatible with the post-mining soil, landform and water conditions. Lake levels are expected to rise and fall over 10 m due to the strong links between creek flows, creek bed infiltration / groundwater recharge and subsequent groundwater rise. Bore observations suggest the rapid rise in groundwater level, and slow decline, will occur regardless of whether the lake is connected to a creek or catchment area. This dynamic lake environment is commonly associated with wetlands, but is not readily identified with existing Central Pilbara ecosystems. Consequently, the characteristics and completion criteria that will define a stable, self-sustaining ecosystem in the lake fringe habitat zones will be different from those used to define rehabilitation success elsewhere, and are subject to further study and validation.

Water quality is expected to vary from one lake to another, as groundwater moves through one lake system to another, depending on whether the lake behaves as a groundwater through-flow or sink system, and is expected to change over time. Groundwater modelling suggests the Oxbow West and JC lakes will act as groundwater sinks, that is, most of the water entering these voids will leave via evaporation. As a result, the lake water salinity within these lakes is expected to steadily increase over the long term. All of the other pit lakes are expected to behave as groundwater through flow lake systems.

Unfortunately, the interactions between the closure landform, surface water and groundwater systems at Yandicoogina are very complex. Computer programs commonly used to model and / or simulate groundwater and lake conditions struggle to define how water will move and how water quality may change over time; especially at spatial and temporal scales that enable environmental impacts to the groundwater dependent ecosystems to be conclusively resolved. Ongoing review and update of the water models is required throughout the life of the operation to improve the model predictions and during the post-mining period to validate the outcomes.

[3] “Pre-disturbance” is defined as period prior to any mining activities taking place within the catchment.

CLOSURE GUIDELINES CHECKLIST

Q	Mine Closure Plan (MCP) Checklist	Y/N/ NA	Page No.	Comments	Change from previous version (Y/N)	Page No.	Comments
1	Has the Checklist been endorsed by a senior representative within the operating company?	Y			NA		
2	Are you aware that from 2015 all MCPs will be made publically available?	Y			NA		
3	Is there any information in this MCP that should not be publicly available?	N			NA		
4	If “Yes” to Q3, has confidential information been submitted in a separate document / section?	NA			NA		
5	Does the MCP cover page include: Project Title, Company Name, Contact Details (including telephone numbers and email address) Document ID and version number, Date of submission (needs to match the date of this checklist)	Y			Y		Contact changed
6	State why the MCP is submitted (e.g. as part of a Mining Proposal, a reviewed MCP or to fulfil other legal requirement)			Referral under Part IV EP Act	Y		
7	Does the project summary include land ownership details, location of the project, comprehensive site plans and background information on the history and status of the project?	Y			Y		HIY referenced instead of RTIO
8	Does the MCP include a consolidated summary or register of closure obligations and commitments been included?	Y	22		Y		New register generated
9	Have all stakeholders involved in closure been identified?	Y	24		N		
10	Does the MCP included a summary or register of historic stakeholder engagement been provided, with details on who has been consulted and the outcomes?	Y	24		Y		Updated
11	Does the MCP include a stakeholder consultation strategy to be implemented in the future?	Y	23		N		
12	Does the MCP include agreed post-mining land use, closure objectives and conceptual landform design diagram?	Y	30		Y		New landform design image
13	Does the MCP identify all potential (or pre-existing) environmental legacies which may restrict the post mining land use (including contaminated sites)?	Y	34		N		
14	Has any soil or groundwater contamination that occurred, or is suspected to have occurred, during the operation of the mine, been reported to DER as required under the Contaminated Sites Act 2003?	NA			N		

Q	Mine Closure Plan (MCP) Checklist	Y/N/ NA	Page No.	Comments	Change from previous version (Y/N)	Page No.	Comments
15	Does the MCP include an appropriate set of specific completion criteria and closure performance indicators?	Y	32		Y		pH of lake water added
16	Does the MCP include baseline data (including pre-mining studies and environmental data)	Y	34		N		
17	Has materials characterisation been carried out consistent with applicable standards and guidelines (e.g. GARD Guide)?	Y	46		N		
18	Does the MCP identify applicable closure learnings from benchmarking against other comparable mine sites?	Y		See Appendix B & C	Y		New review included
19	Does the MCP identify all key issues impacting mine closure objectives and outcomes (including potential contamination impacts)?	Y	84		Y		Updated
20	Does the MCP include information relevant to mine closure for each domain or feature?	Y	93		N		
21	Does the MCP include a gap analysis / risk assessment to determine if further information is required in relation to closure of each domain or feature?	Y	85		N		
22	Does the MCP include the process, methodology and has the rationale been provided to justify identification and management of the issues?	Y	84		Y		Risk assessment process clarified
23	Does the MCP include a summary of closure implementation strategies and activities for the proposed operations or for the whole site?	Y	89		N		
24	Does the MCP include a closure work program for each domain or feature?	N		To be developed prior to closure	NA		
25	Does the MCP contain site layout plans to clearly show each type of disturbance as defined in Schedule 1 of the MRF Regulations?	N		State agreement site not subject to MRF	NA		
26	Does the MCP contain a schedule of research and trial activities?	Y	89		Y		Updated
27	Does the MCP contain a schedule of progressive rehabilitation activities?	N		Indicative closure schedule provided. Opportunities for rehab assessed annually	NA		
28	Does the MCP include details of how unexpected closure and care and maintenance will be handled?	Y	94		Y		Updated
29	Does the MCP contain a schedule of decommissioning activities?	N		To be developed prior to closure	NA		
30	Does the MCP contain a schedule of closure performance monitoring and maintenance activities?	N		To be developed prior to closure	NA		
31	Does the MCP contain a framework, including methodology, quality control and remedial strategy for closure performance monitoring including post-closure monitoring and maintenance?	Y	97		N		

Q	Mine Closure Plan (MCP) Checklist	Y/N/ NA	Page No.	Comments	Change from previous version (Y/N)	Page No.	Comments
32	Does the MCP include costing methodology, assumptions and financial provision to resource closure implementation and monitoring?	Y	101	Financial provision not included	N		
33	Does the MCP include a process for regular review of the financial provision?	Y	101		N		
34	Does the MCP contain a description of management strategies including systems and processes for the retention of mine records?	Y	102		N		

I hereby certify that to the best of my knowledge, the information within this closure plan is true and correct and addresses the relevant requirements of the *Guidelines for Preparing Mine Closure Plans* approved by the Director General of Mines.

David Bloor
General Manager - Health, Safety and Environment

MINISTERIAL STATEMENT COMPLIANCE CHECKLIST

The Yandicoogina Closure Plan has been prepared to satisfy multiple objectives, including compliance with obligations arising from environmental approvals.

This checklist has been provided to facilitate audits of compliance against Ministerial Statement 914 Condition 9-3, which specifies: "*The Yandicoogina Decommissioning and Rehabilitation Plan required pursuant to Condition 9-1 shall set out procedures to:*" (as follows)

Clause		Relevant sections	Page
(1)	manage long-term hydrogeological impacts of mining the channel iron deposit	Section 17	68
(2)	model the long-term hydrological impacts, particularly the water levels and quality both in the pit void and downstream of waste material landforms	Section 17	68
(3)	manage over the long-term the surface water systems affected by the open pit	Section 16 and 17	63
(4)	progressively rehabilitate all disturbed areas to a standard suitable for the agreed end land use(s), with consideration and incorporation of:		
	(a) the characteristics of the pre-mining ecosystems within the project area (through research and baseline surveys)	Section 14	48
	(b) the performance of previously rehabilitated areas within the mining lease	Section 14	60
	(c) the performance of rehabilitation areas at the proponent's other operations in the Pilbara	Appendix B & C	
	(d) best practice rehabilitation techniques used elsewhere in the mining industry	Appendix C	
(5)	develop and identify completion criteria	Section 11	32
(6)	monitor rehabilitation to assess the performance of all rehabilitated areas against the completion criteria	Section 23	97
(7)	report on the rehabilitation and monitoring results	Section 14	60
(8)	remove all infrastructure	Section 15	62
(9)	develop management strategies and/or contingency measures in the event that operational experience and/or monitoring identify any significant environmental impact as a result of the proposal	Section 22	94
(10)	manage and monitor mineral waste including physical characteristics and acid or neutral metalliferous drainage using national and international standards and updates	Section 13.5	45
(11)	develop a 'walk away' solution for the decommissioned mine site	Section 16.1 *Discussion also in Appendix D*	63

INTRODUCTION TO CLOSURE PLANNING

1. What is a closure plan?

A closure plan documents strategies to achieve the desired post-closure landform and avoid or mitigate potential social and environmental impacts associated with site closure, to an extent that is fiscally appropriate. As such, closure plans provide the framework for planning and implementing mine. Closure plans also document tasks the HIY has committed to undertake to improve closure outcomes.

Closure plans are intended to be used by site personnel to inform on-going planning decisions, and to ensure closure is integrated into operational activities. Closure plans are also one of the methods used by the business to communicate its closure strategy to stakeholders, including regulators.

2. The closure planning process

Closure plans are regularly updated to account for changes resulting from:

- amendments to the mine plan;
- improvements of the site closure knowledge base (e.g. through daily activities, technical studies and research actions, progressive rehabilitation);
- new or amended regulation;
- changes to surrounding land uses; and
- evolving stakeholder expectations.

Review processes bring experts together to discuss current performance, proposed mine changes and opportunities to improve closure outcomes. At the end of the review process, improvement actions are assigned and the closure plan is updated.

A key output of closure planning is the development of a closure cost estimate. Closure provisions are subsequently integrated into our business planning processes to ensure funds will be available to close the site effectively.

The detail of each closure plan increases as the knowledge base develops. When the site moves to within five years of scheduled closure, studies will be completed to define how infrastructure, decontamination, rehabilitation, the workforce and communications will be managed throughout the mine closure period (and beyond), specific to the site conditions at the end of mining. Stakeholder engagement and endorsement of the final completion criteria is facilitated at this time.

In the final closure plan update (also referred to as the Decommissioning Plan), location specific management plans are provided for each closure domain. These detailed plans cover the physical closure, dismantling and subsequent rehabilitation implementation requirements. The supporting technical reports that have been used within the closure plan to predict the post-closure outcomes are also appended to the final closure plan.

3. Closure terminology

This closure plan is accessed by various groups within Rio Tinto as well as external stakeholders, including Western Australian State Government regulator and advisory departments and Traditional Owner groups. The following clarification is provided to define how the following terms are used within this closure plan:

- A mine void refers to the cavity created in the natural geology in order to mine ore, which extends below the natural surface.

- A pit refers to total area from which material was removed. A pit may include shallow depressions, where material is removed for construction purposes e.g. a borrow pit, and / or quarries where no surface depression is created, but instead part of a rock outcrop is removed.

- Post-mining landform refers to the shape of the land that would be generated as a result of implementation of the current operational mine plan and standard operating practice. Issues that could potentially arise from this scenario, and strategies to manage them, are the focus of this closure plan.

- Final landform designs refer to the individual feature or domain-based landform shaping requirements required to achieve the closure objectives.

- Closure landform refers to the overall shape of all the land disturbed by mining activities after rehabilitation earthworks are complete.
- Post-closure landform encompasses the closure landform and the surrounding undisturbed land, to describe the wider catchment conditions.
- Pre-mining refers to the condition of the environment immediately prior to ground disturbance activities.
- Pre-disturbance refers to the general condition of the environment prior to any mining activities, including the Yandicoogina operation, commencing in the catchment. Within the context of this closure plan pre-disturbance conditions are inclusive of impacts associated with pastoral use.

PURPOSE AND SCOPE

4. Purpose

Planning for closure of a site is a critical business process that demonstrates HIY's commitment to sustainable development. The report follows the format and content requirements for mine closure plans as recommended in the Closure Guidelines and Ministerial Statement 914 Condition 9 *Decommissioning and Rehabilitation*.

This closure plan has been prepared to support the Yandicoogina Iron Ore Project PBS and Oxbow East referrals under Part IV of the EPA Act.

This update also includes information developed as part of ongoing closure plan revisions and information developed in response to key stakeholder feedback, including:

- improvements to the visual presentation of the closure landform designs;
- additional water balance information developed for proposed pit lakes at PBS;
- revision of the end of mine life date, such that the final deposit is listed as PBS;
- inclusion of conceptual closure options for prospective areas. These options are presented for consideration in cumulative impact, integrated mine planning and to facilitate discussion with key stakeholders and are not intended to be approved by regulators for implementation;
- change of the pit naming convention from Oxbow to Oxbow West; and
- inclusion of the proposed Oxbow East.

This closure plan supersedes all previous closure, decommissioning and rehabilitation plans for Yandicoogina.

5. Scope

This plan covers the closure, rehabilitation and decommissioning of facilities and disturbed areas associated with mining activities at Yandicoogina, including:

- open cut pits, mineral waste dumps, haul roads and associated ground disturbance;
- dewatering borefield, pipelines, discharge outlets and associated infrastructure;
- processing facilities, conveyor infrastructure, and associated facilities and infrastructure; and
- administration buildings, camp, associated facilities and infrastructure, sealed and unsealed roads.

Decommissioning and removal of the rail network has been specifically excluded from this closure plan in accordance with *Iron Ore (Yandicoogina) Agreement Act 1996*, clause 39 (2) (refer to Appendix A). This exclusion is subject to review with each revision and update of the closure plan.

This mine closure plan update has been developed using information current as at March 2015.

PROJECT SUMMARY

6. Description of operation

6.1 Overview

Yandicoogina (Figure 1) is located in the Shire of East Pilbara, approximately 90km northwest of Newman within the Weeli Wolli Creek catchment. The mine is sufficiently remote that mining is operated on a fly-in fly-out (**FIFO**) basis.

The mine is one of several operations within a localised area along a CID (Figure 2). The CID is characterised by continuous iron mineralisation along a palaeochannel in the lower reaches of the Weeli Wolli Creek catchment. The CID snakes over 100km from the Munjina Claypan in the west down Marillana Creek and its tributaries and into Weeli Wolli Creek, terminating somewhere under Fortescue Marsh.

The first mine in the catchment to be developed, commencing in 1991, was the BHP Billiton Iron Ore Yandi mine (also known as Marillana Creek) located approximately 12 km west and immediately upstream of Yandicoogina on Marillana Creek. BC Iron Limited (formerly Iron Ore Holdings) with Mineral Resources operate Phils Creek Iron Ore Mine, located immediately north and upstream of Yandicoogina on Phils Creek. Other iron ore mining companies seeking to establish operations in the immediate vicinity of Yandicoogina include:

- BC Iron Limited Iron Valley project, situated approximately 5km to the north-east, adjacent to Fortescue Metals Group (**FMG**) Nyidinghu project;
- FMG Nyidinghu project, located immediately downstream of the Yandicoogina mining lease (M274SA) adjacent to Weeli Wolli Creek; and
- Brockman Mining Limited Marillana Iron Ore Project, located approximately 20km to the north of Yandicoogina and downstream of the BC Iron Limited Iron Valley and FMG Nyidinghu projects.

Due to the proximity of the mines, mining and closure activities at Yandicoogina are expected to influence the mine and closure strategies at the BHP Billiton Iron Ore Yandi mine, the BC Iron Limited Iron Valley project and the FMG Nyidinghu project.

Other major mines within the Weeli Wolli Creek catchment, upstream of Yandicoogina and adjacent to Weeli Wolli Creek, include:

- BHP Billiton Iron Ore Mining Area C mine and Jinidi expansion project, located approximately 32 km to the south-east of Yandicoogina; and
- Hamersley HMS Hope Downs 1 mine, located approximately 22 km to the south of Yandicoogina.

Rio Tinto group companies also hold leases over the Snooker and Meander deposits, located upstream of the BHP Billiton Iron Ore Yandi mine. As Yandicoogina is located downstream and outside the influence of these areas, closure is not expected to impact these areas. However, activities at these mines and at BHP Billiton Iron Ore Yandi mine may influence the Yandicoogina’s mine and closure strategies.

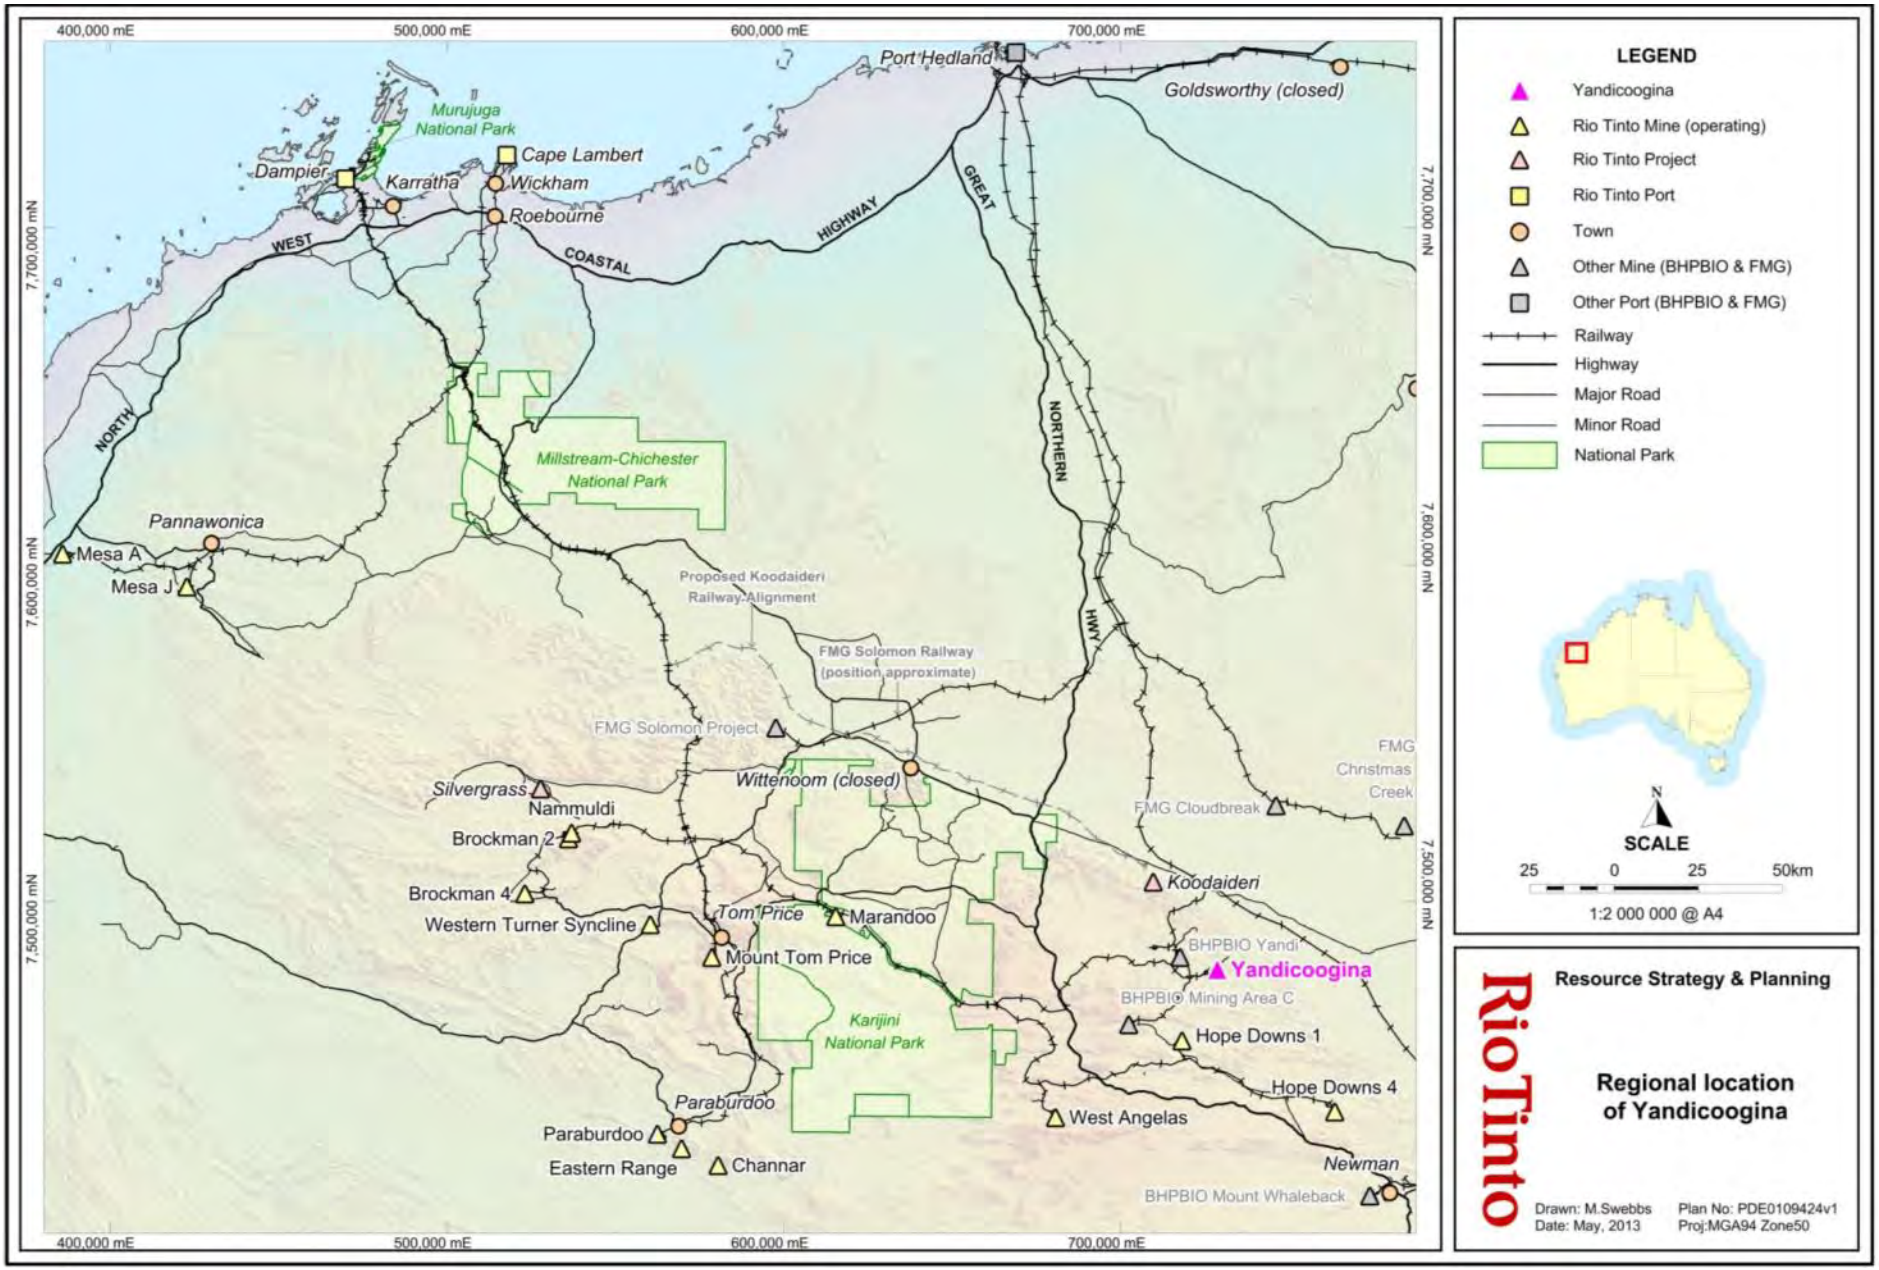

Figure 1: Location of Yandicoogina mine.

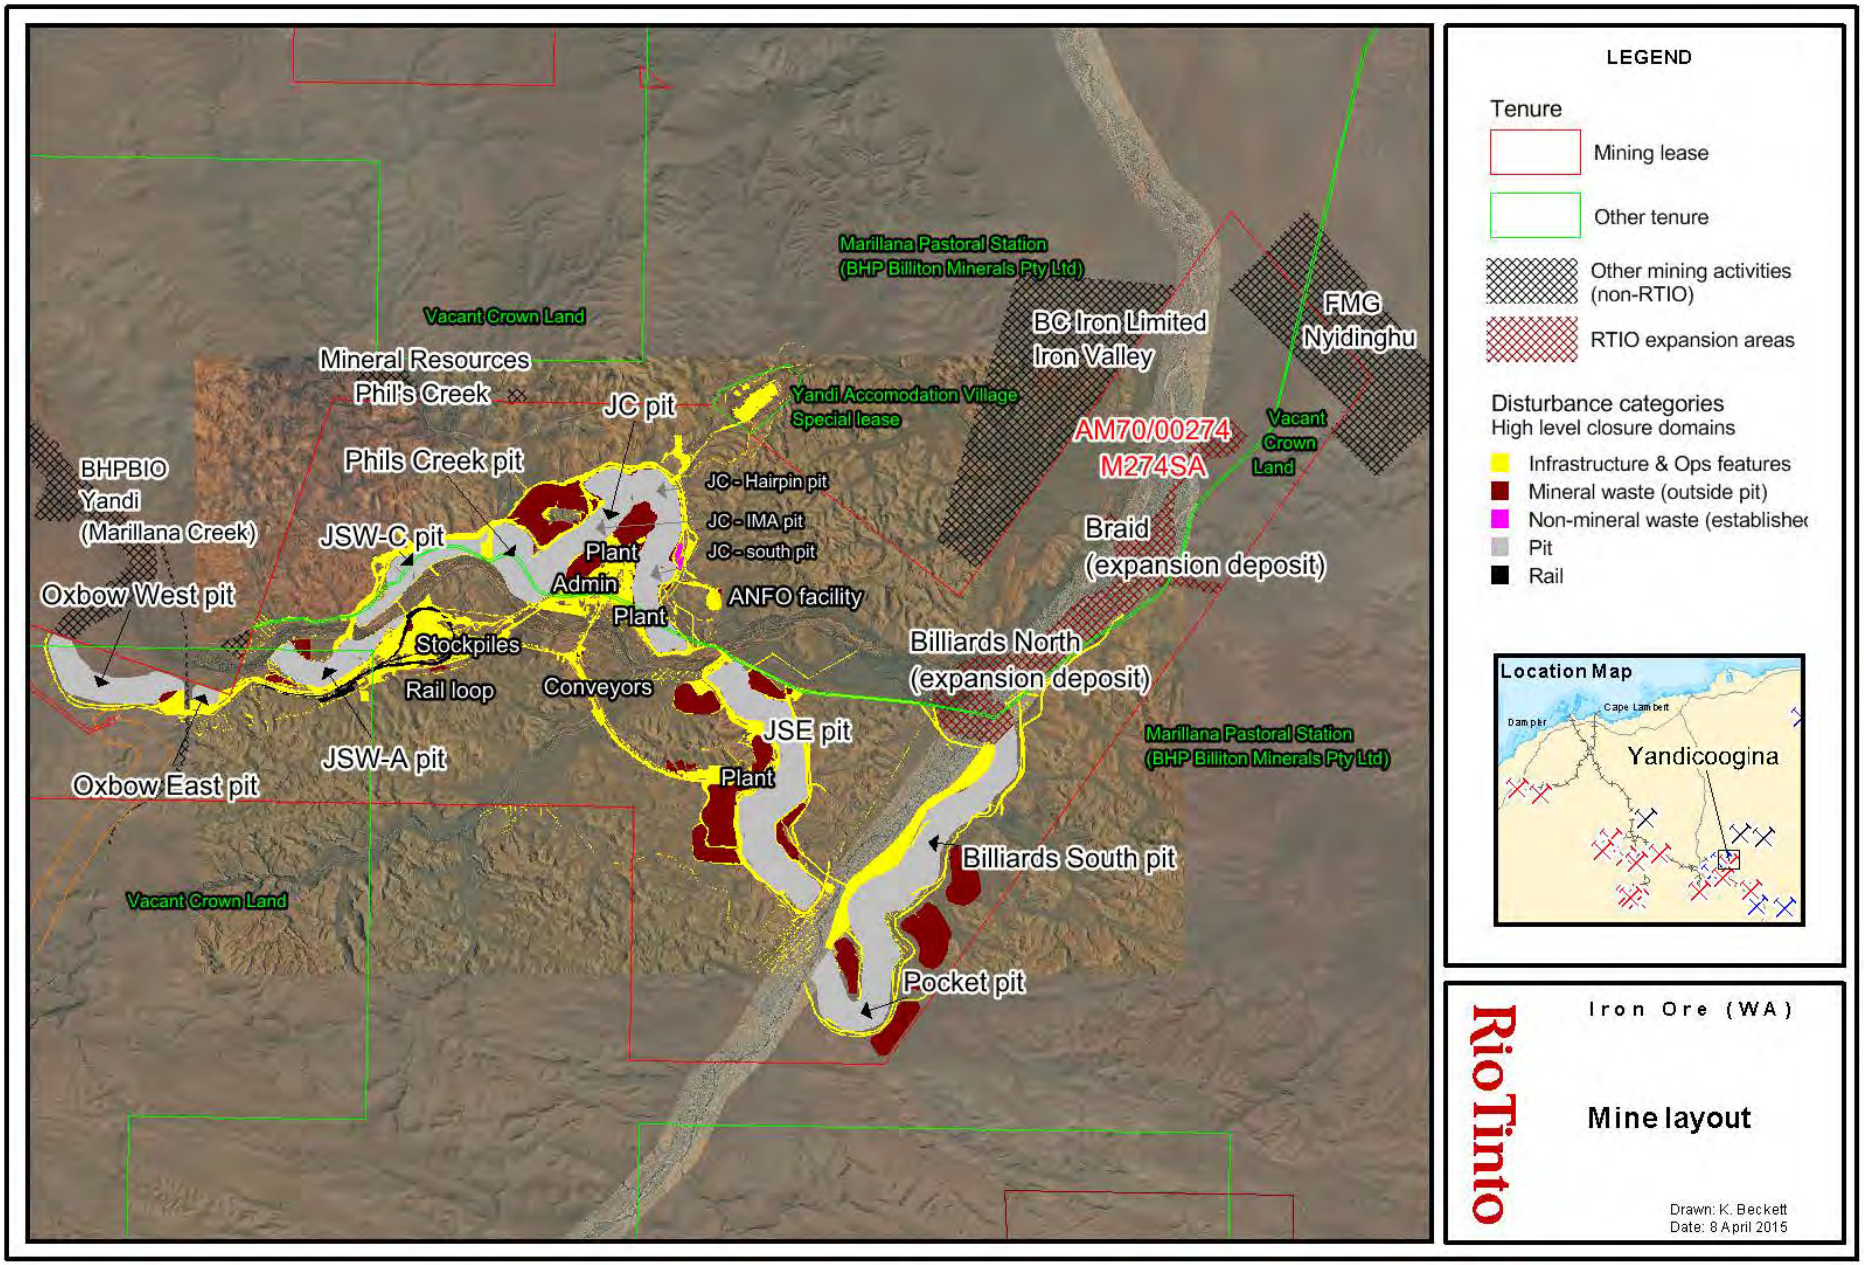

Figure 2: Yandicoogina mine layout.

6.2 Closure plan development history

The initial Yandicoogina mine proposal, which covered the western half of the Junction Central deposit, was approved under Part IV of the EP Act in 1996. The resulting Ministerial Statement, 417, identified long term management of water and associated vegetation as key closure issues. The proposal to extend the mining area to the east (over the Junction Central Hairpin and Waterstand areas) was approved in 1999 as an amendment to Ministerial Statement 417, Ministerial Statement 523.

In these initial proposals, it was identified that Yandicoogina was unlikely to have sufficient mineral waste to cover the exposed groundwater table, such that the creation of pit lakes at Yandicoogina was required. This requirement was acknowledged in the initial Yandi Operations Closure Statement in 1999. A closure plan for Yandicoogina was subsequently approved by OEPA in August 2000. The plan was then updated for internal use in 2001.

The Yandicoogina closure plan was significantly updated in 2003 and provided as part of the 2005 Junction South East (**JSE**) referral that resulted in Ministerial Statement 695. In the 2005 Yandicoogina closure plan, HIY suggested that an adjacent hill could be mined to fill the JSE mine void to the 490mRL to prevent the formation of a permanent pit lake. Ministerial Statement 695 included Condition 6 *Post-closure Backfill Source* requiring HIY to address issues other than water management associated with this closure strategy, including Aboriginal ethnographic and archaeological, vegetation, flora and fauna values. This condition provided a turning point for the closure planning strategy for Yandicoogina, which until this point had been focused on the protection of groundwater quality values over all other environmental and social values.

In 2008, a closure management study for Yandicoogina was reviewed by the Department of Industry and Resources (now DMP), in accordance with Ministerial Statement 695 Condition 5-1. The Department of Industry and Resources' review stated the closure management study did not meet the requirements of condition 5.1[4].

A closure plan for Yandicoogina was subsequently included in a revised proposal submitted under Part IV of the EP Act for the Junction South West (**JSW**) and Oxbow referral. Ministerial Statement 914 issued in 2012 encompassing the entire Yandicoogina operation, superseding Ministerial Statements 417, 523 and 695 for the Yandicoogina Operations, in accordance with section 45B of the EP Act. This 2012 Yandicoogina closure plan acknowledged that mining neighbouring hills to suppress the groundwater table would require significant additional clearing, and was no longer consider to be the preferred closure strategy.

Ministerial Statement 914 Condition 7-3 introduced a new requirement for closure planning, to ensure "there is no irreversible impact to riparian vegetation or groundwater dependent ecosystems" along both Marillana and Weeli Wolli Creeks. Compliance with this condition had the potential to conflict with some proposed closure strategies presented in the 2012 Yandicoogina Closure Plan.

The 2014 Yandicoogina Closure Plan was submitted to the OEPA, in accordance with Ministerial Statement 914 Condition 9-1, on 31 March 2014 and approved on 23 January 2015. Areas for improvement identified by regulators in the 2014 review have been addressed in this closure plan.

6.3 Mine layout

Yandicoogina utilises standard truck and shovel methods to develop open pit iron ore deposits. The deposits include (from upstream to downstream): Oxbow West, Oxbow East, JSW areas A (**JSW-A**) and C (**JSW-C**), Junction Central (**JC**), Junction South East (**JSE**) and PBS. Prospective areas include the Billiard North and Braid.

At the point of closure Yandicoogina will include:

- open cut pits developed to depths below the natural groundwater table;
- temporary out-of-pit mineral waste dumps and in-pit backfilling of exhausted mine areas;
- topsoil and subsoil stockpiles for mine site rehabilitation;
- a dewatering system including groundwater bores, pipelines, water storage areas and discharge outlets;
- roads including light vehicle / heavy vehicle access and haul roads, and several floodways;
- flood protection infrastructure, including levees along Marillana Creek and Weeli Wolli Creek, diversion of Phils Creek, minor creek diversions levees and drains. Some levee and diversion structures will be retained on closure;

[4] Letter from Ross Atkin, Project Manager Investment Facilitation (DOIR), dated 8 October 2008, available at RTIO-HSE-0071273

- infrastructure associated with ore haulage to processing facilities at JC and JSE, and rail load out facilities south-east of JSW;
- power and communications infrastructure; and
- other supporting infrastructure including accommodation village, administration buildings, maintenance workshops and associated utilities and services.

Key aspects of the post-mining landform include:

- 8 mine voids that extend below the water table;
- 7 or more waste dumps located within the mine voids. The toe of each dump will extend to the base of the pit, below the natural groundwater table. In some locations the toe of the dump may already be underwater due to recovery of the groundwater table;
- over 10 temporary stockpiles of mineral waste (waste dumps) located external and adjacent to the mine voids, which will need to be transported back into the mine void prior to rehabilitation;
- 3 in pit waste fines cells in JC and a network of waste fines cells in JSE; and
- a specially designed and constructed land bridge that connects Phils Creek back to Marillana Creek along the original flow path.

Note, a full site inventory is included in closure cost estimate reports for the site and is not reproduced in this report.

6.4 Mine development and schedule

JC was the first deposit to be developed at Yandicoogina and has been operating continuously since 1998. Mineral waste (overburden) was deposited outside of the pit area to the north of the operations adjacent to Phils Creek and topsoil was stockpiled immediately south of the mine area, where they remain today. As void space became available, mineral waste was deposited directly into the mined out sections of the void (backfilled). Mined out areas of the JC mine void have also been converted into waste fines storage areas for the benign waste residue generated by wet processing of the iron ore. Mineral waste will be continually deposited back into the JC mine void until the deposit is exhausted.

Development of JSE commenced in 2006. Dewatering challenges prevented the full vertical extent of the deposit from being mined simultaneously; and as a result, the mineral waste from JSE has had to be placed in temporary stockpiles external to the pit. The JSE mine void has also been converted into a waste fines storage area.

Development of JSW commenced in 2013. The JSW ore body extends under Marillana Creek, although mining is limited to areas outside the 100 year floodplain. The last 800 m of Phils Creek has been diverted, temporarily, to facilitate mining under Phils Creek. This section of Phils Creek is expected to be reinstated prior to closure. Mineral waste from JSW is deposited into existing mine voids in JC and JSW.

Oxbow West, Oxbow East and PBS are expected to be developed after 2017. Mineral waste from Oxbow West and Oxbow East will be deposited into the JSW mine voids. Mineral waste from PBS will be placed external to the mine void until areas of the PBS pit are exhausted, at which time the mineral waste will backfilled directly into the PBS mine void.

The major development milestones, based on the current mine plan, are presented in Table 1. It should be noted that the mine plan is subject to constant review and modification, and these timeframes may differ in future closure plan updates.

Table 1: Pit development schedule

Deposits	Commence	Ore exhausted
Oxbow West	2018	2025
Oxbow East	2017	2020
JSW-A	Underway	2020
JSW-C	Underway	2018
JC	Underway	2017
JSE	Underway	2019
PBS	2017	2032

CLOSURE OBLIGATIONS AND COMMITMENTS

7. Legal obligations

A closure obligations register is presented as Appendix A, in accordance with the format prescribed in the Closure Guidelines. It contains a list of obligations from the following instruments:

- *Iron Ore (Yandicoogina) Agreement Act 1996*;
- Ministerial Statement 914 (Yandicoogina Iron Ore Project – Expansion to Include Junction South West and Oxbow Deposits);
- EPBC Decision Notice 2011/5815;
- relevant Native Vegetation Clearing Permits; and
- relevant leases held pursuant to *Land Administration Act 1997*.

The register also identifies legislation, standards and guidelines that may not apply to Yandicoogina specifically, but that may be relevant to closure of mine sites generally.

This closure plan has been prepared to support the Yandicoogina Iron Ore Project PBS and Oxbow East referrals under Part IV of the EPA Act, and additional specific obligations may arise through these processes. These will be documented in the next update of the Yandicoogina closure plan.

STAKEHOLDER CONSULTATION

8. Stakeholder consultation

8.1 Consultation process

Stakeholder consultation is undertaken to ensure all stakeholders have their interests considered during closure planning. HIY has established processes and protocols for consultation with each of its key stakeholders. This work expands on the principles established by HIY's approach to Communities and Social Performance. Most closure consultation is conducted within this existing framework.

Consultation is commenced in the early stages of the closure planning process, and continues through to site relinquishment. The consultation strategy used by HIY is designed to:

- identify stakeholders and interested parties;
- develop a targeted consultation plan to reflect the needs of the stakeholder groups and interested parties;
- integrate the consultation plan into the mine planning/closure planning process; and
- where practicable, work with communities to manage the potential impacts of mine closure.

Closure consultation is usually conducted within a broader consultation framework, as a component of on-going consultation forums. For example, consultation with State and Local Government stakeholders occurs as part of regular meetings held with individual agencies. Consultation on specific issues is also undertaken outside of these regular meetings as the need arises. Consultation with other stakeholders is conducted in a manner that is appropriate to the stakeholder and the specific issues requiring discussion.

The timing of discussions and discussion focus will change as the project matures or new deposits are discovered and developed. The focal areas for discussion are illustrated in Table 2.

Table 2: Closure discussion framework

Stage	Focus
Prior to deposit development	Undertake stakeholder identification and stakeholder mapping. Commence closure-specific discussions with key stakeholders. Discuss and agree (where relevant) key environmental, cultural and social values and closure objectives. (Usually undertaken in conjunction with environmental approval discussions.) Review public comments provided though public environmental review processes to identify additional stakeholders and / or concerns.
During operations	Ensure closure objectives and indicative closure criteria remain relevant and appropriate. Communicate outcomes of studies undertaken to improve the closure knowledge base, reduce closure risks or improve closure strategies, as part of the closure plan review process. Include closure in Traditional Owners liaison forums, established under the terms of Indigenous Land Use Agreements with relevant groups.
In the lead up to closure (development of Decommissioning Plan)	Undertake communication campaign to finalise completion criteria through key stakeholder consensus. Discussion future uses for infrastructure with other parties, i.e. for sale of equipment. Commence workforce communication strategy.
Post-closure	Establish a public awareness campaign to demonstrate progress of closure against completion criteria.

8.2 Communication register

Key stakeholders in the closure of Yandicoogina are listed in Table 3. This list is dynamic and is expected to evolve over time. The communications register (Table 4) summarises the discussions that have been held with stakeholders with respect to closure.

Table 3: Key stakeholders

Category	Stakeholder
Commonwealth Government	Department of the Environment
State Government	Department of State Development (**DSD**)
	Department of Aboriginal Affairs (**DAA**)
	Department of Mines and Petroleum (**DMP**)
	Office of the Environmental Protection Authority (**OEPA**)
	Department of Parks and Wildlife (**Parks and Wildlife**)
	Department of Environment Regulation (**DER**)
	Department of Water (**DOW**)
	Department of Regional Development and Lands (**RDL**)
	Department of Agriculture and Food WA (**DAFWA**)
	Main Roads WA (**MRWA**)
	Pastoral Lands Board
Local Government	Shire of East Pilbara
Community	Banjima people
	Nyiyaparli people
	Yinhawangka (formerly Innawonga) people
	Marillana Pastoral Station
	Fortescue Metals Group (**FMG**)
	BC Iron Limited
	BHP Billiton Iron Ore
	Brockman Mining Limited
	Mineral Resources
	Hamersley HMS Pty Limited

Table 4: Stakeholder engagement (communications) register

Date(s)	Title of communication	
Stakeholders	**Outcomes**	**Resolution and related actions**
1996	Junction Central environmental approvals	
EPA public process, public submissions from: Conservation Council, Dept Aboriginal Affairs, Dept Conservation & Land Management, Dept Minerals & Energy, Dept Resources Development	The main closure concerns identified by stakeholders were: • salinity of any remaining pit voids; and • aquifer rebound, and vegetation stress caused by depressed groundwater levels. A commitment was made to develop a decommissioning plan at least 2 years prior to closure: the EPA considered this to be insufficient, and imposed a condition requiring the plan to be developed within 5 years of commissioning.	Commitment to develop a decommissioning plan at least 5 years prior to closure was adopted.
1998	Agreement on key environmental criteria	
Department of Environment, Water & Rivers Commission	Closure performance criteria agreed as part of the 1998 closure planning process. Agreed criteria were: • maintain beneficial use (stock watering) water quality in Weeli Wolli braided area; • limit extent and intensity of impact of drawdown on creek and phreatophytic vegetation to within 1 to 2 km of the pit; and • limit the potential for saline development of in-pit water to less than 15,000mg/L.	These criteria were re-affirmed in the 2003 closure plan update and approved by the DEC in 2005. Note, the FMG Nyidinghu project is now located within the Weeli Wolli braided area. The potential mining influence on this location suggests the Weeli Wolli braided area is no longer a suitable measurement location.
2005	Junction South East environmental approvals	
EPA public process. Consultation was undertaken in preparation of Environmental Protection Statement with: Environmental Protection Authority, Dept Environment, Dept Conservation & Land Management, Conservation Council, Wildflower Society, Gumala Aboriginal Corporation, BHP Billiton Iron Ore, Hope Downs Management Services.	Closure related issues raised by stakeholders related to the following issues: • Salinity of mine void lakes; • Surveys and rehabilitation plans for 'Backfill Hill' prior to mining for backfill material; • Mechanisms for development of completion criteria; • Undertaking closure planning as a component of operational mine planning; • Minimisation of the time between mining and rehabilitation. The final proposal approved by the EPA included the following closure strategy (developed after stakeholder consultation, and not questioned during the public appeal period): "*Use out of pit waste dumps and ROM pad, plus additional mined fill, to backfill the final pit void to at least 490mRL. Rehabilitation of backfilled material to commence once final landforms are constructed and stable*."	A closure plan was submitted in 2008 to comply with the commitment to revise the 2003 Closure Plan to include JSE within 12 months of commissioning.

Date(s)	Title of communication	
Stakeholders	**Outcomes**	**Resolution and related actions**
2010	Junction South West and Oxbow expansion	
Office of the Environmental Protection Authority, Department Environment & Conservation, Department of Water, Department of Mines & Petroleum	Several meetings were held with Government agencies concurrent with Junction South West and Oxbow expansion proposal, including a one day workshop 28 May 2010 where closure objectives and options were discussed. Departmental officers agreed that it may be appropriate to review existing objectives, but indicated that such decisions would need to be made by the OEPA. Efforts to engage discussion with the OEPA during the course of the study were unsuccessful. A formal letter was sent to the OEPA on 18 June 2010[5], with no response. DMP officers suggested that an objective be included that relates to erosion management. Departmental officers agreed that the existing closure strategy (partial backfill) is likely to be inappropriate, but indicated that formal endorsement of alternative strategies would need to be made by the OEPA. Departmental officers did not endorse any particular alternative closure strategy on the basis that further information is required to enable reasonable assessment. However; there was some qualified support for the 'channel' and 'pit void' options.	An indicative completion criteria relating to landform stability has been included in the closure plan.
Gumala Aboriginal Corporation	Half day workshop 24 March 2010 to discuss ethnographic values relevant to closure, to introduce closure options, and obtain feedback on options[6]; and Attendance at the Gumala elders meeting 20 August 2010 to discuss issues specific to the 'channel final landform configuration' (the preferred landform scenario presented in this study report). Concerns were initially raised that the final landform would be different to the pre-mining landscape. No specific ethnographic values that may affect closure planning were identified in the discussions. It was clear at this stage that the Traditional Owners did not wish to provide definitive answers regarding the project, as the options discussed were at a broader strategic level. With respect to the channel configuration, the following issues were identified: • Any standing water should be of suitable quality to maintain a functional ecosystem; • The channel should be constructed in such a manner that enables egress to people or animals that enter; • Heritage surveys conducted to date are not sufficient to identify impacts. Surveys of	Concerns raised by Gumala have been discussed in the closure plan. Engagement with Traditional Owners is proposed to continue via the regular GAC Monitoring and Liaison Meetings

[5] Correspondence to Office of the Environmental Protection Authority dated 18 June 2010, RTIO-CR-0022848

[6] Workshop outcomes are documented in memo RTIO-CR-0024696. The summary of outcomes was also forwarded to Gumala Aboriginal Corporation on 26 March 2010

Date(s)	Title of communication	
Stakeholders	**Outcomes**	**Resolution and related actions**
	additionally impacted areas would be required; • Consideration should be given to maintaining access from one side of the channel to the other; and • Further discussions will be required with Traditional Owners when more specific closure plan details have been established.	
2013	Traditional Owner liaison meetings	
Gumala Aboriginal Corporation	At the June 2013 Yandicoogina Land Use Agreement Monitoring and Liaison Committee an overview of the mine closure process was presented to the GAC board members. It was agreed at the meeting to form a sub-committee / working group to address issues relating to closure and land management. The terms of reference for the sub-committee / working group are yet to be resolved.	HIY subsequently (October 2013) met with the Gumala Aboriginal Corporation Lore and Culture Committee to discuss participation of Elders in the closure working group. A decision on Elder's participation and representation is still pending.
2014	Pocket and Billiard South expansion	
Elders representing the Banjima, Nyiyaparli and Yinhawangka peoples	At this forum, HIY presented the key outcomes of heritage, environment and closure associated with the proposed Pocket and Billiard South expansion project at Yandicoogina. The closure objectives were reaffirmed with the Elders, and clarification of the predicted outcomes for closure of the Yandicoogina site as approved today and including outcomes should expansion continue through to the Billiard North area were discussed.	Water quality was a primary concern for the participants. HIY committed to continue to apprise the community on updates to water quality predictions through the Gumala Monitoring and Liaison Committee.
OEPA, DMP, DoW, Parks and Wildlife	HIY presentation of the Pocket and Billiard South expansion proposal at various forums.	No closure specific actions identified.
2015	Pocket and Billiard South expansion	
OEPA, DMP, DoW and Gumala Aboriginal Corporation	HIY presentation of the Pocket and Billiard South expansion proposal at various forums.	No closure specific actions identified.
2015	Yandicoogina Closure – BHPB & RTIO	
BHP Billiton Iron Ore	HIY presented the Yandicoogina closure plan. BHP Billiton advised they are starting a major update to the Yandi closure plan, including design of Marillana Creek realignment. General discussion between subject matter experts regarding modelling of pit lakes, groundwater movement and surface water – approaches and boundary condition controls. HIY emphasised that current modelling predictions are based on BHP Billiton's published closure outcomes, and expectation that Marillana Creek hydrological regime will not be changed by BHP Billiton realignment activity. It was established that surface water connectivity to groundwater system was different at each site.	No closure specific actions identified.

8.3 Ongoing consultation synopsis

8.3.1 Regional community and local government

Yandicoogina is a remote mine site. The workforce is FIFO, housed in purpose built accommodation areas, with a small proportion (10%) of staff working permanently from the Perth main office. The majority of the FIFO personnel are permanent employees that live in Perth. The nearest town to Yandicoogina, Newman, is located 90km south-east. Newman is ostensibly linked to BHP Billiton Mt Newman iron ore mine, located on the outskirts of the town. Yandicoogina has negligible interaction with Newman or any other local towns. Closure of Yandicoogina has not been discussed with the regional community or Shire of East Pilbara.

No significant non-Indigenous cultural heritage values have been identified through the broader consultation and research activities undertaken to date. It is recognised that locations along Weeli Wolli Creek are opportunistically accessed by the general public for camping, fishing and other associated recreation activities.

Community engagement with respect to closure is expected to commence approximately 5 years from scheduled closure.

8.3.2 Aboriginal groups

Yandicoogina straddles the native title boundary between Banjima land (west) and Nyiyaparli land (east) (Figure 3). The Yinhawangka people, who share a common language (Banjima) with the Banjima and Nyiyaparli peoples, were heavily involved in development of the Yandicoogina Land Use Agreement and are also closely linked to the mine development. Members of these language groups are geographically dispersed with key locations being Wakathuni and Bellary near Tom Price, Onslow, Roebourne, Karratha and Port Hedland.

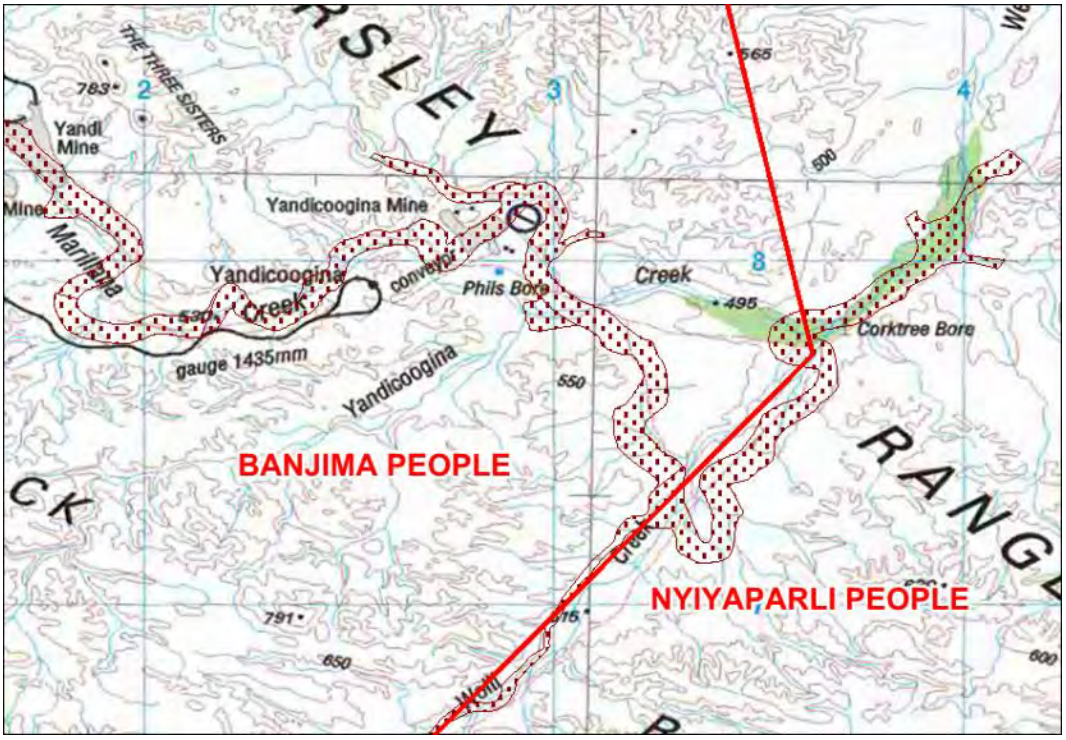

Figure 3: Native Title boundaries.

Consultation with Banjima, Nyiyaparli and Yinhawangka on life of mine planning aspects, including closure, is undertaken through regular Monitoring and Liaison Committee Meetings. This committee is a joint forum of HIY senior leaders and Gumula Aboriginal Corporation who represent the interests of the Banjima, Nyiyaparli and Yinhawangka people. Extensive archaeological and ethnographic surveys have been undertaken within the Yandicoogina locality, principally in association with mining activities in the area. Closure aspects are also raised and discussed, when appropriate, during ethnographic surveys and similar forums. Where appropriate, this engagement is documented as part of the Cultural Heritage Management System. The outcomes of these sessions and surveys are used to inform the development of closure strategies.

Closure consultation with Traditional Owners, to-date, has focused on landscape-scale changes. Topics discussed with Traditional Owners and their representatives include:

- Preservation of remaining ecosystems and protection for creek banks;
- Lake water quality;
- Ongoing importance of ethnographic and archaeological surveys;
- Role of Gumala Aboriginal Corporation in closure planning;
- Importance of including elders and young people in consultation;
- Management of artefacts at closure;
- Potential community use of site infrastructure after closure; and
- Access through and around the mine and into the lake areas.

Water is a highly valued resource in the Pilbara, and water has high significance for Pilbara Indigenous communities generally[7]. The views represented by the Banjima, Nyiyaparli and Yinhawangka peoples are consistent with those of other Indigenous people of the Pilbara and regions across Australia. Rumley and Barber (2004) explain, '…*that in Indigenous belief systems water is perceived as an elemental part of the broader cultural landscape, held and managed under customary systems of law. Water sources are derived from the actions of mythic beings during the Dreaming and are the most important features in the Pilbara cultural landscape. Sustaining and protecting country, including the relationships Traditional Owners have with particular places, was found to be the primary obligation for people*'.

Marillana Creek, Yandicoogina Creek, Weeli Wolli Creek and Phils Creek have all been identified as places of high cultural significance. Cultural values at Yandicoogina are generally associated with camping, ceremonies and other cultural activities, which are generally undertaken adjacent to these creek systems. Consequently, any proposed long-term alteration to the creeks is of interest to Traditional Owners. Traditional Owners have suggested, however, that pit lakes may be beneficial, e.g. for camping, fishing etc., if the water is of a suitable quality to support natural ecosystems.

Numerous Aboriginal archaeological sites have been recorded in the mine area including artefact scatters, quarries, skeletal material / burial, rock shelters, engraving sites and scarred trees. These sites range from low to high archaeological and cultural significance. At closure, repatriation of cultural artefacts to the Yandicoogina area is anticipated, and thus sustained access to existing heritage sites and agreed repatriation sites will need to be included in the closure landform design.

[7] Rumley & Barber (2004) We Used to Get Our Water Free – Identification and Protection of Aboriginal and Cultural Values of the Pilbara Region, April 2004, Study report prepared for the Water & Rivers Commission

POST-MINING LAND USE AND CLOSURE OBJECTIVES

9. Post-mining land use

The Pilbara is classified as an Extensive Land Use Zone. The majority of the development area overlies the Pastoral Lease L3114 984, owned by BHP Billiton Iron Ore and operated as Marillana Station. (JSW-A and Oxbow partially overlay Vacant Crown Land.) Prior to mining, the land was heavily grazed by cattle.

Traditional Owners, the Banjima and Nyiyaparli peoples, regularly access culturally significant areas in the local area, to maintain traditional law and connection to country. This connection to land is the basis for the formal recognition of Traditional Owner native title rights and interests.

Mining and pastoralism are the only industries that have historically proven viable in the Pilbara. Inland regions are sparsely populated, with the largest inland towns, such as Tom Price, Paraburdoo and Newman, established specifically to support the mining industry.

Pit lakes and the associated lake fringe that will be created on closure (Figure 4) are not expected to be compatible with cattle grazing, but may provide alternate land-use opportunities, including recreation / camping grounds and / or fauna refuge (due to the permanent water supply). These opportunities are subject to further discussion with relevant key stakeholders.

Until the post-mining land use is agreed, the closure and rehabilitation strategy will focus on the following, to ensure the system remains compatible with general Pilbara land uses:

- create landforms that are stable for access by humans and native fauna;
- ensure water systems support existing riparian vegetation and are compatible with the natural system dynamics; and
- establish ecosystems with similar biodiversity and cultural heritage values as surrounding reference sites.

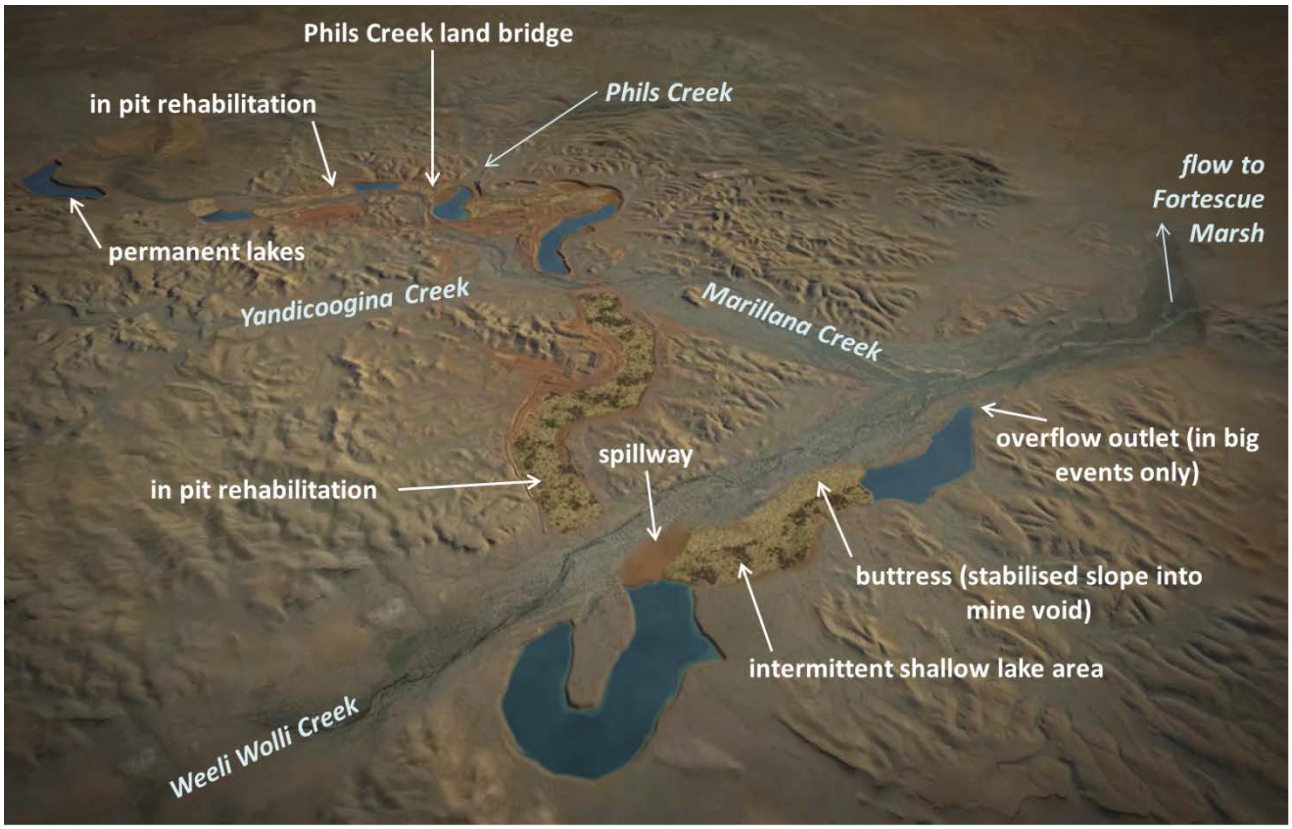

Figure 4: Conceptual landform design for Yandicoogina.

10. Closure objectives

10.1 HIY's vision for closure in the Pilbara

Closure objectives for Yandicoogina have been developed with consideration of HIY's general vision for closure, to:

- relinquish its mining leases to the Western Australian State Government;
- preserve, protect and manage the cultural heritage values of the area in cooperation with the Traditional Owners and other stakeholders;
- develop and implement strategies for closure which consider the implications on local communities;
- achieve completion criteria which have been developed with stakeholders and agreed with Government;
- develop landforms that are safe and stable and compatible with the surrounding environment and post-mining land use;
- achieve environmental outcomes that are compatible with the surrounding environment;
- implement a workforce strategy which addresses the impacts of closure on employees and contractors; and
- achieve successful closure in a cost effective manner.

10.2 Yandicoogina closure objectives

The ultimate goal of mine closure at Yandicoogina is to relinquish the site to the Government. This goal will be achieved once the key stakeholders agree that the condition of the site is compatible with the agreed post-mining land use(s). Table 5 lists the closure objectives developed in consideration of the key stakeholder expectations for mine closure.

Table 5: Yandicoogina closure objectives

	Objective
1	Rehabilitated landforms are stable and designed to manage floodwater appropriately
2	The environmental and cultural heritage values associated with creek flows and function are maintained post-closure
3	Environmental values of Fortescue Marsh are not compromised
3	Water quality within pit lakes support natural ecosystems and are compatible with post-mining land use
4	Alluvial groundwater systems support remnant phreatophytic vegetation
5	Final landforms are rehabilitated to be compatible with post-mining land use
6	Public safety hazards have been addressed

COMPLETION CRITERIA

11. Completion criteria

Completion criteria can be defined as the indicators used to determine whether closure objectives have been met. They are used to measure the success of closure implementation against objectives, and to facilitate relinquishment of mining tenure.

The completion criteria, presented in Table 6, have been developed following consultation with stakeholders and in consideration of the predicted closure outcomes. Measurement processes, and the associated supporting data (evidence and / or metrics), that will be used to calculate or otherwise define the conditions at Yandicoogina are also described in Table 6.

The completion criteria are subject to ongoing review and update, informed by the outcome from studies identified in the closure task list (Table 20) and ongoing stakeholder consultation. As the site approaches scheduled closure the completion criteria will contain more measurable and time-bound parameters.

Table 6: Indicative completion criteria.

Objective	Indicative completion criteria	Process	Evidence or metrics / data
1. Rehabilitated landforms are stable and designed to manage floodwater appropriately	1a. Erosion does not threaten the long term stability of the landform	Visual and measured assessment of erosion from rehabilitated areas for comparison of trends Post-closure evaluation of long-term erosion due to flooding	Rill and gully frequency Gully depth and width Water monitoring: • volumes, flows, levels • quality / chemistry Weather data and climate trends
2. The environmental and cultural heritage values associated with creek flows and function are maintained post-closure	2a. Surface water remains at a level and quality that ensures retention of ecological function and cultural value	Post-closure evaluation of surface water conditions against baseline (pre-mining) conditions and / or reference site trends over time. Post-closure evaluation of ecological values (vegetation and fauna) against baseline (pre-mining) conditions and / or reference site trends over time.	Photographic evidence that: • a disturbance buffer has been maintained • water is present post-closure Ecological survey(s) to determine: • fauna diversity / richness • vegetation, habitat • tree health monitoring Water monitoring: • volumes, flows, levels • quality / chemistry Weather data and climate trends
3. Environmental values of Fortescue Marsh are not compromised	3a. The frequency of large flood events is maintained at the downstream tenement boundary	Post-closure evaluation of flood conditions against baseline (pre-mining) conditions.	Water monitoring: • volumes, flows, levels • quality / chemistry Weather data and climate trends

Objective	Indicative completion criteria	Process	Evidence or metrics / data
4. Water quality within pit lakes support natural ecosystems and are compatible with post-mining land use	4a. Groundwater salinity is not predicted[8] to exceed 2,500mg/L at the downstream tenement boundary. 4b. Lake salinity is not predicted to exceed 4,500mg/L or pH <8.5.	Post-closure evaluation of groundwater recovery conditions against model predictions. Post-closure evaluation of lake water quality recovery conditions against model predictions.	Water monitoring: • volumes, flows, levels • quality / chemistry Weather data and climate trends
5. Alluvial groundwater systems support remnant phreatophytic vegetation	5a. Tree deaths more than 2km from the edge of each pit do not result from water quality or drawdown impacts stemming from the post-closure landform.	Post-closure evaluation of phreatophytic vegetation against post-mining conditions and / or reference site trends over time.	Ecological survey(s) to determine tree health Water monitoring: • volumes, flows, levels • quality / chemistry Weather data and climate trends
6. Final landforms are rehabilitated to be compatible with final land use	6a. Vegetation on rehabilitated land is native and self-sustaining 6b. Habitat for native fauna is provided in appropriate rehabilitated areas 6c. The prevalence of invasive species (weeds, feral animals) is similar to or less than that in nearby reference sites.	Field vegetation monitoring for comparison of trends Field monitoring of fauna habitat indicators for comparison of trends	Vegetation monitoring including: • Species richness • Species diversity • Percentage cover Records of seed provenance Fauna habitat monitoring (may include): • spinifex cover • shrub cover • evidence of scats/tracks • litter cover • indicator species (e.g. ants) Feral animal management records
7. Public safety hazards have been addressed	7a. Measures to eliminate or mitigate public safety hazards have been agreed with stakeholders and have been implemented.	Identification of potential hazards to the public in the decommissioned area. Audit(s) to confirm that hazard mitigation measures have been implemented.	Reports: • Geotechnical evaluation • Fibrous materials audit • Contaminated sites audit • Electrical safety inspection • Public access evaluation • Traditional Owner cultural access requirements

[8] The reference to predicted values reflects the fact that equilibrium conditions may not be reached prior to relinquishment.

COLLECTION AND ANALYSIS OF CLOSURE DATA

The closure knowledge base (Appendix B) is a collection of baseline studies, models and interpretations, which are used to inform the closure planning process presented in this closure plan. The knowledge may be specific to the site or generally applicable to the Pilbara region; and includes information on the performance of closure-related trials completed at other Pilbara mining operations (when appropriate). At this stage of the closure plan development, only summaries of these reports are provided and the relevant information is summarised below. The relevant knowledge base reports will be included in the final closure plan.

12. Climate

Climate, particularly rainfall, rainfall intensity, cyclone frequency and evaporation, influence closure planning aspects such as landform stability and erosion rates, pit lake modelling, and revegetation success.

The climate in the Yandicoogina area can be characterised as arid tropical with two distinct seasons: hot wet summers and cool dry winters. Mean daily maxima temperatures range from 39°C in summer to 24°C in winter. Daily temperature can rise up to 50°C during the summer and drop to 0°C in winter.

Evaporation is the most important factor for biological water use in the region, influencing both plants and animals[9]. Throughout the Pilbara, potential evaporation, estimated to be around 3500mm to 3700mm[10] per year, exceeds average annual rainfall by a factor of at least eight and by up to twenty fold in the south-east (near Yandicoogina).

12.1 Rainfall and significant weather events

Rainfall in the Pilbara averages from 200mm to 400mm per year. The majority of rain falls in the three months from January to March, each typically averaging more than 50mm per month and often falling in heavy rainfall events associated with tropical lows. The period between May and November is practically dry, with average rainfalls of less than 20mm per month.

HIY has maintained a meteorological monitoring station at Yandicoogina since commissioning the mine in 1998. In addition, there are a number of other gauging stations managed by Government departments in the area[11]. However, the climate records are inconsistent, with numerous gaps in the datasets as a result of equipment malfunctions, often during extreme weather events.

From data recorded at Yandicoogina, and augmented by neighbouring stations to create a longer historic record, the average rainfall over the past 20 years at Yandicoogina is approximately 390mm to 400mm per annum. Annual rainfall is highly varied, with recorded rainfall ranging from 148mm to 890mm over a calendar year[12]. The highest recorded monthly rainfall was 480mm during December 1974, which was associated with Tropical Cyclone Joan. This system brought wide spread and, in many locations, unprecedented flooding to the Pilbara. For comparison, a single rainfall event which produces between 200mm and 370mm within 24 to 72 hours over the Marillana Creek Catchment is classified by Engineers Australia (2001)[13] as a 1 in 100 year annual recurrence interval (ARI) rainfall event. An event of this magnitude was recorded at Yandicoogina during January 2003.

[9] N.L. McKenzie, S. van Leeuwen and A.M. Pinder (2009) Introduction to the Pilbara Biodiversity Survey, 2002–2007. Records of the Western Australian Museum, Supplement 78: 3–89, 2009.

[10] Mean annual pan evaporation from Newman. Average annual evaporation rate as measure from Yandicoogina dry bulb data is around 1800mm per year, which more closely approximates actual evaporation from dam situations.

[11] Rainfall records for the Weeli Wolli Creek Catchment include: Australian Bureau of Meteorology (BOM) Rhodes Ridge 007169 (Feb 1971 to Oct 2011), Packsaddle Camp 005089 (Jan 1989 to Jun 2002), and Western Australian Department of Water (DoW) Wonmunna 11247 (Nov 1984 still open), Tarina 11220 (May 1985 still open), Munjina 11186 (Jan 1969 still open), Packsaddle 11196 (Jun 1970 to Sep 1999), Flat Rock 11193 (Mar 1970 still open), Yandicoogina 11217 (Dec 1979 to Apr 1986) and Waterloo Bore 11221 (May 1985 still open). Immediately downstream of Weeli Wolli Catchment in Fortescue Marsh gauges of relevance include BOM Marillana 005009 (Dec 1936 still open) and Sand Hill 005064 (May 1971 to Jul 1984). There are no open, publically available gauges with the Weeli Wolli Creek Catchment for other climate aspects. The closest gauges are approximately 100km away and include: Newman Aero 007176 (1971 still open) and Newman Town 007151 (1965 to 2001) to the east, Wittenoom 005026 (1949 still open) to the west, and Redmont 004043 (1925 still open) to the north. Note most of these records are incomplete.

[12] Using a season split from October to September to encompass the entire wet season, rainfall extremes range from 124mm to 1060mm over 12 months with an average of 390mm.

[13] Institution of Engineers Australia (2001*) Australian Rainfall and Runoff*. Editor-in-chief D.H. Pilgrim, Barton, ACT. This report defines the standards for engineering surface water control structures in Australia.

The north / north-western coastline of Australia has experienced more tropical cyclones than anywhere else on mainland Australia. In this region most tropical cyclones are observed during the late summer, occurring anytime from November through to May with their maximum frequency during January and February. On average, five tropical cyclones are expected off the Pilbara coast each year, with two expected to make landfall. Tropical cyclones and tropical lows commonly produce damaging wind gusts in excessive of 150km per hour, heavy rains and regional flooding.

12.2 Climate change

Our understanding of how climate will change in the future in the Pilbara is guided by the outcomes of climate modelling, commissioned privately by Rio Tinto and other Australian government agencies.

From modelling completed to date, our understanding of Pilbara climate change suggests the region will experience the following climate trends.

- A shift in the historical tropical cyclone season, with an earlier start and potentially later finish.
  - For the period from 2051 to 2099, compared to present day, tropical cyclone frequency could decrease by half while the duration of a given tropical cyclone could decrease by 0.6 days on average when compared to present day. Projections also suggest, however, that tropical cyclones could increase in size and intensity
- Continuation of the highly variable multi-decadal scale rainfall trends.
  - Projected rainfall reductions range from 1 to 24% for mid-century, and 9 to 24% for the end of the century
- A significant warming trend, influencing maximum temperatures, with the largest changes during the January to March period.
  - On average, maximum temperatures are expected to increase by 2.1 to 3.2 ˚C by mid-century and by a total range of 3.8 to 4.6 ˚C by the end of the century. For minimum temperatures the corresponding averaged increases are 1.9 to 2.4 ˚C (mid-century) and 4.1 to 4.6 ˚C (end of the century).

The main climate drivers for the Pilbara are the El Nino Southern Oscillation (ENSO) and Indian Ocean Dipole (IOD) ocean currents. However, these ocean currents are not well represented in most global climate models, and as a result, climate predictions for the northwest of Western Australia can vary significantly. The ENSO and IOD ocean currents are currently being researched by CSIRO. At the same time, modelling is being progressively improved by various Australian Government agencies to expand our understanding of the climate drivers in the southern hemisphere, our understanding the associated impacts on water availability and to predict changes to existing ecosystems.

Consequently, at present, there is insufficient agreement on climate change within the scientific community at the level of detail that is required to inform a detailed assessment of climate change impacts on weather, stream flow, water availability and vegetation response at Yandicoogina. This position will be reviewed periodically and new knowledge will be incorporated into studies as appropriate.

12.3 Climate and landform stability

The heavy, intense rainfall experienced in the Pilbara makes rainfall the key climatic factor that influences surface stability in the Pilbara. Rainfall erosivity (measured in megajoule millimetre per hectare per hour per year - MJ.mm/ha/hr/yr) is the term used to describe the erosive force of rain. For Pilbara sites, long-term annual erosivity values range from ~1,000-1,600 MJ.mm/ha/hr/yr. Rainfall in the Pilbara is typically more erosive than Perth's rainfall, even though it only receives on average half the rainfall that Perth receives on an annual basis. For comparison, average annual erosivity values for Perth are ~1000 MJ.mm/ha/hr/yr from an average of 780 mm of rain a year.

Rainfall erosivity is highly variable from year to year, or even from event to event. Studies of Pilbara rainfall concluded that at Tom Price, for example, erosivity for the period 1998 to 2009 ranged from 212 – 6,349 MJ.mm/ha/hr/yr. The most erosive year recorded was 2007 at Channar, where 421mm fell during February (704mm fell over the whole year). This singular rain period embodied 11,994 MJ.mm/ha/hr/yr of erosive force, or 89% of the entire erosivity of rain for that year. Given the pattern of intense and infrequent rainfall events in the Pilbara, it can be expected that only a few events every year (~1-3 events) will generate the majority of runoff and erosion of that occurs each year.

The studies showed a rapid decline in erosion or sediment yield occurs when annual rain decreases below about 300mm per year due to a corresponding decline in rainfall volumes and rainfall erosivity. However, when annual rainfall increases above ~300mm, vegetation growth increases and becomes increasingly effective in controlling soil erosion. Hence, there is a point of maximum erosion potential at an annual rainfall

value of ~200-400 mm such that surface (vegetation) cover is low due to lack of rain and ineffective for controlling erosion, yet rainfall erosivity is sufficiently high to cause erosion, as observed in the Pilbara.

Outcomes from these studies have informed development of the Rio Tinto Iron Ore (WA) Landform Design Guidelines for achieving stable waste dumps.

12.4 Climate in water models

As a key component of all water models, climate, and the accuracy of future climate predictions, is a major influence in groundwater and surface water predictions.

Most regional groundwater models in the Pilbara, for example, are innately attuned to current climate conditions as they are calibrated to observed groundwater levels. A groundwater level, as measured at a single bore, represents the result of rainfall that has infiltrated through the soil and possibly been subjected to evaporation / evapotranspiration processes. If the water is relatively young and within an unconfined aquifer, as at Yandicoogina, then the groundwater level today is a reflection of the immediate past climate; notably rainfall volumes and flood frequency. As seen in the bore logs, a few years of dry weather results in a drop in the groundwater levels while a few wet years and the levels rise.

As the reaction of a groundwater table to rainfall is not a linear relationship, if climate shifts beyond the observed climate range the model has no guidance as to how the groundwater should behave. As a consequence, the results of these deterministic models may not provide accurate predictions as the climate changes.

To overcome these limitations, work has commenced on the use of stochastic models to examine the interactions between creek and groundwater systems. Stochastic models can calculate the outcome of thousands of different theoretical climate sequences to provide guidance on the probability of certain conditions occurring. At present, the use of stochastic models is limited to simple models due to the computer processing capacity and time required to compute simple situations. However, as technology improves it is anticipated that this constraint may be overcome.

12.5 Climate and vegetation growth

Water is generally the limiting factor for plant growth in the Pilbara’s arid environment. As a consequence of the hot temperatures, high evaporative demand and infrequent and irregular rainfall, much of the vegetation displays xeromorphic adaptations (plant structural adaptations for survival in dry conditions). These adaptations include the ability to regulate water loss from leaves, extract water from very dry soils and match reproductive strategies with wetter periods. Many species are ephemeral and persist in soil banks in between wetter periods.

The adaptive capacity of Pilbara species implies a degree of resilience to changes to hydrological regimes. However, the impacts to Pilbara vegetation as a consequence of climate change are not clear. Changes in vegetation density and water use will alter the amount of runoff that occurs after a rainfall event, which in turn will alter creek flows and groundwater recharge.

Some initial studies within the wider Weeli Wolli Creek catchment are underway to understand how the presence and absence of water affects vegetation growth within riparian corridors. The outcomes from these studies and other evolving research on climate change will be monitored and integrated into Yandicoogina closure studies to inform assumptions on climate influences and impacts.

13. Land

13.1 Geographical overview

Yandicoogina is located near the eastern edge of the Hamersley sub-region, adjacent to the Fortescue Plains sub-region, of the Pilbara biogeographic region[14]. As described in Table 7, the majority of the landscape within the project area is considered typical of the Hamersley sub-region, while the creek systems have affinities with the Fortescue Plains sub-region.

Table 7: Important biogeographic zones

Zone	Description
Hamersley	Mountainous area of Proterozoic ranges and plateaus of mulga woodland bunch grasses on fine textured soils and snappy gum over *Triodia brizoides* on skeletal soils.
Fortescue Plains	Alluvial plains and river frontages, salt marsh, mulga bunch grass and short grass communities on alluvial plains. River Gum woodlands fringe drainage lines. Northern limit of the *Acacia aneura* complex (Mulga).

The topography of the locality is provided Figure 5. The surface topography at Yandicoogina has been shaped by alluvial processes with the existing streams winding between low lying mesas and hills. The dominant landscape features are the ephemeral watercourses that drain to the northeast to Fortescue Marsh. The creek lines follow a surface gradient sloping downwards from west to east (~520mRL at Oxbow to ~480mRL near the Marillana Creek and Weeli Wolli Creek confluence).

A row of small hills rising 800mRL to 900mRL extends from JC to the northwest with a line of slightly higher hills (900 to 1,000mRL) oriented in an east-west direction to the south of the current mining operations. The area immediately south of JSW and Oxbow rises to around 600mRL.

The Yandicoogina ore body is a specific type of paleochannel[15] known as a Channel Iron Deposit (CID). This ancient creek channel is located adjacent to the current Marillana and Weeli Wolli Creeks and crosses underneath these modern day creek channels in various locations, as shown in Figure 5.

The CID mined at Yandicoogina consists of three main layers:

- Overburden material. A mixture of lateritic pisolite, poorly sorted angular to sub-rounded banded iron formation (BIF), chert and dolomite gravels in a sandy matrix. Discontinuous kaolin clay in bands and pods are common in the overburden (occurring less frequently in the iron deposits).
- Iron deposits. Mostly pisolite (iron oxide spheroids) with minor components of clay minerals (mainly kaolinite) and petrified wood mixed through the profile. The iron deposit is up to 70m thick. Once the high quality (economic) iron deposit is removed, a thin layer of clay and non-economic iron is left behind; and
- Basement rocks and altered basement rocks. The basement rocks (Weeli Wolli Formation) are what is left of the original geology that was eroded during the formation of the channel. The basement rocks have fewer fractures, gaps and pore spaces than the overlying iron deposits or overburden, such that groundwater that is accumulated within the channel tends to flow along the channel.

[14] As defined by the Interim Biogeographic Regionalisation for Australia (IBRA) which recognises 85 bioregions across Australia: defined on the basis of climate, geomorphology, landform, lithology, and characteristic flora and fauna attributes (Environment Australia 2000).

[15] Paleochannels are remnants of ancient streams cut into old rocks and filled with sediments from younger rocks; such that they reflect historical drainage lines. The contemporary equivalent is called an alluvial channel.

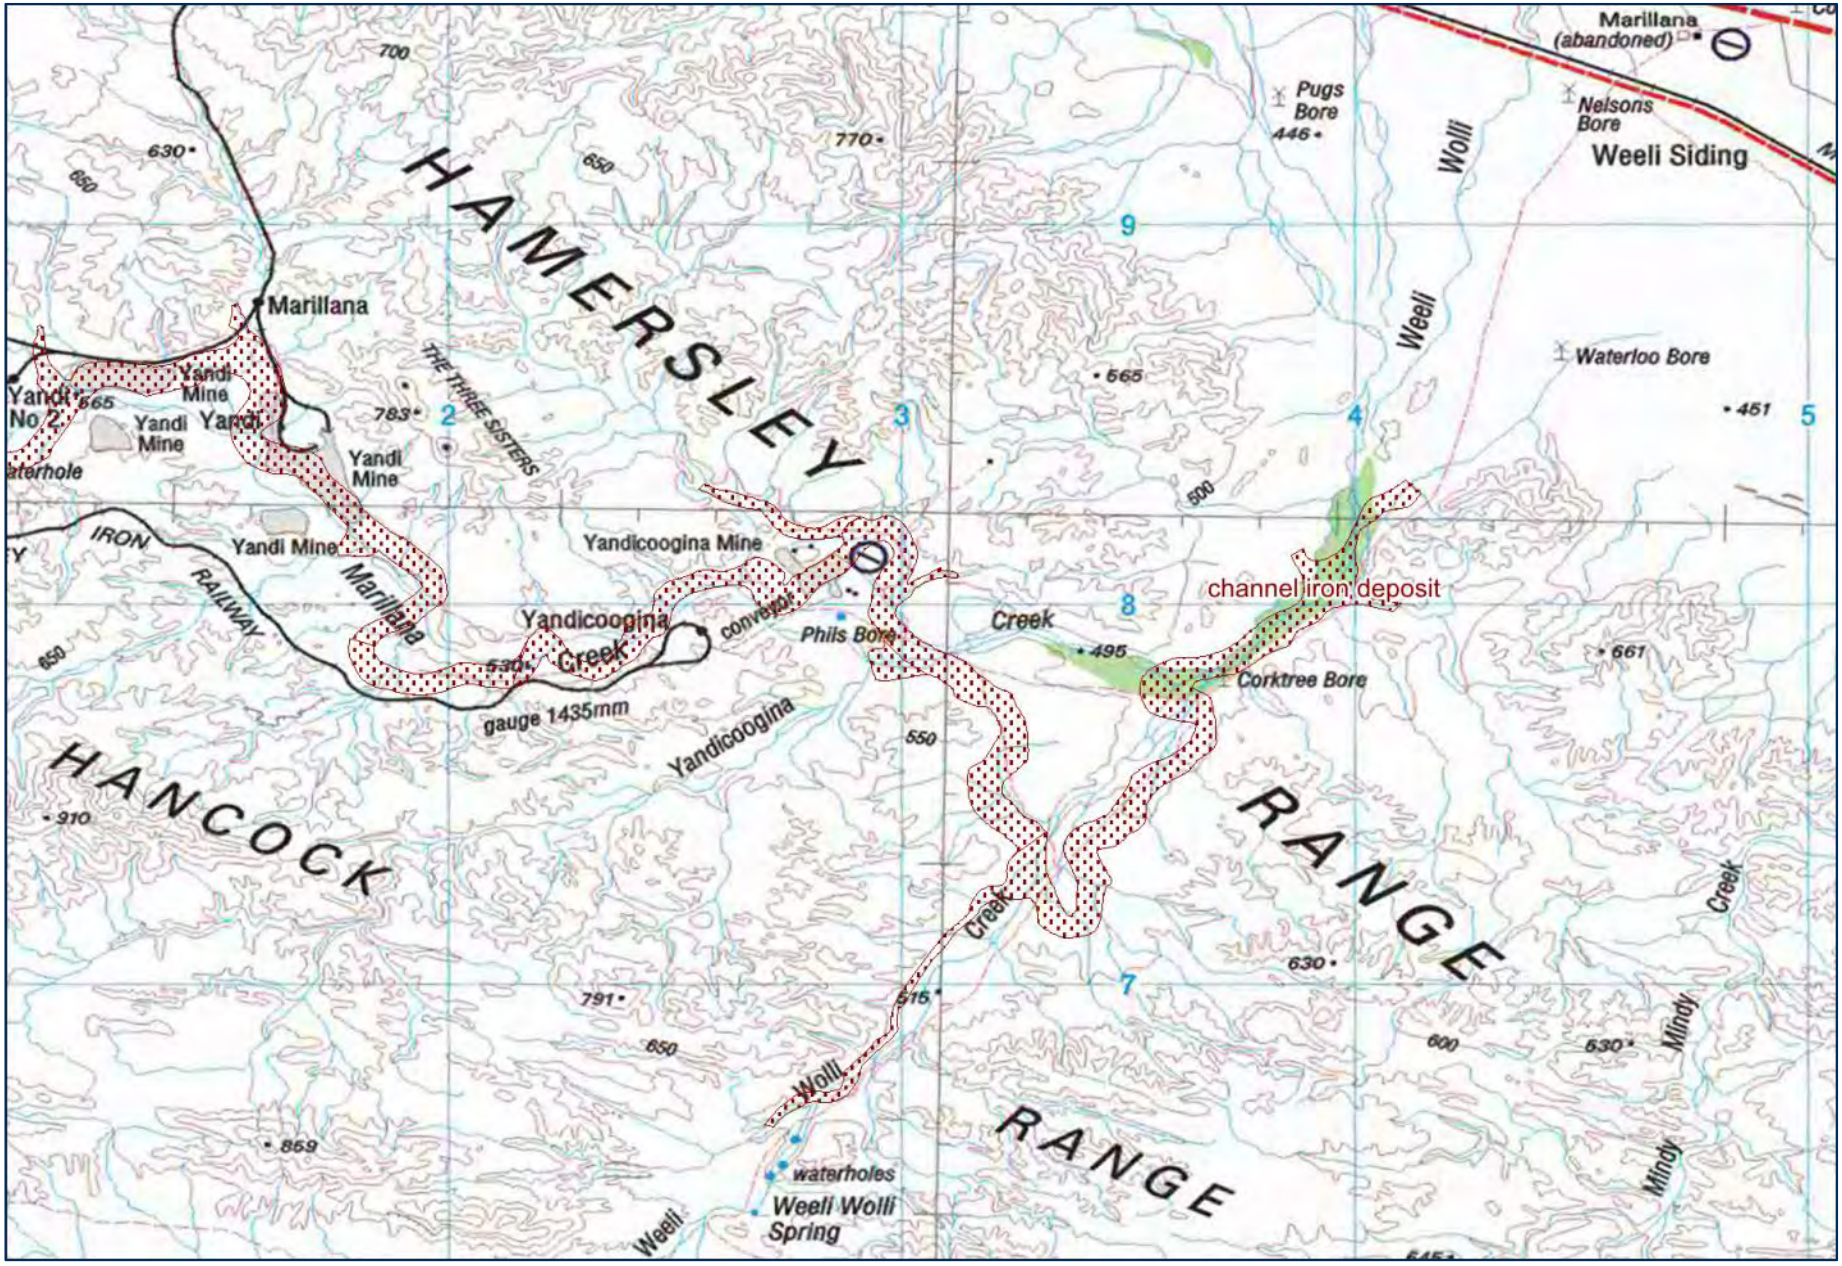

Figure 5: Topographical features including location of the channel iron deposit (CID) palaeochannel.

13.2 Surface water

13.2.1 Creeks

As shown in Figure 5, Yandicoogina is located near the intersection of Marillana Creek and Weeli Wolli Creek. The deposits of Junction Central, Junction South West and Oxbow are located adjacent to Marillana Creek. Junction South East straddles the catchment divide, bound by Marillana Creek to the north and Weeli Wolli Creek to the south, and the proposed expansion deposits of Billiard are located under and adjacent to Weeli Wolli Creek. Marillana Creek is a tributary to the Weeli Wolli Creek system, as part of the regional water catchment known as Weeli Wolli Catchment.

The Marillana Creek system has a total catchment area of 2,250km^2. The headwaters rise from the high relief areas of Hamersley Range where the Creek drains in an east and north easterly direction into the Munjina Claypan. The Claypan has an internally draining catchment area of approximately 274km^2. It is subject to periodic inundation following rainfall events and has the potential to retain surface water flows for lower flood events (≤1 in 10 year annual recurrence interval (ARI)). Water stored in the Claypan is believed to infiltrate and recharge the alluvial systems of Marillana Creek including the CID, and subsequently sustains creek bed (subsurface) flows for longer than (Pilbara) normal periods after flood events.

Water in excess of the basin's holding capacity flows southeast; past Flat Rocks gauging station, BHP Billiton Iron Ore's Yandi mine, Yandicoogina and into Weeli Wolli Creek. Named tributaries of Marillana Creek include Lamb Creek, Iowa Creek, Phils Creek and Yandicoogina Creek.

The Weeli Wolli Creek system, excluding the Marillana Creek catchment area, has a catchment area of 1,750km^2. The headwaters rise from over 50km to the south of the Yandicoogina area, with Weeli Wolli Creek flowing northwest, past the Hamersley HMS Hope Downs 1, BHP Billiton Iron Ore Mining Area C and Jinidi operations, before merging with Marillana Creek (the largest tributary).

As for most parts of the Pilbara, the normal condition for these watercourses is dry. Runoff is ephemeral, occurring only after significant and intense rainfall events. Flow depths in both Marillana and Weeli Wolli Creeks can exceed 5m with velocities through the majority of the channel ranging from 2m/s to 3.5m/s. Large stream flows are generally associated with rain bearing depressions or high intensity cyclonic rainfall that brings heavy rain over a large areas of the catchment.

The flows terminate in Fortescue Valley, north of the Hamersley Range, contributing to Fortescue Marsh; an extensive, intermittent wetland.

Background surface water quality measurements at Yandicoogina are complicated by the discharge of groundwater to Marillana Creek from the BHP Billiton Iron Ore Yandi operation and to Weeli Wolli Creek from Hope Downs 1 operation, both immediately upstream of the Yandicoogina. In one sampling campaign, the chloride concentration 800m down gradient of the BHP Billiton Iron Ore Yandi discharge point was ~125mg/L and increased to ~150mg/L approximately 6km down gradient, towards the terminus of Marillana Creek. Further downstream, in Weeli Wolli Creek, the chloride concentration was observed to decrease to less than 100mg/L as relatively fresh discharged groundwater from the Yandicoogina and the Hope Downs 1 operations mixed with very fresh alluvial water which naturally[16] discharges to the surface.

The background quality of surface water during flood events is undefined, due to the complexity of the sampling requirements and issues around work place safety. However, methodologies to safely sample water during flood events across the Pilbara are being considered; such that samples will be taken once health, safety and environmental protocols can be met.

13.2.2 Pools

Although historically, there have been no permanent surface water bodies present in the local area around Yandicoogina (the closet being Weeli Wolli Spring), discharge from the Yandicoogina and Hope Downs 1 operations has resulted in permanent creek flow and the formation of local semi-permanent pools within Weeli Wolli Creek.

[16] Groundwater that expresses without assistance is called discharge. This should not be confused with water that is released into a creek to manage surplus water which is also referred to as discharge. Natural discharge occurs when the groundwater aquifer is "full", such that slight changes in topography or subsurface changes in hydraulic parameters mean that the volume of water travelling below the ground cannot be sustained, and the water is released to create surface water flows. Depending on the location and frequency of the event, these surface water flows may also be referred to as seeps or springs.

Around a quarter of pools found in the Pilbara's major rivers are naturally semi-permanent to permanent[17]. The pools are sustained by a combination of regular flooding, pool depth (storage exceeding evaporation), groundwater discharge via springs or seepage through porous sediments, and impedance of subsurface flow by bedrock structures at the downstream ends of pools.

Some of these pools are considered fresh (salinity less than 1500mg/l) even though Pilbara evaporation rates significantly exceed rainfall. Different environmental factors naturally manage or offset evapoconcentration (the process whereby salinity increases as water is removed via evaporation) of salts in these pools, including:

- interactions with creeks and creek infiltration, such that flushing removes salts from the pools;
- high groundwater flow rates (i.e. springs or seeps), where the exposure time of water within the pool is reduced, e.g. water quickly infiltrates back into porous sediments;
- wind sheltering, by vegetation or topography, which reduces evaporation rates; and
- shading influence from trees or topography which reduce evaporation rates.

Normally, however, salinity increases between flood events, until pools are completely dry; leaving salts in the base of pools. These salts are subsequently flushed from the pools with each flood event, but can successively contribute to pool salinity prior to a flushing event.

Pools that sustain brackish water qualities (for example, are of stock drinking water quality, up to 4000mg/l) are usually associated with groundwater springs and seeps. These fresher pools provide an important ecological function, especially through periods of drought[17]. In these fresher pools, the groundwater discharge rates usually exceed the evaporation rates and the pools are positioned in the landscape such that the pools maintain a connection to a creek and / or a creek alluvial groundwater aquifer (e.g. within the floodplain). This connection enables salty water and sediments to be flushed from the pool, to be replaced by fresh surface water or fresher groundwater. For this reason, pools with this type of connection to groundwater systems can be considered groundwater dependant ecosystems[18]. These type of pools are noted to occur upstream (e.g. Weeli Wolli Spring) of Yandicoogina, but have not been identified within or downstream of the mine area.

13.2.3 Cumulative effect of landform changes on catchment hydrology

There are a number of reasons why closure strategies permanently alter the local catchment hydrology and change local surface water movement. The principal reason termination or capture of surface water flows is employed is to manage groundwater or pit lake water quality. Diverting runoff, creek flows and / or syphoning a proportion of flood water mine void post closure has been referenced as a water management solution to, for example, "flush" salts out of lakes and into the groundwater system, to flush salts from soils when the groundwater table is very near but not exposed on the surface (subject to groundwater capillary rise) or to add nutrients and aquatic flora / fauna to rejuvenate / sustain aquatic ecosystems. In other closure strategies, the capture of local runoff and creeks is simply a result of the slow, inevitable collapse of local surface water control structures.

Removal of these small volumes of water, when considered on a pit by pit basis, is unlikely to change the flow dynamics of the larger creek systems. However, by examining the catchment as a whole, it was recognised that the cumulative effect of terminating small runoff and flows as a consequence of mining activities across the Marillana / Weeli Wolli Creek catchment could alter the flood regime; and that these changes could have an impact on riparian communities adjacent to Yandicoogina.

A simple study was conducted in 2010 to quantify the potential magnitude of changes to flood frequency in Marillana Creek. The study assumed a worst case scenario whereby all local tributaries that flow over the mapped CID were subject to mining activities and would result in surface water flow entering the mine voids post-closure. These conditions align roughly with the proposed, externally released BHP Billiton Iron Ore Yandi[19] closure strategy and closure options presented by HIY for the 2011 public environmental review of Yandicoogina.

[17] Pinder, A and Leung, A (2009) Conservation status and habitat associations of aquatic invertebrates in Pilbara coastal river pools, Report to the Western Australian Department of Water from Science Division Department of Environment and Conservation, August 2009.

[18] Boulton, A. and Hancock, P.J. (2006). Rivers as groundwater-dependent ecosystems: a review of degrees of dependency, riverine processes and management implications. Australian Journal of Botany 54: 133-144.

[19] BHP Billiton (2004) Marillana Creek (Yandi) Mine : decommissioning and final rehabilitation plan, January 2004

The results showed that at the terminus of Marillana Creek the frequency of overbank flow would reduce from a 10% annual exceedance probability to a 5 % annual exceedance probability. This means that in the future there will only be a five percent chance of overbank flooding occurring in any year, instead of a 10 percent chance. This flood regime change would affect sections of the creek otherwise unaffected by mining activities that support flood plain ecologies, such as *Eucalyptus camaldulensis* (River Red Gum), by reducing the volume of water stored in the floodplain alluvial soils.

It is difficult to implement actions based on theoretical cumulative impact outcomes such as those discussed above. New systems for managing cumulative effects are expected to be developed by regulators in Western Australia following the release of the new Western Australia Government Water Resources Management legislation[20]. Cumulative effect considerations will need to be resolved and integrated into the closure plan once these new systems are in place.

13.3 Groundwater

13.3.1 Aquifers

Groundwater moves principally within two aquifer systems at Yandicoogina, namely through the CID (historical drainage) and alluvial (current drainage) aquifers (Figure 6). The CID and alluvial aquifers are inter-connected and recharged from infiltration generated by water flowing along the creeks. As a result, water quality in the CID and alluvial aquifers is relatively fresh (predominantly <600 mg/L).

The CID and alluvial aquifers are bound by the Weeli Wolli Formation basement rocks, which acts as the regional aquifer. Water moves through this regional aquifer in secondary porosity, associated with, for example, dissolution features in weathered rocks and fractures. As a result, the hydraulic conductivity of the Weeli Wolli Formation at Yandicoogina is significantly lower than the CID and alluvial aquifers and has been described as “relatively impermeable”.

Hydrogeological characterisation of the area has been undertaken since mining first began in the area. Historically, characterisation has focused on the CID. Water flow (through-flow) along the CID is estimated between 1500 m^3/day and 3000m^3/day, depending on the width of the CID channel. Usually the lower through-flow rates are observed at distances furthest from the main creeks. For example, in the mined out CID at JC Hairpin area, where the CID has no direct connection to the creek alluvial system, through-flow was measured to be around 1000m^3/d. The hydraulic conductivity in the CID ranges between 3m/d and 25m/d, with an average of roughly 9m/d.

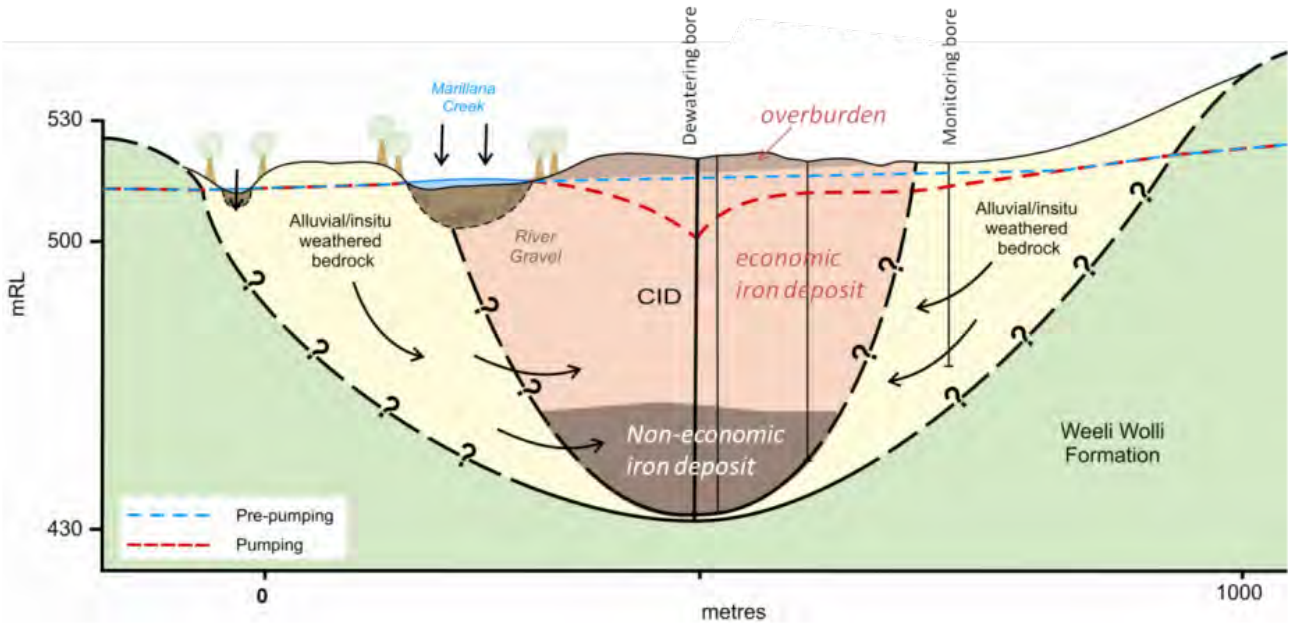

Figure 6: Schematic presentation of groundwater aquifers at Yandicoogina.

The pre-disturbance groundwater contours are illustrated in Figure 7. The groundwater table is located around 2m below the surface of Marillana Creek. This translates to a depth of 20m to 30m below the surface

[20] http://www.water.wa.gov.au/Future+water/Water+reform/default.aspx

in areas of mine away from the creek system in JC. Along the length of the CID, from Oxbow West to Billiard South, the pre-disturbance groundwater elevation changed by around 100m. This represents a groundwater gradient of 0.002 or a 2m decrease in groundwater level for every kilometre along the CID.

The gradient is relatively uniform along the length of the CID, suggesting the CID has a relatively uniform width with no barriers to subsurface flow. It was noted, however, that in the JC Hairpin area, where the CID bends around on itself, the low through-flow rates may indicate a "bottleneck" which could have caused groundwater levels to naturally back up following rainfall/recharge events. This may have led to an increase in preferential flow through the alluvial aquifer system, bypassing the current mining area, and elevating groundwater levels in the CID and alluvial aquifers in the JSW area.

The water table is observed to fluctuate considerably in response to significant rainfall events. For example, groundwater levels increase by around 10m following substantial rainfall events associated with ex-tropical cyclones Claire, Emma, Glenda and Hubert in January to April 2006, and in December 1999 as a result of rainfall Tropical Cyclone John. Over the long term, however, a noticeable trend of increasing groundwater levels has been observed across the region. At monitoring bore YM119 located in the Billiard deposit, for example, a change in average water level from 465mRL in 1991 to an almost steady state level of around 476mRL has been observed. The steady state is interpreted as the aquifer being “full”; a consequence of higher than average rainfall, more than 25 percent over the short term average, between 1995 and 2006 (prior to the establishment of the Yandicoogina reinjection bore and before any influence from the Hope Downs 1 mine discharge). Since 2006, rainfall has remained high and, combined with the dewatering influences from the Yandicoogina and Hope Downs 1 operations, the aquifers in the Billiard areas remain full.

As mining operations have moved closer to the active creek systems, characterisation of the alluvial aquifer has had renewed focus. A comprehensive field campaign was undertaken in 2009 to address knowledge gaps and strengthen the conceptualisation for groundwater model predictions. This work demonstrated that the alluvial aquifers, which were previously assumed to be shallow and poorly connected to the CID, consist of both unconsolidated alluvium and in situ weathered Weeli Wolli Formation bedrock. The alluvial aquifers can extend to depths similar to the CID and have a much higher hydraulic transmissivity and storage capacity than previously thought.

Based on results from the field campaign, horizontal hydraulic conductivity of the alluvial aquifers has been revised to 5 m/day to 10m/day in the upper alluvium and creek bed gravels. It has been estimated that the volume of recharge generated by one large flood event over a 25km length of Marillana Creek is equivalent to approximately 16GL of water and can be as high as 30GL depending on the duration of the event. As a result of this strong connection to the creek system, it has been theorised that a fully dewatered CID could recover to 90 percent of its original groundwater elevation in as few as 10 to 20 years.

Within the groundwater, chloride concentration ranges from 15mg/l (in a CID sample) to a maximum of 280mg/L (in an alluvium sample). The average chloride concentration in the CID is ~120mg/L, roughly 30 percent lower than that of alluvium water. This difference is attributed to the processes of direct evaporation and evapotranspiration by native vegetation along Marillana Creek that act to concentrate salts in the upper profile of the alluvial aquifer.

Total dissolved ions (TDS) of groundwater range from 100mg/l to 1,290mg/l, averaging around 550mg/l in the CID and 600mg/l in the alluvium, but without clear segregation. Groundwater from both aquifers is dominated by bicarbonate anions, contributing to pH conditions ranging from 6.7 to 8.3. Sodium constitutes a higher portion of the major cations, followed by calcium and magnesium.

No significant water quality changes have been detected in the aquifers since the start of routine water quality monitoring at Yandicoogina.

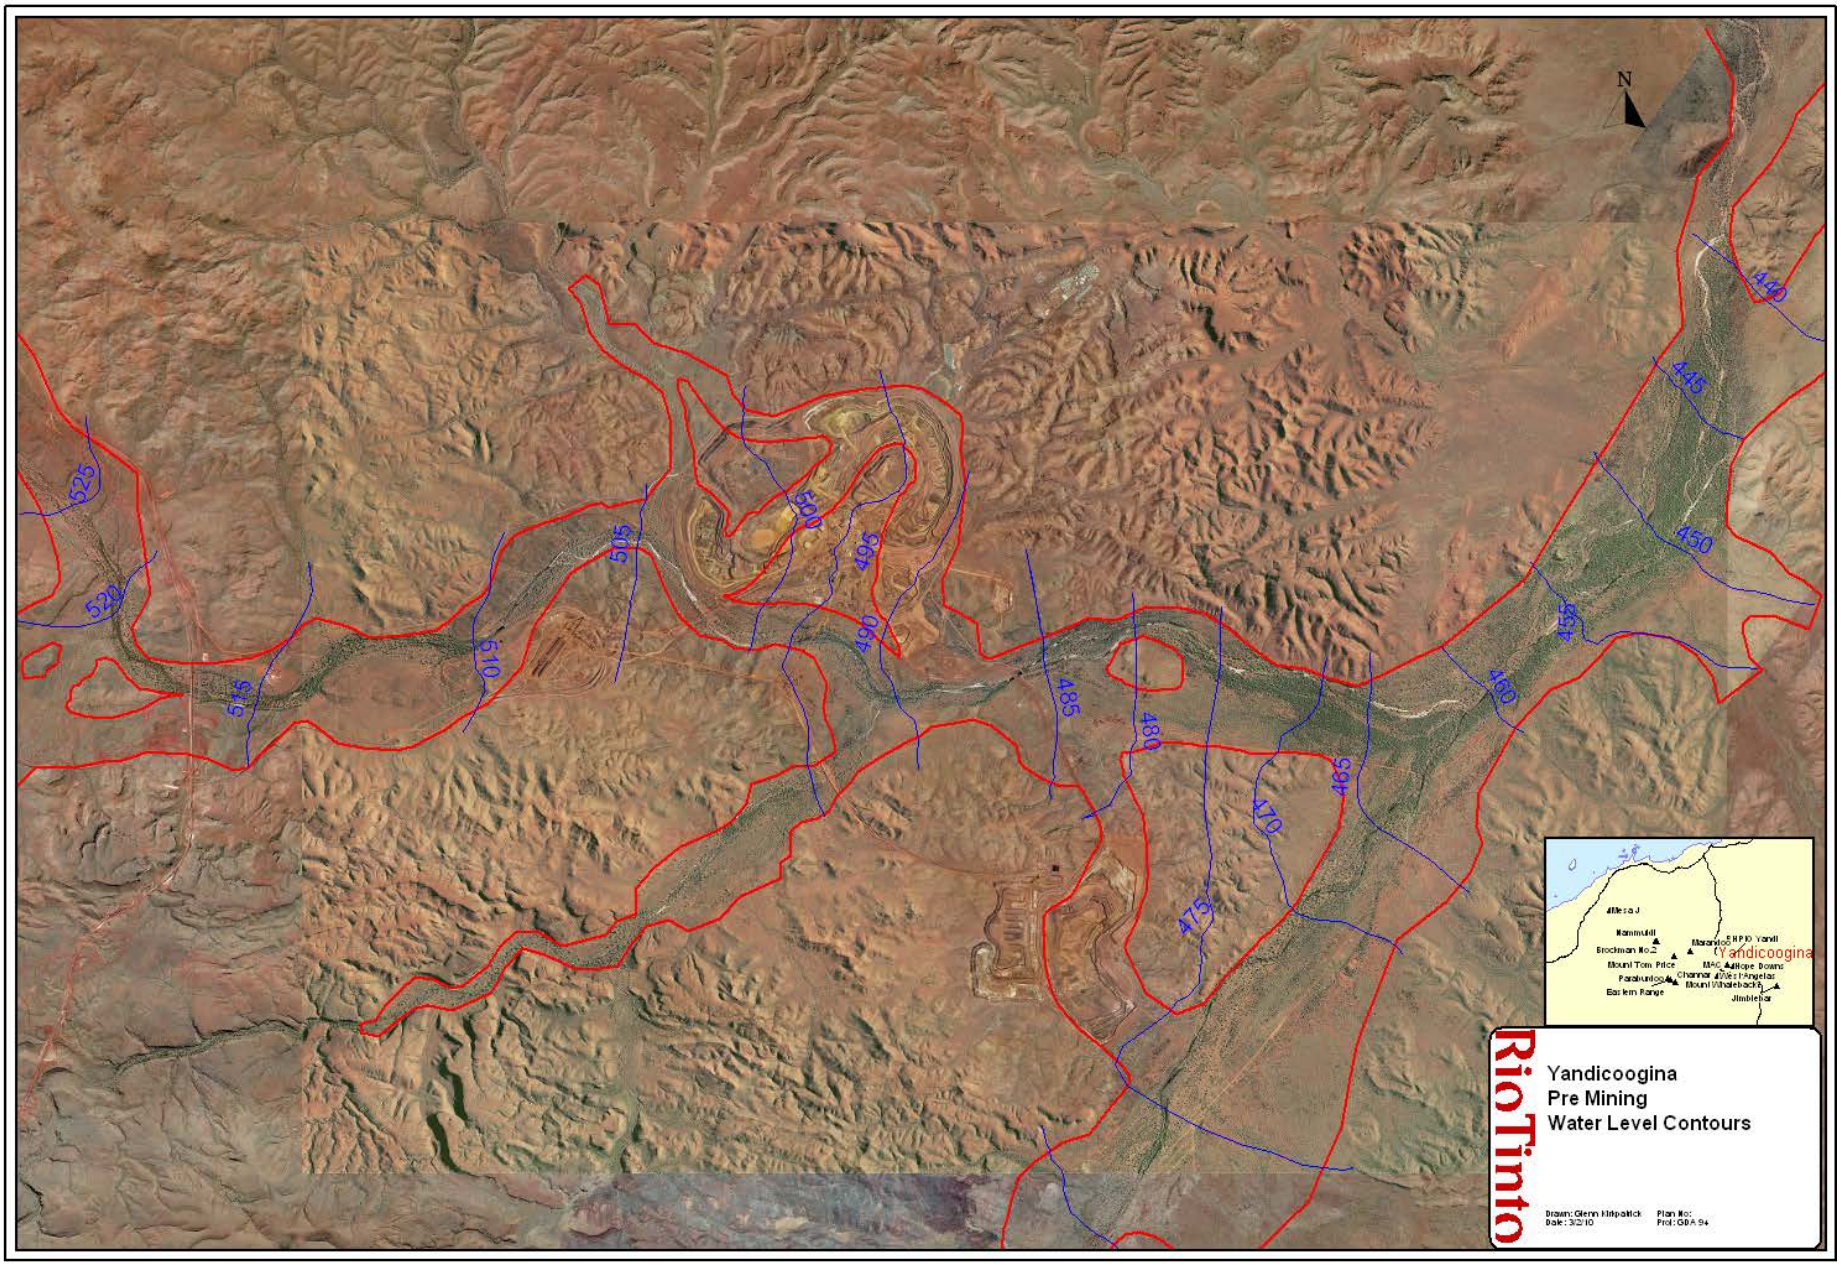

Figure 7: Groundwater pre-disturbance contour map.

13.3.2 Effects of evaporation on water quality

Conceptual water balance models indicate that some landform configurations create highly saline lake waters. Very conservative geochemical modelling was undertaken to understand the effects of trace element leaching from backfill materials and evaporation. The model used measured groundwater quality parameters from Yandicoogina area (highest values ever recorded in any literature), assumed an evaporation rate of 90 percent in an open system (reflecting final salinity concentration in excess of 10,000mg/l) and only allowed hydroxide and carbonates to precipitate.

The geochemical model results indicate the groundwater is supersaturated with respect to carbon dioxide (CO_2). Thus degassing of CO_2 was modelled to occur as the groundwater equilibrates with the atmosphere and mixes with pore waters from backfill materials. Degassing of CO_2 increases the pH of the system from ~7.4 to ~8.6. Equilibrium with the atmosphere and the increase in pH resulted in the precipitation of minerals including calcite and ferrihydrite.

Evaporation of the resulting model fluid caused an increase in the saturation states of many minerals, and resulting precipitates including ferrihydrite, calcite, sepiolite, manganite, tenorite and smithsonite. Subsequent reactions modelled included increased precipitation, element depletion and further degassing of CO_2 due to evapoconcentration, leading to a further reduction in pH and additional precipitation.

Sorption / desorption processes were not considered as part of this modelling. It is recognised, however, that if high pH (alkaline) conditions develop, elements that are present as sorbed species in minerals such as hematite or goethite, but currently below detection limits, could mobilise. Elements of concern that could be mobilised under alkaline conditions include arsenic, selenium and antimony. Alkaline conditions may also mobilise amphoteric elements such as aluminium, which would be otherwise fixed in the system as gibbsite or other minerals.

It is important to note that mineral precipitation predicted by modelling may be reversible in the field if flushing with neutral or slightly acidic water occurs, for example from a rain event or from surface water runoff. Thus, remobilisation of solutes such aluminium, iron, manganese, copper and zinc could occur during rain events. Desorption on the other hand, may not be reversible. Once arsenic, selenium or antimony are mobilised, they may remain in solution even after rain events.

Physical modelling (i.e. evaporation trials) will be required to validate the input parameters before further geochemical modelling of lake specific conditions is undertaken.

13.4 Soil

13.4.1 Local soil

Soils in disturbed areas at Yandicoogina are dominated by alluvium and colluvium materials associated with low slopes and sheetwash areas, presenting as red-brown sandy and clayey loam soils. Along the banks of the Weeli Wolli Creek, and in some drainage lines, calcrete is visible within the soil, creating stony loam soils.

Subsoil has physical properties suitable for plant growth and generally has chemical properties amenable to plant growth, although it does lack the nutrient content, organic matter, soil seed bank and mychorrhizal fungi properties of topsoil.

13.4.2 Soil inventory

The availability of topsoil significantly improves the potential for rehabilitation success. The Rio Tinto Iron Ore Soil Resource Management Work Practice provides guidance on soil collection and appropriate management during the operation of the mine. The procedure aims to maximise topsoil recovery and retaining soil viability and productivity to improve future success of rehabilitation programs.

The Rio Tinto Iron Ore Soil Resource Management Work Practice implemented at Yandicoogina includes:

- stockpiling grubbed surface vegetation to provide a supply of additional seeds and organic matter for the soil;
- collecting more than the minimum 200mm mandated quantity of topsoil where available;
- storage of topsoil in stockpiles no more than 2m high (or one truck paddock dumped tip height, when using larger trucks) in sign posted, restricted access areas;
- collection of subsoil up to 600mm where available;
- collecting additional subsoil where practicable / available;
- maintaining a soil inventory; and

- regularly reconciling the available and project soil requirements to the projected life of mine disturbance areas.

The soil inventory, provided in Table 8, shows that Yandicoogina is not expected to recover sufficient topsoil in order to meet the rehabilitation requirements for the site. This assessment is based on a total disturbance area of approximately 40,600,000m^2, of which 35,900000m^2 is expected to require revegetation (includes areas above the groundwater recovery water table and excluded pit walls and associated geotechnical zones of instability that will not be revegetated), applying soil (a combination of topsoil and subsoil) at a uniform depth of 200mm. It is currently assumed, based on the rehabilitation success at other Pilbara mine sites, that biodiversity can be restored without the need to reconstruct soil horizons.

This inventory will be updated throughout the life of the mine to reconcile closure requirements with soil stockpiles.

Table 8: Soil stockpile volumes (as of 2014).

Material Type	Volume (Mm^3)
Existing stockpiled soil	
Topsoil recovered	*1.1*
Subsoil recovered	*2.3*
Planned (future) soil recovery (JSW, Oxbow, Billiard South only)	
Anticipated topsoil recovery	*3.7*
Anticipated subsoil recovery	*10.9*
Volume required for rehabilitation (disturbance area[21] x 200mm)	7.2
Soil balance (stockpile + planned recovery – rehabilitation requirement)	**+7.4 (surplus subsoil)**

Figure 8: Topsoil stockpile at Yandicoogina, 2013.

13.5 Mineral waste characterisation

13.5.1 Physical properties

Mineral waste generated at the site consists largely of overburden material and CID fines. Characteristics of the material are summarised in Table 9 and Table 10.

Table 9: General properties of the alluvial overburden material at Yandicoogina.

pH	EC1:5	EC1:2	ESP	Potentially dispersive	Exchangeable cations (m.eq./100g)					ECEC
(-)	(dS/m)	(dS/m)	(%)		K	Ca	Mg	Na	Al	
6.5	0.02	0.04	3.1	No	0.42	1.85	0.82	0.1	0	3.2

[21] The disturbance area requiring soil application is assumed to be the total disturbance footprint at the end of the mine life minus pit areas that do not require rehabilitation. Rehabilitation area has been assessed as a three-dimensional surface.

Table 10: Particle size distribution of the alluvial overburden material at Yandicoogina.

Rock >45mm (%)	Pebbles 22-45mm (%)	Gravel 2-22mm (%)	Fine Fraction <2mm (%)	Coarse Sand (%)	Fine Sand (%)	Silt (%)	Clay (%)
1	0	18	81	40	44	4	12

The majority of the mineral waste (386Mm^3) is expected to be of high erodibility, and will require conservative landform design parameters to be used in order to create stable slopes. A small volume (2 Mm^3) of low erodibility mineral waste may be mined; however there is no plan to segregate this material for use at closure at this stage.

Mineral waste has been used at other Pilbara mining operations as an alternative growth media to topsoil. In general, the soil structure created using inert mineral waste has been shown to be relatively stable, with only slight or no dispersion upon re-moulding and was not prone to hardsetting. This indicates that the mineral waste creates a relatively stable soil structure that is not easily degraded. Similar outcomes are expected from the Yandicoogina mineral waste, and will be tested as part of site rehabilitation trials.

13.5.2 Geochemical properties

HIY has implemented an extensive program of geochemical testing, over several years, to understand the potential for acidification and / or metal enrichment to occur as a result of the various waste types. Static tests have been conducted on all waste types, with more comprehensive sequential leach and kinetic tests undertaken on materials with uncertain test results or considered to pose significant geochemical risk. The sequential leach and kinetic testing regimes also included samples of materials which were identified as low risk in order to confirm that this is indeed the case. All tests were conducted in accordance with the *Global Acid Rock Drainage (GARD) Guide.*

No sulphides, the primary source of acid drainage issues, have been identified in the host geology or mineral waste at Yandicoogina. Although it is recognised that some minerals, such as alunite and jarosite, that contain sulphates and pose a low geochemical risk, due to self-limiting chemical processes, may be present in small quantities at Yandicoogina in the alluvium, weathered channel alluvial material and to a lesser extent the Weeli Wolli formation. The total sulphur concentration of the 99th percentile of all sampled processed ore and waste at Yandicoogina is less than 0.02%, suggesting the overall acid rock drainage risk is low to nil.

Neutral mine drainage and saline drainage are characterised by pH levels of above 6. Neutral mine drainage is generally characterised by a sulphate concentration of more than 1,000mg/L, while saline drainage is characterised by a total dissolved salt concentration of more than 1,000mg/L. Elevated concentrations of elements of interest may be present under neutral or saline drainage conditions because:

- there was an excess of neutralization potential (NP) from in situ rock or waste rock that reacted with and consumed acid in the waters. As a result no acidic conditions are observed or ex situ downstream, or
- elements, i.e. antimony, arsenic, cadmium, molybdenum, selenium and zinc, remain relatively soluble under neutral pH conditions, or
- elements are released through rapid or accelerated weathering.

Mineral wastes were classified as non-saline and non-sodic, with no sample presenting above the 15% threshold for exchangeable sodium percentage (ESP), the indicator of high sodicity. Mineral waste and ore lithologies were shown to be enriched in iron, arsenic and tin against the crustal abundance index.

Sequential extraction test work demonstrated that iron, arsenic and tin are incorporated in the crystalline iron oxides and silicates which reduce the potential for the minerals to be released. However, the potential for contaminant release still exists under slightly alkaline and saline environments. Thus saline drainage, and not neutral mine drainage, conditions are anticipated to evolve at Yandicoogina post-closure. The release of contaminants is limited, however, due to the combined effects of sorption and low mineral solubility under neutral pH conditions.

Leach tests conducted on waste rock and waste fines presented circum-neutral pH values between 6.5 to 8.5 and EC values of around 650µS/cm for waste rock and 70µS/cm for waste fines, regardless of test conditions.

Readily detectable elements within the waste rock included the major elements Ca, Mg, Na, K, Cl, Si and SO4 and the trace elements Al, B, Ba, F, Fe, Sr and Zn. The highest concentrations of elements were recorded in the low contact ratio leach tests. The majority of the elements were source term limited, such that low masses were present in the samples and would be completely dissolve during the test. The test work also indicated that elements Al, Ba, F and Si may be solubility controlled.

The characteristics of the waste fines materials are similar to the waste rock, with the exception that low contact ratio leach tests contained low but detectable concentrations of Cd, Cr, Cu, Pb, Mn and Ni. These elements were not detected in the 2:1 L:S leach.

Selenium, a non-metallic chalcogen, has also been identified by the EPA as an element of concern in some Pilbara iron ore lithologies. Studies in the JSW and Oxbow deposits found that selenium does not occur at elevated concentrations compared with background materials. Gardiner (2003)[22] reported dissolved selenium concentrations of up to 2.94 µg/L in pre-mining groundwater measurements within the Yandicoogina CID aquifer. These concentrations are below the ANZECC/ARMCANZ Guidelines[23] for selenium trigger values for freshwater aquatic ecosystems (trigger value <5 µg/L for protection of 99% of species).

Iron mineralogies are often associated with low mobility of metalliferous and other elements. Iron oxy-hydroxides have high sorption capacities for arsenic and selenium[24] [25], and consequently these materials have been used around the world for treating water enriched in these elements (via adsorption to the hydrated iron hydroxide surface). The overall risk posed by selenium release to the surface environment from mineral wastes is considered to be negligible. The oxidation state of the iron-rich lithologies would prevent major chemical change from mining and storage activities.

13.5.3 Fibrous materials

Naturally occurring silicate minerals can have fibrous habitats that can pose a health risk if the fibres are of a respirable size, become airborne and are inhaled. The fibrous silicate minerals crocidolite and actinolite have been encountered in the Yandicoogina region. Crocidolite has been encountered in alluvial/colluvial material that overlies the CID. This material has been transported from weathered crocidolite seams located in the hills surrounding the deposits. Discontinuous actinolite seams have been encountered in Dolerite during excavation for rail cuttings, the F5 canyon and a number of areas in proximity to the loop. This material was encapsulated in the fibrous waste dump highlighted in Figure 9.

Figure 9: Fibrous materials intersected during construction of the rail loop are encapsulated within this mineral waste dump inside the rail loop. Waste dumps containing fibrous materials will be rehabilitated in situ on closure.

When fibrous materials are encountered, management of the material is guided by the Rio Tinto Iron Ore (WA) Fibrous Mineral Management Plan. The plan includes:

- undertaking risk assessments prior to entering or disturbing areas with potential fibrous risk, to ensure appropriate personal protection equipment is worn as well as personal dust monitoring; and

[22] Gardiner SJ (2003) Impacts of mining and mine closure on water quality and the nature of the shallow aquifer, Yandi iron ore mine, Master of Science Thesis, Curtin University of Technology, Perth.

[25] Rovira M, Gimenez J, Martınez M, Martınez-Llad X, de Pablo J, Martı V & Duro L (2008) Sorption of selenium(IV) and selenium(VI) onto natural iron oxides: Goethite and hematite, *Journal of Hazardous Materials*, Vol. 150, pp:279–284

- encapsulating intersected / identified fibrous mineral waste in 2 m thickness of non-fibrous mineral waste, in a location where the material will not be disturbed on closure.

If fibrous minerals are confirmed to be present in the alluvial / colluvial materials immediately adjacent to disturbed areas, there is a potential for these materials to be disturbed as part of rehabilitation activities, i.e. grading. In which case, following a risk assessment, fibrous mineral management will be integrated into the decommissioning and rehabilitation implementation plans for affected areas.

13.6 Other potential contamination

A preliminary site investigation was carried out at Yandicoogina to establish potential sources of contamination resulting from the current and historical site activities. The main sources of contamination present at Yandicoogina today are at the hydrocarbon (mainly diesel) storage / handling facilities and fuel pumps facilities. No locations have currently triggered reporting thresholds under the *Contaminated Sites Act 2003.* Other potential sources of contamination include vehicle wash-down and maintenance facilities, waste oil handling facilities, liquid waste storage facilities, ammonium nitrate and fuel oil, equipment laydown, landfill, wastewater treatment and land farm facilities.

HIY manages contaminated sites in accordance with a Contaminated Sites Management Plan (**CSMP**), and relevant contaminated sites and environmental legislation. The CSMP outlines how HIY will manage all potentially contaminated sites, on a site-by site basis. It provides for internal management, whilst also adhering to relevant regulatory requirements. The CSMP applies to all Rio Tinto facilities and assets, including mine sites, exploration / evaluation projects, port and rail facilities and pastoral stations.

Site closure will undoubtedly involve a change in land use, as such; the significance of any site contamination may change. A contaminated sites assessment will therefore be undertaken prior to closure, and specific plans developed, as part of the decommissioning process, to remove or manage contamination where appropriate.

14. Biodiversity

14.1 Flora, fauna and vegetation

Baseline surveys were undertaken prior to mining disturbance and environmental reviews have been undertaken regularly throughout the life of the mine to verify environmental condition and track changes to the environment as a consequence of mining.

As captured in Appendix B, surveys and environmental reviews cover:

- terrestrial vegetation and flora;
- terrestrial and subterranean fauna (including Short-Range Endemic (SRE) invertebrates, troglofauna and stygofauna);
- riparian vegetation and flora; and
- aquatic fauna.

14.1.1 Terrestrial habitat

Six broad habitats types have been identified across the Yandicoogina area. These habitats include hilltop, gullies, slopes, plains, creeks and drainage lines. Characteristics of these habitat types are provided in Table 11. On closure, the characteristics of the landscape will be altered to introduce terminal (internal draining) basins, permanent pit lakes, and wetland areas with direct connection to the existing creek systems. Table 11 describes the characteristics typical of these different drainage habitat types, based on similar landscape features located elsewhere in the Pilbara.

Table 11: Habitats considered in closure planning.

Habitat	Description
Hill habitats	
Hilltop	 Hills, ridges, plateaux remnants and breakaways of varied geological origin. Soil is generally skeletal sandy clay loams with greater than 80% stony detrital material. Under natural conditions this habitat zone is characterised by a scattered overstorey of Snappy gum *Eucalyptus leucophloia*, Bloodwood *Corymbia hamersleyana*, Kanji *Acacia inaequilatera* and/or *Hakea chordophylla* over moderately dense spinifex, predominantly *Triodia* aff. *basedowii*, with some *T. wiseana* on slopes. Rocky, sheltered ridges and breakaways provide a suite of specialist plants or species more typical of lowlands. This habitat is characterised by a low diversity of microhabitats. In general there are few to no logs, little woody debris, and very few hollows in trees. The shallow soil is often hard and unsuitable for burrowing fauna. Although the exposed bedrock can provide a few niche habitats in the form of cracks and crevices. This habitat zone will be present in undisturbed areas around the mine and may evolve around the edge of the disturbed mine area, especially where the pit shell intersects local hills. However this habitat type will not be restored or rehabilitated as part of the closure plan.
Gullies	 Small gullies in upper hills with small, stony creeks. Under natural conditions gully habitats are only marginally different from the community that happened to surround them. Usually species poor, with occasional eucalypts over *Triodia* aff. *basedowii* and *T. wiseana*. This habitat creates a diverse array of microhabitats. The habitat often contains rock shelters in the form of overhangs, cracks, crevices, caves and areas for water to pool during the wet season. Vegetation provides microhabitats in the form of logs, debris and hollows. This habitat zone will be present in undisturbed areas around the mine. However this habitat type will not be restored or rehabilitated as part of the closure plan.

Habitat	Description
Valley habitats	
Slopes	 Stony lower slopes with quaternary colluvium and situated below the surrounding hill systems. Under natural conditions major soil types include red loamy earths and red shallow loams. Vegetation is characterised by hard and soft spinifex grasslands and scattered mulga (*Acacia aneura*) shrublands, as seen in the western half of the Oxbow area and in the JSW-A area pre-mining. This habitat is characterised by a low diversity of microhabitats with few logs and woody debris, and very few tree hollows. The soil is usually hard and unsuitable for burrowing fauna. The Western Pebble-mouse traditionally inhabits this habitat zone as it creates its Pebble mounds on the rocky scree. This habitat zone will be present in undisturbed areas outside of the mine. Opportunities for successful rehabilitation of this habitat are limited to areas where soils remain stony after disturbance.
Plains	 Undulating, low stony plains and alluvial flats. Under natural conditions soils vary from relatively deep, stony, skeletal red clay loams on low undulating plains to deep red clay loam soils with massive clay substrates on Mulga flats. Vegetation is characterised by scattered low trees over sparse mixed shrubs i.e. *Acacia* spp. and *Grevillea* sp. and various species of spinifex. Alluvial soils may also support Mulga *Acacia aneura* and other Acacia communities over a moderately rich assemblage of shrubs, herbs and tussock grasses. Spinifex is less conspicuous in this community than most other habitats; however *Triodia wiseana* and *T. pungens* are frequently present. This habitat type contains limited microhabitats with the dominant Acacia species providing no tree hollows, few logs, limited leaf litter and sparse vegetation. This habitat zone will be present in undisturbed areas outside of the mine and has the most potential for successful rehabilitation, for example in low disturbance areas where topsoil is available and the substrate has not been disturbed.

Habitat	Description
Drainage habitats	
Creeks	 A linear habitat characterised by regular surface water flows, defined banks and associated riparian vegetation corridor. The creek habitat includes areas that are periodically flooded due to high surface water flow volumes (floodplains) and are usually associated with accessible groundwater and increased soil water (bank) storage potential. Creeks in the Yandicoogina area include Weeli Wolli Creek, Marillana Creek, Phils Creek and Yandicoogina Creek. Vegetation is characterised by a mixture of woodlands (including River Red Gum *Eucalyptus camaldulensis*, Coolibah *E. victrix* and other tree species), shrublands and hummock grasslands, including riverine fringing vegetation of grasslands and herbs. Spinifex was comparatively sparse in drainage lines, and usually comprised *Triodia pungens* or *T. longiceps*. Creek habitats act as wildlife corridors that help flora and fauna disperse across the landscape. There is a high diversity of microhabitats including logs, debris, tree hollows and soft soils, as well as temporary and permanent pools. This habitat zone will be present in undisturbed areas outside of the mine. Disturbed creek habitat will be rehabilitated to restore creek functionality.
Drainage line	 A linear habitat that begins at the top of hills and runs to the surrounding plains, or encompasses small tributaries that eventually flow into larger river and creek habitat types. Vegetation composition is usually similar to the neighbouring habitat but with increased vigour and density due to sustained, elevated soil moisture following rainfall events. Drainage line habitat act as wildlife corridors that help flora and some fauna disperse across the landscape. There is a moderate diversity of microhabitats with some logs, debris, occasional tree hollows and isolated pods of soft soils. Surface water is more likely to persist in this habitat after it has evaporated elsewhere, providing a refuge for fauna. This habitat zone will be present in undisturbed areas outside of the mine. Drainage line habitat will be rehabilitated / created as part of local drainage controls. Where drainage line habitat is created, erosion control mechanism will need to be integrated into the drainage line rehabilitation design.

Habitat	Description
Terminal basin	 Land that due to its shape captures and holds surface water runoff. The landform shape facilities the settling of silts and sediments, often creating a clay pan or hard pan over time. Vegetation communities are designed to accommodate periodic, sustained flooding as well as periods of drought. As few vegetation species are capable of withstanding the extreme conditions, species diversity within and coverage across the habitat may be low. This habitat type can contain limited opportunity for fauna re-colonisation if the ground becomes a hard pan, preventing trees from establishing and thereby limiting log and leaf litter generation. This habitat zone will be introduced in constructed low lying topography within backfilled pit landforms, e.g. above existing waste fines cells, as part of the surface water management design. The terminal basin areas will capture and contain rainfall within the former pit areas, to minimise runoff and subsequent erosion across the backfilled landform.
Pit lake	 A water body created through the process of mining below the water table. Water within the mine void is sustained by the local groundwater system. Water quality may vary over time, and could become unpalatable or highly saline over time. Landforms will not be specifically engineered for long-term landform stability, with the exception of the creation of safe egress areas. Scree slopes are likely to form over time as the pit walls erode. The pit walls and floor will not be revegetated, although vegetation and weeds may opportunistically colonise the evolving scree slopes. This habitat may attract fauna and is susceptible to weeds. Intensive monitoring and management may be required to ensure that the resulting environmental conditions are within an established, acceptable range. This habitat zone will be introduced at Oxbow East and Oxbow West.

Habitat	Description
Wetland	 Habitat created through the process of mining below the water table where mine voids are rehabilitated to function as a lake system. The water body is readily accessible to fauna and humans, and the quality of the water is anticipated to be suitable for the proposed function of the lake. The fringe of the lake may be vegetated to ensure an adequate diversity of species is present to support a self-sustaining ecosystem. However, all of the pit walls surrounding the lake may not be stabilised, such that some minor pit wall erosion may occur. Aquatic fauna and aquatic fauna habitat are not anticipated to be included in the rehabilitation process, but are expected to develop over time through natural recovery processes. This habitat zone will be introduced to create wetlands in the JSW-A, JSW-C, Phils, JC, Pocket and Billiard South mine voids.

The key characteristics for three common habitat types at Yandicoogina, plains, slope and hilltop habitats, are presented in . These statistics were established in 2009 based on the anticipated rehabilitation requirements at Yandicoogina. Further work is required to define metrics and key values associated with the proposed terminal basin, drainage line and wetland habitats.

Table 12: Yandicoogina reference site vegetation statistics.

	Lower slopes / flat - Plains habitat	Midslopes - Slope habitat	Upper slopes - Hilltop habitat
Bare ground (%)	20.8 ± 4.2 (std error)	10.8 ± 2.1 (std error)	12.1 ± 2.5 (std error)
Live plant density (plants/m^2)	Range 2.3 – 2.6	Range 2.6 – 6.0	Range 4.2 – 10.9
Foliage cover (%)	Range 27.3 – 31.9	Range 32.1 – 33.2	Range 18.7 – 29.0
Species richness (per m^2)	Range 0.7 – 1.1	Range 0.4 – 1.0	Range 0.5 – 0.85
Dominant plants (average alive plants/m^2)	Perennial grasses (1.65) Shrubs (0.6) Perennial herbs (0.2)	Perennial grasses (3.5) Shrubs (0.2) Perennial herbs (0.04)	Perennial grasses (5.8) Sedge (2.0) Shrubs (0.1)
Dominant plants (alive % foliage cover)	Perennial grasses (21.4) Shrubs (5.8) Trees (2.0)	Perennial grasses (26.6) Shrubs (4.5) Trees (1.5)	Perennial grasses (23.0) Shrubs (1.9) Trees (0.2) Sedge (0.1)

Hummock grassland of *Triodia pungens* with *Eucalyptus gamophylla*, *Corymbia hamersleyana*, *Hakea lorea*, and Acacia sp.

Table 13 and Table 14 list the significant fauna and flora (respectively) that are likely to occur or have been found at Yandicoogina, and their habitat relationships.

Table 13: Significant fauna with potential to occur within the local Yandicoogina area, and its relationship to habitat types.

Fauna species	Conservation status	EPBC Act status	Habitat occurrence	Comments
Dasyurus hallucatus (northern quoll)	Schedule 1	Endangered	Gullies Disturbed	Habitat for this species is rocky ridgelines and rocky gorges.
Pezoporus occidentalis (night parrot)	Schedule 1	Endangered	Plains	Prefers dense, low vegetation for day shelter. Most records come from hummock grasslands with spinifex (Triodia), from areas dominated by samphire, or particularly, where these two habitats are juxtaposed
Rhinonicteris aurantia (Pilbara orange leaf-nosed bat)	Schedule 1	Vulnerable	Gullies Hilltop	Caves near water provide suitable roosts. Caves near Oxbow area provides only potential habitat.
Liasis olivaceus barroni (olive python)	Schedule 1	Vulnerable	All hill habitats	Widespread in rocky areas, showing a preference for rocky habitats near water, particularly rock pools
Falco hypoleucos (grey falcon)	Schedule 1	Vulnerable	Acacia woodland Mulga woodland Drainage habitats	Ranges across habitats in search of food. Prefers lightly wooded coastal and riverine plains.
Falco peregrinus (peregrine falcon)	Schedule 4	-	All habitats	Ranges across habitats in search of food
Ramphotyphlops ganei	Priority 1	-	All habitats	Prefers moist gorges.
Pseudomys chapmani (western pebblemound mouse)	Priority 4	-	All hill habitats	Recorded in area. Habitat for this species is rocky, hummock grasslands, with little or no soil. The western pebble-mound mouse occupies burrows beneath mounds of pebbles. Mounds are most common on the spurs and lower slopes of ridges
Macroderma gigas (ghost bat)	Priority 4	-	Gullies Hilltop	Roost in caves, rock piles and abandoned mines. Will travel 2 km from roost to hunt. Caves near Oxbow area provides only potential habitat
Ardeotis australis (Australian bustard)	Priority 4	-	Plains	Recorded in area. Habitat preferred by this species lightly wooded country next to daytime shelter of thickets or long grass.
Burhinus grallariuss (bush stone-curlew)	Priority 4	-	All valley habitat	Habitat preferred by this species is tussock grassland, Triodia hummock grassland, grassy woodland and low shrublands
Merops ornatus (rainbow bee eater)		Migratory	All valley habitats	Found within open forests, woodlands and shrublands, and cleared areas. Open pit walls may be utilised to build nesting tunnels
Neochmia ruficauda subclarescens (star finch)	Priority 4			Recorded in area. Typically confined to reedbeds and adjacent vegetation communities along permanent waterways

Table 14: Significant flora and its relationship to habitat across Yandicoogina.

Flora taxon	Conservation status	EPBC Act status	Habitat occurrence	Habitat comments
Lepidium catapycnon	Threatened*	Vulnerable*	Hilltop	Skeletal soils. Break of slope topography, hillsides
Rhodanthe ascendens	Priority 1		Plains	Clay soils
Stylidium weeliwolli	Priority 2		Drainage	Occurs mainly along major water courses in seasonally damp or wet areas, including root mats of Melaleuca, on floodplains and in seepages around granite rocks.
Rostellularia adscendens var. *latifolia*	Priority 3		Hill	Ironstone soils. Near creeks, rocky hills
Sida sp. Barlee Range (S. van Leeuwen 1642)	Priority 3		Hill	Skeletal red soils pockets. Steep slope.
Themeda sp. Hamersley Station (M.E. Trudgen 11431)	Priority 3		Plains	Red clay. Clay pan, grass plain
Rhynchosia bungarensis	Priority 4		Hill	Pebbly, shingly coarse sand amongst boulders
Goodenia nuda	Priority 4		Plains	Wide alluvial plain or creek beds. Red brown clay loam, ironstone.

*Currently subject to re-evaluation of conservation status.

The surveys show that most of the vegetation communities found at Yandicoogina and the fauna habitat they support are widespread and well represented regionally. Riparian vegetation along Marillana and Weeli Wolli Creeks is considered locally significant, due to the relatively limited extent of this vegetation type compared with other locally occurring vegetation types and the ecological services that it provides in the local area. These services include:

- provision of structural habitat elements, such as tree hollows;
- protection of creek banks from erosion;
- protection of water quality through sediment trapping and nutrient stripping, and
- transfer of subterranean water and nutrients to the surface environment by some of the dominant tree species.

Consequently, creek and wetland habitat is considered to be of elevated value due to the diversity of microhabitats and potential to support conservation significant fauna species. Drainage line and gully habitats are considered to have moderate habitat value, due to the number of fauna that may utilise the area; while slopes, plain, hilltop, pit lake and terminal basin habitats have low habitat value.

Impacts to the riparian systems are anticipated during mining operations. The Yandicoogina Environmental Management Plan has been implemented (in accordance with MS 914 Conditions 7 and 8) to ensure adequate protection of the waterways and associated riparian vegetation.

The operation is not expected to impact the conservation status of any flora or fauna species, populations or fauna habitat. This includes changes to fauna and flora abundance, species diversity, geographic distribution and / or productivity at species or ecosystem levels.

As Yandicoogina is not predicted to impact the conservation significance of any species, ecosystem restoration activities and reintroduction of fauna are not planned as part of the rehabilitation activities.

14.1.2 Subterranean habitat

Subterranean fauna are animals that inhabit underground habitats and include:

- stygofauna - obligate, groundwater dwelling aquatic fauna, and
- troglofauna - obligate, subterranean dwelling fauna occurring in the unsaturated profile above the water table.

Stygofauna and troglofauna are known to occur in a range of habitats in the Pilbara region, but can potentially have restricted distributions based on their evolutionary history and specialised habitat requirements. The CID at Yandicoogina does not provide ideal troglofauna habitat due to frequent inundation during periods of heavy rainfall. Three potentially troglobitic species have been collected, none of which are endemic to the area.

At least 150 species of stygofauna have been recorded in the Pilbara[26] with 500–550 taxa[27] estimated to remain undescribed. Prior to 2011, 15 new (undescribed) taxa, currently only known to be present within Marillana and Weeli Wolli Creeks, had been identified. For this reason, subterranean fauna habitat is considered to have biodiversity value.

A subterranean fauna management plan was implemented at Yandicoogina to address possible direct and indirect impacts to subterranean fauna affected by mining. The plan included regular sampling and morphological analysis, identification of species whose long-term survival is at risk and procedures to avoid or minimise the impacts on these species, and analysis of physical environmental (habitat) data.

Work, completed in accordance with the plan, demonstrated that the taxonomic composition of the stygobitic fauna recorded at Yandicoogina remained similar over multiple recording campaigns. These results suggest that an abundant and diverse stygal community remains within the aquifers of the Yandicoogina creek systems, years after the commencement of the dewatering at the operation, and shows that impacts to subterranean fauna are localised to the immediate mine areas. Consequently, targeted creation of stygofauna habitat is not considered to be required for the closure of this site.

Closure and post-closure impacts to the stygofauna populations may arise as a consequence of predicted changes to groundwater quality (salinity and / or pH). The potential response of remnant stygofauna populations at Yandicoogina to potentially altered groundwater conditions is currently unknown; although stygal communities are known to be present in the brackish water condition of the Fortescue Marsh[28].

14.2 Local environmental values

Creek systems in the Yandicoogina area offer deeper soil types (alluvium), with capacity to store water in between rainfall events. This stored soil water is used to sustain plant growth through dry periods. Some of the larger tree species have root systems that enable access to water stored deep within the alluvium, and in some cases are able to access the groundwater table on an ongoing or transient basis. The key tree species are *Eucalyptus victrix* (Coolibah), *Eucalyptus camaldulensis* (River Red Gum) and *Melaleuca argentea* (Silver Cadjeput).

The paperbark species *Melaleuca argentea* occurs in areas of shallow groundwater and is regarded as being dependent on groundwater to meet its ecological water requirements[29][30] *Eucalyptus camaldulensis* and *E. victrix* occur extensively along Marillana and Weeli Wolli Creeks. These species are known to use a range of mechanisms to regulate their water use in response to changes to water availability, such as: stomatal control[31], cell-wall elastic adjustment and osmotic adjustment[32], leaf area equilibration[33], and self thinning[34].

[30] O'Grady AP, Eamus D, Cook PG & Lamontagne S (2005) Comparative water use by the riparian trees *Melaleuca argentea* and *Corymbia bella* in the wet–dry tropics of northern Australia, *Tree Physiology*, vol. 26, pp: 219–228

[31] For example White DA, Turner NC & Galbraith JH (2000) Leaf water relations and stomatal behaviour of four allopatric Eucalyptus species planted in Mediterranean southwestern Australia, *Tree Physiol* , vol. 20, pp: 1157-1165

These adaptations and the ability to extract water variably through deep tap roots or shallow lateral roots, depending on relative water availability, make the Eucalypt species relatively resilient to water table fluctuations; although they will still exhibit stress when soil water content goes above or below an optimal level.

Downstream of Yandicoogina, the Fortescue Marsh area has important conservation values[35] and has been recognised by the Western Australian Department of Parks and Wildlife as a Priority Ecological Community[36] (PEC) Priority 1. The marsh is rich in plant and animal species of high conservation value and is part of an ancient and complex array of alluvial aquifers and groundwater systems. It is sustained by floodwater from the upper Fortescue River catchment[37], of which the Weeli Wolli catchment comprises around half the source catchment, and local rainfall. Regular flooding of the fringing vegetation around the wetland is required to flush salts from the soil into the underlying groundwater table. This flushing is necessary to periodically reduce the stress on the samphire and halophytic vegetation[38], providing the ecosystem with a period of rejuvenation. It is recognised that changes to the large flood regime of Marillana or Weeli Wolli Creek could potentially have an impact on the health of the Fortescue Marsh.

Upstream of Yandicoogina PBS deposit, on Weeli Wolli Creek, the Weeli Wolli Spring riparian woodland and forest associations (approximately 15km upstream from the Marillana and Weeli Wolli Creek confluence) have been identified as a PEC (Priority 1). There is no evidence of an environmental connection between conditions at Weeli Wolli Spring and Yandicoogina, such that no impact on the Weeli Wolli Spring community is expected as a consequence of the Yandicoogina development.

Upstream of the Yandicoogina Oxbow West deposit, on Marillana Creek, the BHP Billiton Iron Ore operates the Yandi (also known as Marillana Creek) mine. The dewatering and closure activities at the BHP Billiton Iron Ore Yandi mine have and will continue to have an impact on the environmental conditions in Marillana Creek. Environmental factors that are influenced by BHP Billiton Iron Ore Yandi activities and in turn influence environmental conditions at Yandicoogina include groundwater levels, groundwater quality, surface water flows and surface water quality.

[32] For example Lemcoff JH, Guarnaschelli AB, Garau AM & Prystupa P (2002) Elastic and osmotic adjustments in rooted cuttings of several clones of *Eucalyptus camaldulensis* Dehnh. from southeastern Australia after a drought, *Flora - Morphology, Distribution, Functional Ecology of Plants*, vol 97, pp: 134-14

[36] Priority Ecological Communities (PECs) are poorly understood ecological communities, which potentially have high conservation values and may be subject to threatening processes. They are classified as either priority 1, 2 or 3; ranked in order of priority for survey and/or definition of the community, and evaluation of conservation status. It is noted that areas of Fortescue Marsh will change to conservation tenure following the renewal of Western Australian pastoral leases in 2015.

[38] Huxtable, D. (2013) Perspectives on ecological water requirements for plant communities of the Fortescue Marsh, in Proceedings of the Fortescue Marsh workshop, 26 March 2013.

14.3 Weeds

A total of 21 introduced flora species (weeds) were recorded in the Yandicoogina area prior to disturbance (Table 15). None of these species are listed as Declared Plants for the Pilbara region under the *Agriculture and Related Resources Protection Act 1976*.

Table 15: Weeds identified within the project envelope

Scientific Name	Common Name	Priority Classification
Acetosa vesicaria	Ruby Dock	Moderate
Aerva javanica	Kapok Bush	Low
Argemone ochroleuca subsp. Ochroleuca	Mexican Poppy	Low
Bidens bipinnata	Bipinnate Beggartick	Low
Cenchrus ciliaris	Buffel grass	Low
Cenchrus setiger	Birdwood Grass	Low
Citrullus colocynthis	Colocynth	Low
Cucumis melo subsp. Agrestis	Ulcardo Melon	Low
Cynodon dactylon	Couch	Low
Datura leichhardtii	Native Thornapple	Low
Helichrysum luteoalbum	Jersey Cudweed	Low
Malvastrum americanum	Spiked Malvastrum	Negligible
Portulaca oleracea	Purslane	Low
Setaria verticillata	Whorled Pigeon grass	Low
Sigesbeckia orientalis	Indian Weed	Low
Sisymbrium irio	London Rocket	Low
Sisymbrium orientale	Indian Hedge Mustard	Low
Solanum nigrum	Black Berry Nightshade	Low
Sonchus oleraceus	Common Sowthistle	Negligible
Tribulus terrestris	Caltrop	Low
Vachellia farnesiana	Mimosa Bush	Low

Buffel grass (*Cenchrus ciliaris*) was widespread and abundant prior to mining as a result of pastoral activities. Other species generally occurred as scattered individuals or in isolated patches. Mesic habitats such as creeklines and floodplains are particularly susceptible to weed invasion, and comprise the main areas around the mine supporting significant weed infestations.

Procedures to identify, control and eradicate target weeds and monitor weed control measures are in place to minimise the spread of weed species, prevent the introduction of new weeds and control and/or eradicate both noxious and environmental weeds in the mine area. Weed eradication programmes at Yandicoogina currently target *Acetosa vesicaria* (Ruby dock), *Aerva javanica* (kapok bush), *Malvastrum americanum* (spiked malvastrum), *Ricinus communis* (castor oil plant), *Setaria verticillata* (whorled pigeon grass) and *Vachellia farnesiana* (mimosa bush).

14.4 Progressive rehabilitation activities

Opportunities to undertake progressive rehabilitation at Yandicoogina have been limited as the majority of the disturbed area is still being used to support mining activities. Some rehabilitation of borrow areas has been undertaken, as discussed below. A review of standard rehabilitation practice performance was undertaken in 2015. This review (Appendix C) assessed the performance of rehabilitation undertaken on landforms similar to those that are expected to be present at Yandicoogina. The review indicates that standard rehabilitation practice is expected to achieve the required rehabilitation results for valley and hill type habitats associated with general landforms, long-term and short-tern disturbance areas; however, further research is required to develop rehabilitation strategies for drainage habitats.

14.4.1 Borrow pits

Borrow pits associated with the railway at Yandicoogina were rehabilitated in the second half of 1998. Rehabilitation monitoring commenced in 1999 and continues today. Monitoring results suggest that vegetation communities, in general, are similar to that of reference sites (Figure 13), while classification analysis showed there was no clear difference between the rehabilitated and reference sites in terms of their overall species composition.

Burning has occurred in both control sites and rehabilitation areas. The density and numbers of species present at control sites was observed to change after burning, often resulting in significant increases in plant species and resulting increased vegetation cover and diversity. However, analysis suggests rehabilitated sites do not respond to burning in the same manner, such that burning of rehabilitated sites does not result in long-term differences in vegetation composition.

Figure 13: Comparison of reference site 434 (left) and rehabilitated borrow pit area 434 (right) in 2013, 15 years after rehabilitation.

Figure 14 illustrates the difference in rehabilitation performance five years and 12 years after rehabilitation. After 12 years a small number of species present in reference sites have yet to be recorded in rehabilitation areas or are present only in lower numbers. However, there is a trend to gradual increase in species diversity. For example, in 2007, 20 species were recorded in reference sites that were not present in rehabilitation areas. By 2010 the number of species not identified in rehabilitation areas had reduced to 10, two of which were only recorded as a single plant across all reference sites.

Species found to be present in rehabilitated borrow pits at densities lower than in their reference sites comprise *Acacia aneura, Acacia dictyophleba*, *Acacia atkinsiana*, *Triodia pungens* and *Triodia wiseana*. Reasons for the lower abundance of some species in rehabilitation may include influence of fires, different densities prior to clearing and topsoil handling techniques.

Figure 14: Borrow Pit 417, with *Triodia* ground cover and *Acacia ancistrocarpa* and *A. atkinsiana* upper storey in 2003 (left) five years after rehabilitation, and in 2010 (right) 12 years after rehabilitation was completed.

14.4.2 Drainage shadow

Drainage shadow monitoring on Hamersley Iron's Yandicoogina railway commenced in 1998 and was completed in 2004. The monitoring program was designed to assess whether construction and operation of the railway had any indirect impact on the survival and health of Mulga, *Acacia aneura*. It was postulated that downslope impacts in the drainage shadow area might occur, with limited upslope impacts due to flooding also considered.

The results showed that although numbers of all mulga age classes and dead mature mulga appeared to be higher in some upslope transects, over time there was no clear statistically significant difference between the upslope and downslope transects.

CLOSURE RELATED DATA AND ANALYSIS

15. Removal of infrastructure

Decommissioning is anticipated to commence at the cessation of mining activities, as most areas of the mine, mine equipment and infrastructure will be fully utilised until the end of the mine life. However, as with progressive rehabilitation, opportunities to decommission areas in advance and facilitate rehabilitation will be reviewed through the mine planning process.

HIY has generic strategies for the removal of infrastructure, and develops location specific decommissioning plans as part of the decommissioning study, which will be undertaken 5 years prior to closure. Strategies involve:

- negotiating with Government prior to the removal of infrastructure as required under State Agreement requirements;
- actively seeking opportunities to recycle or reuse infrastructure that is to be removed;
- removing any environmentally hazardous materials in accordance with Controlled Waste Regulations; and
- where recycling and reuse opportunities are not available or viable, demolishing inert infrastructure and burying it onsite.

The decommissioning requirements for infrastructure at Yandicoogina are outlined in Table 16.

Table 16: Decommissioning requirements for Yandicoogina.

Category	Strategy
General	• Any equipment, steel structures or material that is not suitable for reuse are to be completely removed to an approved disposal site. • If encountered, any asbestos-containing building product or pipe work is to be disposed appropriately.
Above ground structures (e.g. buildings, tanks, rail)	• Brick, block work and steel frame structures are to be dismantled and salvaged or appropriately disposed. • Any container or tank that has held hazardous materials is to be drained/emptied and then disposed. • Bullet tanks and storage tanks 4 m diameters and less will be disposed of whole. Bins and storage tanks greater than 4 m diameter will be cut into transportable sizes for removal.
Reinforced soil walls	• Remove any structures, footings, slabs and equipment supported by the wall and its backfill. • Dismantle wall and remove backfill back to a natural surface profile. Any part of the wall that will be more than 1m below the finished ground surface can remain in place.
Concrete or sleeper-type retaining walls	• Remove any structure, footings, slabs and equipment supported by the wall. • Excavate soil from back of wall to a depth sufficient to allow the next two steps to be safely accomplished. • Remove any tiebacks and associated infrastructure that are within 1 m of the finished ground level.
Ground slabs	• Remove all attached steelwork, block work, services and equipment. • Break up and dispose of the concrete and full removal is practicable / required. • Otherwise leave the slab in place and cover with earth to a natural profile, and with minimum cover of 1 m.
Footings and associated pedestals	• Remove all attached steelwork and equipment. • If the footing and associated pedestals are less than 2 m^3, remove and dispose of them. • Otherwise cut and remove pedestals if required, and cover with earth to a natural profile, and with minimum cover of 1 m.
Above-ground concrete plinths (e.g. pump plinths) and structures (e.g. crusher blocks)	• Remove all attached steelwork and equipment. • Where practicable, remove concrete intact to disposal. • Otherwise, break concrete items and remove to disposal.
Culverts	• Remove all fill back to natural surface profile. • Remove culvert.

Category	Strategy
Sedimentation basins, ponds and reservoirs	• Dispose of liquid and sediments prior to deconstruction. • Break up and remove all concrete.
Roads and hardstand areas	• Remove any bituminous material to a disposal pit. • If roads were treated with salt or an acid based dust suppressant then clean fill maybe required over the road so that plant germination is not suppressed
Below ground infrastructure	• Services and infrastructure less than 1 m below ground level to be removed. • Services and infrastructure greater than 1m below ground level to be left in situ.
General areas	• Dispose of rubbish and any other decommissioning debris in an appropriate manner. • Remove any contaminated soil or designated hazardous materials that area to be remediated separately.

16. Landform design

16.1 Landform design strategy

HIY aims to create landforms that are safe and stable, considered aesthetically compatible with the surrounding landscape, supportive of native vegetation, and are non-polluting. It was recognised that integration of pit lakes into the closure landform for Yandicoogina was a necessity as there was not enough mineral waste generated by the mining process to backfill the voids to above the groundwater recovery levels. In consideration of how topography can influence water systems, six different landform combinations, using mineral waste volumes generated through mining to create landforms and control water movement, were investigated at Yandicoogina. Each closure scenario investigated was selected because it influenced the surface and ground water systems differently, and had the potential to achieve different environmental and social closure outcomes.

The six scenarios investigated, presented and illustrated in Appendix D, were:
1. No backfill (all voids become lakes);
2. Backfill to pre-mining water table (material would be mined, removing adjacent hills to achieve this scenario);
3. Maintaining creek flows (with lakes);
4. Multiple small, deep lakes (Weeli Wolli Creek captured);
5. One permanent lake (large lake captures Weeli Wolli Creek); and
6. Continuous channel (large lake in palaeo valley, all creeks captured).

Scenario 3, to maintain creek flows, was considered by HIY to provide the optimal closure outcome for the Yandicoogina area, based on the currently proposed life of mine plan (including development of the potential future expansion Billiard North and Braid deposits). The landform design for Yandicoogina considered different stakeholder / environment needs and the post-closure land-use options. Key drivers for the design of the post-closure landform were, in order of priority:
- safe, stable, non-polluting landforms;
- preservation of creek ecosystems, including riparian habitat;
- minimum impact to surface water flow paths, volumes and levels;
- achieving the lowest lake water salinity, preferably stock drinking water quality (4000mg/l) or lower; and
- minimum rehandle of mineral waste.

However, it is recognised that the mine plan may change in the future, for example, if new ore deposits are identified or if restrictions to the mine plan occur (i.e. for environmental or heritage reasons). Rio Tinto will continue to evaluate the impact of mine plan changes on closure outcomes, and this could result in a need to modify the closure landform in the future.

The “maintaining creek flows” scenario prioritises the use of available mineral waste to stabilise the pit walls, strengthen flood bunds and thereby preserves the creek systems as far as practicable. No attempt to suppress the groundwater table is made. Instead deep lakes are encouraged to form in the all pits except JSE, and excess mineral waste not required to support the creek system is placed to reduce the surface area of the lakes, rather than reduce the depth of the lake.

A conceptual landform was generated by prioritising mineral waste placement into the following locations:
- Phils Creek reconstruction. Phils Creek is removed as part of the JSW pit development. Additional mineral waste would be used to strengthen the land bridge (constructed during operations) by increasing the

buttressing either side of the land bridge. This configuration would minimise the potential for pit walls to collapse and increase resilience to large flood events.

- Marillana Creek between the JSW A and C areas. The area where Marillana Creek divides the JSW –A (southern) deposit from the JSW-C (northern) deposit restricts surface water flows between two flood bunds. Once the ore is removed, the bridge of CID ore and alluvium that remains under Marillana Creek has the potential to collapse into the void. Mineral waste would be used here to strengthen the pit walls and, leaving the flood bund in place, strengthen the flood bund. This configuration would increase resilience to large flood events.
- JSW-A adjacent to Marillana Creek. Mineral waste would be used at the southern end of the deposit to strengthen the pit wall adjacent to the Marillana Creek floodplain. The flood bund would be left in place and waste would be built up behind it to strengthen flood bund. This configuration would increase resilience to large flood events.
- Billiard South adjacent to Weeli Wolli Creek. Mineral waste would be used along the length of the deposit located within the Marillana Creek flood plain to strengthen the pit wall. An additional ramp area would be constructed to provide a controlled entry point and to convey floodwater from Weeli Wolli Creek into base of the pit. The entry point is expected to be towards the centre of the pit, such that the ramp would need to extend north and south across the width of the mine void into pit lakes created at either end of the mine void.
- JSE pit. Mineral waste would be used to suppress the groundwater table at JSE. This would prevent the permanent drawdown of the groundwater table under Weeli Wolli Creek adjacent to the JSE deposit.

With this landform configuration, a conceptual water balance model was compiled. The model suggested the groundwater table would recover to approximately pre-disturbance levels, in spite of the creation of several lakes.

16.2 Mineral waste management

The majority of the mineral waste is expected to be inert and highly erodible. Mineral waste dumps have been constructed in pit where possible; however a number of external waste dumps will be constructed throughout the mine life. These waste dumps will be removed and rehandled at closure (and opportunistically during the mine life), to place the mineral waste in strategic locations as illustrated in Figure 17.

This will include the use of mineral waste to:

- backfill and suppress the groundwater table. This mineral waste landform will construct a mostly flat surface, below the level of the original topography. Where the mineral waste landform ends, and the future pit lakes will form, (Figure 15) the mineral waste will be shaped to create a stable slope. Backfill elevations are shown in Figure 17.
- buttress pit walls located adjacent to creeks, as illustrated in Figure 16. These support structures are constructed as an in pit waste dump which merges into the natural land / levee (adjacent to the creek) and is rehabilitated to create a stable slope inside the mine void.

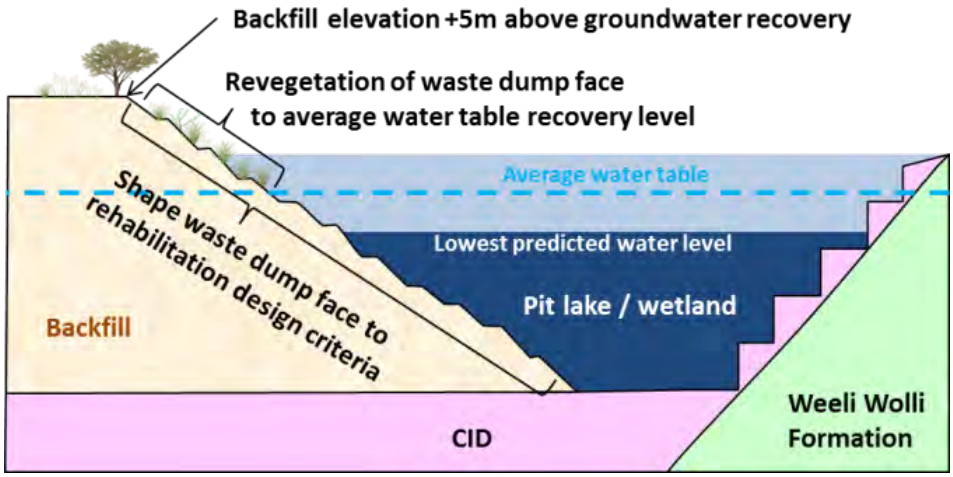

Figure 15: Schematic representation of mineral waste adjacent to future lake area.

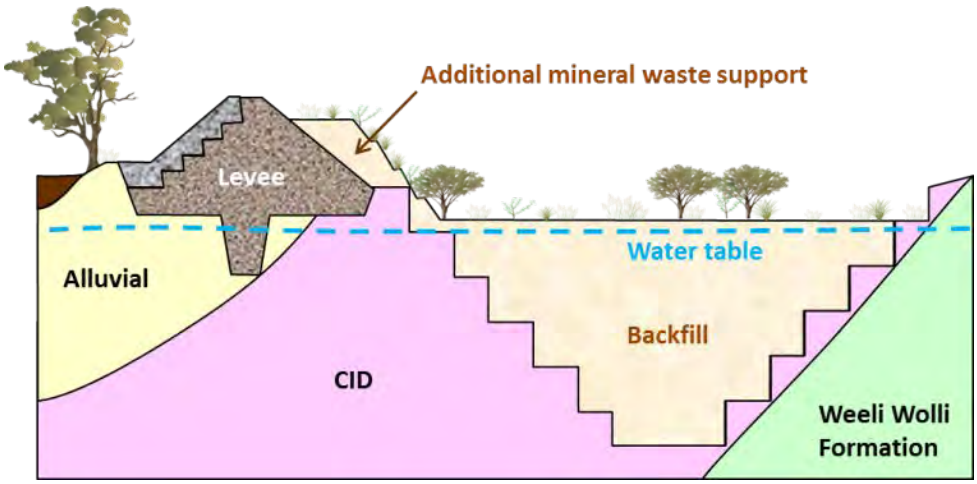

Figure 16: Schematic representation of mineral waste supporting the pit wall adjacent to a creek.

All of the mineral waste will be rehabilitated in accordance with waste dump design criteria described in Table 17.

Table 17: Rehabilitation landform design for mineral waste.

Waste dump	Slope angle (degrees)	Lift height (m)	Berm width (m)	Back slope angle (degrees)	Comments
All mineral waste	20	5	10	5	Additional erosion protection may be required for drainage and surfaces at lake fringe. To be resolved during detailed rehabilitation planning.

The rehabilitation waste dump design criteria (Table 17) conform to the internal guidelines, which outline a process for developing waste dump designs to take into account:

- specific mineral wastes present in each dump;
- climatic conditions present at the site;
- location, including in pit disposal / backfill and surface water considerations;
- maximum dump height and footprint constraints;
- shape of waste dump, preferably to minimise surface area to volume ratio;
- shaping options for the top of the waste dump.

Slope angles that conform to the guidance are predicted to have an average erosion rate (averaged over the entire slope length) of <5 t/ha/y, together with a predicted maximum erosion rate at any point on the slope of <10 t/ha/y, such that rilling, and consequently gullying potential will be minimised. Erosion rates on the final landforms may differ from these values, due to variations in waste types, surface treatments, plant growth and drainage controls.

The final landform design is reviewed by a multi-disciplinary team and includes lift height, slope angle, minimum berm width and supplementary measures, i.e. selective material management, surface treatment and drainage management, for factors that cannot be resolved through landform shaping alone.

Rehabilitation trials have commenced at the base of the Phil's Pit, where the groundwater table is exposed across the pit floor, to investigate how mineral waste stability performs under saturated conditions, similar to those that will be present at the lake fringes. Two slope angles have been created, a conservative 10 degree slope and the standard 20 degree slope. Performance of these slopes angles, slope lengths and associated lift heights will be evaluated over time to identify any structural issues that may develop due to the future lake (saturated mineral waste) conditions.

Waste dump specific implementation plans, including drainage controls resulting (discussed below) from run on and incident rainfall, will be developed prior to rehabilitation. No implementation plans have been developed to date.

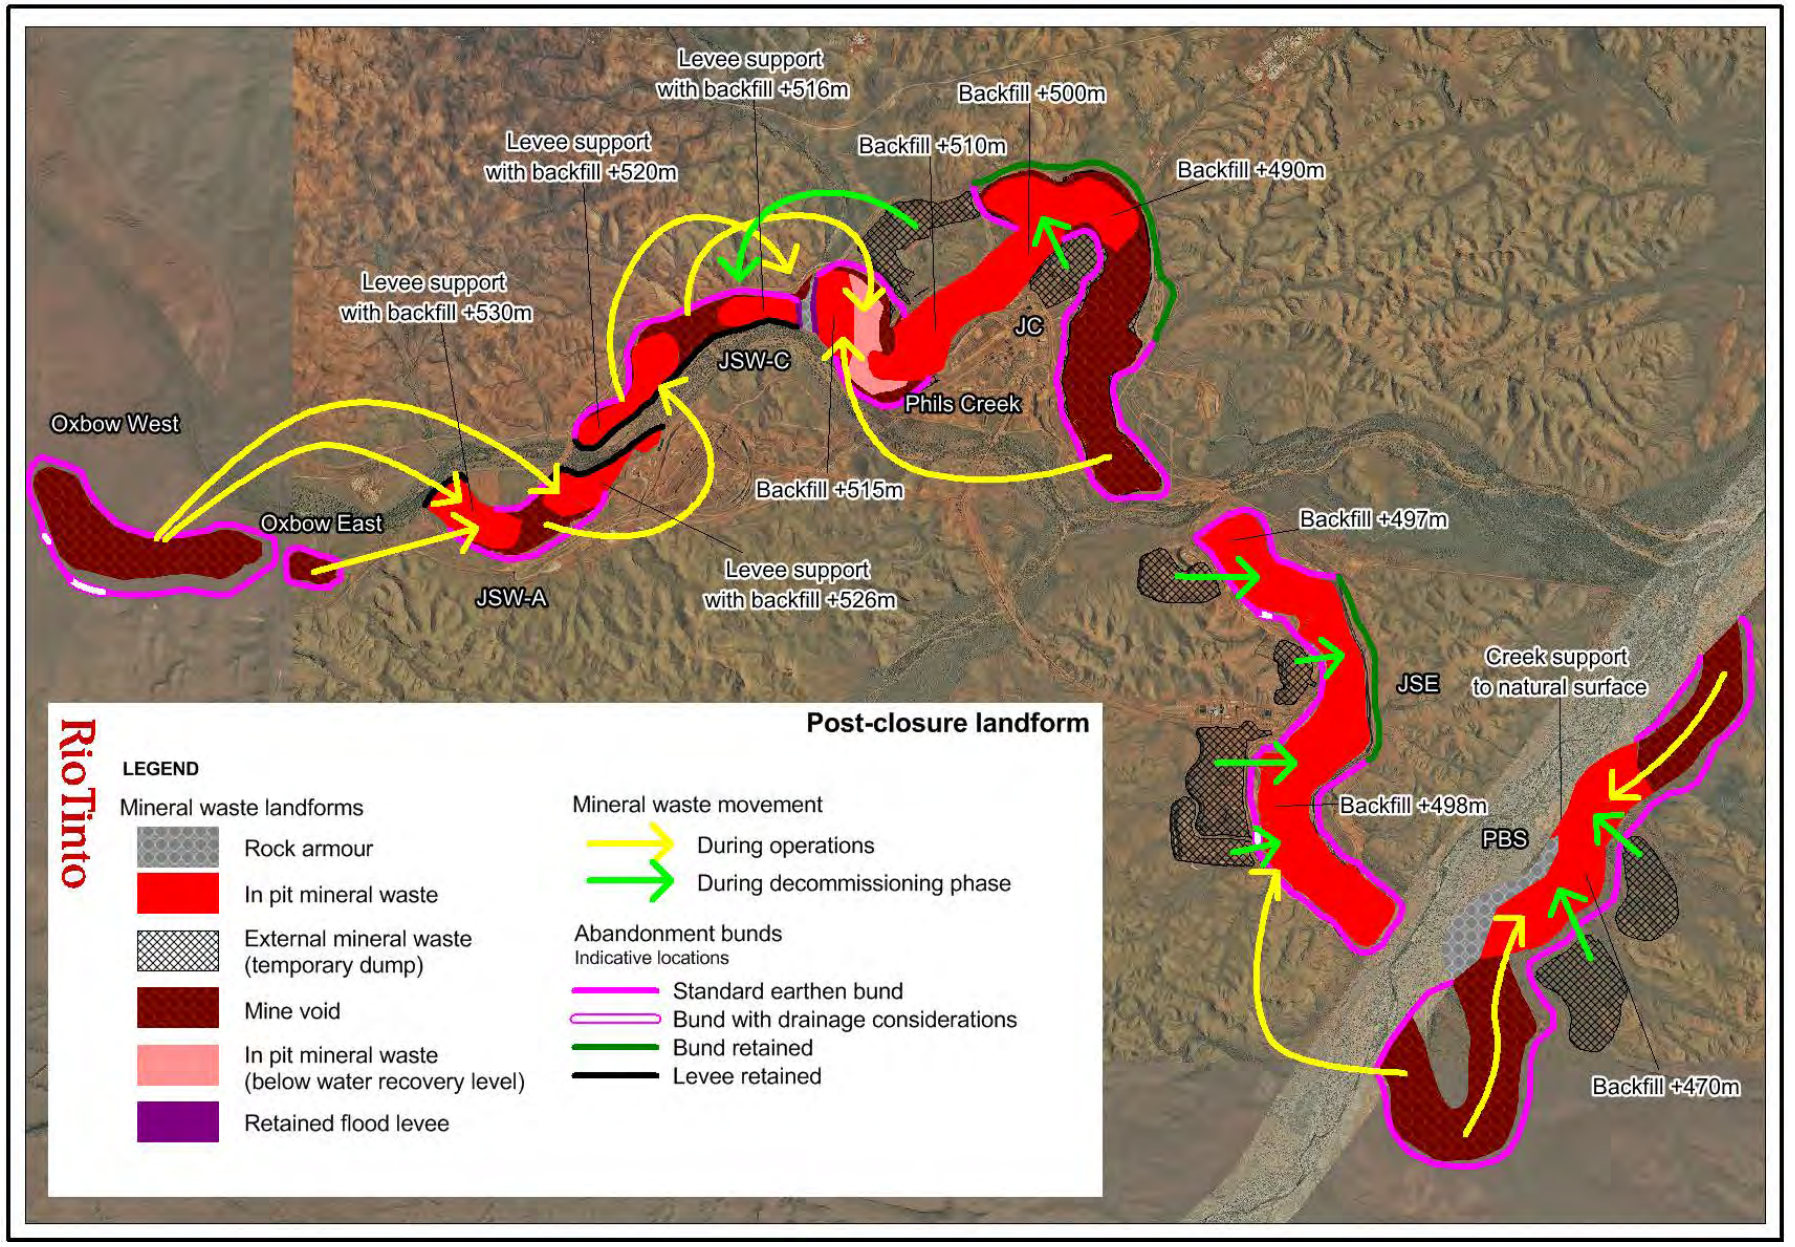

Figure 17: Yandicoogina mineral waste proposed rehandle / reclamation strategy.

16.3 Waste fines cell

Two waste fines cells have been created in the JC pit and a third waste fines cell has been established in the centre of the JSE pit. Another waste fines cells is expected to be established within the JC void before the end of the mine life.

Hydrogeological studies have been completed which demonstrate that the waste fines cells are not an impediment to groundwater flow. This is because the 10m to 15m thick continuous, non-economic geological units left intact at the base of the Yandicoogina CID have demonstrated, in the field and through modelling, that they have the capacity to sustain groundwater flow of around 10m/day.

The established waste fines cells in the JC pit will be rehabilitated to integrate into the JC in-pit landform. This will include:

- review of the landform elevation, to confirm if the elevation of the final lift on the waste fines cells is above the long-term projected groundwater. Where the final lift is below the long term groundwater elevation mineral waste will be used to cover the waste fines cell and raise the surface to above the long-term projected groundwater elevation;
- review of the surface conditions on the waste fines cells, to confirm if, on drying, the surface materials would be subject to wind erosion on drying. If wind erosion is likely to occur, mineral waste or subsoil will be blended into the surface material or placed as a cap to create a competent surface layer; and
- landform shaping, including battering of slopes to appropriate angles, to blend the location into the surrounding in-pit landform.

This approach would also be employed as part of the rehabilitation for the JSE waste fines cell. The future JC waste fines cell, however, is expected to be fully submerged beneath the recovered water table (JC pit lake) and would not be rehabilitated.

As the waste fines cells have been constructed below the long-term projected groundwater elevation, the waste fines materials are expected to remain relatively ‘wet’ (i.e. will not dry out). Consequently, surface subsidence, often associated with the drying of waste fines cells, is not expected to be a significant issue at Yandicoogina.

16.4 Flat and undulating areas

The majority of the infrastructure areas can be described as flat or undulating areas. This includes areas such as laydown areas, haul roads, building sites and bitumen roads. Rehabilitation of these areas is subject to detailed design during the decommissioning study in accordance with the following guidelines:

- Any steep slopes that have been artificially constructed will be dozed or shaped to less than 20 degrees or rock armoured to prevent erosion, unless it can be demonstrated that the structures are stable in the long term. (High disturbance areas)
- Areas with less than 1m relief will be re-contoured, to control runoff and so that the landform blends in with the surrounding landscape. If the area is large with a slight slope, then shallow windrows may be constructed on the contour approximately every 50m to prevent erosion from large sheet water flows. (Moderate disturbance)
- Where practical, areas will be ripped or scarified to remove compaction and encourage water infiltration and plant growth. On slopes, areas will be ripped parallel to the topographic contours. Roads are usually ripped along their length if they are not wide enough for contour ripping. Compacted areas such as haul roads require deep ripping.

17. Water management

17.1 Minor drainage works

Minor drainage works will be required to reinstate natural flow paths through disturbed areas prior to revegetation. This includes, following the removal of infrastructure:

- removing culverts and diversions;
- reinstating minor drainage lines / surface water flow systems, preferable along pre-disturbance flow paths;
- undertaking minor landscaping to recreate appropriate creek bed slopes and banks; and
- implementing localised surface water controls on large flat disturbed areas, to manage incident rainfall and local catchment run-on / run-off.

Minor drainage design works require a comprehensive understanding of the local long-term landforms. As a result closure drainage designs cannot be effectively generated until the future landform is known and no further land disturbance is proposed. Figure 18 illustrates some of the basic minor drainage works that are expected to be required as part of the minor drainage design activities.

In general, re-instated and constructed drainage will be designed in accordance with the following guidelines:

- The final profile of the constructed drainage line will consist of a flat base and sloped banks to allow for free drainage. Depth should not exceed 0.5m.
  The channel width will be determined based on the estimated volume of water that is anticipated to flow down the channel. In areas where friable, easily erodible material exists, or where there is the potential for high flow velocities, it may be necessary to cover the base of the constructed channel with competent rock .
- Where possible, the channel will be designed to meander such that the constructed channels have characteristics similar to the surrounding region, e.g. are not all linear features.
- The constructed channel will be blended in with any natural drainage lines.

Minor drainage design activities will be undertaken as part of progressive rehabilitation activities or during the decommissioning study.

17.2 Creek management

Major drainage works will be required to reconstruct sections of major creeks significantly altered through the act of mining. This includes:

- removal of the Phils Creek diversion and reconstruction of the Creek along its original alignment;
- repair of the Marillana Creek floodplain, including removal of the flood levee, and construction of the Marillana Creek to PBS pit lake spillway; and
- (potentially) modification to levee locations to expand the floodplain width between the JSW-A and JSW-C mine voids.

Physical design and construction of major surface water management structures is guided by the Rio Tinto Environmental Design Principles for Permanent Facilities. These principles aim to:

- ensure the long term safety and stability of engineered landforms e.g. considering local climate and climate change;
- ensure local drainage is reinstated in such a way that impacts on local hydrology is limited e.g. maintain flows, minimise erosion and sedimentation; and to
- ensure the latest design practice and monitoring evidence are used to guide design.

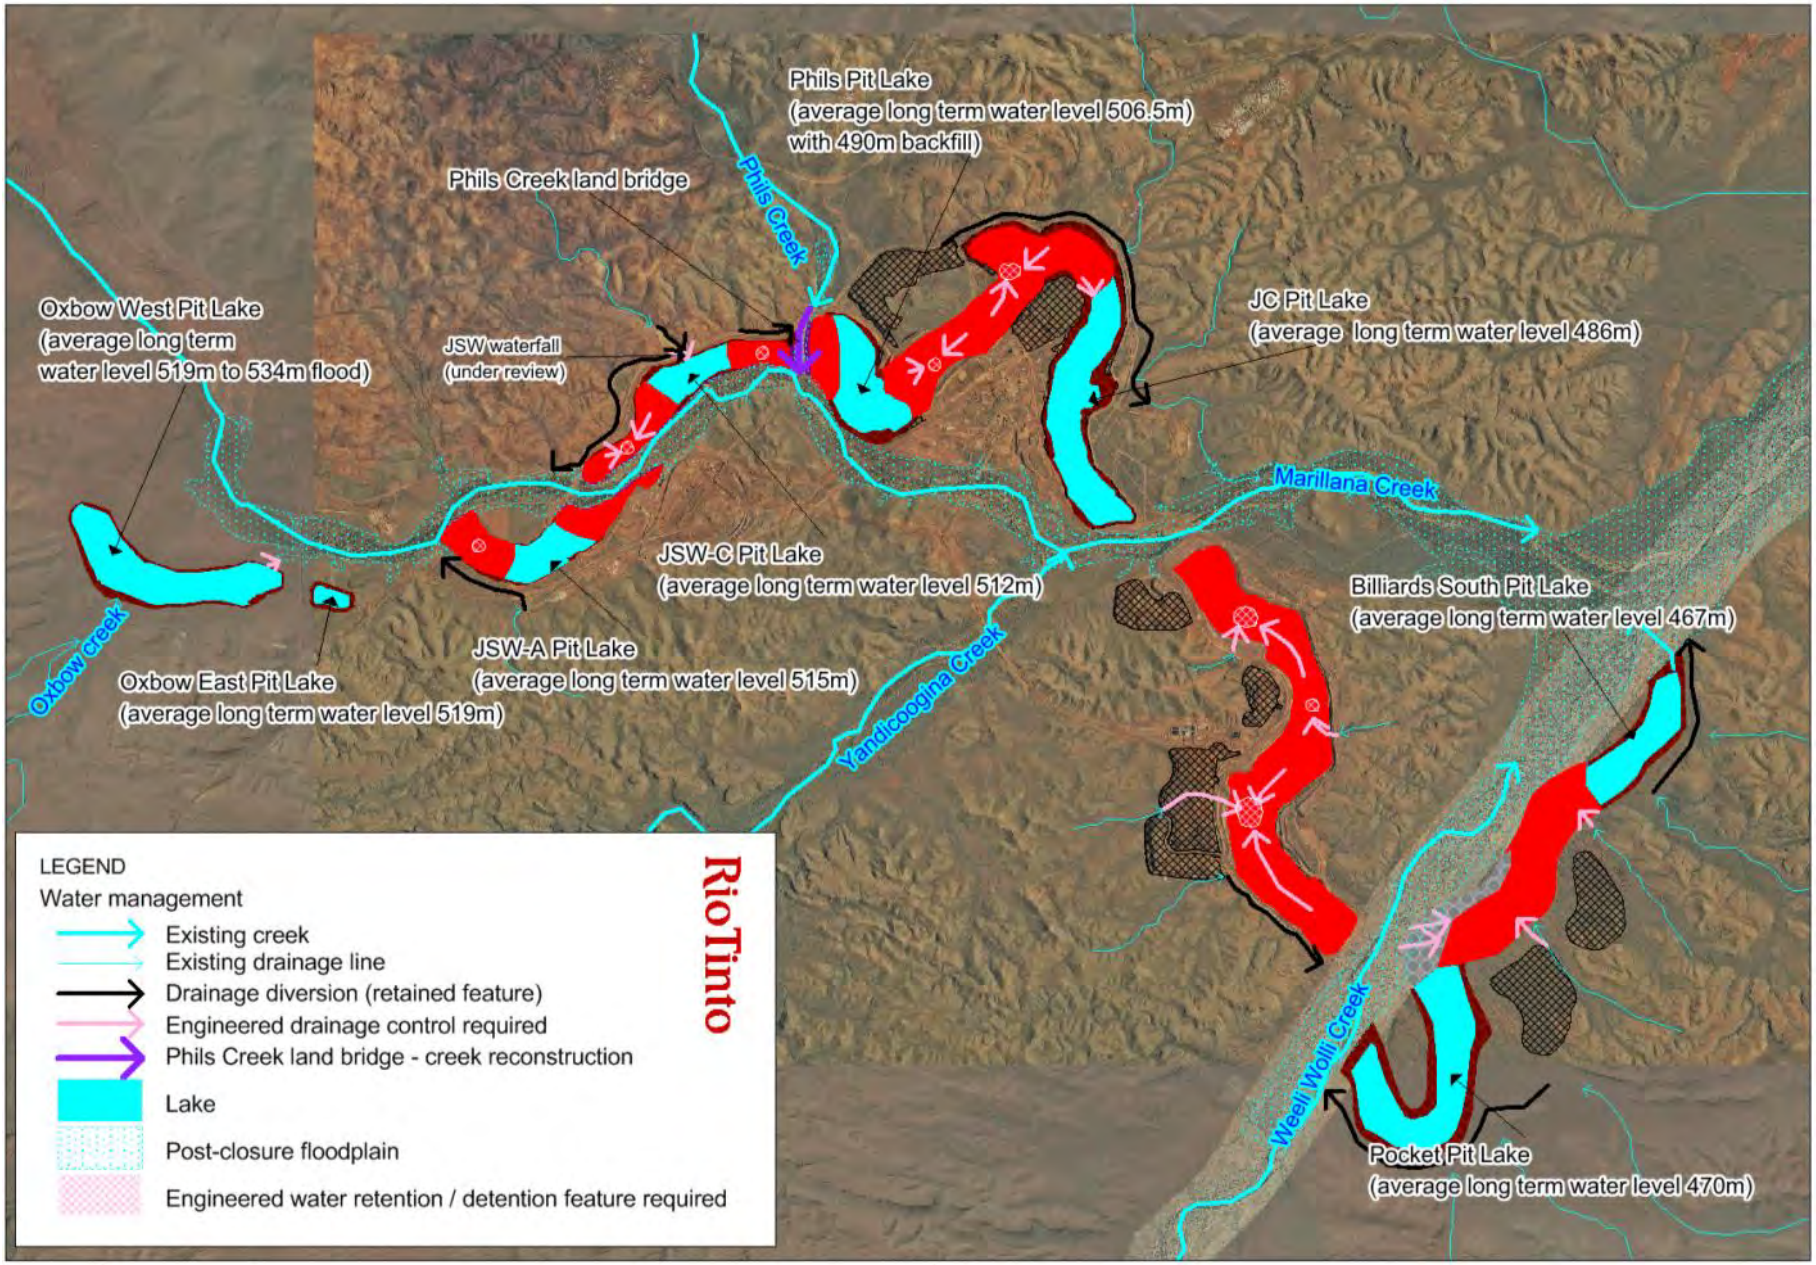

Figure 18: Post-closure landform water conditions. Proposed drainage works are shown in pink.

17.2.1 Phils Creek reconstruction

Phils Creek has been temporarily diverted through the active mine area while ore from beneath Phils Creek is mined. During the operation of the mine, a land bridge will be constructed across the mined void, using mineral waste and specialised compaction techniques to reinstate the original Phils Creek flow path to Marillana Creek. The width of the flood plain will not be reinstated during this initial build; instead, flood levees and appropriately sized rock armour will be used to contain the flood water and prevent erosion.

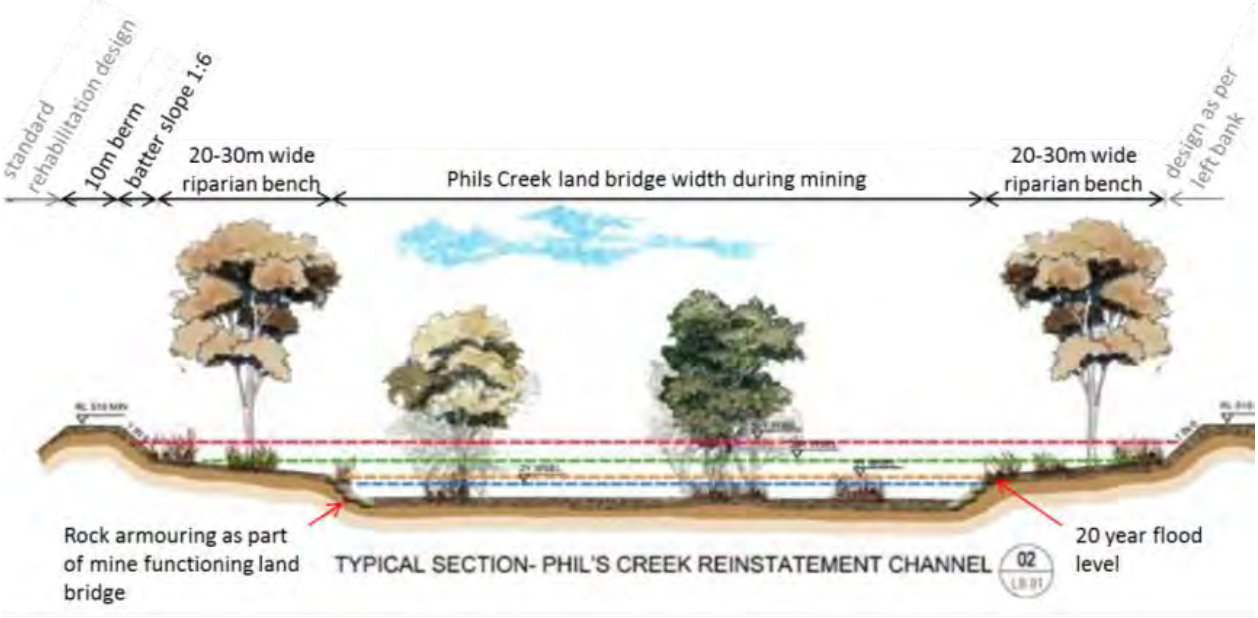

Figure 19: Conceptual design of the Phils Creek closure landform (profile view).

The performance of the Phils Creek land bridge will be extensively monitored during the operation of the mine, to ensure any early settlement, subsidence or erosion is appropriately managed.

The design of the Phils Creek land bridge will be altered at closure to facilitate larger flood events (Figure 19 and Figure 20). This will involve widening the distance between the top half of the levees to create an artificial flood plain. The flood plain will help to reduce the flood flow velocities and thereby reduce the potential for erosion. The levee thickness will also be increased, to strengthen the structures and allow for redundancy, such that erosion of the levee landforms does not result in the collapse of the levee into the foreseeable future.

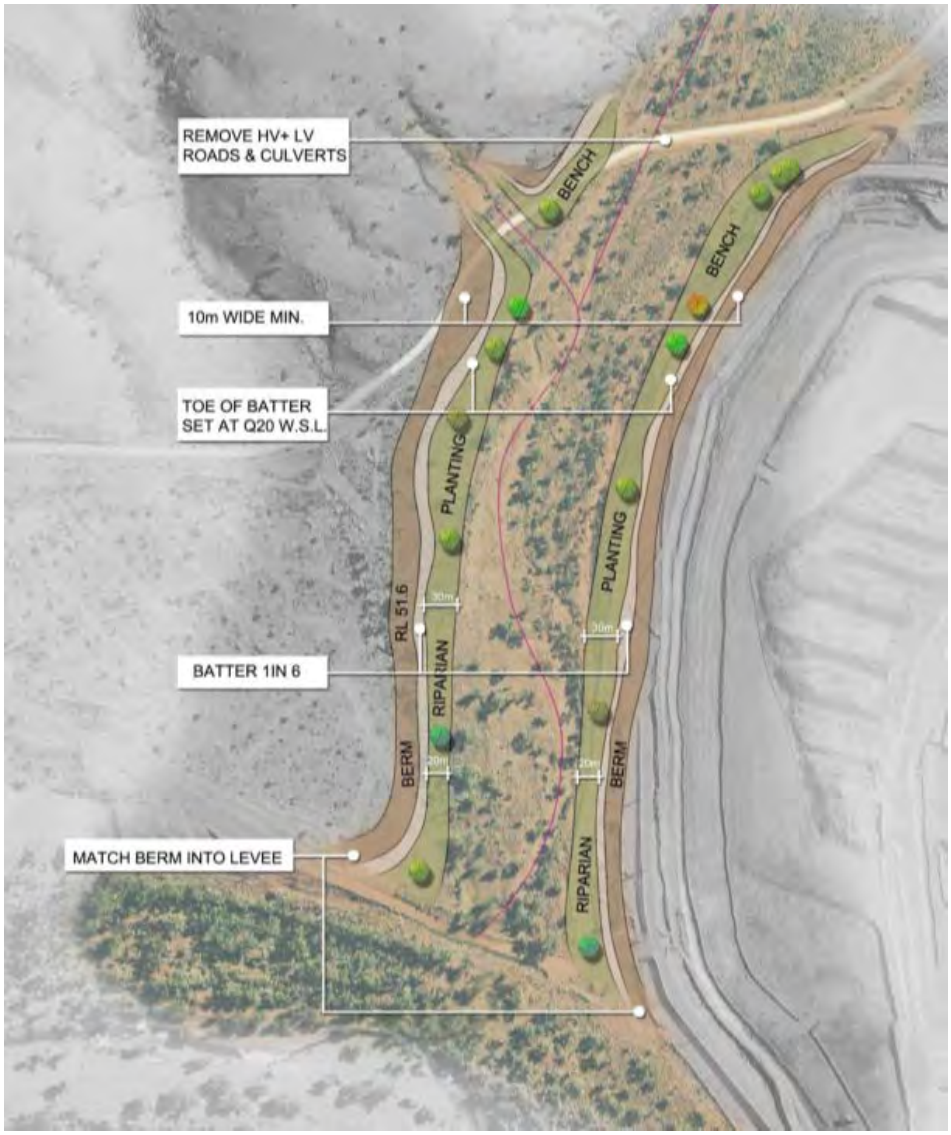

Figure 20: Conceptual design of the Phils Creek closure landform (plan view).

17.2.2 PBS pit lake spillway

Conceptual design of the PBS pit lake flood spillway will be undertaken following confirmation of the PBS pit design and associated geotechnical and hydrogeological studies. The design is expected to utilise mineral waste and the PBS pit wall buttress to create a ramp of appropriate gradient and erosion protection to convey flood water from the Marillana Creek floodplain to the pit lakes, without creating erosion (or head cut) in the Marillana Creek floodplain.

17.2.3 JSW-A and JSW-C floodplain

The levees adjacent to JSW-A (Figure 21) and JSW-C on the edge of the Marillana Creek floodplain, are proposed to remain and be strengthened at closure, to prevent large events from eroding the in-pit mineral waste wall buttresses.

A preliminary review of the hydraulic performance of Marillana Creek identified that high flow velocities were evident in the creek bed between JSW-C and JSW-A during large flood events; such that over the very long term bed erosion could occur.

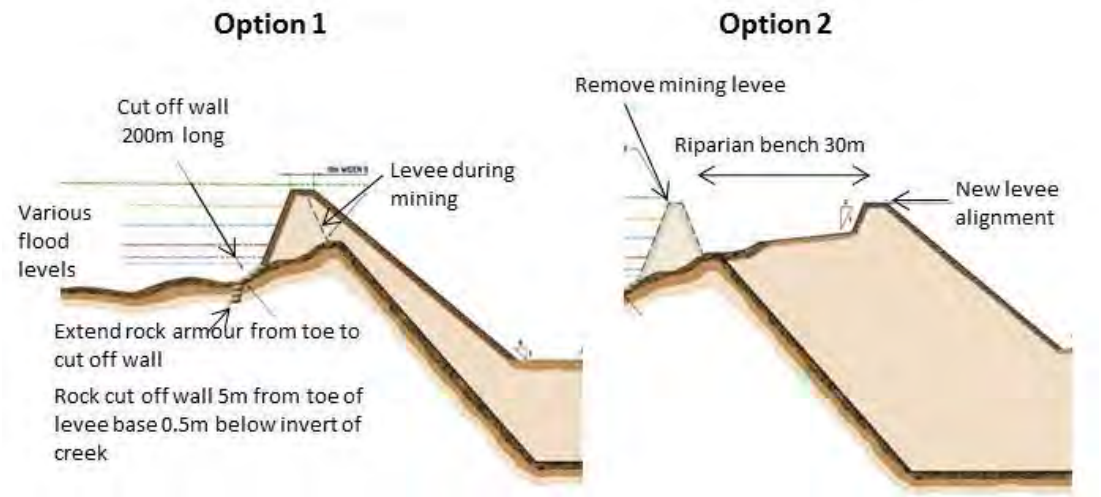

Figure 21: Design concepts for the JSW-A flood levee, retained as constructed during operations (left) or modified to reduced stresses incurred during large flood events (right).

Further hydraulic modelling is required to verify if the retention of the levees has the potential to increase that rate of bed erosion in Marillana Creek between JSW-C and JSW-A, considering changes to future climate and future catchment hydrology. Alteration to the levee configuration (Figure 21 Option 2 and Figure 22), including increasing the width of the floodplain by removing and relocating the levees at closure may need to be considered to mitigate the erosion.

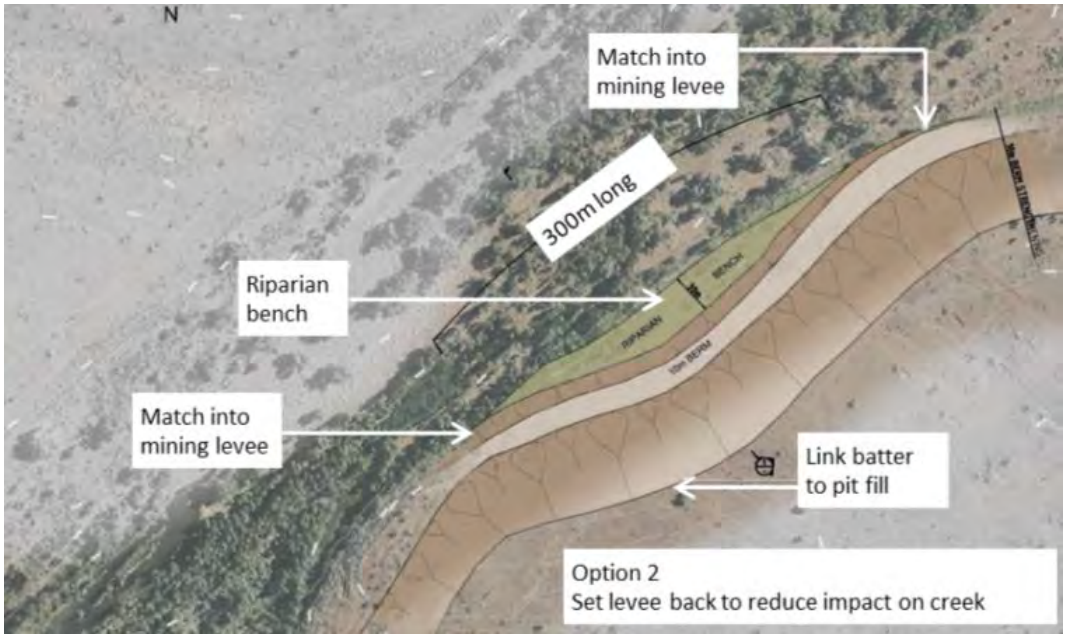

Figure 22: Design concepts for the modified JSW-A flood levee (plan view).

17.3 Groundwater and pit lake formation

17.3.1 General groundwater recovery

Groundwater levels at Yandicoogina have been suppressed over a long period of time, decades in some location, to facilitate mining. When groundwater dewatering ceases, however, the groundwater system is not expected to behave as it did prior to mining, due to changes in the CID aquifer, including:

- removal of large sections of the CID aquifer as economic ore;
- return of mineral waste fines and coarse (normal) mineral waste to the mine voids; and
- inability to suppress the entire length of the groundwater table, which will enable pit lakes to develop.

Groundwater models have been developed to simulate groundwater recovery and post-mining groundwater movement (Figure 23).

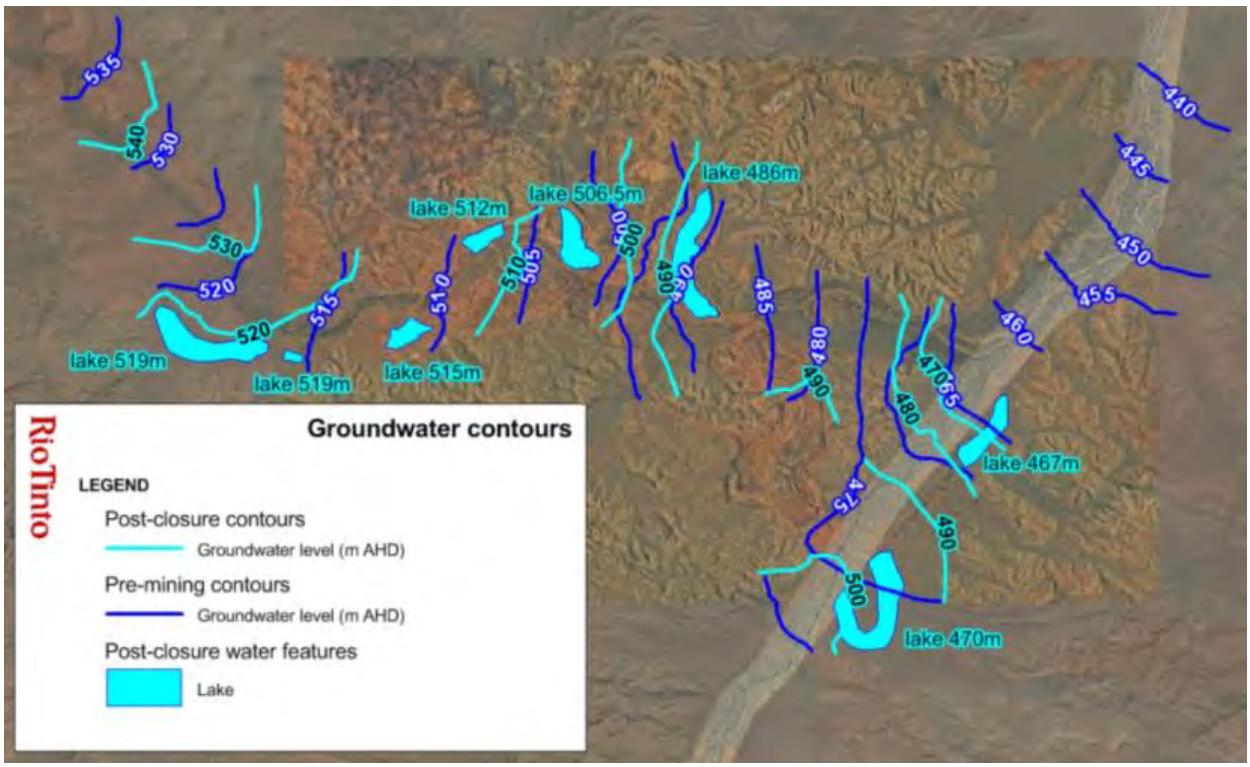

Figure 23: Groundwater recovery contour map.

The latest groundwater recovery model considered the interaction of surface water flows, groundwater aquifers and lake storage and utilises the latest surface water flow predictions for the Marillana and Weeli Wolli Creek catchment areas and rainfall predictions for the region.

The modelling suggests that:

- Groundwater flow rates will change, due to the different properties of the material within the CID (around 15m/d for coarse mineral waste and <1m/d for waste fine cells).
- Groundwater levels will return to approximate pre-mining groundwater levels (Figure 23), with the exception of JC pit lake, where the groundwater table will be permanently suppressed for a radius of 1km - 2km due to evaporation processes. This impact equates to a 1m - 2m permanent reduction (within the natural observed seasonal variation) in the alluvial groundwater aquifer levels beneath Marillana Creek, along a kilometre stretch of Marillana Creek within the Zone 2a[39] riparian reach, adjacent to JC pit lake. (Note the extent of the depressed groundwater is predicted to be similar in extent to the existing mine dewatering cone of depression, although substantially shallower.)
- Groundwater flow directions will reverse (compared to pre-mining conditions) through the JSE section of the CID, due to the suppression of the groundwater table at JC pit lake.

Monitoring evidence suggests that large flood events will rapidly recharge depleted groundwater aquifers, such that, once dewatering stops, groundwater systems can substantially recover (over 80 percent recovery) in as little as 10 years at JSW, although water levels could take up to 40 years to stabilise at JC.

This groundwater recovery model will be reviewed and updated intermittently, during the life of the operation, as more information and improved software capabilities are available.

Due to the complexity of the creek, groundwater and lake interactions at Yandicoogina, existing computer programmes struggle to model how water will move and the quality change at spatial and temporal scales that enable environmental impacts, especially the effects on groundwater dependent ecosystems, to be conclusively resolved.

This issue is currently managed by sequential modelling, using the results from the regional groundwater model as control or seed conditions within detailed, local water balance models. Results from the individual JSE, Oxbow West and PBS mine voids are described below. Models for the JC and JSW areas will be developed following the next update to the groundwater recovery model.

[39] Commensurate with impact Zone 2a as defined within the Report and recommendations of the Environmental Protection Authority, Yandicoogina Iron Ore Project - Expansion to include Junction South West and Oxbow Deposits, Report 1448 August 2012.

From the groundwater recovery models, basic lake water depths to lake area relationships suggest that the water column within all of the pit lakes will be mixed once a year (monomitic). Consequently, it is appropriate to assume that the lake water within the water balance models will be fully mixed, of equal salinity down the water column, and oxygenated.

17.3.2 JSE water conditions

On closure, the JSE mine void will be backfilled to supress the groundwater table and prevent the formation of a permanent lake. As the void will not be backfilled to surface, it will be the lowest point in the local catchment; and as such, surface water runoff will naturally flow into and be trapped within the void.

With a limited supply of mineral waste material available, to ensure that the combination of natural groundwater variations, incident rainfall and surface water run-on did not create a permanent lake, the minimum cover depth for the JSE void was calculated using an ecological water balance.

For the purpose of this water balance, a permanent lake was defined as: the presence of more than 10cm of water for more than 30 days on average each year. It was also assumed that waste fines cells would extend through the majority of the JSE mine void as a series of cells, filled from south to north to the 495mRL and separated by walls constructed from coarse mineral waste.

The model was calibrated to the regional groundwater recovery model, such that groundwater was sourced from the beneath Weeli Wolli Creek, tracked through different waste fines cells and backfilled coarse mineral waste (new aquifers), and returned to the Marillana Creek CID / alluvial aquifer. This regional recovery water level varied from 497.3m RL under Weeli Wolli Creek to 490.9m RL under Marillana Creek.

Inputs were also received via surface water runoff from the adjacent catchments and rainfall, and removed via evaporation (when present as a lake / pond) and evapotranspiration (based on a specified vegetation profile).

The water balance used a three layer model to simulate potential water conditions including ponding on the surface, the water content of coarse mineral waste backfill and the water content in the waste fines cells. The depth of the coarse mineral waste was subsequently minimised to determine the thickness (Figure 24) necessary to ensure that 10cm of water was not present for more than 30 days on average each year.

(Note these landform design requirements to suppress the groundwater table at JSE have been incorporated into the mineral waste management backfill / landform design, as presented in Figure 17.)

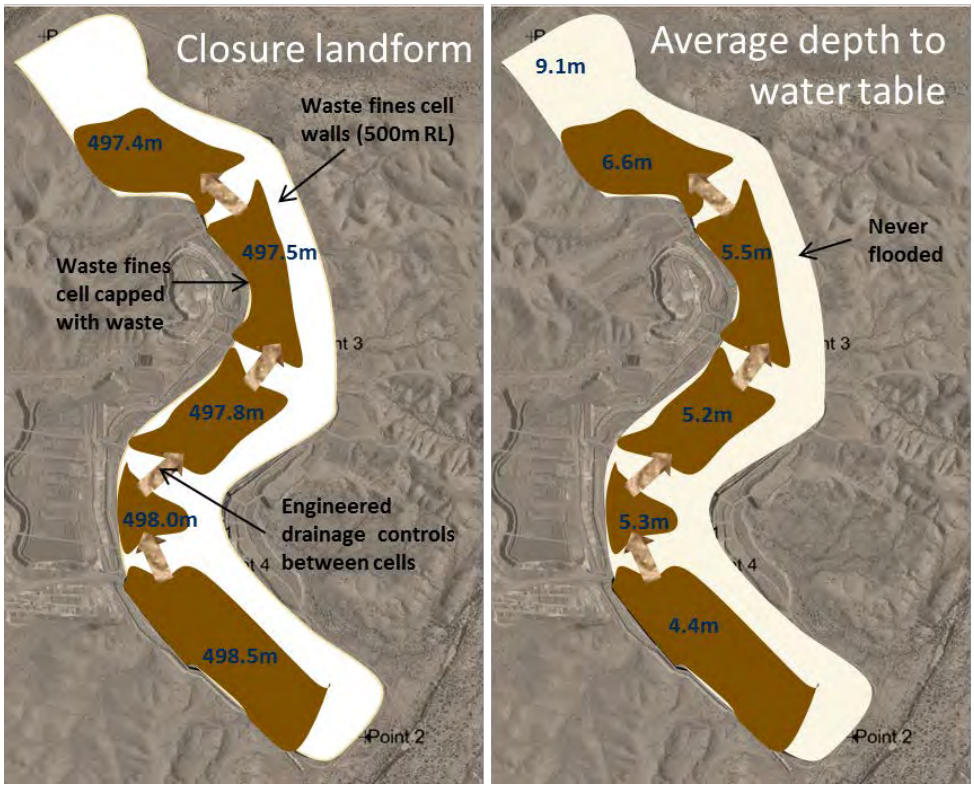

Figure 24: Junction South East (JSE) landform design requirements to suppress water table.

Due to the sloping groundwater table, the resolved landform surface of the coarse mineral waste (over the waste fines cells) was also sloped. Surface water trapped within the mine void is subsequently expected to flow from south to north following large storm events, creating a temporary pond at the northern tip of the void (Figure 25). This configuration had the additional advantage of applying recharge directly into the groundwater depression created by the presence of the JC lake, which may assist in reducing the impact of the JC pit lake cone of depression.

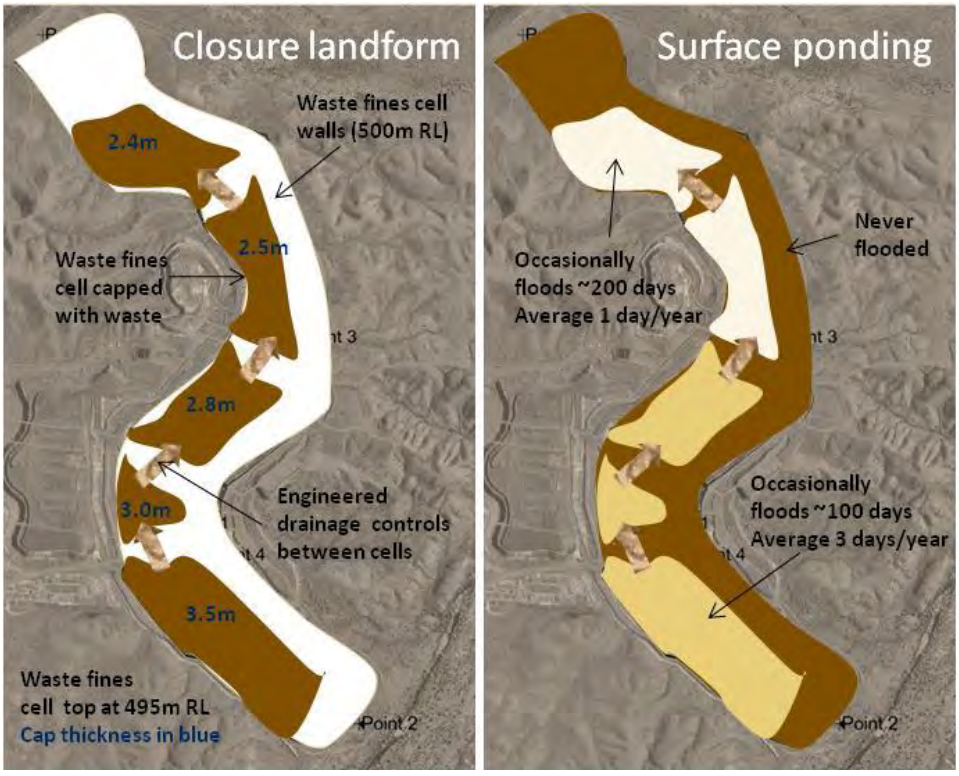

Figure 25: Surface water conditions anticipated to occur in the JSE closure landform.

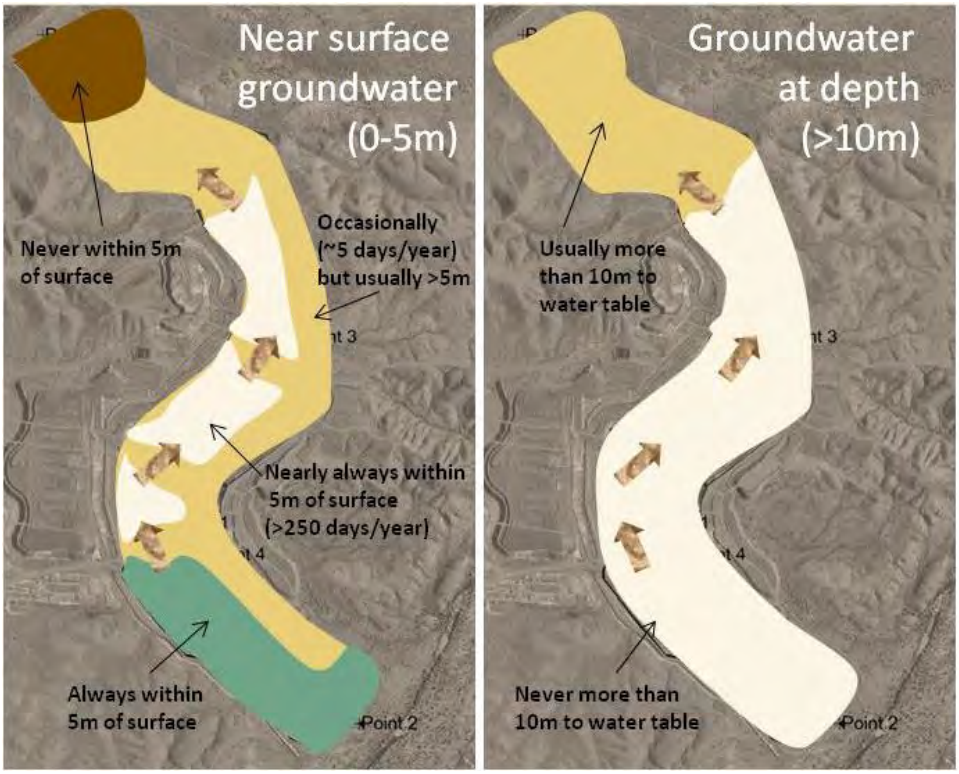

Figure 26: Groundwater conditions anticipated to occur in the JSE closure landform.

The model also enabled the spatial variability in water availability to be resolved across the JSE backfilled void. As illustrated in Figure 26, in the southern end of the void groundwater will be constantly near to the surface, providing access to water through prolonged droughts. In the southern tip, the lowest point within

the void, the area is expected to experience prolonged water logging after heavy rains. While the centre of the mine void will receive only incident rainfall. It is expected that this water availability guidance will be used assist with the selection of appropriate in-pit vegetation, as part of wider rehabilitation plans.

17.3.3 Oxbow West lake model

A simple water balance model was developed for Oxbow West lake to characterise salinity and water levels. The model used the same parameters as employed in the groundwater recovery model: groundwater, surface water flows from the oxbow catchment and climate sequences to calibrate the water balance, then simulated alternate evaporation and rainfall sequences through a Monte Carlo process to determine salinity and water levels. This modelling approach enabled detailed daily and monthly variability, i.e. temporal peaks in water levels created by minor flood events, to be resolved which cannot be achieved using the groundwater recovery model alone. As with the groundwater recovery model, this model used the latest information available, such that the results supersede previous water level and quality predictions for Oxbow West.

The water balance results aligned with the groundwater model predictions, estimating that water levels would recover to around 514mRL (±1m with 25% certainty), approximating the pre-mining groundwater level. This water level was sustained by a combination of groundwater, surface water and rainfall inflows. For example, nearly half of the water presenting in the lake each year was due to groundwater inflows, another 30 percent was due to runoff from the catchment above the lake and the remainder was from direct rainfall. The water level never reached the top of the pit and it was found that the lake never received sufficient water so as to over top the pit wall.

Although the lake levels reached approximate pre-mining levels, the additional detail provided by the water balance revealed the lake was most likely to behave as a sink.

The detailed outputs from the new Oxbow West water balance model suggest that groundwater levels in the adjacent Marillana Creek alluvial aquifer will be slightly higher than Oxbow West lake, which although subject to flooding is also subject to continual evaporation. This balance will prevent water from Oxbow West pit lake from flowing back into the Marillana Creek alluvial aquifer and is likely to terminate longitudinal flow down the CID, in favour of infiltration from the overlying Marillana Creek alluvials. As a consequence, salts, delivered through the CID groundwater system (via the BHP Billiton Iron Ore Yandi mine), were predicted to build up in the lake in perpetuity. When inflow salinity was set at 1100mg/l[40], after 300 years the salinity was predicted to exceed 10,000mg/l.

It was observed as part of the water balance modelling that, due to the coarse grid cell size required to run the groundwater model, the groundwater model over-estimates the storage capacity of Oxbow West's lake by roughly 30 percent. A separate water balance was subsequently run, using the same input parameters, to quantify the sensitivity of the lake water levels and salinity to the geometry of the void.

With a smaller mine void, a more accurate reflections of the mine void Rio Tinto are expected to build, the water level recovered to a higher level, 528mRL (±1m with 25% certainty), due to the smaller lake surface area and associated lower annual evaporative volume. If the water levels recover to 528mRL, it is possible for the lake to overtop and for water from the lake to return to Marillana Creek. Under these conditions the salinity was predicted to stabilise at 2,700mg/L after 2000 years, remaining fresh (below 1,500mg/l) for the first 500 years.

The large difference in water salinities and water levels resolved in these two models show that the water balance in this location is very sensitive to the closure landform design. At present, the void modelled water balance for Oxbow West has not considered the development of the small, neighbouring Oxbow East (future) pit lake or how the adjacent tenure holder, BHP Billiton Iron Ore, plan to develop the CID adjacent to Oxbow West[41]. However, it would be reasonable to assume that development of the adjacent BHP Billiton Iron Ore tenure CID would result in the creation of another pit lake. Consequently, the annual evaporative losses are more likely to increase, reflecting the modelling outcomes from the larger mine void – the development of highly saline (sink) lake that is not connected (downstream) to Marillana Creek or the

[40] This value is the estimated groundwater salinity at Oxbow as a result of mining activities at BHP Billiton Iron Ore Yandi, as published in BHP Billiton (2004) Marillana Creek (Yandi) Mine: decommissioning and final rehabilitation plan, January 2004.

[41] Rio Tinto is not privy to the proposed mine development activities or strategies of BHP Billiton Iron Ore, which would constitute the release of commercially sensitive information to a competitor, and could breach antitrust laws. A legal framework has yet to be identified that will enable the exchange of commercially sensitive information between Rio Tinto and its competitors. As a consequence, Rio Tinto is not in a position to resolve cumulative catchment impacts that are sensitive to mine development strategies i.e. final landform designs.

associated Marillana Creek alluvial aquifer. On this basis, further management planning will assume the worst case scenario, where saline conditions evolve, until future modelling is able to demonstrate otherwise.

17.3.4 PBS lake model

Employing the same methodology used to generate the Oxbow West lake model, a water balance model was developed for the PBS lakes to characterise salinity and water levels. The schematic water balance used for this analysis is presented in Figure 27.

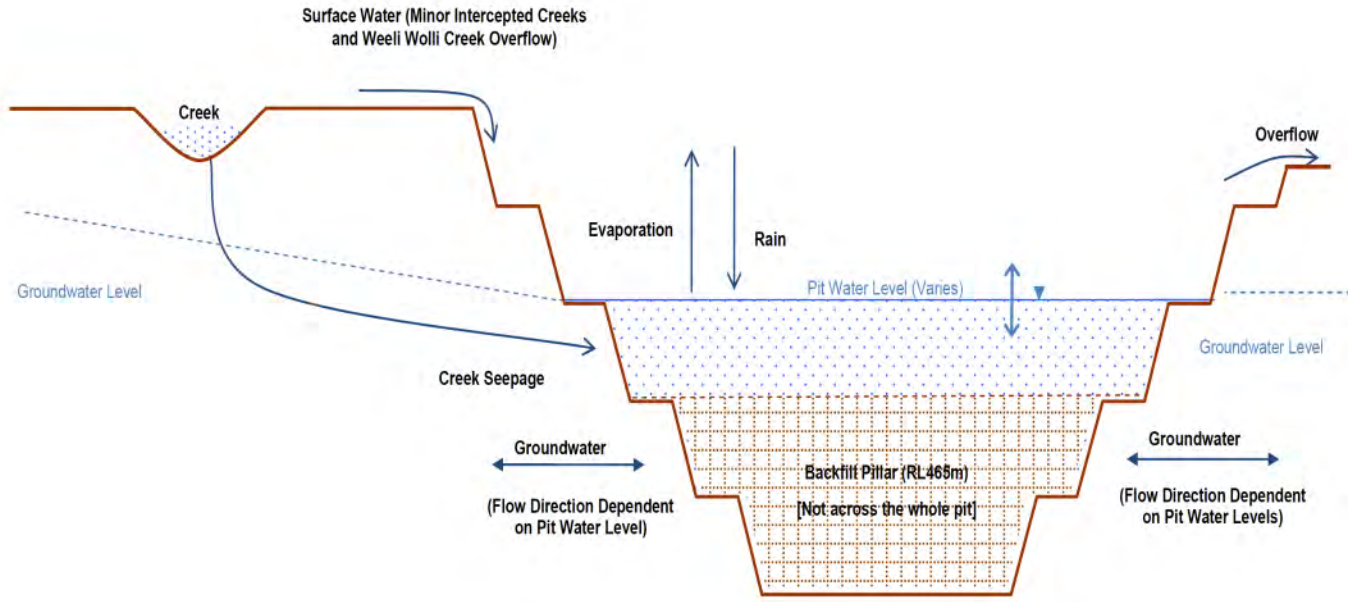

Figure 27: Schematic of the water balance used to simulate lake salinity and water level changes in the PBS mine void over the next 1000 years.

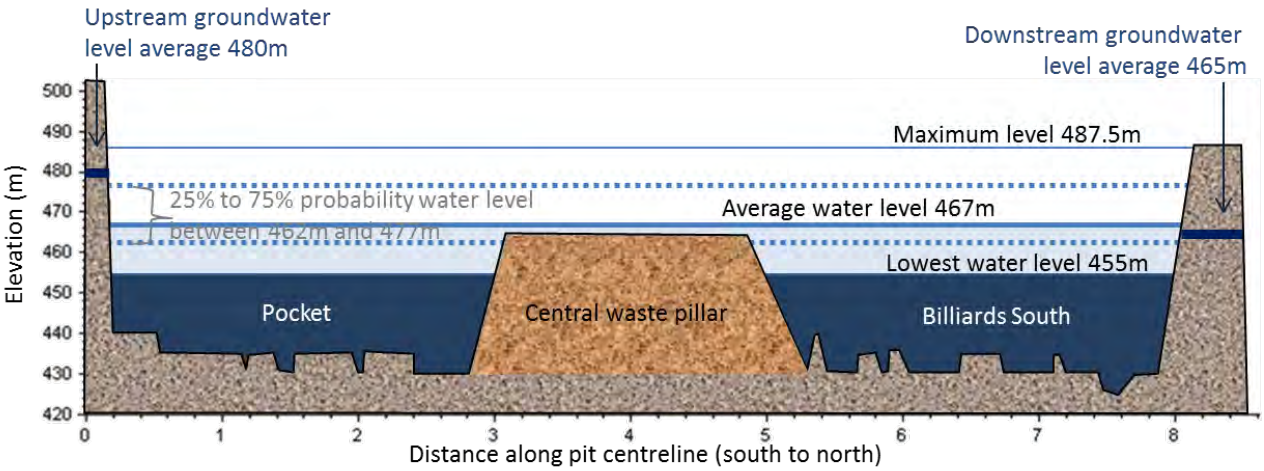

Figure 28: Long section through the PBS pit, presenting the statistical water level results from the water balance model.

The model results suggest:

- There is an eighty percent chance that flood water volumes from Weeli Wolli Creek in excess of 1000m^3 will flow into the void each year. The inflows contribute to a reduction in the pit lake salinity and are expected to deliver nutrients and aquatic fauna / flora to the lakes.
- An average of 10% of the flood water volume from Weeli Wolli Creek could be captured in the PBS mine void with each flood event.
- The void would overtop approximately 1.5 times every 100 years due to very large flood events in Weeli Wolli Creek. These very large floods would remove a substantial portion of the salts that have built up in the PBS lake.
- Removal of the PBS lake water through overtopping is expected to increase the salinity Weeli Wolli Creek flood water to a maximum of 300mg/l. This water quality is within the natural range observed in pools following flood events and as such is not expected to have an impact on the downstream environment.

- Lake levels (Figure 28) would average approximately 2m above the downstream recovered groundwater level of 465m RL, with median lake levels ranging between 1m and 6m above the downstream recovered groundwater level, creating a through flow lake system.
- During extreme drought periods the water could drop to as low as 8m below the downstream recovered groundwater level. The lake would cease to be a through flow system during these periods and the lake salinity would increase significantly.
- Salinity would be highly variable with time. One large inflow event which restored through flow conditions could reduce lake salinity by 1000mg/l. One large inflow event resulting in an overtopping event could reduce lake salinity by 3000mg/l.
- After 75 years there was a 50 percent probability that the salinity would still be fresh (<1000mg/l) and after 1000 years there was a 50 percent probability that the salinity would be 3000 mg/l, with extreme outcomes from the Stochastic modelling ranging from 200mg/l to 13,000 mg/l after 1000 years.

18. Plant and soil development

18.1 Habitat planning

A habitat is made up of physical factors such as soil, moisture, range of temperature, shelter and availability of light as well as biotic factors such as vegetation, availability of food and the presence of predators. Habitats provide a simple method of dividing the land into areas with common characteristics.

On closure, the land will be returned to self-sustaining ecosystems using native species of local provenance. The physical factors associated with the closure landform provide a starting point to identify which habitat units could best be reinstated across the mine area, given the changes to the land resulting from mining activities, in order to establish native self-sustaining ecosystems.

Flora, fauna and vegetation survey (baseline) data has been used to understand and group the area's pre-mining biodiversity / ecosystem values. When disturbed areas are no longer required to support mining activities, the areas may be progressively closed and rehabilitated. The habitat plans, as illustrated in Figure 29 (JSE in isolation) and Figure 30 (the entire area), provide the strategic vision to assist with the local planning activities.

Figure 29: Rehabilitation strategy for the JSE closure landform.

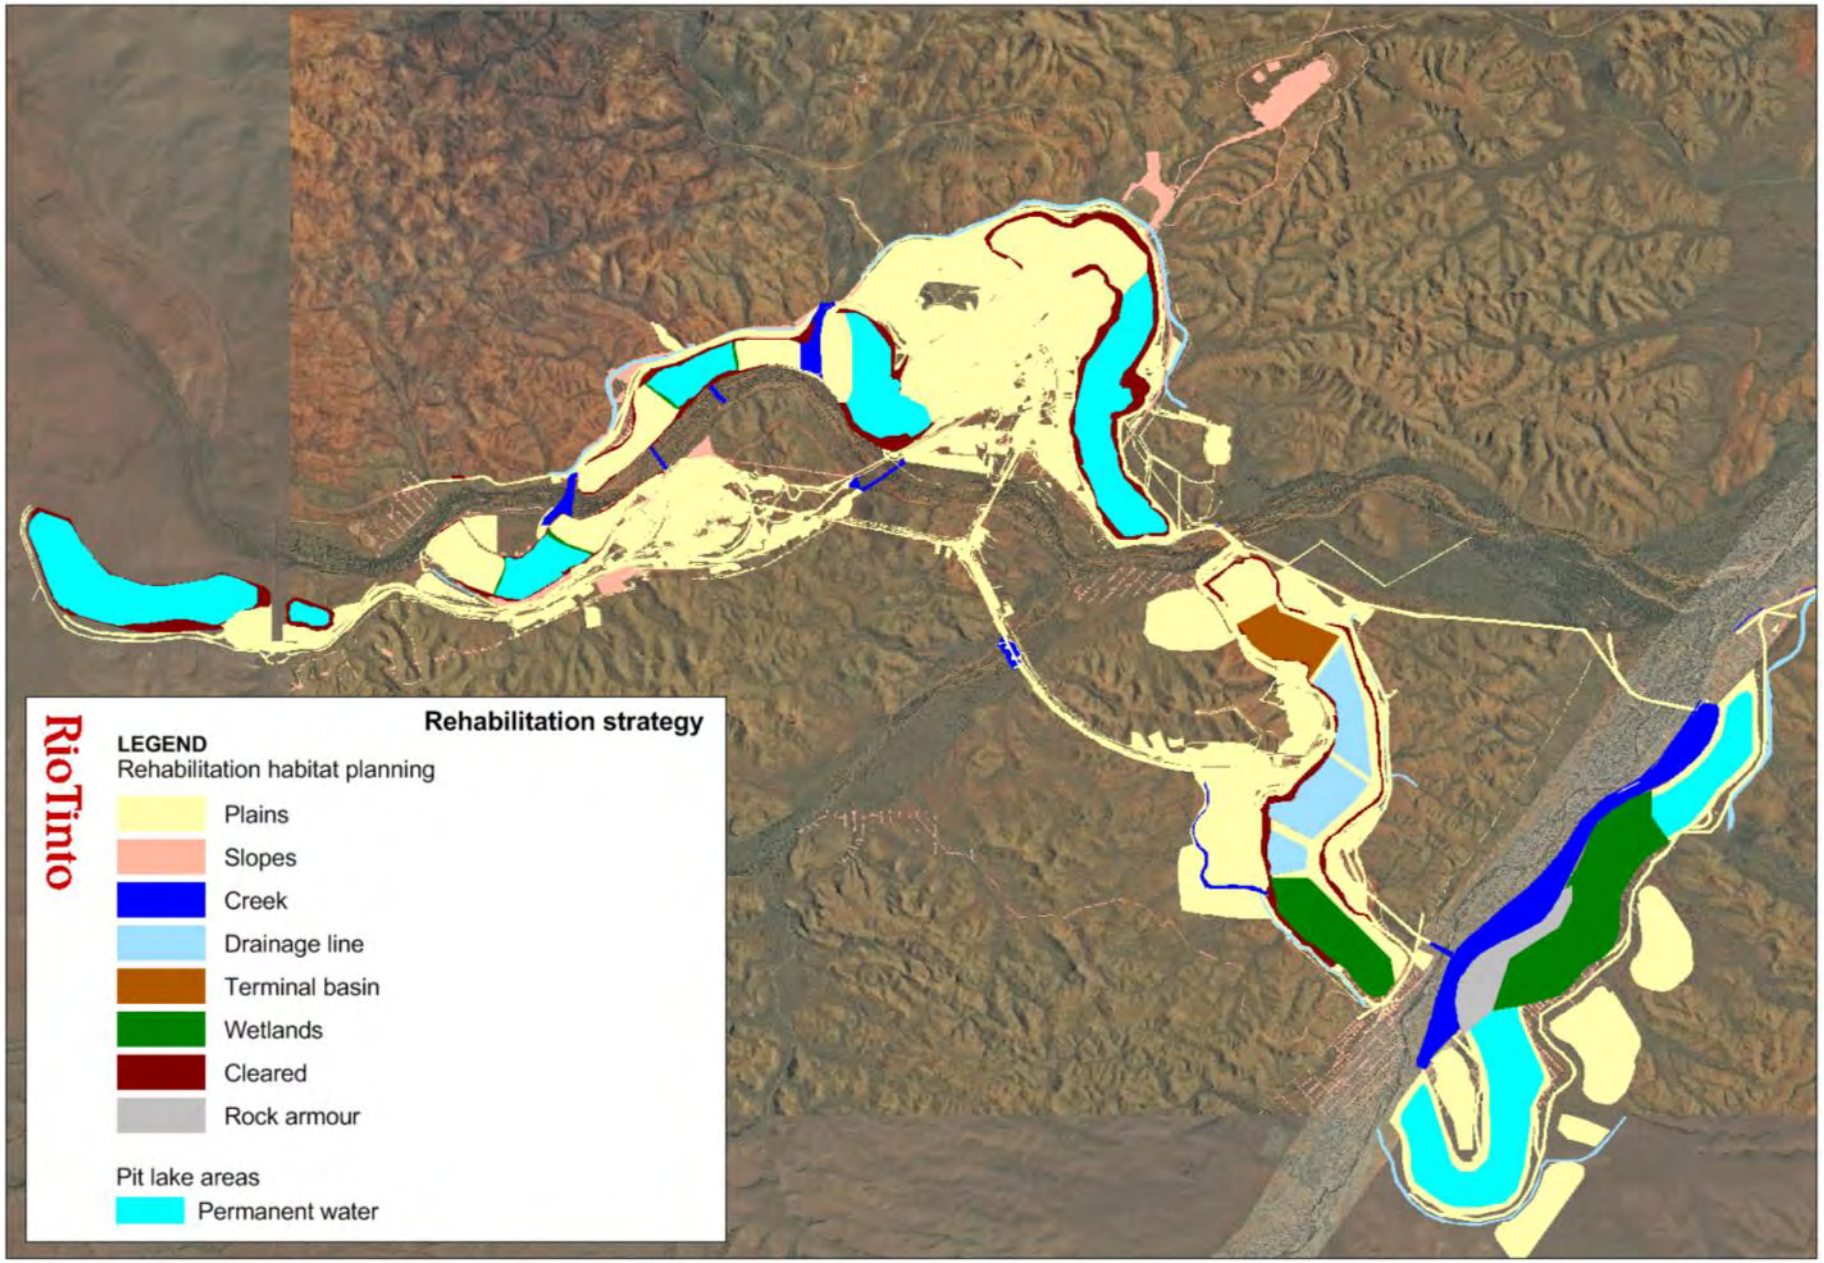

Figure 30: Rehabilitation strategy for the Yandicoogina closure landform.

The habitat units are expected to reflect the pre-mining biodiversity / ecosystem values through the habitat characteristics described in Table 11.

Habitat elements that are considered as part of the rehabilitation, including progressive rehabilitation, design include:

- selection of vegetation characteristics of the desired habitat unit e.g. known to provide preferred food or shelter preference;
- ability to reuse retained woody debris, to provide fauna refuge and microhabitats;
- ability to integrate rocky features, i.e. oversized waste burden or scree slopes, into the design for aesthetics and fauna use;
- requirements for rapid generation and retention of leaf litter using small-scale topography (e.g. furrows created from ripping);
- establishing soil depth and considering opportunities to use subsoil or inert mineral waste to build habitat for burrowing fauna;
- preserving connectivity with unmined areas, and maintaining the quality of these habitats; and
- managing feral predators and herbivores across both reference and rehabilitated areas.

If only a low level of land disturbance has occurred, the land can usually be returned to a standard similar to the pre-mining habitat. However, some mine related activities, such as the termination or modification of drainage flow paths and the introduction of new topographical features (waste dumps, tailing dam, mine voids etc.), can substantially change the physical habitat characteristics of the land.

In these situations, alternate habitat types have been selected. These alternatives have been drawn from the pre-mining habitats in the surrounding area. For example, a laydown area built up with inert mineral waste over a former hill habitat area is proposed to be revegetated to mimic the adjacent plains habitat as the land is now flat and is more likely to evolve a soil profile similar to the plains habitat units. Figure 31 illustrates the pre-mining habitat distribution and how alternative habitats are proposed to be introduced as part of rehabilitation activities, based on the different material and water conditions that will be present at closure. The planned rehabilitation habitats are usually located adjacent to undisturbed habitat of the same habitat type, in order to provide a means for natural migration of flora and fauna.

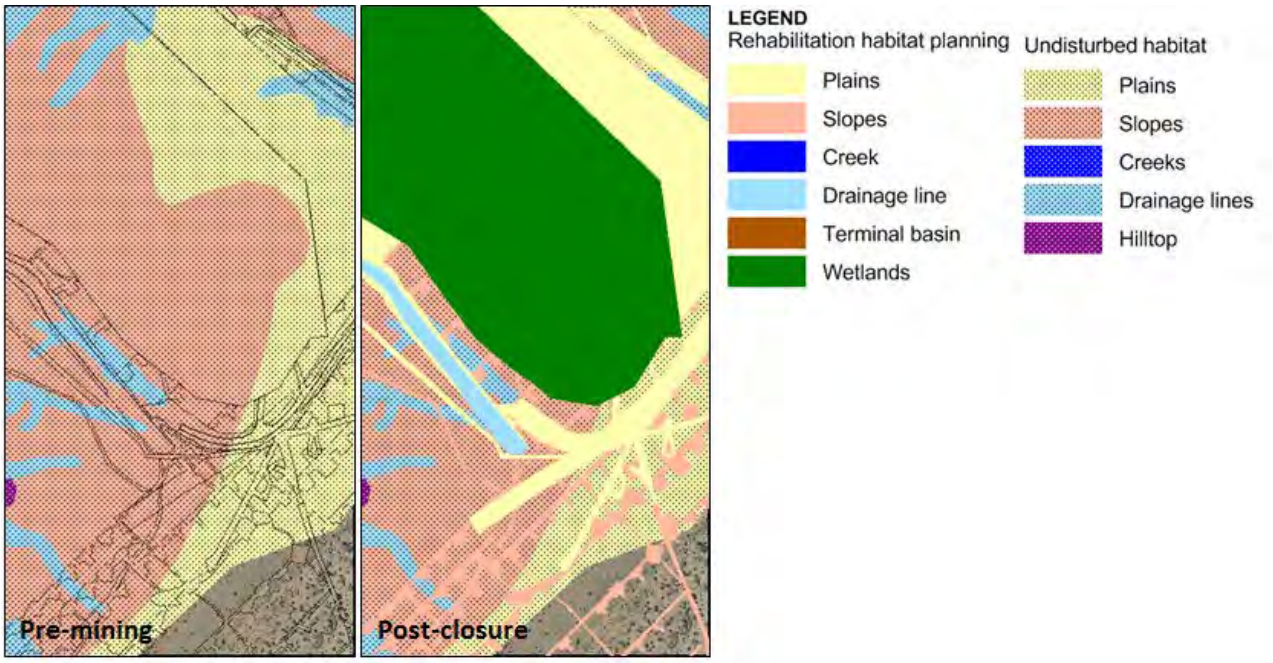

Figure 31: Comparison of pre-mining habitat areas and proposed closure habitat areas at the southern end of JSE.

The presence of permanent standing water (lakes) at Yandicoogina as part of the closure landform introduces new physical characteristics to the landscape: the potential for high soil water availability, littoral zone development around the edge of lakes, and the water bodies themselves. At this stage of the closure plan development, the wetland and pit lake habitat units represent undifferentiated water body of unknown ecosystem function. It is expected that these units will be split into different management units based on water quality and potential land-use / ecosystem viability following rehabilitation trials when more detailed information on vegetation and landform performance is available.

Through the act of mining, there will also be areas associated with the pit development that cannot be rehabilitated due to safety and access issues. This usually includes the pit high walls and benches, within the geotechnical zone of instability, and areas above the high wall where access is cut off as ore is mined. These areas are demarcated as cleared habitat units. Usually these areas have little to no soil cover, and are subject to erosion over time.

It is expected that the majority of the site will be rehabilitated as part of mine closure, with the rehabilitation design developed as part of the decommissioning plan.

18.2 Revegetation

Topsoil will be spread over reconstructed landforms and deep ripped to enhance seed establishment. Stockpile vegetation is then returned to the area.

Monitoring has shown that in small disturbed areas adjacent to existing vegetation or in areas where fresh topsoil can be utilised (e.g. borrow pits), appropriate species are generally re-established without the need for additional seed. This is because the seed bank in the fresh topsoil remains viable, resulting in good germination and growth, and in very small areas seeds can ingress from surrounding vegetation.

In most cases, however, locally collected seed is needed to assist in revegetation and the creation of a self-sustaining ecosystem. Over time the viability of seeds in stockpiled topsoil decreases, and thus the quality of the topsoil deteriorates. In addition the topsoil that was salvaged prior to disturbance may not contain seeds of all the target species of its new location / habitat.

Revegetation activities and replacement of topsoil should ideally be timed so that rehabilitated areas are completed prior to the summer wet season, usually commencing in November. This should give the seeds in the rehabilitation area the best chance of germination and survival.

Seed mixes for rehabilitation are preferentially of local provenance. Specific seed mixes are selected to provide a range of species appropriate to the desired habitat (Table 11), taking into consideration landscape position and slope. In areas where erosion risks are identified, seed mixes may be modified to include or increase the portion of species that provide rapid cover.

Seeds will be purchased from commercial seed suppliers immediately prior to rehabilitation. Seed mixes will, preferentially, be sourced for local provenance and will be selected to provide a range of species appropriate to the desired habitat, taking into consideration landscape position and slope. In areas where erosion risks are identified, seed mixes may be modified to include or increase the portion of species that provide rapid cover.

Seed mixes may also include species of cultural significance to Traditional Owners, such as bush tucker and medicinal plant, if and when identified through ongoing consultation with Traditional Owners.

The inclusion of rare and threatened species in rehabilitation programmes is limited by:

- habitat preference (preference for drainage lines, gullies, calcretes or other habitat not suitable or similar to those likely to be present in the rehabilitation landscapes);
- abundance – very few populations or small populations from which to source seed;
- difficult taxonomy / unresolved taxonomy issues and thus status of species highly uncertain; and / or
- growth form – e.g. short lived annual species with preference for growth under woodland canopies;

Other issues include the availability of seed at the time when rehabilitation occurs and seed dormancy.

In consideration of these issues, only three species from the significant flora list (Table 14) have been identified that could be considered in future rehabilitation programmes at Yandicoogina:

- *Lepidium catapycnon* in hill habitat rehabilitation;
- *Sida* species Barlee Range in valley floor habitat rehabilitation; and
- *Themeda* species Hamersley Station in valley floor habitat rehabilitation.

Research undertaken into rehabilitation of the *Lepidium catapycnon* [42] found that the use of the growth hormone gibberellic acid enabled germination rates approaching 90 percent in the laboratory and concluded that good germination results are likely to be possible in the field. Test and transplant work for this species is

[42] Department of Conservation and Land Management (now DEC), The germination requirements of seeds of the rare Hamersley *Lepidium catapycnon* (Brassicaceae), February 2000, report to BHP Iron Ore Pty Ltd.

ongoing; however, the availability of seed and habitat requirements may limit the re-introduction of this species at Yandicoogina.

Inclusion of *Sida* species Barlee Range in rehabilitation is currently limited due to seed collections issues and potential seed dormancy, but is otherwise expected to be suitable for inclusion in the rehabilitated habitat zone seed mix.

Themeda species Hamersley Station has a preference for heavy, clay soils. This restricts potential use of this species to areas with a high soil fine fraction. These conditions may develop in the closure landform at the waste fines cell areas. However, conditions will need to be verified in the field, after landform shaping, to confirm suitability for rehabilitation purposes.

18.3 Creek (discharge) recovery

Dewatering discharge undertaken during operations extends the duration of creek flow within the naturally ephemeral Yandicoogina creek systems. This activity has created water logged areas and permanent pools within the Marillana and Weeli Wolli Creeks. As mining activities draw to a close, the volume of discharge will taper then cease at the end of mining, returning the creeks to their pre-existing ephemeral regime. Water will not be artificially sustained to the creeks after the cessation of mining.

Environmental management plans have been implemented at Yandicoogina to respond to any impacts relating to the modification of major creek system or associated riparian vegetation communities. This includes potential impacts and mitigation associated with creek discharge.

From our current understanding and observations during operations, riparian vegetation is expected to achieve a new equilibrium without human assistance. Examples of the natural progression and re-establishment of a new equilibrium can be observed in the understorey surrounding around former permanent discharge sites i.e. D03.

Monitoring of creek ecosystem health will continue throughout the operation of Yandicoogina, in accordance with the site environmental management plans. Contingency plans, to mitigate or remediate areas of the creek that have been substantially degraded as a consequence of the cessation of the dewatering activities, will be discussed with key stakeholders and developed, if required, as part of the Decommissioning Study.

18.4 Fauna colonisation

Fauna species are not proposed to be introduced to the area on closure. Natural migration of fauna species into rehabilitated land will be encouraged by selecting seed mixes that produce vegetation communities that are linked to pre-mining habitat units. Most post-mining habitat units are also connected to similar undisturbed habitat, which helps fauna to migrate.

Ridges, outcropping, caves and gorges represent preferred habitat for the Northern Quoll (*Dasyurus hallucatus*), Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) and Pilbara Olive Python (*Liasis olivaceus barroni*) will remain post-closure in areas adjacent to current mining activity. However, no habitat reconstruction or artificial micro-habitats construction to support colonisation of these species is proposed as part of this closure plan.

Australian Bustard (*Ardeotis australis*), Rainbow Bee-eater (*Merops ornatus*) and Star Finch (*Neochmia ruficauda subclarescens*) prefer tussock grassland, Triodia hummock grassland, grassy woodland, and low shrublands, associated with Valley habitats. Rehabilitated plains and slope habitats are expected have characteristics similar to those preferred by these avifauna species.

The creation of pit lakes and wetlands represents a departure from the pre-mining environment. The nearest permanent water bodies are located 10km upstream (Weeli Wolli Springs) and 40km downstream (Fortescue Marsh). These water bodies present dramatic differences in water quality, with the former being fresh and the latter ranging from sub-potable to hypersaline (depending on the length of time since last rainfall). This suggests aquatic fauna in the local area can be sustained in and around water bodies of varying salinity.

All sites of permanent water (whether saline or fresh) are considered significant refuges for fauna during years with below average rainfall. It is expected that wetland habitats introduced at Yandicoogina will be capable of supporting a variety of fauna, including fish, birds, tortoises and frogs. However, further study and field trials are required to validate this assumption.

19. Post-closure safety features

19.1 Abandonment bunds

Abandonment bunds will be constructed around the perimeter of mine voids to prevent inadvertent access to the zone of geotechnical instability around the mine voids. Indicative locations for abandonment bunds have been included in Figure 17. The abandonment bunds are expected to include a combination of earthen bunds, retained levee structures (as described previously) and retained earthen bunds (already present on site, usually associated with existing drainage controls).

The earthen bund will be constructed from inert mineral waste. The dimensions of the abandonment bund will be with a height of at least 2m and width of at least 5m at the base, with side slopes greater than 15 degrees (depending on the material type characteristics). This design will be modified at select locations, indicated in Figure 17, where to accommodate surface water. These design modification will be developed as part of the rehabilitation design and discussed with key stakeholder prior to implementation, to ensure the proposed barricades achieve the required safety performance,

19.2 Access to heritage sites

Traditional Owners require ongoing access to sites of cultural significance. Safe access to locations of cultural significance will be discussed with Traditional Owners prior to closure, with consideration given to neighbouring land users' activities (i.e. other mine developments) and other land-use conflicts that may restrict access to the culturally significant sites over the long term.

19.3 Signage

Signage will be developed in consultation with the relevant authorities immediately prior to closure. This includes signage of an appropriate size, colour and font, and safety symbols, where appropriate.

IDENTIFICATION AND MANAGEMENT OF CLOSURE ISSUES

20. Issue evaluation

A closure risk assessment was completed on the proposed closure strategy for Yandicoogina. The assessment was completed by a panel of multi-disciplinary subject matter experts with the aim of:

- identifying hazards, aspects and opportunities that could influence the successful closure of the site;
- evaluating the resulting risks to people, property and the environment; and
- defining the actions required to reduce the risk to below the risk acceptance threshold.

20.1 Hazard / aspect identification

The context and acceptability criteria for the risk analysis was established by reviewing baseline studies, stakeholder consultation, learnings from work undertaken at other sites, and research etc. to identify any knowledge gaps.

Controls and commitments that are currently in place to manage each hazard were subsequently identified. This identification process included a review of the effectiveness of current management plans, procedures, work practice guidelines etc. to identify any management gaps.

summarises the topics raised / discussed during the evaluation session(s). Aspects reviewed as part of the closure risk evaluation included:

- mineral waste characterisation;
- pit lakes and ground water;
- landform stability;
- surface water implications;
- decontamination;
- biodiversity;
- visual amenity;
- cultural heritage; and
- local communities, communication and consultation.

Table 18: Closure context for Yandicoogina risk evaluation process.

Aspect	Current status
Landform	• Mineral waste is highly erodible, but will be returned to mine voids for rehabilitation. Will still need to construct stable landforms from mineral waste within mine void and requires incident rainfall management. • Mineral waste proposed to be used to ensure long term stability of Phils Creek land bridge and pit wall sections in / adjacent to creeks. • Pit lakes will be established in all former pits. Stability of waste on pit lake fringes to be investigated as part of rehabilitation trial.
Water	• Surface water flood regimes to be maintained post-closure. • Some peak flood water volume from Weeli Wolli Creek will enter PBS pit lakes. Local creek above Oxbow West pit will flow into void. All other lakes are disconnected from creek systems. • Groundwater system will be depleted through mining but will recover quickly due to strong creek flow recharge relationship. • All pit lakes will be groundwater dependent. • Groundwater and pit lake water levels and water quality strongly influenced by landform design.
Contamination	• Low risk of mining designated hazardous fibres. • Some historic now encapsulated problematic fibres. Fibres could also be encountered in alluvial materials during rehabilitation implementation. • Low risk of acid drainage. No significant contamination or hazardous waste issues identified. • Evidence emerging of potential alkalinity increases from extreme evapoconcentration of groundwater, could affect mobilisation of trace elements in mineral waste post-closure.
Biodiversity	• No impact to conservation status of any flora or fauna species, populations or fauna habitat expected from closure implementation. • Rehabilitation techniques for new habitats i.e. evaporation basins and permanent deep lakes, is untested, requires extensive research. • Control of invasive species critical to rehabilitation success.

Aspect	Current status
Community	• Interaction and potential impacts of post-mining landform to / on cultural heritage values to be investigated. • Roads / paths through the closure landform to access cultural sites to be incorporated into closure landform design. • Minimal community financial impact expected as 100% FIFO site.

20.2 Risk evaluation

Risk was evaluated on the basis of the maximum reasonable outcome consequence and the likelihood of that consequence occurring, e.g. rare, unlikely, possible, likely or almost certain. Risks were evaluated inclusive of current management and commitments, and represent current residual risk. The risk register developed for Yandicoogina is included in Appendix E. A summary of the risk titles and evaluated risk class are provided in Table 19.

Consequences included in the evaluation were:

- Health: reversible health effects of little concern (very low) to multiple fatalities (very high);
- Personal safety: inconvenient first aid treatments (very low) to multiple fatalities (very high);
- Environment: reversible impact (very low) to widespread, long-term impacts (very high). As some environmental impacts can escalate if immediate identification and remediation is not possible, environmental consequences are also evaluated by:
  - On-site: referring to impacts that occur during the pre-closure and decommissioning phases, when staff are able to utilise site equipment and quickly react to remediate impacts; and
  - Off-site: referring to impacts that occur during the post-closure phase, when remediation may not immediately follow impact identification, due to a need to bring equipment and experts back to site to remediate.
- Community trust: mistrust amongst a small section of the wider community (very low) to widespread mistrust with key stakeholders (very high); and
- Compliance: non-conformance to internal requirements (very low) to prosecution for breach of regulatory licence(s) (very high).

Risks resolved from the evaluation were classified as follows:

- Low (Class I): Risks that are below the risk acceptance threshold and do not require further management.
- Moderate (Class II): Risks that lie on the risk acceptance threshold and require regular review to ensure management remains adequate and fit-for-purpose.
- High (Class III): Risks that, based on the current level of knowledge, could exceed the risk acceptance threshold and require proactive management and / or resolution of knowledge gaps.
- Critical (Class IV): Risks that, based on the current level of knowledge, will exceed the risk acceptance threshold and need urgent and immediate attention to develop an alternative approach.

Actions were assigned to risks that exceeded the risk acceptance threshold. Actions were also assigned to address knowledge gaps and assigned where subject matter experts requested the performance of existing controls and commitments be re-evaluated at some later date.

Table 19: Summary of closure risks at Yandicoogina.

Risk title	Maximum reasonable consequence evaluation		Risk
	Likelihood	Consequence	
Under-estimated general contaminant clean up requirements	Rare	Low	Class I
Under-estimated acid and / or metalliferous drainage management requirements during operations (pre-closure) & decommissioning phase	Rare	Low	Class I
Acid and / or metalliferous drainage generation (after closure) creates a contaminated site	Possible	Low	Class II
Human health impacts from in situ fibrous material exposures	Rare	Moderate	Class II
Lake and / or lake fringe habitat has undesirable impacts on general ecosystem function.	Unlikely	Moderate	Class II
Lake poses public liability and / or health risk	Rare	Low	Class II
Degradation of regional groundwater quality or levels	Rare	Moderate	Class II

Risk title	Maximum reasonable consequence evaluation		Risk
	Likelihood	Consequence	
Wall failure within mine void compromises closure outcomes	Unlikely	Moderate	Class II
Built landforms (excluding mine void areas) erode and / or collapse	Unlikely	Low	Class II
Surface treatment on landforms limits vegetation growth	Unlikely	Moderate	Class II
Vegetation is not self-sustaining (due to cattle grazing impacts)	Unlikely	Moderate	Class II
Access through area post-closure poses public liability risk	Unlikely	Moderate	Class II
General environment outside of approved mine disturbance areas is adversely impacted	Possible	Low	Class II
Adverse impact to flora or fauna with conservation status or wider regional impact to high value environment	Unlikely	High	Class III
Heritage site condition / cultural value is degraded as a result of implementing the closure plan	Possible	Low	Class II
Consultation fails to identify stakeholder concerns	Rare	Moderate	Class II
Closure outcomes do not meet stakeholder(s) / community expectations	Unlikely	Moderate	Class II
A stakeholder's expectations conflict with that of another stakeholder, causing delays to plan approval and / or closure	Unlikely	Moderate	Class II
Closure strategy prevents or limits future exploitation of resources	Likely	Low	Class I
Mine closure has a significant, long-term detrimental impact on local communities	Rare	Very low	Class I
Closure is not implemented in accordance with the approved closure plan	Rare	Moderate	Class II

20.3 Key risks

Of the 21 risks evaluated, one risk was identified that exceeded the risk acceptance threshold. This high (Class III) risk was associated with adverse impact to significant fauna. Studies will be undertaken required to assess the impact of closure implementation on significant fauna, including species of conservation value, in order the develop actions to reduce the risk to below the acceptable risk threshold.

Other risks that were assessed to have been adequately managed, yet still require significant additional work prior to closure, include risks associated with land form stability, water management and water quality, and stakeholders (i.e. post-mining land-use). A summary of these risks and required actions is provided below.

20.3.1 Closure landform

Yandicoogina's mineral waste is dominated by highly erodible alluvial and colluvial material. The challenges associated with managing highly erodible waste are reduced by utilising, where ever possible, mined out void to store waste during operations and the return of waste to the void during closure. Rehabilitation designs for in pit waste dumps have accounted for the erodibility properties of the material, regardless of whether the mineral waste dump is located above or below the water table, e.g. will eventually be underwater as part of the lake edge.

It is recognised, however, that additional erosion management may be required in locations that receive surface water runoff or creek flows. Management of these aspects will be guided by waterway design principles. Detailed hydrological and engineering assessment will be undertaken during the decommissioning study to design structures, sympathetic to the natural environment, to control erosion. It is recognised that some rocky capping material may be required to assist in erosion control; however a review of the site material inventory has shown that the required material will not be mined as part of the normal development process and will need to be sourced from elsewhere once the exact specifications are understood.

Walking tracks will be required through the Yandicoogina area to facilitate specific Traditional Owner land-use requirements, e.g. to access to repatriated cultural artefacts and culturally significant sites. Due to the high potential for tracks to erode or cause erosion, detailed landscape design studies during the

decommissioning study will be undertaken to ensure the tracks do not facilitate additional erosion of built structures.

Historically, mining at Yandicoogina has minimised interactions with creek systems. The Yandicoogina life of mine plan, on which this closure plan is based, anticipates mining activities to occur closer to and within some the flood plain of major creeks. Investigations are currently underway to review the geotechnical stability of the geology left in situ adjacent to the creeks, to understand how to best construct mineral waste pillars / buttress that will be used to stabilise pit walls adjacent to creek systems and to return Phils Creek to its original alignment.

Closure landforms approved by the OEPA, in accordance with MS 914 Condition 9-1, have been developed based on approved deposits and subsequent mineral waste generation. This landform aims to stabilise creek systems and achieve a closure landform that minimises evapotranspiration. Variations to the closure landforms have been developed based on various expansion cases, to inform future mine plan develops and to assist with cumulative impact assessments.

20.3.2 Water

The hydrology of the creeks in the Yandicoogina area is well understood, and with the exception of the PBS deposit, the creek hydrology is expected to be unaffected by the closure landform. Data will continue to be collected during operations to verify and improve our understanding of surface and subsurface water interactions within the creeks. Mining through Phils Creek, for example, is expected to provide an opportunity to verify the geometry of the alluvial systems used in various models, as well as providing an opportunity to validate preferential flow movement along and between layers exists within the alluvial aquifer.

The process of mining the Yandicoogina CID will not produce enough mineral waste to backfill the areas excavated below the water table. As a consequence the closure landform must incorporate pit lakes. Basic water balance modelling has shown that water quality, lake levels and the associated groundwater system will evolve differently under different closure landform designs, e.g. the positioning of large pit lakes can create local groundwater depressions, which in turn control groundwater movement through the CID and former mining areas. The closure landform for Yandicoogina has been designed in consideration of these interrelationships, including the development of local groundwater sinks at Oxbow West and JC. Consequently, through implementation of this closure landform, the groundwater model predicts that outside of the mining disturbance areas and more than 2km from the Oxbow and JC mine voids, water levels will be largely predicted to return to pre-disturbance levels.

A groundwater sink will be established at Oxbow West by leaving the entire pit shell as a lake area, maximising potential evaporation. The resulting Oxbow West (pit) Lake will be dependent on groundwater inflows, which are expected to be impacted by the closure landforms implemented at BHP Billiton Iron Ore Yandi Mine, with a minor surface water flow contribution from a truncated local creek (a former small tributary to Marillana Creek). As a groundwater sink, the salinity of the lake is expected to increase over time to create a saline lake. However, the lake is disconnected from Marillana Creek proper, and, as a groundwater sink, saline groundwater is not expected to interact with Marillana Creek or its associated groundwater aquifers.

Consultation with the BHP Billiton Iron Ore Yandi mine is required to ensure the groundwater quality and level assumptions used in the models, based on predicted outcomes from the BHP Billiton Iron Ore Yandi mine closure, are accurate. Further refinement of the Oxbow West water balance water quality modelling is also required, integrating the additional evaporation from proposed Oxbow East pit and latest pit shell produced for the Oxbow West deposit, to update the water quality predictions.

The groundwater model suggests that, due to the groundwater sink in Oxbow West, the groundwater aquifers downstream of Oxbow East, including JSW-A, JSW-C and JC, will receive groundwater sourced from the adjacent Marillana Creek alluvial aquifer system. The water quality of the Marillana Creek alluvial system is relatively fresh. Consequently, the JSW-A and JSW-C groundwater though flow pit lakes are expected to contain freshwater. As a groundwater sink, the salinity in JC will also increase over time. However, as the incoming groundwater quality is relatively fresh, the lake water quality is expected to remain fresh to brackish for a significant period of time (several hundreds of years). Further work is required to understand updates to the groundwater model, following development of the Oxbow area, to ensure these conclusions remain valid. Water quality, including evolution over time, will also need to be developed.

The Pocket and Billiard South deposit requires a small encroachment of mining to occur within the Weeli Wolli Creek floodplain. Based on the current closure design, there is an eighty percent chance that some water from Weeli Wolli Creek will flow into the void each year, delivering nutrients and aquatic fauna / flora to the lakes. By design, only the peak of flows would overtop the pit wall and enter the mine void via an

engineered spillway, such that water flow down the low flow channel of Weeli Wolli Creek will remain unchanged. Further work is required to review the spillway design and siting, based on the as built conditions around the pit.

Occasionally, e.g. 3 times in every 200 years, the volume of water entering the PBS mine void will be sufficient to flush the area, allowing water to exit the area at the northern tip of the pit. A large proportion of the accumulated lake salts are expected to be removed from the system during these events, which will reset the salinity in the lake chain. This behaviour will be similar to the hydrological flood regime system observed in Fortescue Marsh. Although the ratio of outflow to Weeli Wolli Creek flood water is very low, suggesting dilution of the salts in the flood water would not have an effect on the Weeli Wolli Creek ecosystem, further work is required to validate this assumption.

The closure landform design will be refined through stakeholder feedback and in consideration of mine activities, evolving knowledge and monitoring data. Further monitoring and modelling is required to resolve the water quality evolution within the lakes and to continue to refine the groundwater model (including surface and groundwater interactions). Opportunities to enhance the recovery of the groundwater will be investigated.

Recent investigation into the effect of evapoconcentration processes on Yandicoogina groundwater showed there is the potential for alkaline water conditions to affect mobilisation of trace elements. Further investigations are required to determine if any problematic trace elements are present in natural background water and / or could be desorbed / released under future water conditions. Further studies may also be required to determine the frequency of potential water quality issues and the interaction with the local environment.

The cumulative effects of mining in the Weeli Wolli catchment and the influence of climate change are poorly understood with respect to the changes to water conditions after closure. This situation is mainly driven by regional unknowns, i.e. what other mines will develop, when will they develop, what impact will they have on the environment and how will their changes affect water quality and quantity. Within the existing modelling, a basic assumption for increased groundwater salinity has been used as an input, based on published literature. However, this condition is not expected to accurately reflect post-mining or climate changes to water quality, and will need to be reviewed and revised as further literature becomes available.

During the closure modelling processes, it was noted by water modelling experts that it is not possible to simultaneously model the water quality and level information using normal commercial software. This is due to the complexity of the surface water, groundwater and multiple lake interactions at Yandicoogina combined with the size of the model and (grid) resolution at which environmental impacts should be assessed. To achieve the current results, different water model programmes have been employed. It is anticipated that as technology improves, more advancements in water modelling software will improve modelling capabilities.

During operations, the groundwater table will be suppressed within all pits until rehabilitation and closure activities have been completed, in order to maintain a safe working environment within the mine voids. This could mean that dewatering could occur across a large proportion of the entire site, including exhausted pits, for many decades to come. An opportunity to reduce the dewatering requirements through large, progressive rehabilitation campaigns has been identified and will be investigated over the next few years, to ensure the solution does not sterilise future resources. By reducing the dewatering requirements, the groundwater table will recover earlier than the groundwater recovery model predictions.

Furthermore, given the long mine life estimated for the Yandicoogina deposits, it may be possible to utilise surplus water generated from active mine areas to enhance groundwater recovery. For the most part, this could be achieved through the creation of pit lakes, by discharging surplus water into the landscaped mine voids, whereby the water will dissipate into waste material located within the pits and eventually link up with the in situ groundwater aquifers.

Further investigations, modelling and stakeholder engagement will be undertaken to understand if enhanced groundwater recovery may be pursued without compromising safety, the environmental or social values in the region.

20.3.3 Biodiversity

The closure landform will be rehabilitated to a wide variety of habitats, ranging from exposed bare rock areas associated with the pit walls, to Acacia dominated plains-style habitat similar to the pre-disturbance habitat, to the creation and introduction of wetland habitats surrounding the pit lakes. Standard landform design and revegetation practices are considered sufficient to establish an appropriate degree of biodiversity in areas that will be revegetated for non-water related habitats.

However, in recognition of the limited experience in rehabilitating habitats associated with water, Rio Tinto has commenced research programmes and rehabilitation trials are underway and are expected to be completed prior to decommissioning to provide informed instruction for water related habitats. These studies include how seeds collected from the local creeks systems respond to groundwater and generic mineral waste (growth media), whether these species thrive post-germination with variable access to the groundwater table, which plant species combination(s) ensure wetland and floodplain vegetation communities are self-sustaining, what landform shapes support lake littoral zone development and what management is required to ensure water quality in the recovering lakes remain non-toxic and promotes ecosystem development.

Studies are ongoing to integrate Priority flora species into rehabilitation programmes. There is also an opportunity to integrate habitat preferences for the Northern Quoll and Pilbara Olive Python into the rehabilitation design, if such information becomes available.

It is hypothesised that stygofauna populations may be impacted by changes to groundwater quality, as predicted by groundwater modelling and as a consequence of other mining activities and / or climate change. Further study is required to review the impact of closure on the local stygofauna populations and to identify any potential mitigation strategies that may be implemented as part of rehabilitation programmes.

It is also recognised that invasive species management will be a critical factor in the successful rehabilitation of Yandicoogina. However, this management plan will not be required or developed until the decommissioning phase, five years prior to closure.

20.3.4 Stakeholders

Mining activities and by extension closure activities, often occur in close proximity to areas of cultural significance to Traditional Owners. Archaeological and ethnographic surveys are undertaken as required across Yandicoogina to identify and catalogue important features and salvage artefacts (where appropriate).

The extensive cultural heritage work associated with the expansion of the site has constrained engagement on closure with Traditional Owners, and it is recognised further consultation and engagement is required to ensure Traditional Owners values are respected and integrated (where appropriate) into the closure plan.

Post-mining land use has yet to be discussed with key stakeholders. Rio Tinto will continue to investigate the legal processes required to be observed to established post-mining land use.

It has been noted with regards to several aspects of closure that the cumulative effects of mining within the Weeli Wolli catchment and their respective closure landforms could have unforeseen consequences for the closure success at Yandicoogina. At present no formal, legal avenues exist to share information with mining competitors operating in the Pilbara regarding their anticipated closure outcomes and impacts on the environment. As a consequence inputs into the closure plan are limited to externally published reports generated through, for example, public environmental reviews.

20.4 Task list

summarises the actions identified through the risk evaluation process that require research or form part of significant ongoing investigations. It is not expected that this list includes all of the mine activities undertaken that relate to closure, only the key activities that are necessary to manage or prevent high or critical closure risks.

Table 20: Yandicoogina closure research and ongoing investigation task list.

Aspect	Ref	Detailed action descriptions	Due date
Contaminants	YA-43	Complete Phase 1 and Phase 2 (where required) contaminated sites investigations and required actions to remediate contamination.	2027
	YA-29.	Undertake alkaline leach tests on Yandicoogina waste materials.	2016
	YA-44	Update groundwater recovery (level) model to include latest data, Oxbow East and PBS lake scenarios.	2018
	YA-45	Develop local scale groundwater model and associated water quality model for JSW through to JC. (Assumes water divide after Oxbow West still exists after groundwater recovery model is updated.) Confirm that JC has no hypersaline (as an indicator of potential contamination) water quality risk.	2020

Aspect	Ref	Detailed action descriptions	Due date
	YA-46	Develop local scale (joint) groundwater model and associated water quality model for Oxbow East and Oxbow West. Investigate if surface water flow will reduce / eliminate pH 9 conditions or control aqueous metal / metalliod conditions	2020
	YA-47	Before ground disturbance, review potentially hazardous fibrous materials status to resolve areas of hazardous materials.	2032
	YA-48	Implement Fibrous Materials Management Plan in designated hazardous fibrous areas as part of progressive rehabilitation / decommissioning activities	2032
Void management	YA-34	Review the available water balance model technology to enable improved prediction of pit lake water levels.	annual
	YA-49	Update local scale groundwater model and associated water quality model for PBS. Confirm water quality of contributions to Weeli Wolli Creek	2022
	YA-19	Assess the impacts of flood water flushing of PBS lake on downstream vegetation and fauna (towards Fortescue Marsh)	2024
	YA-50	Consider early development of pit lake at Yandicoogina to study chemical / geochemical / biogeochem water quality evolution / behaviour and use to calibrate models for other lakes	2018
	YA-13	Undertake research to improve knowledge of rehabilitation of new landforms / habitats, including the best methods for restoration of Pilbara creek habitats / establishment of novel lake fringe ecosystems.	2018
	YA-38	Undertake rehabilitation trials for different landform and substrate types to inform restoration / rehabilitation plans	annual
	YA-51	Integrate results from aquatic fauna heavy metal studies into closure plan	2018
	YA-17	Assess the ability of pit lake water to sustain aquatic flora and fauna, and support other species.	2027
	YA-52	Investigate means to deter feral / unwanted predator species from lake areas	2021
	YA-53	Understand which characteristics of lake ecosystem health also address / minimise public health risks	2018
	YA-54	Predict how the lake ecosystem will evolve, consider timeframe and biodiversity over time	2021
	YA-32	Complete drilling required to improve hydrogeological conceptual model relevant to the closure plan	2021
	YA-33	Undertake program (i.e. drilling) to develop a better understanding of surface water and groundwater interactions.	2024
	YA-37	Review the behaviour of Phils Creek during mining to understand the amount of leakage, to inform the water modelling	2024
	YA-55	Investigate the long term implications of groundwater quality changes on stygofauna populations	2027
	YA-39	Review the geotechnical stability of pit walls and design requirements for creek supporting structures	2022
	YA-41	Assess the stability of pit walls adjacent to the BHP Billiton Iron Ore rail and identify a management strategy to ensure continuity of the rail post-closure.	2022
	YA-56	Identify and manage location for flow of surface water flow into the Oxbow pits.	2025
	YA-57	Identify and manage location for flow of surface water flow into the PBS pit.	2027
Landforms	YA-58	Undertake detailed hydrological and engineering assessment to determine the extent of structures required to control erosion at JC.	2017
	YA-59	Undertake detailed hydrological and engineering assessment to determine the extent of structures required to control erosion at JSW.	2024

Aspect	Ref	Detailed action descriptions	Due date
	YA-60	Undertake detailed hydrological and engineering assessment to determine the extent of structures required to control erosion at Oxbow.	2025
	YA-61	Undertake detailed hydrological and engineering assessment to determine the extent of structures required to control erosion at JSE	2027
	YA-62	Undertake detailed hydrological and engineering assessment to determine the extent of structures required to control erosion at PBS	2027
	YA-35	Identify sources of backfill material and capping material to achieve closure landform.	2027
	YA-63	Undertake regular reviews of the Phils Creek landbridge performance to understand any potential implications to closure, and modify / complete detailed closure design as appropriate.	annual
	YA-64	Complete rehabilitation designs for large process / crusher facilities.	2027
	YA-65	Investigate and implement opportunities for rehabilitation trials	annual
	YA-09	Develop (and maintain) a progressive rehabilitation schedule.	annual
	YA-14	Investigate creek rehabilitation requirements, considering landform pre-preparation, topsoil application and if tube stock is necessary to achieve required outcomes.	2017
	YA-66	Engage with key stakeholders to define post-closure land use	2020
	YA-67	Identify what mine features key stakeholders want to be retained, including access roads.	2027
	YA-68	Review liability of retention of mine features and agree where ownership of liability for retained features will be transferred.	2027
	YA-36	Consider the landscape design requirements for the repatriation of cultural artefacts back into the closure landform.	2021
	YA-69	Review the design of retained featured, i.e. roads, to ensure they are fit for purpose.	2027
	YA-70	Investigate and implement infrastructure options to prevent / discourage access use of retained access routes, i.e. for monitoring, where appropriate.	2027
Regional aspects	YA-18	Assess the impacts of closure implementation on groundwater dependent vegetation.	2024
	YA-12	Assess impacts of closure implementation on stygofauna populations.	2027
	YA-71	Assess impacts of closure implementation on species of conservation significance.	2024
	YA-21	Finalise the Yandicoogina Cultural Heritage Management Plan (to include closure strategies) and implement it as a working document.	annual
	YA-23	Undertake a gap analysis to identify areas requiring heritage survey and areas of significance which should be avoided and managed.	annual
	YA-24	Undertake heritage surveys as required (ethnographic and archaeological) with the traditional owners.	annual

CLOSURE IMPLEMENTATION

21. Closure domains

Closure domains are used to group areas with common features, rehabilitation and decommissioning requirements. Closure domains that have been established for Yandicoogina include:

- generic site areas, as described in Table 21, that may be rehabilitated on an ad hoc basis, when the disturbed area is no longer required to support the operations. No rehabilitation schedule is available for these areas, with the majority of the rehabilitation expected to be undertaken at the end of the mine life in 2032; and
- constructed landforms, as described in Table 22, that have the potential to be rehabilitated once mining ceases in the local area. An indicative schedule indicating when the associated subdomains would be available for rehabilitation is provided.

Refinement of the closure domains and associated detailed plans for the rehabilitation and decommissioning of these areas will be developed as areas become available or alternatively during the decommissioning study.

Table 21: Yandicoogina general area implementation strategies by closure domain.

Domain	Implementation strategy	Relevant indicative completion criteria
Borrow pits	• No backfill required • Reshape to a self-draining landform and contour to blend with local landscape. • Respread topsoil windrows and stockpiled vegetation onto disturbed area. Deep rip and seed, if required.	1a, 2a, 6a, 6b, 6c, 7a
Landfill	• Cap with at least 2m of competent inert material. • Respread topsoil windrows and stockpiled vegetation onto disturbed area. Deep rip and seed.	1a, 2a, 6a, 6b, 6c, 7a
Highly disturbed area	• Demolish or dismantle built structures to footing level. Remove bitumen and concrete. Dispose of demolition material to an appropriate waste site. • Undertake extensive earthworks and reshaping of areas to create a compatible landform consistent with the surrounding natural relief and landforms. • If the area is very compacted additional ripping may be required • Natural drainage lines to be re-established where practicable. • Topsoil, deep rip, seed treatment and spread stockpiled vegetation	1a, 2a, 6a, 6b, 6c, 7a
Moderately disturbed area	• Demolish or dismantle built structures to footing level. Remove bitumen and concrete. Dispose of demolition material to an appropriate waste site. • Contour to either return the area to natural relief or create a compatible landform consistent with the surrounding natural relief and landforms. • Natural drainage lines to be re-established where practicable. • Topsoil, deep rip, seed treatment and spread stockpiled vegetation	1a, 2a, 6a, 6b, 6c, 7a
Low level disturbance	• Scatter any dead vegetation or rocks over the rehabilitated surface to increase habitat diversity and reduce wind and water erosion. • Natural drainage lines to be re-established where practicable. • Where topsoil has not been removed and compaction is limited to two wheel tracks the area will be left to rehabilitate naturally. Other tracks should be ripped. • On slopes, rip parallel to contours. • Topsoil (as required), deep rip, seed treatment and spread stockpiled vegetation.	1a, 2a, 6a, 6b, 6c, 7a

Table 22: Yandicoogina void and waste dump implementation strategies and schedule by closure domain.

Domain	Implementation strategy	Area	Relevant indicative completion criteria	Indicative closure schedule
Temporary waste dumps	• Rehandle mineral waste into strategic locations to achieve closure landform (Figure 17) • Rehabilitate footprint in accordance with the Highly disturbed area domain.	All external waste dumps ROM pad	1a, 2a, 6a, 6b, 6c, 7a	2032
Pit areas	• Backfill ~10m above groundwater recovery level, in accordance with closure landform design strategy (Figure 18). • Shape open faces of mineral waste materials according to design requirements (Table 17). • If waste fines cells are present and above water table, cap with 2m layer of inert waste or as otherwise defined, in accordance with the JSE landform design strategy (Figure 24). • Landscape surface to include surface drainage and erosion controls, as appropriate. Refer to specific closure design for the Phils Creek landbridge area. • Identify and stabilise, where required, safe egress routes to future lake areas. • Considering surface water requirements, construct abandonment bund (or similar) around the perimeter of exposed high wall and open faces, unless bound by steep topography, outside zone of geotechnical instability. Shrub and/or tree planting at the outside edge of bund to lessen visual impact (where possible). • Rehabilitate areas in accordance with habitat planning strategy (Figure 29 and Figure 30). Includes topsoil and mulch spread over the mineral waste surface to a maximum depth of 200mm, deep rip and seed. No revegetation undertaken in areas that will be under water • Identify and implement means to declare public safety risk and restrict public access.	Oxbow West pit Oxbow East pit JSW-A pit JSW-C pit Phils Creek reconstruction Phils Creek pit JC IMA pit JC central pit JC south pit JSE pit Pocket pit Billiard South pit	1a, 2a, 3a, 4a, 4b, 5a, 6a, 6b, 6c, 7a	2026 2026 2027 2025 2026 2024 2018 2018 2019 2032 2032 2032

22. Premature closure and other factors

The closure implementation schedule may be influenced by factors outside of the current mine plan. These factors include:

- suspension of operations under care and maintenance; this could occur if production costs exceed product value, e.g. due to commodity price changes;
- unexpected closure; this could occur if there was major change in global demand for iron ore; and
- future proposals; these could occur if iron ore deposits of appropriate quality are identified adjacent to the existing deposits.

22.1 Care and maintenance

In the event of temporary closure, measures will be undertaken to transfer the site from operations into a care and maintenance regime and relevant authorities notified. A Care and Maintenance Plan will be developed prior to the care and maintenance period which demonstrates how on-going environmental obligations associated with the site will continue to be met during the period of care and maintenance. Social obligations and responsibilities will also be addressed in this plan.

22.2 Unexpected closure

Whilst HIY considers the risk of unexpected closure to be minimal, there are numerous factors that could force early closure of one or several sites. Even if some level of contraction were to occur, it is reasonable to assume that Rio Tinto would continue to operate in the Pilbara and that it could continue to manage closure of Yandicoogina.

This closure plan has been produced to support the application to expand mining at Yandicoogina. If no further approval for mining is granted, the site would need to close ahead of the current schedule.

At the current stage of development, closure of the site is expected to generate the closure landform concept illustrated in Figure 32. Without further approval to mine, there is likely to be a deficit of mineral waste material available to suppress the groundwater table within the JSE mine void. These lakes are expected to act as groundwater sinks and will draw water from the aquifers beneath the Weeli Wolli and Marillana Creeks. As groundwater sinks, it is expected that salts derived from the groundwater supply would build up in the lakes over the long term, leading to highly saline lake water. It is also possible that the highly saline water could periodically have high pH levels. The high pH could result in the release trace metals into the lake water with the potential for bioaccumulation of metals within the fringing vegetation.

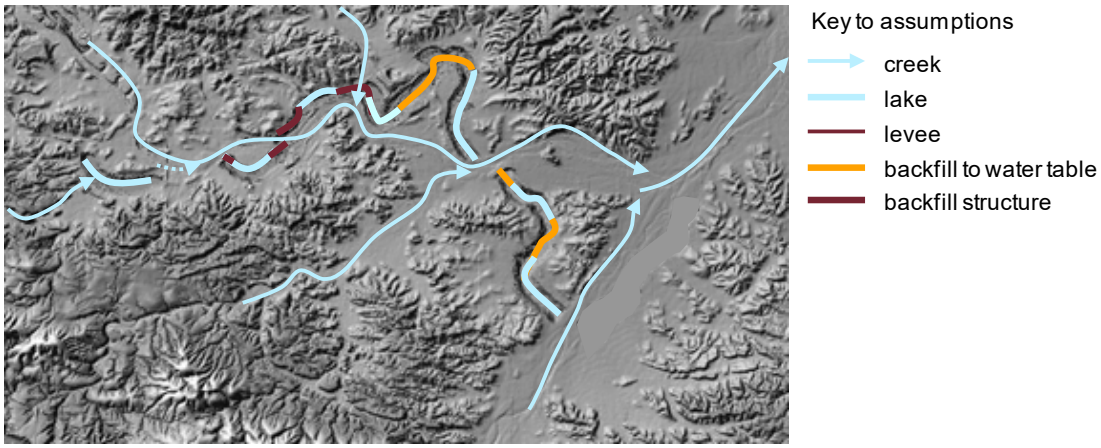

Figure 32: Contingency plan illustrating a closure landform if no further approvals are granted.

In the event of unplanned or sudden closure, HIY will notify all relevant authorities including the DMP. The existing closure plan for the site would then be revised and a Decommissioning Plan prepared and submitted to the DMP and other relevant authorities within three months of notification of closure. The Decommissioning Plan will include undertaking detailed consultation with stakeholders. Once the plan is approved by the relevant authorities, work will commence on closure implementation activities.

22.3 Prospective areas

There are several deposits, including Billiard North and Braid, which are reported as part of the ore reserves for the Yandicoogina operations. Closure information relevant to these expansion deposits is provided in this section in order to facilitate discussions with key stakeholders, and is not intended for regulatory approval at this time. Detailed closure plan information for these expansion deposits will be developed as and if mining studies progress, prior to regulatory approval to mine these deposits being requested.

22.3.1 Billiard North deposit

The Billiard North deposit is located to the north of the Billiard South deposit and is located beneath Weeli Wolli Creek. Mining of this deposit will necessitate the alteration of Weeli Wolli Creek in order to access the ore. There will not be sufficient mineral waste generated through the mining of this deposit to facilitate the reinstatement of Weeli Wolli Creek. Instead it is proposed to flood the mine void and create a sustainable, freshwater lake ecosystem in the Weeli Wolli Creek.

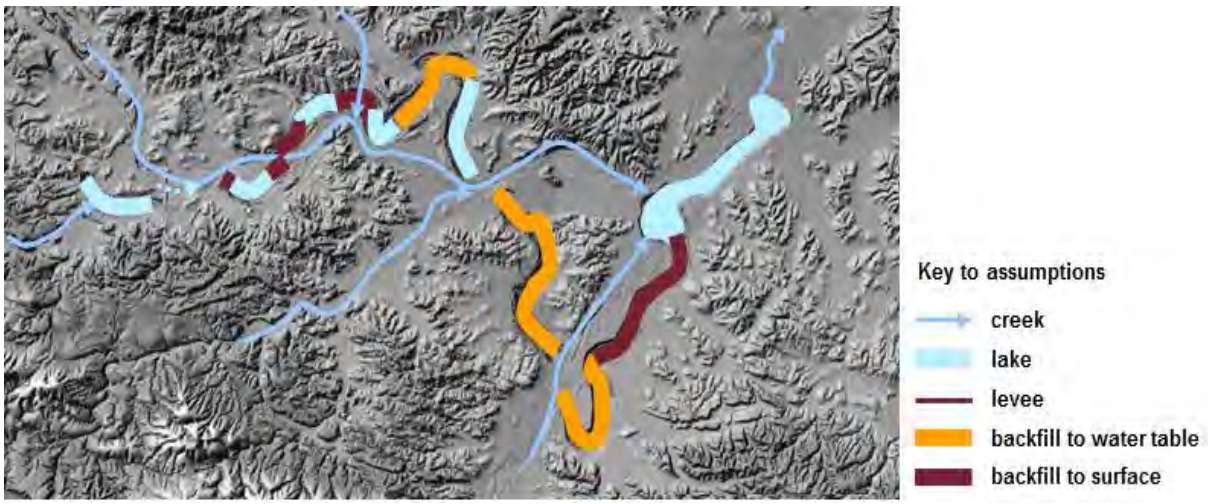

Figure 33: Closure concept for Yandicoogina incorporating the expansion development at Billiard North.

In this concept (Figure 33), mineral waste generated through the mining of the Billiard North deposit would be used to backfill the Billiard South and Pocket mine voids to the pre-mining level. Vegetation and topsoil cleared from the Billiard North area would be used to re-establish and potentially expand the Weeli Wolli Creek flood plain vegetation communities across the Billiard South deposit.

22.3.2 Braid deposit

The Braid deposit is located to the north of the Billiard North deposit. The same closure landform concept discussed for Billiard North is expected to be employed, placing mineral waste generated through the mining of Braid into the void generated by Billiard North, such that areas of Weeli Wolli Creek could be re-established (Figure 34).

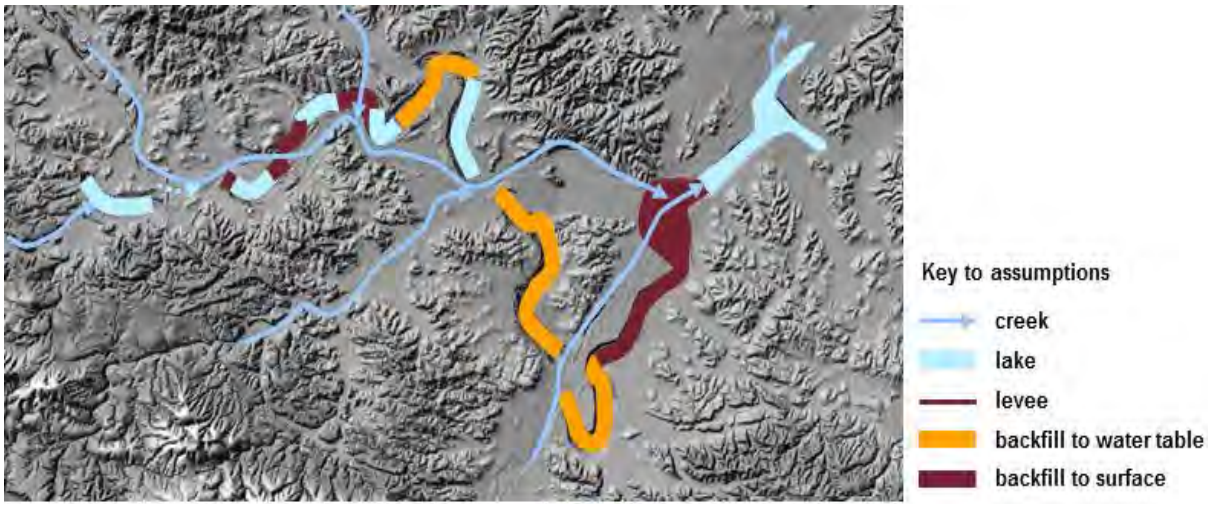

Figure 34: Closure concept for Yandicoogina incorporating the continuing expansion development at Braid.

CLOSURE MONITORING AND MAINTENANCE

23. Closure monitoring programs

An extensive environmental monitoring program is underway at Yandicoogina to track the performance of the operation, identify potential environmental impacts and to better understand the environment surrounding the mine in order to avoid or minimise future environmental impacts. This includes:

- Baseline monitoring, which is conducted as operations expand into new mining areas; and
- Operational monitoring, which occurs throughout the life of the mine, in line with regulatory requirements and the operational standards.

A summary of the information currently collected by the operation and used to inform the closure plan is listed in Table 23. Note the frequency of data collection is indicative only, with monitoring frequency (and some parameters) adapted to reflect the changing certainty (increasing and decreasing) of various aspects as the mine develops.

Table 23: Existing monitoring programmes

Aspect	Location	Frequency	Parameters measured
Soil quality	Land farm	Quarterly	TRH, pH, Total N, Total P, Soil Moisture, C:N:P Ratio, BTEX, PAH , heavy metals
Riparian vegetation	Yandicoogina	Annually	Aerial photography, DMSI
Riparian vegetation	Weeli Wolli and Marillana Creeks	Quarterly 6 monthly	Digital Cover Photography (DCP) Community structure, species diversity and abundance
Riparian vegetation	Whole site	Annually	Sum of approved clearing areas within riparian vegetation communities
Weeds	Whole site	Ongoing	Visual with annual eradication programme
Meteorological	Yandicoogina Weather Station	Monthly	Monthly rainfall total
Groundwater quantity	Abstracted water	Continuous	Volume abstracted
Groundwater quality / quantity	Mine aquifers	Monthly	pH, EC, Temperature, Run Hours, Cumulative Flow, Instantaneous Rate Flow, Water Level Elevation
Groundwater quality / quantity	Mine aquifers	Annually	pH, EC, TDS calculated, Na, K, Ca, Mg, CL, CO3, HCO3, SO4, NO3
Groundwater level	Whole site	Monthly	Water level elevation
Surface water quantity	Discharge outlets	Monthly	Cumulative volume discharged (m3)
Surface water quantity	Weeli Wolli Creek	Ongoing	Extent of the saturated creek bed
Discharge quality	Discharge outlets and creek alluvium water	Quarterly 6 monthly	TDS, TSS, EC, pH, Total P, Total N, NO3, NH3, Se, Hg, pH, EC, TDS, TSS, Al, Ca, Mg, Na, K, SO4, Pb, Cu, Fe, Mn, Mo, Zn, As, Cd, Cr
Aquatic invertebrates	Weeli Wolli Creek	6 monthly	Aquatic invertebrate abundance and diversity
Subterranean fauna/habitat	Yandicoogina	Opportunistic	Stygofauna assemblages (with groundwater quality)
Geomorphology / bathymetry	Discharge outlets	6 monthly & after flood events	Inspection and photographic records to monitor for erosion

Aspect	Location	Frequency	Parameters measured
Geomorphology / bathymetry	Marillana Creek (select locations)	6 monthly	Channel cross sectional area

Results from the operational environmental monitoring program that are relevant to closure are summarised in the *Collection and analysis of closure data* section of this report.

A phased approach to closure monitoring is proposed for Yandicoogina:
- Pre-closure monitoring: occurs as the site approaches closure to establish post-mining baseline conditions (where required). Aspects that may need to be collected to establish the post-mining conditions include water levels outside the active mine area, riparian vegetation condition, and potentially terrestrial fauna;
- Decommissioning monitoring: conducted during the period of active site decommissioning and rehabilitation. This monitoring plan will be developed as part of the Decommissioning Plan, to ensure the activities do not adversely impact the environment; and
- Post-closure monitoring: conducted on a scheduled basis until the completion criteria have been met. This monitoring plan will be developed as part of the Decommissioning Plan.

The monitoring aspects expected to be undertaken at each phase of monitoring are listed in Table 24. This monitoring is undertaken to inform Rio Tinto internal quality control and assurance processes as well as to demonstrate that closure objectives have been met. It is expected that the monitoring programmes will be sufficiently flexible to enable adjustments to be made if results indicate that more or less monitoring is warranted at any particular phase. Completion criteria monitoring will continue until stakeholders agree that the completion criterion has been achieved.

Table 24: Expected components of the closure monitoring program

	Phase		
Monitoring aspect	Pre closure	Decommissioning	Post closure
Vegetation (rehabilitation) #	✓	✓	✓
Erosion #	✓	✓	✓
Weeds #	✓	✓	✓
Fauna #	✓	✓	✓
Stygofauna	✓		✓
Feral animal	✓	✓	✓
Ecological function	✓		✓
Water quality and contaminants	✓	✓	✓
Groundwater levels and quality	✓	✓	✓
Heritage	✓	✓	

These monitoring activities also part of the Rio Tinto Iron Ore Rehabilitation Monitoring Procedure.

23.1 Vegetation

Rehabilitation monitoring tracks the progress and evaluates successional development of rehabilitation areas. This information is used to assess progress towards long term rehabilitation objectives and to improve rehabilitation techniques.

The Rio Tinto Iron Ore Rehabilitation Monitoring Procedure details the monitoring methodology for recording and assessing vegetation development. In the current procedure, characteristics as listed below are recorded by quadrat at intervals along transects at established rehabilitation and associated reference sites:
- number of plants by species;
- percentage cover by species;
- bare areas in quadrat;
- percentage of perennial cover;
- percentage of spinifex cover;
- percentage of grass cover (excluding spinifex);
- percentage of native perennial shrub cover (0.5m to 2m);
- percentage of litter cover;

- percentage of tree cover >2m;
- presence of annuals;
- presence of weeds species; and
- if burnt since last monitoring.

Qualitative assessment of erosion, soil surface, perennial vegetation cover, species richness, weeds and general condition is also recorded.

Monitoring of rehabilitation and reference sites is generally scheduled annually for the first three years after establishment, biennially from years five to nine and (approximately) triennially thereafter, until sufficient information is gathered to validate the performance of the rehabilitation.

Analysis of the trends observed at rehabilitation sites over time and in comparison to reference sites is being studied to develop an understanding of rehabilitation quality and successional processes in our rehabilitation.

23.2 Erosion

Erosion monitoring will involve the examination of transects for the number of rills and gullies, recording their width and depth. These measurements are compared over time to determine if the landform has stabilised; for example erosion rates are within the accepted completion criteria range or rill and gully geometry is similar to the surrounding landscape. If a landform fails to stabilise, further management / intervention will be applied.

23.3 Weeds

Weed management programs will be developed for each phase of closure during the decommissioning study, to reflect the different work programmes and associated risks. These programs will define procedures to identify, control and eradicate target weeds and monitor weed control measures to minimise the spread of weed species, prevent the introduction of new weeds and control and/or eradicate both noxious and environmental weeds across the rehabilitated area.

For example, the pre-closure weed management program will focus on annual weed eradication and control, as mining and associated disturbance activities will still be occurring in the area. During the decommissioning phase, weed management will emphasise weed hygiene, in order to minimise the spread of weeds with the significant increase in vehicle and earth movement activities. During the post-closure phase, weed management will focus on monitoring, which will be undertaken as part of the rehabilitation monitoring activities, with inspection and trigger / response remediation actions.

23.4 Fauna

Invertebrates have a major role in the success of rehabilitation efforts because they facilitate a variety of ecosystem processes, such as litter decomposition and nutrient cycling, herbivory, seed dispersal, soil aeration and drainage, pollination and provision of a source of food for vertebrate predators.

Invertebrates can be encouraged by providing areas of thick, widespread litter cover over part of the area, logs and standing dead wood. Vertebrates are usually the last to recolonise, once complex vegetation assemblages and invertebrate prey are established.

The Rio Tinto Iron Ore Rehabilitation Monitoring Procedure details the monitoring methodology for recording and assessing fauna re-colonisation and habitat development. The current monitoring procedure includes the following fauna habitat and utilisation indicators:

- number of logs (>10cm diameter and >30cm long);
- number of rocks (>15cm diameter);
- presence of scat;
- presence of ants;
- general animal sighting (including tracks, burrows and nests);
- flowering and fruiting species; and
- extent of grazing.

Fauna monitoring is completed concurrently with vegetation monitoring and is continued until sufficient information is gathered to validate the performance of the rehabilitation.

23.5 Stygofauna

Targeted studies of stygofauna assemblages will be undertaken during the post-closure monitoring to quantify and validate impacts to and / or expansion of stygofauna populations following the recovery of the groundwater system at Yandicoogina. The study scope will be resolved with key stakeholders during the decommissioning study.

23.6 Feral animal management

Feral carnivores (e.g. cats, dogs, foxes) can create locally increased predation pressure on native fauna as well as increase competition with native species for resources such as space (territory), water and food.

Feral herbivores (e.g. cattle, camels, donkeys) can also have a significant impact in Rangeland areas, such as the Pilbara. In dry times, grazing pressure reduces the abundance of palatable native species, impacting biodiversity and can create conditions that encourage weeds to grow. Foot traffic impacts the soil conditions, and in combination with over grazing, can encourage erosion. Foot traffic has also been the cause of damage to cultural landmarks and Aboriginal sites. Overgrazing and damaged soils has a low-on effect to native fauna species that rely on this vegetation for food and shelter.

Feral animals will continue to be managed in accordance with the existing site Feral Animal Management Plan during the pre-closure and decommissioning phases. The Feral Animal Management Plan conforms to meets current national guidelines, i.e. Codes of Practice for the humane control of invasive species published by the Department of Environment.

23.7 Ecological function

Targeted monitoring of select ecological functions may be required to ensure that biological, geological and chemical interactions associated with lake water quality and lake fringe vegetation have evolved as predicted. Monitoring requirements for validating these ecological functions will be resolved with key stakeholders during the decommissioning study.

23.8 Water quality and contaminants

Water monitoring networks will be established during the life of the mine and during the decommissioning phase to validate surface water and lake model predictions. It is expected that monitoring for water level, pH, EC, TSS, alkalinity/acidity, major cations and anions (including key nutrient indicators) will be undertaken every six months until sufficient information is gathered to validate the water recovery and quality predictions.

23.9 Groundwater levels and quality

Water monitoring networks will be established during the life of the mine and during the decommissioning phase to validate groundwater modelling predictions. It is expected that monitoring for water level, pH, EC and temperature will be undertaken every six months until sufficient information is gathered to validate the water recovery and quality predictions.

23.10 Heritage

Heritage will continue to managed and monitored in accordance with the Cultural Heritage Management System until the land tenure is relinquished to the State Government. This process ensures that significant Aboriginal and environmental sites are not disturbed without authorisation.

FINANCIAL PROVISION FOR CLOSURE

24. Principles of cost estimation

Closure cost estimates are determined in accordance with internal accounting policy methods, with the level of accuracy increasing as the site approaches closure. During the life of the operation, two closure costs will be developed:

- A Present Closure Obligation (**PCO**) which is indicative of costs associated with closure of the mine given its current footprint; and
- A Total Projected Closure (**TPC**) cost which predicts the cost (in current terms) associated with closure at the end of the life of the mine. The TPC includes areas that are not currently approved, but that feature within the life of mine plan and that are considered likely to be developed in the future

The cost estimates consider the following components:

- Decommissioning (i.e. removal of infrastructure)[43];
- Final landform construction;
- Rehabilitation and biodiversity management;
- Heritage management;
- Workforce management (i.e. training costs and redundancy payments)[44];
- Monitoring costs;
- Costs associated with the development of a Final Decommissioning Plan;
- Costs associated with undertaking a final shutdown of operations;
- Allowance for failed rehabilitation or pollution that may necessitate rework of rehabilitation areas;
- Assignment of indirect costs in accordance with Rio Tinto Accounting Policy; and
- A contingency allowance.

The amount recognised for closure at any given time will be determined by using the best and most recent estimate of the expected cost at that time.

The PCO estimate for each site is revised on an annual basis, whilst the TPC estimate is revised whenever a formal closure plan review is conducted. Note that for commercial reasons the actual estimate is not documented in this closure plan.

[43] The decommissioning cost estimate assumes that infrastructure will be demolished and buried on site. However; opportunities for salvage and recycling will be sought as the site approaches closure.

[44] Workforce management costs are only included in the TPC.

MANAGEMENT OF INFORMATION AND DATA

25. Data and information management

25.1 Iron Ore Document Management System (IODMS)

HIY operates a comprehensive document management system, with electronic records of all key information and data. The document system, known as Iron Ore Document Management System (IODMS) is linked to other business units within the Rio Tinto group of companies, and processes are in place to ensure that the data contained within this system is appropriately backed up and protected. Each document stored within this system is given a unique document number which identifies the document and enables it to be accessed. This system will continue to operate following site closure, and all relevant data will be retained accordingly.

An audit will be conducted prior to closure to ascertain whether there is any additional information stored in hard copy form at the site. Such data will be scanned and entered into IODMS to ensure that it is appropriately retained post-closure.

Hard copies of confidential information stored at the site (such as employee records) will be destroyed at the time of closure.

25.2 Closure knowledge base

The closure knowledge database is a knowledge management process designed to bring closure related research and monitoring outcomes together into one searchable location. Key characteristics stored in the knowledge base include where the report is housed and how the report outcomes can be applied to closure.

25.3 EnviroSys

EnviroSys is a desktop application, with a web based interface, that manages environmental and hydrogeological parameters collected in the field and their logical context. The tool is used to store, monitor and analyse those parameters and report trends on data collections.

Data collected includes:

- groundwater – biological, chemical, field, levels, production;
- marine water – biological, chemical, field;
- soil chemistry;
- surface water – biological, chemical, field, levels, production;
- tonnes and moisture;
- water meters; and
- weather (rainfall, temperatures etc.).

EnviroSys is used to support the building of closure knowledge bases, as well as ensure compliance with operating licenses pertaining to data management.

25.4 Legal and other requirements system

The Legal and Other Requirements System (LAORS) is used by HIY to manage the following:

- Approval and Legislation Reports which provide a high level snapshot of approvals and legislation and is used to check the status and expiry dates of approvals.
- Approval and Legislative Requirements Reports which lists
  - accountabilities for specific conditions within approvals and clauses within legislation;
  - required actions to comply with approvals and or legislation; and
  - due dates for specific requirements.
- Statutory Position Appointed Persons reports which list individuals appointed to a statutory position.
- Statutory Position Accountabilities Reports which identify clauses of legislation that the statutory position is accountable for.

APPENDIX A

26. Appendix A Yandicoogina legal obligations

YANDICOOGINA CLOSURE OBLIGATIONS REGISTER

Legal Obligations

Ministerial Statement 914	
Condition No.	**Closure conditions**
6-1	The proponent shall ensure that the discharge of excess water from the Yandicoogina Iron Ore Project - Expansion to Include Junction SouthWest and Oxbow Deposits as a result of mining does not cause long term impacts to environmental values of the Weeli Wolli Creek System.
6-2	To verify that condition 6-1 is being met, the proponent shall develop an Environmental Values Statement for the Weeli Wolli Creek System that defines the environmental values of the Weeli Wolli Creek System to the satisfaction of the CEO in consultation with the DEC.
7-3	The proponent shall manage the proposal in a manner that ensures there is no irreversible impact to riparian vegetation or groundwater dependent ecosystems within Zones 1, 2, 2a, 3, 3a, 4 and 5.
9-1	Within 12 months following commissioning of the Junction South West or Oxbow pits, whichever is first, the proponent shall prepare and implement a Yandicoogina Decommissioning and Rehabilitation Plan in accordance with the Guidelines for Preparing Mine Closure Plans, June 2011 and any updates to the requirements of the CEO on advice of the Department of Mines and Petroleum.
9-2	The Yandicoogina Decommissioning and Rehabilitation Plan required pursuant to condition 9-1 shall ensure that closure planning and rehabilitation are carried out in a coordinated, progressive manner and are integrated with development planning, consistent with current best practice, and the agreed land uses.
9-3	The Yandicoogina Decommissioning and Rehabilitation Plan required pursuant to condition 9-1 shall set out procedures to: (1) manage long-term hydrogeological impacts of mining the channel iron deposit; (2) model the long-term hydrological impacts, particularly the water levels and quality both in the pit void and downstream of waste material landforms; (3) manage over the long-term the surface water systems affected by the open pit; (4) progressively rehabilitate all disturbed areas to a standard suitable for the agreed end land use(s), with consideration and incorporation of: (a) the characteristics of the pre-mining ecosystems within the project area (through research and baseline surveys); (b) the performance of previously rehabilitated areas within the mining lease; (c) the performance of rehabilitation areas at the proponent's other operations in the Pilbara; and (d) best practice rehabilitation techniques used elsewhere in the mining industry. (5) develop and identify completion criteria; (6) monitor rehabilitation to assess the performance of all rehabilitated areas against the completion criteria; (7) report on the rehabilitation and monitoring results; (8) remove all infrastructure; (9) develop management strategies and/or contingency measures in the event that operational experience and/or monitoring identify any significant environmental impact as a result of the proposal; (10) manage and monitor mineral waste including physical characteristics and acid or neutral metalliferous drainage using national and international standards and updates; and (11) develop a 'walk away' solution for the decommissioned mine site.
9-4	The proponent shall review and revise the Yandicoogina Decommissioning and Rehabilitation Plan required by condition 9-1 at intervals not exceeding three years.
9-5	The proponent shall make revisions of the Yandicoogina Decommissioning and Rehabilitation Plan required by condition 9-1 publicly available.

YANDICOOGINA CLOSURE OBLIGATIONS REGISTER

Legal Obligations

EPBC Decision Notice 2011/5815	
Condition No.	**Closure conditions**
13	The person taking the action must rehabilitate all potentially suitable habitat for EPBC Act listed threatened species that is disturbed during construction and operation. The rehabilitation must be developed in consultation with a suitably qualified expert and must include, but not necessarily be limited to: a) baseline data of the characteristics of the pre-mining ecosystems within the development footprint; b) use of plant species of local provenance that are compatible with land system units that provide suitable habitat for EPBC Act listed threatened species; and c) monitoring and evaluation annually for three years or until establishment.

Iron Ore (Yandicoogina) Agreement Act 1996	
Clause No.	**Closure obligations**
6(1)(l)	Subject to the provisions of this Agreement the Company shall on or before 31 December 1997 submit to the Minister to the fullest extent reasonably possible its detailed proposals (including plans where practicable and specifications where reasonably required by the Minister) with respect to the production of up to 15,000,000 tonnes of iron ore per annum for transportation from the mining lease and transport and shipment of iron ore produced which proposals shall make provision for the Company's workforce and associated population required to enable the Company to mine and recover iron ore from the mining lease and transport and ship the iron ore and shall include the location, area, lay-out, design, quantities, materials and time programme for the commencements and completion of construction or the provision (as the case may be) of each of the following matters, namely: (l) an environmental management programme as to measures to be taken, in respect of the Company's activities under this Agreement, for rehabilitation and protection and management of the environment.
9(1)	Subject to clause 10, if the Company at any time during the continuance of this Agreement desires to signficantly modify, expand or otherwise vary its activities carried on pursuant to this Agreement (other than under clause 12C) beyond those activities specified in any approved proposals it shall give notice of such desire to the Minister and within 2 months thereafter shall submit to the Minister detailed proposals in respect of all matters covered by such notice and such of the other matters mentioned in subclause (1) of Clause 6 as the Minister may require.
13(1)	The Company shall in respect of the matters referred to in paragraph (1) of the subclause (1) of Clause 6 which are the subject of approved proposals, carry out a continuous programme of investigation research and monitoring to ascertain the effectiveness of the measures it is taking both generally and pursuant to such approved proposals as the case may be for rehabilitation and the protection and management of the environment.

13(2)(a) and (b)	The Company shall during the currency of this Agreement submit to the Minister: (a) not later than the 30th day of June, 1998 and the 30th day of June in each year thereafter (except those years in which a comprehensive report is required to be submitted pursuant to paragraph (b) of this subclause) a brief report concerning investigations and research carried out pursaunt to subclause (1) and the implementation by the Company of the elements of the approved proposals relating to the rehabilitation, protection and management of the environment in the year ending the 30th day of April immediately preceding the due date for the brief report; and (b) not later than the 30th day of June 2000 and the 30th day of June in each year thereafter if so requested by the Minister from time to time, a comprehensive report on the result of such investigations and research and the implementation by the Company of the elements of the approved proposals relating to the rehabilitation, protection and management of the environment during the three year period ending the 30th day of April immediately preceding the due date for the detailed report and the programme proposed to be undertaken by the Company during the following three year period in regard to investigation and research under subclause (1) and the implementation by the Company of the elements of the approved proposals relating to the rehabilitation protection and management of the environment.
39(2)	Except as otherwise determined by the Minister and subject to the provisions of subclause (3), upon the cessation or determination of this Agreement all buildings, erection and other improvements erected on the land then occupied by the Company under the mining lease or any other lease, licence easement or other title made under or pursuant to this Agreement or held pursuant hereto shall become and remain the absolute property of the State . . .
39(3) (a) and (b)	(a) In the event of the Company immediately prior to the cessation or determination of this Agreement or within 3 months therefrom desiring to remove any of its fixed or movable plant and euipment or any part thereof from any part of the land occupied by it at the date of such cessation or determination it shall give to the State notice of such desire and thereby shall grant to the State the right or option excercisable within 3 months thereafter to purchase in situ such fixed or moveable plant and equipment at a fair valuation to be agreed between the State and the Company or failing agreement determined by arbitration under this Agreement. (b) If the State does not exercise the right or option referred to in paragraph (a) the Company may on the expiry of the 3 month period referred to, or sooner with the consent of the Minister, remove the fixed or movable plant and equipment to which the right or option refers.

Native Vegetation Clearing Permit	
Permit No. 4716/2 (Transmission line)	
Condition No.	**Closure conditions**
10	Retain and spread vegetative material and topsoil The Permit Holder shall: (a) retain the vegetative material and topsoil removed by clearing authorised under this Permit and stockpile the vegetative material and topsoil in an area that has already been cleared. (b) within 12 months following clearing authorised under this permit, revegetate and rehabilitate the areas that are no longer required for the purpose for which they were cleared under this Permit by: (i) ripping the ground on the contour to remove soil compaction; (ii) re-shaping the surface of the land so that it is consistent with the surrounding 5 metres of uncleared land; and (iii) laying the vegetative material and topsoil retained under Condition 10(a). (c) within 4 years of laying the vegetative material and topsoil on the cleared area in accordance with Condition 10(b) of this Permit: (i) engage an environmental specialist to determine the species composition, structure and density of the area revegetated and rehabilitated; and (ii) where, in the opinion of an environmental specialist, the composition structure and density determined under Condition 10(c)(i) of this Permit will not result in a similar species composition, structure and density to that of pre-clearing vegetation types in that area, revegetate the area by deliberately planing and/or direct seeding native vegetation that will result in a similar species composition, structure and denisty of native vegetation to pre-clearing vegetation types in that area and ensuring only local provenance seeds and propogating material are used.

Land Administration Act 1997	
Lease L21122. The installation or construction and the use, operation and maintenance of fibre-optic cables and associated repeater stations for rail radio communications and for ancillary and incidental purposes thereto in accordance with the Approved Proposals.	
Condition No.	**Closure conditions**
10.3 Yielding up	(a) On the expiration or earlier determination of the Term the Lessee must: (i) surrender peaceably and yield up the Land (and subject to clause 10.4 all improvements on the Land) to the Minister clean, free from rubbish and in a state of repair and condition as shall be consistent with the Lessee's covenants and obligations under this Lease, the Agreement and the Approved Proposals to the absolute satisfaction of the Minister; (h) The Minister, in the Minister's own name or as the attorney of the Lessee in the name of the Lessee, is entitled to institute all proceedings against any office or company which issues a policy of insurance required by other money payable under any indemnity in favour of the Lessor or the Minister. The Lessee appoints the Minister the attorney of the Lessee for that purpose.
10.4 Ownership of improvements upon determination of Term	(a) Except as otherwise determined by the Agreement Minister and subject to clause 10.4(b), when the Term expires or determines upon the cessation or determination of the Agreement all buildings erections and other improvements erected on or below the Land shall become and remain the absolute property of the Lessor without the payment of any compensation or consideration to the Lessee or any other party and free and discharge from all mortgages and other encumbrances. The Lessee shall do and execute and cause to be done and executed all such deeds, documents and other acts, matters and things (including surrenders) as the Lessor may reasonably require to give effect to the provision of the subclause. (b) In the event the Lessee immediately prior to the expiration or determination of the Term upon the cessation or determination of the Term upon the cessation or determination of the Agreement or within the following 3 months wishes to remove all or any of its fixed or moveable plant and equipment from any part of the Land the Lessee must give to the Lessor notice of such wish and must grant to the Lessor the right or option exercisable within the following 3 months to purchase in situ such fixed or movable plant and equipment at a fair valuation to be agreed between the Parties or failing agreement as determined by arbitration under the Agreement. If the Lessor does not exercise that right or option the Lessee may on the expiration of the 3 month period, or sooner with the consent of the Agreement Minister, remove the fixed or moveable plant and equipment to which the right or option relates.

Lease L21123. The construction, provision, extension, use, operation and maintenance on the Land of an accommodation village and for ancillary and incidental purposes thereto in accordance with the Approved Proposals.	
Condition No.	**Closure conditions**
10.3 Yielding up	(a) On the expiration or earlier determination of the Term the Lessee must: (i) surrender peaceably and yield up the Land (and subject to clause 10.4 all improvements on the Land) to the Minister clean, free from rubbish and in a state of repair and condition as shall be consistent with the Lessee's covenants and obligations under this Lease, the Agreement and the Approved Proposals to the absolute satisfaction of the Minister; (ii) undertake a program of rehabilitation of disturbed land (including making the land surface safe, stable and able to support a self-regenerating ecosystem) as shall be consistent with the Lease, the Agreement and the Approved Proposals to the satisfaction of the Minister; and (iii) remove and fixtures, fittings or any other property on the Land (other than casings for bores constructed in accordance with the Approved Proposals) as may be required by the Minister and the Agreement Minister (and whether before or after the expiration of any option period as referred to in clause 10.4(b)) to those Minister's absolute satisfaction; and (iv) promptly make good to the satisfaction of the Minister or the Agreement Minister (as the case requires) any damage caused by the removal in clause 10.3(a)(iii). (b) The Lessee's obligations under clause 10.3(a) shall survive the expiration or earlier determination of the Term.
10.4 Ownership of improvements upon determination of Term	(a) Except as otherwise determined by the Agreement Minister and subject to clause 10.4(b), when the Term expires or determines upon the cessation or determination of the Agreement all buildings erections and other improvements erected on or below the Land shall become and remain the absolute property of the Lessor without the payment of any compensation or consideration to the Lessee or any other party and free and discharge from all mortgages and other encumbrances. The Lessee shall do and execute and cause to be done and executed all such deeds, documents and other acts, matters and things (including surrenders) as the Lessor may reasonably require to give effect to the provision of the subclause. (b) In the event the Lessee immediately prior to the expiration or determination of the Term upon the cessation or determination of the Term upon the cessation or determination of the Agreement or within the following 3 months wishes to remove all or any of its fixed or moveable plant and equipment from any part of the Land the Lessee must give to the Lessor notice of such wish and must grant to the Lessor the right or option exercisable within the following 3 months to purchase in situ such fixed or movable plant and equipment at a fair valuation to be agreed between the Parties or failing agreement as determined by arbitration under the Agreement. If the Lessor does not exercise that right or option the Lessee may on the expiration of the 3 month period, or sooner with the consent of the Agreement Minister, remove the fixed or moveable plant and equipment to which the right or option relates.

Lease L21124. In accordance with the Approved Proposals, the construction, provision, extension, use, operation and maintenance of a railway and associated access road to extend the Lessee's Hamersley railway line from Marandoo to Yandi via Homestead Junction and for ancillary and incidental purposes thereto including to the extent permitted by Approved Proposals the construction, use, operation and maintenance of borrow pits and water bores.	
Condition No.	**Closure conditions**
10.3 Yielding up	(a) On the expiration or earlier determination of the Term the Lessee must: (i) surrender peaceably and yield up the Land (and subject to clause 10.4 all improvements on the Land) to the Minister clean, free from rubbish and in a state of repair and condition as shall be consistent with the Lessee's covenants and obligations under this Lease, the Agreement and the Approved Proposals to the absolute satisfaction of the Minister; (ii) undertake a program of rehabilitation of disturbed land (including making the land surface safe, stable and able to support a self-regenerating ecosystem) as shall be consistent with the Lease, the Agreement and the Approved Proposals to the satisfaction of the Minister; and (iii) remove and fixtures, fittings or any other property on the Land (other than casings for bores constructed in accordance with the Approved Proposals) as may be required by the Minister and the Agreement Minister (and whether before or after the expiration of any option period as referred to in clause 10.4(b)) to those Minister's absolute satisfaction; and (iv) promptly make good to the satisfaction of the Minister or the Agreement Minister (as the case requires) any damage caused by the removal in clause 10.3(a)(iii). (b) The Lessee's obligations under clause 10.3(a) shall survive the expiration or earlier determination of the Term.
10.4 Ownership of improvements upon determination of Term	(a) Except as otherwise determined by the Agreement Minister and subject to clause 10.4(b), when the Term expires or determines upon the cessation or determination of the Agreement all buildings erections and other improvements erected on or below the Land shall become and remain the absolute property of the Lessor without the payment of any compensation or consideration to the Lessee or any other party and free and discharge from all mortgages and other encumbrances. The Lessee shall do and execute and cause to be done and executed all such deeds, documents and other acts, matters and things (including surrenders) as the Lessor may reasonably require to give effect to the provision of the subclause. (b) In the event the Lessee immediately prior to the expiration or determination of the Term upon the cessation or determination of the Term upon the cessation or determination of the Agreement or within the following 3 months wishes to remove all or any of its fixed or moveable plant and equipment from any part of the Land the Lessee must give to the Lessor notice of such wish and must grant to the Lessor the right or option exercisable within the following 3 months to purchase in situ such fixed or movable plant and equipment at a fair valuation to be agreed between the Parties or failing agreement as determined by arbitration under the Agreement. If the Lessor does not exercise that right or option the Lessee may on the expiration of the 3 month period, or sooner with the consent of the Agreement Minister, remove the fixed or moveable plant and equipment to which the right or option relates.

YANDICOOGINA CLOSURE OBLIGATIONS REGISTER
Relevant Legislation

Closure planning and implementation requires consideration of general legislative requirements beyond those that apply to a specific site. A list of potentially relevant legislation is provided below, but is not necessarily exhaustive. A comprehensive legal review will be required as closure approaches to ensure that all relevant legislative requirements are identified.

Australian Commonwealth Legislation

Environmental Protection and Biodiversity Conservation Act 1999
Native Title Act 1993
Aboriginal and Torres Strait Islander Heritage Protection Act 1984
Workplace Relations Act 1996

Western Australian State Legislation

Environmental Protection Act 1986
Environmental Protection Regulations 1987
Environmental Protection (Controlled Waste) Regulations 2004
Environmental Protection (Unauthorised Discharges) Regulations 2004
Contaminated Sites Act 2003
Contaminated Sites Regulations 2006
Conservation and Land Management Act 1984
Mining Act 1978
Mining Regulations 1981
Parks and Reserves Act 1895
Rights in Water and Irrigation Act 1914
Wildlife Conservation Act 1950
Aboriginal Heritage Act 1972
Aboriginal Affairs Planning Authority Act 1972
Mines Safety and Inspection Act 1994
Mines Safety and Inspection Regulations 1995
Occupiers Liability Act 1985
Criminal Code Compilation Act 1913

Relevant Guidelines and Standards

Closure planning and implementation requires consideration of relevant guidelines and standards, some of which may have regulatory consequence through being referenced in regulatory documents. A list of key guidelines and standards that are routinely considered is provided below, but is not exhaustive due to the breadth of the closure planning discipline. This closure plan has been prepared so as to be considered with relevant content of these guidelines and standards.

Guideline or Standard	**Author**
Guidelines for the Preparation of Mine Closure Plans (2015)	Western Australian Department of Mines and Petroleum and Environmental Protection Authority
Leading Practice Sustainable Development Program for the Mining Industry - Mine Closure and Completion (2006)	Commonwealth Department of Industry Trade and Resources
Mine Rehabilitation Handbook (1998)	Minerals Council of Australia
Guideline for the Assessment of Environmental Factors: Rehabilitation of Terrestrial Ecosystems (2006)	Western Australian Environmental Protection Authority
Australian and New Zealand Guidelines for Fresh and Marine Water Quality (2000)	Agriculture and Resource Management Council of Australia and New Zealand and the Australian and New Zealand Environment and Conservation Council
Mine Void Water Resource Issues in Western Australia (2003)	Western Australian Water and Rivers Commission
Contaminated Sites guideline series	Western Australian Department of Environmental Regulation
Environmental Notes on Mining: Acid Mine Drainage (2009)	Western Australian Department of Mines and Petroleum
Environmental Notes on Mining: Waste Rock Dumps (2009)	Western Australian Department of Mines and Petroleum
Safety Bund Walls Around Abandoned Open Pit Mines (1997)	Western Australian Department of Industry and Resources
Global Acid Rock Drainage Guide (2014)	International Network for Acid Prevention
Australian Standard 2601: The Demolition of Structures (2001)	Standards Australia
Australian Standard 4976: The Removal of Underground Petroleum Storage Tanks (2008)	Standards Australia
Demolition Work Code of Practice (2015)	Safe Work Australia

APPENDIX B

27. Appendix B Closure knowledge database report summaries

Rio Tinto Yandicoogina closure knowledge database

The closure knowledge database is a summary of the technical reports that directly or indirectly contribute to the development of the closure plan. These documents do not form part of the report and are for indicative purposes only.

The knowledge and understanding of closure issues and management strategies evolve and improved over time, coincident with the development of the mining operation. As a result, some components of some reports and studies may be superseded by new research or studies. While the closure plan addresses the current state of understanding and strategy for closure, the closure knowledge database captures the historical development of closure knowledge, and demonstrates how experience and knowledge developed at other Rio Tinto sites has been considered during the development of the closure plan and across the life of the operation. Accordingly, some information presented in the closure knowledge database may be obsolete.

Technical reports supporting the closure of the operation will be presented as part of the last plan produced prior to the implementation of closure (also known as the Decommissioning Plan).

CONFIDENTIAL

Geochemical characterisation

Review of Waste Rock Geochemistry a.General Overview of Acid Base Accounting — **2006**

This report contains a general overview of acid base accounting and a summary of the geochemical test work that has been previously completed for various sites and lithologies.

Internal reference: RTIO-PDE-0021130

There are large discrepancies in the total sulfur concentration measured using XRF and LECO machines. The XRF machine underestimates the sulfur concentration at values greater than 2%. Materials with total sulfur concentrations less than 0.1% can contain low capacity PAF material, however, it is considered only to be low additional acid and metalliferous risk if the boundary for inert material and potentially acid forming material is shifted from 0.02%S to 0.1%S. A paste pH result of less than 7 should be sent to the black shale dump and a paste pH result of greater than 7 can be sent to an inert material waste dump.

Yandicoogina Mineral Waste Risk Assessment: Acid Rock Drainage Potential — **2007**

Potential for acid and metalliferous drainage has been assessed for the Yandicoogina mine site.

Internal reference: RTIO-PDE-0033672

For all processed ore and waste at Yandicoogina Junction Central the overall acid and metalliferous drainage (AMD) risk is low to nil. Specifically, the AMD risk at Junction Central, Junction South East and Billiards deposits is considered low and the risk at Junction South West deposit is low to nil. The acid and metalliferous drainage risk is slightly greater (low to medium) at the Yandicoogina Snooker and Meander deposits. Elevated sulfur concentrations were found in the alluvium, weathered channel, alluvials and to a less extent in the Welli Wolli formation. The enriched elements for the various deposits mostly included Fe, As and Sn.

Mineralogical Analysis of Potentially Acid Forming Materials — **2008**

Quantitative mineralogy (QEM-Scan) for samples of rock collected from Tom Price, Channar, West Angelas, Brockman, Paraburdoo, East Extension, Western Turner Syncline and Hope Downs 1 North was undertaken. Comparisons were made between two methodologies use to characterise potentially acid forming materials; acid base accounting and mineralogical analysis.

Internal reference: RTIO-PDE-0053725

All samples contained elevated total sulfur concentrations and the lithologies were either shale, banded iron formation or dolomite. Pyrite was the dominant mineral contributing to acidity and the dominant sulfate secondary mineralisation consisted of alunite and jarosite.

Determination of ARD potential of Rio Tinto Iron Ore (WA) Waste Rock Samples — **2008**

This report investigates the use of mineralogy to predict acid and metalliferous drainage potential. Analysis of numerous rocks was undertaken using QEM-SCAN.

Internal reference: RTIO-PDE-0051613

Areas of waste rock which have underdone oxidation can be identified where sulfur-bearing minerals vary between samples in the form of pyrite, alunite and jarosite. The variability of gangue mineral phases suggest that some areas of composite waste rock pile may provide some neutralising potential while other areas will have no neutralising potential. Variable textural and mineralogical controls on sulfide mineral occurrence result in decreased accessibility of pyrite to oxidising fluids.

Contaminant Leaching from Non-Sulfidic Waste Material — **2011**

The available leach extract data and information pertaining to the distribution of metals and metalloids in non sulfur materials at neutral pH was reviewed. Based on this review conceptual models for controls on their leaching and mobility were developed.

Internal reference: RTIO-HSE-0145041

The review found that contaminant leaching from non-sulfidic materials was generally very limited. Usually the pH in leach tests was near-neutral (pH 6 to 8), and dissolved contaminant concentration were at or below detection limits. It is believed that a primary leachable contaminant source is the oxidation of sulfide minerals. Release from oxidising sulfides leads to release of soluble reaction products. Under neutral pH conditions, there is the potential for release of these contaminants when those products dissolve.

Environmental Status of Selenium (Se) in the Pilbara Region of Western Australia – Potential Risk from Iron Ore Mining **2011**

Internal reference: RTIO-PDE-0103857

This report includes information about Selenium geochemistry, distribution in the environment, occurrence in rocks in the Pilbara and potential risks to the environment.

The Selenium (Se) content of shales containing significant pyrite should be recorded as part of the overall risk assessment for acid and metalliferous mine drainage. However, it should also be noted Se solubility is far less constrained by pH than in the case of metals and near neutral drainage may contain significant Se concentrations in solution. It would be most useful to study the Selenium budget of the wetlands in the Pilbara as, apart from the chance poisoning of livestock from the consumption of plants that have taken up high concentrations of Selenium, impacts are most likely to be felt in wetlands receiving mine site drainage.

Contaminant Leaching from Low-Sulphur Waste Minerals (Summary) **2011**

Internal reference: RTIO-PDE-0090689

RTIO's Geochemical Database was reviewed and based upon this data, conceptual models for controls on the leaching and mobility of a range of metals and metalloids were developed. This summary also describes potential controls on the amount of dissolved element that may be released. This is a summary of a comprehensive report RTIO-PDE-0100104.

For most contaminants, dissolved concentrations at circum neutral pH (pH 6 to 8) were very low, typically at or below detection limit. Geochemical modelling indicates that water-rock interactions are controlled by equilibrium, for salt, carbonates and sulphates this equilibrium is often source term limited whilst hydroxyl-sulphates and hydroxides are solubility controlled. Results also indicate that sorption plays an important role in solute concentration; weak (but detectable) sorption occurred for selenium and zinc whilst the strongest sorption was evident for cobalt. The review suggested that storage waste facilities containing low-sulfur materials pose a low level of environmental risk however, there is a small risk of increased in mobility of some contaminants if acidic conditions arise. Acidic conditions can sometimes arise from the interactions between iron and aluminium hydroxyl-sulphates and hydroxides.

Preliminary results of geochemical characterisation of Yandicoogina samples **2012**

Internal reference: RTIO-PDE-0109618

This memo summarises the results of preliminary solid extra element analysis, short term liquid extract/leach testing and phase 1 acid base accounting (ABA) completed on samples obtained from the Yandi Junction South West (JSW) drilling programme completed in June 2011 and grab samples selected by mine geology in 2009 and 2011 from Junction Central (JC) and Junction South East (JSE).

The results indicate that soluble metals/metalloids are generally below the trigger values outlined in the ANZECC water guidelines and Yandi background water values. Where there are exceedances, the trigger values (normally associated with ANZECC water guidelines for 95% protection of freshwater species) were lower than the detection limits used in the analysis. All samples were above drinking water trigger values and stock water guideline trigger values.

RTS058 Geochemical testwork on Low Sulfur samples from Yandi (Phase 1 and 2) **2012**

Internal reference: RTIO-PDE-0099036

This testwork undertakes geochemical characterisation (ABA and leach testing) on Yandicoogina samples (RC, Grab, tailings) to support the assumption that low grade and waste material is unlikely to pose an environmental risk. This work was conducted to support the Yandi JSW approvals.

Reverse circulation (Junction SW) and grab (Junction Central/SE) samples had negligible sulfur content (<0.1%) and were confirmed to be Non Acid Forming (NAF) and had little neutralising capacity. The exception were samples from the alluvium, where there is neutralising capacity that could counter any acid formed. All samples were enriched (when compared to the average crustal abundance) in As, Au, Bi, Sb, Se and Hg though static leach testing has indicated that these elements were not readily leached upon contact with water. For waste fine samples there was negligible sulfur (><0.04%) and all were confirmed to be NAF. Similar to the RC and grab samples, the waste fines samples were enriched in As, Au, Se and Hg, though these elements were not readily leached. The supernatant solution from the waste fines samples were also tested. The pH of the solutions were neutral and were chemically similar to leaches of the waste fines solids. High Fe and Al concentrations in the leach tests were deemed to be in excess of the solubility limits and it is assumed that the elements were present as colloids rather than being dissolved. Follow up testing will be conducted to confirm

RTS058 Yandi Project: Geochemical Testwork on Low Sulfur Samples - Supplemental Samples **2013**

Internal reference: RTIO-PDE-0103854

This work was carried out to test the assumption that low grade and waste from Yandicoogina is unlikely to pose a risk to the environment. This report discusses the results of 19 additional samples supplementing the initial batch of 95. See RTIO-PDE-0099036 for additional information.

The 18 waste rock samples submitted for analysis this time around have been characterised as having low sulfur contents ranging from below the detection limit to 0.26%. The sulfur is either present as sulfides or more likely sulfates and were classified as non-acid forming (NAF) or Uncertain (UC-NAF), having little to no neutralising capacity. Minor and trace elements that were enriched compared to the average crustal abundances include As, B, Bi, Sb, Se and Tl, with element leachability generally limited in pH neutral de-ionised water. One (1) tailings sample was submitted with the results similar to the tailings samples submitted initially. The sample had negligible sulfur and was classified as NAF-Barren due to little to no neutralising capacity. The only enriched minor or trace element was Se and once again the leachability of elements was generally low.

Assessment of Yandicoogina water quality at closure **2013**

Internal reference: RTIO-PDE-0113542

This Technical Memorandum addresses the potential leachability of minor and trace element from backfill materials, and the effects of evaporation on the concentrations of these elements. The report includes an overall water quality assessment for the site based on historical minor and trace elements records, a review of leach tests conducted on Yandi materials, and limited conceptual modelling to illustrate the potential effects of evaporation on water quality and minor and trace element concentration.

The 2011-2013 dataset indicates that in general groundwater at Yandi is of HCO3 type with pH values ranging from 6.7 to 8.3. No clear segregation between alluvium and the deeper CID aquifer was observed in terms of salinity. No changes in salinity or major-ion chemistry were observed. Trace elements such as As, Cr, Ni, Sb and Se have been detected. Poor correlation between reported TDS and EC values was identified in the data. Recent nitrogen exceedances observed at the site appears to originate at surface water discharges, potentially from wash down bays. The water quality data suggests Pilbara creeks have different properties; Marillana Creek is circum-neutral to slightly alkaline, Weeli Wolli Creek is slightly alkaline, while Homestead Creek (not located in catchment area) is neutral. Total dissolved solids indicate that Weeli Wolli is slightly fresher than Marillana Creek. Leach test results suggests that most elements will be mobilized in an initial flush of water from significant rainfall events. Modelling results indicated that groundwater is supersaturated with respect to CO2. Thus, degasing of CO2 may occur as groundwater equilibrates with the atmosphere and mixes withh pore waters from backfill materials; which in turn would increase pH from ~7.4 to ~8.6. A second evapoconcetration phase could drive CO2(g) to exsolve, such that pH could increase to as high as 9.1. These conditions would influence trace element mobility.

RTS058 Yandi Project: Geochemical Test work on low sulfur samples – supplemental leach testing **2013**

Internal reference: RTIO-PDE-0110708

This work forms part of ongoing geochemical characterisation. Leach test, work presented in this report, explored contamination under a wider range of geochemical conditions, following work completed in August 2012 and January 2013.

Mineralogical assessment was completed on 11 waste rock samples and 1 tailings sample. The composition of all leachates was comparable, irrespective of test conditions. The solutions were circum neutral (pH between 7.8 and 8.5 for waste rock and pH 6.5 to 7.6 for tailings) and dilute (average EC approximately 650 uS/Cm for waste rock and 70uS/cm for tailings). Readily detectable elements included major elements: Ca, Mg, Na, K, Cl, Si and SO4 and trace elements AL, B, Ba, F, Fe, Sr and Zn. As expected, the highest concentration of elements were recorded in low L:S leach tests, the majority of which were source term limited (ie very low masses were present and are expected to dissolve completely during the test.) Test work and PHREEQC modelling indicated that AL, Ba, F and Si may be subject to a solubility control in the waste rock samples. In the tailings sample, low but detectable concentrations included: Cd, Cu, Pb, Mn and Ni.

Geochemical Assessment of Tailings from Yandi, Paraburdoo, Tom Price, Brockman 4 and Mesa J **2014**

Internal reference: RTIO-PDE-0123030

This report presents the results from geochemical testing and saline solution extraction of tailings samples from Yandi, Paraburdoo, Tom Price, Brockman 4 and Mesa J deposits.

Overall the tailings from these operations are unlikely to generate acid and are not expected to leach significant levels of metals under oxidising or saline conditions.

Oxidation and solute accumulation in dewatered pit wall rocks **2014**

Internal reference: RTIO-PDE-0109045

Dewatering and removing the water table may result in de-saturation of sulphide-bearing lithologies. This study was undertaken to review how oxygen ingress and consequent sulphide oxidation of Mount McRae Shales could impact water quality when the groundwater table rebounds after mining.

Large Scale Column Construction Procedure and Initial Chemistry **2014**

Internal reference: RTIO-PDE-0123894

Large scale column experiments have been constructed to examine the reactivity of hot and cold black shale material in an operational environment. The memo describes the construction of the columns and the first geochemistry data collected after small rainfall events at Rhodes Ridge.

Initial results suggest that effluent water retains the chemistry of the incident rainfall. Constituents to note in the initial chemistry include nitrate and ammonia detected in the hot black shale effluent. This study provides an important comparison between laboratory characterisation studies and field reactivity of waste rock. Data from the large scale column tests can be applied to reactivity of in pit waste/talus as well as waste rock dumps. It can be used as an intermediate to predict long term reactivity of waste rock.

Physical characterisation

Yandi Geology: Stratigraphy, Lithology, Chemistry, Alterations and modelling parameters — 2004

Internal reference: RTIO-PDE-0012215

This report describes in detail the geology of the Yandi area. Detailed litho-chemical descriptions of each unit are included along with modelling parameters current as of March 2004. Also included are stratigraphic columns, which illustrate the time relationships between the various units. Finally, a table illustrating the main alteration types encountered in the Yandi area, which are routinely logged, are also included for reference.

The Yandicoogina (Yandi) iron ore reserves form part of an extensive series of Channel Iron Deposits (CID) located in the eastern Hamersley Province of the Pilbara region in northwest Western Australia. The ores commonly outcrop as a series of low mesas beside the Marillana, Yandicoogina and Weeli Wooli Creeks and are commonly referred to as “pisolitic limonites” (England 1998). CID is a collective term allocated to material comprising concentric shells of limonite and vitreous goethite (Fe203.H20) around nuclei of hematite (Fe203), goethite, turgite (Fe203.nH20) and iron oxide replaced wood that have accumulated in palaeo-river channels. CID are characterised by the presence of fossilised wood fragments and absence of lithic rock fragments within ore. HI geologists have subdivided the CID into 6 main material types: Eastern Clay Conglomerate / Laterite - Mottled orange-brown and grey-white clays (after dolerite), BIF and ferricrete fragments. Weathered Channel - Partially lateritised upper surface of the CID, which is silicified and penetrated by clay filled solution pipes, but still retains recognisable CID texture. SiO2 & Al2O3 are elevated at the expense of Fe in the weathering process. Goethite Vitreous Upper (GVU) - The Upper Ore Zone is approximately 20m thick and is moderate in silica and low in alumina. The GVU is slightly magnetic with confirmed presence of kenomagnetite. It is thought this zone was above the palaeo-watertable. Goethite Vitreous Lower (GVL) - The Lower Ore Zone is low in silica, moderate in alumina, and approximately 25m thick. It is thought this zone was below the palaeo-watertable. Limonite Goethite Channel - This material forms the footwall of the orebody. It is a clay-rich, leached, yellow, ochreous goethite (limonite) zone. It contains occasional lenses of CID material. Basal Conglomerate – This basal clastic facies of the channel unconformably overlies the Weeli Wolli Formation. The unit varies in thickness from a few centimetres up to 8m and is generally only present in the centre of the channel. The GVU and the GVL are the only units that currently fall within economic mining parameters.

Net solute load response to the installation of infiltration limiting dry cover systems over acid forming waste piles — 2014

Internal reference: RTIO-PDE-0128431

This work was conducted to verify the central design concept of store-and-release covers over sulfidic above water table waste dumps that is, whether limiting net percolation volume through the cover results in a lesser sulfate and acidity load being realised generated and passing through the dump.

The results from this thesis project confirm that the central aim of store-and-release covers to reduce net percolation volume is a valid measure for reducing the net loading of sulfate and acidity. The mechanism through which decreasing net percolation (applied water volume) results in a lesser sulfate and acidity load was identified, however further work in a site context is needed to assess how this relationship between percolation volume and loading persists in the real-world environment.

Groundwater

Hydrogeology review for proposed HI (Yandi) extended mine closure plan — 1998

Internal reference: RTIO-HSE-0070352

This report reviewed the hydrology and hydrogeology of the eastern section of the Channel Iron Deposit (CID) in the palaeo-valley of Marillana Creek, known as the Junction Deposit mine. (Note: The impacts of several closure options are discussed, but may now be invalidated by subsequent expansion activities.)

The principal aquifer in the area of the Junction Deposit is the CID itself with a transmissivity of about 3500 m2/d and estimated throughflow of 2.5 to 3 ML/d. Alluvium beneath Marillana Creek is an aquifer of lesser importance, because of a smaller cross-sectional area and lower hydraulic conductivity. Water levels in the CID are controlled by recharge from Marillana Creek. Marillana Creek normally flows for a period of only 30 to 60 days following heavy rain. During these periods the creek loses water to underlying alluvium. In several places the creek alluvium overlies the CID, which is also recharged by the creek flow. Streamflow loss in the area of the Junction mine during the first flow in the wet season is estimated to be at least 100 ML per kilometre of length along the creek bed. The loss of water by evapotranspiration from pools and riparian vegetation near the Junction mine is estimated to be 0.3 ML/d from each kilometre of the creek bed.

HI Yandi: Phil's Creek and Hairpin Dewatering Borefield Installation Program 2002 — 2002

Internal reference: GDSR 4397

This report examines the hydrogeological characteristics of the intersection of Phil's Creek CID and Marillana CID within the Hairpin area.

The primary targets of new dewatering bores has been cavernous intersects within the Limonite Goethite Unit (situated below the Main Ore Zone) within the Channel Iron Deposit. Transmissivity values derived from the new bores at Hairpin and Phil's Creek indicate that the hydraulic characteristics of the CID aquifer in each of these areas has been influenced by a progressive reduction in the saturated thickness of the aquifer since dewatering commenced. A numerical groundwater model has been constructed based on this field work and is being used to complete a review of the closure impacts at Yandi.

Yandicoogina Water Balance - Pre and Post Mining Hydraulics and Hydrochemistry **2010**

Internal reference:
RTIO-PDE-0073467

The study was undertaken to: update the conceptual hydrogeological model; define the pre mining and current groundwater conditions and hence impacts from mining operations on the flow system; determine the importance of creek seepage into the CID aquifer and mine pits; and provide information on water quality and quantity.

The groundwater level response to changes in the water budget due to natural and human induced processes is immediate, suggesting good connection between various aquifers and creek systems. Long term observations indicate water levels can rise by up to 10m in the CID aquifer after intense rainfall events. This translates to approximately 16GL of water and can be as high as 30GL per event over a 25km length of Marillana Creek. The chloride (Cl) concentrations show 20% of water discharged from the mine is lost by evaporation and evapotranspiration. As a result CID salinity increased by 20% up to the 12km down gradient from Junction Central, beyond which no increase in Cl concentration was observed.

Yandicoogina hydrogeological assessment of the CID & adjacent floodplain **2010**

Internal reference:
RTIO-PDE-0071209

This hydrogeological investigation was undertaken to mining at Oxbow, Junction South West (JSW) and the northern end of Junction South East (JSE). The principal objective of the study was to gain a better understanding of the hydrogeological setting of the Yandicoogina region.

This hydrogeological investigation obtained aquifer parameters for Oxbow and JSW, surface water groundwater interaction, and estimates of dewatering volumes for Oxbow and JSW. Drilling outside the CID aquifer revealed that the material surrounding the CID aquifer in the flood plain is unconsolidated alluvium or in situ weathered Weeli Wolli Formation bedrock. Regardless of the weathering history and origin of the deposits, the material is characterised by hydraulic properties that allow for leakage to the CID, and that this leakage may be greater than previously anticipated. The thickness of the flood plain material at JSW and Oxbow is variable (20 - >50m) depending on elevation and proximity to Marillana Creek.

Yandicoogina hydrogeological assessment of the CID & adjacent floodplain - Bore Installation, test pumping and analyses 2008/09 **2010**

Internal reference:
RTIO-PDE-0071209

The principal objective of the study was to gain a better understanding of the hydrogeological setting of the Yandicoogina region. The hydrogeological investigation focused on obtaining aquifer parameters at principally Oxbow and JSW, surface water groundwater interaction, and estimates of dewatering volumes for the proposed expansion sites.

Drilling outside the Channel Iron Deposit (CID) in the floodplain of Marillana Creek revealed that the material surrounding the CID aquifer in the flood plain is unconsolidated alluvium or in situ weathered Weeli Wolli Formation bedrock. Regardless of the weathering history and origin of the deposits, the material is characterised by hydraulic properties that allow for leakage to the CID, and that this leakage may be greater than previously anticipated. The minimum thickness for the floodplain material that occurs adjacent to the CID deposit is estimated from drilling at JSE to be 37m. The thickness of the flood plain material at JSW and Oxbow is variable (20 - >50m) depending on elevation and proximity to Marillana Creek. Hydraulic connection between the flood plain, the weathered basement and the CID aquifer was confirmed during the test pumping program, where constant rate test pumping showed that the bores installed in the flood plain sediments or weathered basement of the Weeli Wolli Formation adjacent to the CID respond to pumping in the CID aquifer. The CID hydraulic conductivity for was calculated between 3m/d and 25m/d, with an average of roughly 9m/d. Specific yield was more difficult to determine from testing but ranged over two orders of magnitude from 0.01 to as high as 0.3. Yield from the constant rate pumping tests ranged from 60L/s up to 100L/s (the upper limit of the pumping equipment).

Yandicoogina Operations Groundwater Operating Strategy **2012**

Internal reference:
RTIO-HSE-0057642

All water licences contain a set of terms and conditions detailing the licensee's responsibilities and specifying the volume of water that may be taken in any given year (the water entitlement or allocation). This groundwater operating strategy describes how groundwater is managed at the Yandicoogina operation to comply with licence conditions and is a condition of the water licence. As such the report is updated regularly to reflect current operating practice.

Yandicoogina operate several borefields in order to supply drinking water and dewater aquifers ahead of mining. The volume of water abstracted is in excess of site requirements and several discharge outlets are used to dispose of excess water to adjacent creek systems. The plan specifies monitoring activities to include groundwater water levels, electrical conductivity (EC), pH and temperature sampled from selected bores, and total volumes, nutrients (Total-P, Total-N, NO3 and NH3) and metals (Se and Hg) at discharge outlets. Other parameters sampled include Na, K, Ca, Mg, Cl, CO3, HCO3, SO4 and NO3 from some bores and at some discharge outlets and within the local creek system pH, EC, TDS, TSS, Al, Ca, Mg, Na, K, SO4,Pb, Cu, Fe, Mn, Mo, Zn, As, Cd, Cr, TRH.

Surface water

Marillana Creek catchment hydrology and local catchment impacts Yandicoogina +52 Mtpa Expansion Prefeasibility Junction South West (Stage 1) and Oxbow deposits **2008**

Internal reference: RTIO-PDE-0047262

This report describes the hydrology of Marillana Creek past the Oxbow and JSW deposits and provides a conceptual surface water management plan for local, natural surface water runoff.

Flow volumes along Marillana Creek at Oxbow and JSW deposits range from 60 m3/s for a 1 in 2 year average recurrence interval (ARI) to 4700 m3/s for a 1 in 500 year ARI event. Flood protection for the Oxbow and Junction South West deposits is required to minimise the environmental impacts, continue natural flows where possible and protect the pit and pit walls from surface water runoff. A protection level of between 1 in 20 and 1 in 100 year ARI is recommended. Diversion of natural surface water runoff away from the active mine areas from local catchments will be required as part of the mine plan.

Yandicoogina Surface Water Management Report **2010**

Internal reference: RTIO-PDE-0072516

This report describes the interaction between natural surface water runoff, the local environment and the Yandicoogina mine during operations. Closure management is not addressed in this report.

Environmental issues relating to surface water at the Yandicoogina Operation include the potential for surface water runoff from the operation to become contaminated and discharge into the environment, and alteration of natural surface water flow by structures/operations, thereby affecting downstream vegetation or causing flooding/ponding upstream. Management actions implemented at the mine include treatment of surface water prior to discharge into the natural environment and maintaining natural drainage patterns where possible. Yandicoogina mine activities encroach on regional and local floodplains of Marillana Creek and its tributaries. To manage flood risks during the wet season, Yandicoogina JC and JSE currently employ a combination of “sump and pump” and “diversion” surface water management strategies. Sumps are dewatered with portable and permanent pipe and pumping systems. Diversion levees and channels are employed around the JC and JSE operations to prevent flooding from surface water runoff and to minimise pit wall instability associated with runoff flowing uncontrolled over the pit crest. Expansion of the current mine operation will further encroach into regional and local floodplains of the Marillana Creek, Weeli Wolli Creek catchments and their tributaries, necessitating additional surface water management requirements.

Marillana Creek regional flow balance and catchment hydrology **2010**

Internal reference: RTIO-PDE-0081939

At the cessation of mining pit voids adjacent to and intercepting local tributaries to Marillana Creek, Marillana Creek floodplain and possibly Marillana Creek proper may collect or divert tributary flows, while others may only collect local surface water runoff and incident rainfall. This report assess how the hydrological regime of the Marillana Creek catchment will be altered when mine closure and rehabilitation activities are completed at Yandicoogina and BHPIO Yandi mines.

Modelling suggests that the truncation of local creeks associated with leaving pit voids will change the flood frequency and thus lower flood potential within Marillana Creek. For example, at the terminus of Marillana Creek bank full conditions, the maximum capacity of the creek within the banks, will reduce from a 10 year average recurrence interval (ARI) to a 20 year average recurrence interval; such that overbank flooding will only occur after an event greater than a 1 in 20 year ARI. This flood regime change will affect sections of the creek that support riparian vegetation such as Eucalyptus camaldulensis (River Red Gum), whose existence is associated with surface flooding characteristics.

Marillana Creek Regional Flow Balance – Pre and Post-mining comparison **2010**

Internal reference: RTIO-PDE-0072519

A study of the regional flow balance of the Marillana Creek catchment was carried out to identify and compare the response of the catchment to different storm events under pre and potential post-mining conditions. The study presumes BHPIO and RTIO will divert Marillana Creek flows around their deposits while truncating some tributaries.

It was determined that under pre-mining conditions Marillana Creek would flow on average 200 days per year. Continuous flow was recorded at Flat Rocks between 2000 and 2004, with over 350 flow days recorded per year during that period. This may attribute to creek bed interflow which enables water to return to the surface during dry periods and the potential storage capabilities of the retention basins located in the Upper Marillana Creek catchment. The study demonstrated that the creek system would experience approximately 27% reduction in flow contribution at closure, with the RTIO and BHPIO Yandicoogina mine operations individually accountable for 17% and 10% of the total flow reduction. The flood peaks for all ARI rainfall events would also decrease by approximately 50% at the catchment outlet. The cumulative impacts associated with flow reduction and change in catchment water balance post-mining would modify the flood regime and reduce the flooding potential of the creek system. This may result in decreased water availability for riparian ecosystems on floodplains and ultimately lead to biodiversity change within the creek

Baseline hydrology assessment for Yandicoogina discharge **2012**

Internal reference: RTIO-PDE-0074001

This baseline hydrological/hydraulic assessment was carried out to access the existing situation and movement of discharged water along the creek systems and to predict the likely behaviour of the released water for various discharge scenarios. Closure implications are not addressed in this report.

The assessment demonstrated that historically discharged water would not have extended past the Marillana Creek catchment outlet at the confluence with Weeli Wolli Creek; hence anecdotally no flow contribution to Weeli Wolli would have been expected. This suggests the wetting front in Weeli Wolli Creek is likely to have resulted from surplus water discharged from the Hope Downs 1 mine operation. A discharge footprint of 16.3km down gradient from the Weeli Wolli – Marillana Creek confluence was estimated for the maximum modelled 110GL/year regional surplus discharge (based on existing infrastructure). An option to relocate the discharge location in Marillana Creek down gradient from the mine operations would extend footprint to approximately 6.7km to 17.3km down gradient from the Weeli Wolli – Marillana Creek confluence for modelled volumes of 55GL/year to 110GL/year.

Weeli Wolli Creek hydrology and floodplain assessment **2013**

Internal reference: RTIO-PDE-0117748

This flood study defines the hydrological regime and natural flow conditions for Weeli Wolli Creek and investigates several conceptual flood protection levee options for safe mining of the Billiard South deposits within the Weeli Wolli Creek floodplain.

A RORB rainfall runoff model was developed and calibrated to observed data at gauging stations within the regional Weeli Wolli Creek catchment. The calibrated RORB model was used to simulate design flood peaks and hydrographs for the study area. The expected 2, 1 and 0.5 % AEP flows estimated for Billiard South are 2200 m3/s, 4070 m3/s and 4900 m3/s, respectively. The 0.5 % AEP event was selected as the design standard for the levees based on the expected 20 to 30 years of operational life of the infrastructure. The modelling suggests that flood protection may require levee heights, depending on the alignment, ranging from 4.8 m to 6.5 m.

Water interactions and pit lakes

Impacts of mining and mine closure on water quality and the nature of the shallow aquifer, Yandi Iron Ore Mine. Masters Thesis **2002**

Internal reference: GDSR 4746

This study was completed as part of a Masters of Science qualification at Curtin University of Technology. The study aimed to: determine the current water quality in the aquifers; predict future water quality after waste rock from the mining has been returned to the channel; and predict the physical properties of the groundwater system after the waste has been returned to the channel, with a focus on assessing changes in permeability occurring as a result of siltation or secondary mineral formation.

Overburden material that will constitute the backfill was found to have high concentrations of (by material type) Alluvium - As, Fe, Se, Sb, Ba, Te; Eastern clay conglomerate - Pb, Mo, Fe, As, Se, Te, Sb, Ba; and Weathered channel horizon - Mo, Fe, Sb, As, Se, Ba. The Weathered channel horizon was found to contain bands of smectite clay. This clay is known to swell when wet up to 20 times its dry volume. This may impair the permeability of an aquifer with significant amounts of this clay. A solution with a high sodium chloride concentration may inhibit this swelling. The current groundwater quality is slightly acidic or slightly alkaline, and is typically of calcium/magnesium bicarbonate to sodium carbonate. The majority of the bores sampled met the Australian guidelines for potable water with sample three exceedances noted for pH and Pb. The leachate tests indicated: pH may rise towards 8.4 due to the buffering of carbonate minerals; TDS may increase as soluble minerals dissolve into the groundwater; conditions for anoinic elements such as antimony, arsenic, cobalt, chromium, gallium and molybdenum will become more favourable due to the rise in pH; minerals such as diaspore, leonhardite, quartz, ZnSiO3 and hematite will start to precipitate as they become saturated in solution; some elements will reduce in concentration as minerals are precipitated. (Four backfill and landform shaping options were also reviewed as part of this work, however, these options are invalidated by the expansion of the site.)

Yandicoogina closure options: preliminary water modelling results **2012**

Internal reference: RTIO-PDE-0103618

This document intends to provide the basis of a technically defensible, integrated closure plan with respect to managing water quantity and quality post mining at Yandicoogina through the use of water balance modelling. The main objectives for water management at closure will be: to create stable landforms, maintain surface water and groundwater throughflow (albeit with no pre-determined water table elevation), and maintain surface water and groundwater quality to within acceptable limits for the agreed post closure land uses. Salinity levels post-closure were modelled for various scenarios: All pits left open (No Backfill Option) The mining of a complete channel as an open void (Continuous Channel Option) The combination of mining Oxbow, Junction Southwest A and Junction Southwest C pits as open voids and the partial backfilling of Junction Central, Junction Southeast Extension and Billiard South to specified levels (Selected Backfill Option) The mining of individual pits, achieving in-pit backfill to 2m above pre-mining ground water level (Complete Backfill Option)

Water balance modelling results showed the No Backfill Option with open pits act as sinks for groundwater. As such, water cannot leave these pits and salt levels increase, creating a hypersaline environment. The Continuous Channel Option assumes that a creek and lake system is established at the base of the mined out pit from which water would flow into the undisturbed Weeli Wolli Creek channel. Evapo-concentration of salinity is low and the water quality remains fresh—pit salinities of 130mg/L assuming natural creek salinities of 50mg/L. This is because discharge through the system exceeds evaporation. The Selected Backfill Option seeks to optimize the limited backfill material available. Water levels in the backfilled pits reflect the backfill level. After rainfall events, evaporation occurs which quickly reduces water levels back to the backfill level from which no further evaporation occurs. Groundwater throughflow is maintained and the area in which evaporation can occur is reduced, thereby reducing salinity to around 4,800mg/L. However with additional strategic use of remaining backfill, water quality may be improved. Water modelling of the in-pit backfill to 2m above pre-mining water table indicated salinity could increase to 3,800 mg/L at the Billiard pit. This was because the modelling showed the water table would fluctuate and rise more than 2m above the pre-mining water table, exposing the water table to evaporation processes. Diverting surface water into the pits to decrease salinity induced dilution temporarily, but only by 1000mg/L at the Billiard pit. Surface water management studies showed that a combination of diversion drains, bunding and backfilled pit sections (landbridges) will be required to manage surface water drainage during mining. However no recommendations for post-closure management were developed. An internal review of other closure requirements will be necessary to identify the preferred post mining landform option.

"Impacts of mining and mine closure on water quality and the nature of the shallow aquifer, Yandi Iron Ore mine" by Sean Gardiner: Background to study and summary of findings **2012**

Internal reference: RTIO-PDE-0103858

This document summaries the background to, findings and / or relevance of a geochemical investigation of waste rock at Yandi that was undertaken as a part of a study conducted by Masters Student Sean Gardiner from Curtin University of Technology.

The MSc thesis presents considerable information on groundwater quality in the vicinity of Yandi Mine at the time of the study (1998). Whilst, it gives some useful information on the local geochemical background in one area of the Pilbara region it is of insufficient scope to provide meaningful scale to any potential geochemical contamination.

Closure and water strategy synergies at Yandicoogina **2013**

Internal reference: RTIO-HSE-0201688

This memo records a facilitated discussion which looked at opportunities for additional or alternative water disposal options that facilitate closure.

An opportunity to dispose of surplus water by creating pit lakes in the Yandicoogina mined out voids before the planned closure was identified. This concept would require in pit waste dump landscaping / shaping activities to commence as soon as practicable. Water would then be disposed into the void, to create the lake. Appropriate wetland revegetation activities could then commence around the lake fringe. Groundwater re-circulation volume would increase as a result of this activity; however the environmental benefit are anticipated to outweigh the re-circulation impact.

Oxbow Pit Lake – Stochastic salinity and water level conditions post closure **2013**

Internal reference: RTIO-PDE-0116562

The report presents the outcomes of a simple water balance developed to simulate the behaviour of water in Oxbow Pit, based on a 2013 Yandicoogina Closure Groundwater Model.

The predictive model estimates that the steady state water level in Oxbow pit will fluctuate around 514m RL with no likelihood of the pit overtopping. Total Salt Load and salinity continue to slowly rise, reaching approximately 8.7 ×108 kg and 26,000mg/L respectively after 2000 years. If a 30% smaller pit shell is used (within the error range of the groundwater model) values are more likely to fluctuate around 528mRL. It is unlikely the smaller Oxbow pit will overtop; only 14 of the 100 realisations run over a 2000 year period overtopped the pit on at least one occasion. Total salt load and salinity stabilise after 400 years at approximately 1.2 ×108 kg and 2,700 mg/L respectively.

Technical Memorandum: Laboratory modelling for Yandi Selenium concentration **2014**

Internal reference: RTIO-PDE-0118277

This study reviews the potential effect of evaporation on selenium concentration increases in surface water environments and/or during development of mine pit lakes based on water samples from the Yandicoogina Oxbow area. The study includes laboratory scale experiments to measure changes in selenium concentrations, with different acidity levels, by simulating the process of evapoconcentration.

Findings to date show background selenium concentrations on average at<0.002mg/L from Yandicoogina bores. The modelling results showed that Se > 0.01mg/L (the ANZECC 95% limit for the aquatic ecosystems) was measured when evapoconcentration levels exceeded 93.75%. At 98% evaporation Se >0.055mg/L (the ANZECC 80% limit for the aquatic ecosystems) was measured. Changes to pH did not appear to influence the Se results, although a slight increase in general cations was observed under acidic conditions.

Flora

Flora and Vegetation Yandicoogina Junction Area **1995**

Internal reference: RTIO-HSE-0057043

This report summaries the results of a vegetation survey completed of the Yandicoogina Junction area.

A total of 57 plant families and 336 vascular plant species were recorded. No declared or priority flora species were located. Acacia (Mimosaceae), Cassia (Caesalpiniaceae) and Triodia (Poaceae) dominate the vegetation of the Yandicoogina Junction area. A total of 18 plant communities were defined, of these the plant communities of significance are: the Woodlands of Eucalyptus camaldulensis, selected flats and the restricted and localized low shrubland of Eremophila spp, Senna spp and Acacia spp.

Flora and Vegetation Northern Transport Corridor Yandicoogina Junction Project Area **1995**

Internal reference: RTIO-HSE-0014649

This report summaries the results of a vegetation survey completed for the Northern Transport Corridor option for the Yandi Junction Project area.

A total of 57 plant families and 334 vascular plant species were recorded. No declared Rare Flora were located. 2 priority flora speices were recorded; Triumfetta sp. Rudall subsp. Woodstock and Goodenia stellata. Acacia (Mimosaceae), Cassia (Caesalpiniaceae) and Triodia (Poaceae) dominate the vegetation of the transport corridor. A total of 22 plant communities were defined, of these the plant communities of significance are: selected flats supporting Hummock Grasslands due to their species richness.

Yandicoogina Railway Drainage Shadow Monitoring 2001 **2001**

Internal reference:

Drainage shadow monitoring on Hamersley Iron's Yandi railway commenced in 1998. The monitoring program was designed to assess whether construction and operation of the railway had any indirect impact on the survival and health of Mulga, Acacia aneura. It was postulated that downslope impacts in the drainage shadow area might occur, with limited upslope impacts due to flooding also considered.

The results show that although numbers of all mulga age classes and dead mature mulga appeared to be higher in the upslope transects in 2001, none of the results could be interpreted as indicating a difference between them and the downslope transects. However, it was not possible to draw any clear links between vegetation dynamics and the presence of the railway line, and it was recommended monitoring continue.

Yandicoogina Railway Drainage Shadow Monitoring 2002 **2002**

Internal reference:

Drainage shadow monitoring on Hamersley Iron's Yandi railway commenced in 1998. The monitoring program was designed to assess whether construction and operation of the railway had any indirect impact on the survival and health of Mulga, Acacia aneura. It was postulated that downslope impacts in the drainage shadow area might occur, with limited upslope impacts due to flooding also considered.

Similar trends were observed to previous years, with few statistical difference upslope and downslope of the railway. The Highway transects appears to have reached a successional stage where the number of mature mulga have increased, dead mature mulga have decreased and there is some recruitment occurring.

Yandi Expansion Areas Rare Flora Survey - Feb 2003 **2003**

Internal reference: RTIO-HSE-0014711

This document provides a description of the survey methodology and findings of the rare flora survey of the Yandicoogina expansion area.

Large portions of the study area had been either burnt or disturbed in the last few years. Vegetation types varied considerably with landform and included Artistida grassland in disturbed borrow pits, mulga shrublands on clayey plains, hummock grasslands with shrub over storeys of varying density on stony hills and eucalypt woodlands within the Marillana Creek. No declared rare fauna were recorded from the 6 areas surveyed. Six priority flora were recorded from the expansion area. Several mounds of the priority 4 Western Pebble-mound Mouse, Pseudomys chapmani, were recorded, some of which may be active. Two uncapped drill holes and a small fenced area containing numerous bags of aboriginal stone artefacts were located during the survey.

Yandi Mine Expansion Rare Flora Survey **2003**

Internal reference: RTIO-HSE-0014739

This report summaries the results of a survey for flora of conservation significance at the Yandi Mine Expansion Project. Survey comprised three separate areas which surround the mine operation.

A total of 130 species of vascular flora belonging to 73 genera and 34 families was recorded. No DRF were located. 4 Priority flora were recorded: 3 Priority three species: Themeda sp. Mt Barricade, Eriachne tenuiculmis and Rhyncosia sp. Bungaroo Creek and 1 Priority 4 species: Goodenia stellata.

Yandi 2003 Infill Drillling Rare Flora Survey **2003**

Internal reference: RTIO-HSE-0014747

This report summaries the results of a survey for flora of conservation significance completed for an infill drilling program at Yandi, 2003.

A total of 158 vascular species from 38 families were recorded. No DRF were located. Three Priority flora were recorded: Two Priority 3 (Themeda sp. Mt Barricade, Eriachne tenuichulmis) and one Priority 1 (Eriachne sp. Hamersley Range Hilltops).

Yandi 2004 Infill Drillling Rare Flora Survey **2003**

Internal reference: RTIO-HSE-0014744

This report summaries the results of a survey for flora of conservation significance completed for an infill drilling program at Yandi, 2004.

A total of 158 vascular species from 38 families were recorded. No DRF were located. Two Priority flora were recorded: Priority 1 (Eriachne sp. Hamersley Range Hilltops) and Priority 4 (Goodenia stellata).

Yandicoogina Railway Drainage Shadow Monitoring 2003 **2004**

Internal reference:

Drainage shadow monitoring on Hamersley Iron's Yandi railway commenced in 1998. The monitoring program was designed to assess whether construction and operation of the railway had any indirect impact on the survival and health of Mulga, Acacia aneura. It was postulated that downslope impacts in the drainage shadow area might occur, with limited upslope impacts due to flooding also considered. Monitoring of dead Mulga was discontinued as there were problems with species identification, fire, etc. that affected the accuracy of the data.

Similar trends were observed to previous years. None of the changes, ie recruitment, appear to be linked to any difference between Mulga communities located upslope and downslope of the railway line.

Yandicoogina Railway Drainage Shadow Monitoring 2004 **2004**

Internal reference:

Drainage shadow monitoring on Hamersley Iron's Yandi railway commenced in 1998. The monitoring program was designed to assess whether construction and operation of the railway had any indirect impact on the survival and health of Mulga, Acacia aneura. It was postulated that downslope impacts in the drainage shadow area might occur, with limited upslope impacts due to flooding also considered. Monitoring of dead Mulga was discontinued as there were problems with species identification, fire, etc. that affected the accuracy of the data.

In general the proportion of Mulga in each age class remained unchanged. It was concluded that vegetation dynamic differences between upslope and downs slope populations could be identified. Such that the rail has not influenced the survival or health of the Mulga. Monitoring was discontinued.

Yandi Expansion Vegetation and Flora Survey **2004**

Internal reference: RTIO-HSE-0013321

This report summaries the results of a vegetation survey completed of the Yandi Expansion area.

20 vegetation types were identified with vegetation considered to be in very good to excellent condition. A total of 319 taxa of native vascular flora from 150 genera belonging to 53 families was recorded. 13 introduced species were also recorded. No DRF were located. Five Prority flora were recorded: two priority 2 (Olearia fluvialis, Sida sp. Barlee Range), two priority 3 (Abutilon trudgenii ms, Themeda sp. Hamersley Station) and one priority 4 (Goodenia stellata). No TEC's or DRF were recorded and none of the vegetation types are considered to be of regional conservation significance.

Vegetation mapping and rare Flora Searches of Yandi Backfill Hill **2005**

Internal reference: RTIO-HSE-0014923

This document provides an account of the methodology, findings and recommendations of the botanical survey of the Backfill Hill, an area of proposed additional source material that would be mined solely to backfill pit voids in the Yandicoogina mine.

The vegetation types identified at Backfill Hill are comparable with those mapped for the surrounding area and were in very good condition and generally typical of the Newman area. 122 species of flora were recorded. No declared rare flora or priority flora were recorded from the Backfill Hill area, and a single record of Buffel Grass Cenchrus ciliaris in the survey area.

Yandi JSE - Conservation Significant Vegetation, Flora, Fauna and Fauna Habitat Assessment **2005**

Internal reference: RTIO-HSE-0059518

This assessment establishes the conservation significance of and impacts to flora and fauna in the Yandicoogina JSE project area.

None of the 21 vegetation types identified from the area are Threated Ecological Communities, neither are they significant at the level of the Pilbara bioregion. Vegetation of conservation value at the Hamersley subregion comprises vegetation types 1c of breakaways and vegetation types 3c, 3d, 3e, 3f and 3h of major creeklines.

Yandi Riverine Monitoring Data 2005 E. camaldulensis results **2005**

Internal reference:

Surplus water obtained from dewatering of Hamersley Iron's Yandi mine is discharged into Marillana Creek. Monitoring commenced in 1997 to determine whether the water discharge is having an impact on sensitive plant species including large Acacias, Atalaya hemicaulca, Eucalypts (E. camaldulensis, E. victrix) and Melaleuca spp.

Results for 2005 show that the majority of trees at the site are stressed. For example, only 3 of the original 18 trees at the Upstream control site remain alive. However trees in Weeli Wolli and Phils Creek remain in good health.

Yandicoogina Revegetation Reference Sites **2009**

Internal reference: RTIO-HSE-0098922

This report documents the establishment and monitoring of baseline (control) vegetation transects in unmined areas adjacent to Yandicoogina operations.

A total of 82 vascular plant taxa from 45 plant genera and 23 plant families were recorded in the Yandicoogina control transects and one priority flora species. Average plant density and species richness varied between transpects. Although it was noted that recent fire events near transpects C1, C2 and C4 may have contributed to higher species richness. The average foliage cover for each transect varied with no definite pattern in relation to landscape. Pperennial grasses dominated all components of the landscape. Midslope transects recorded the lowest bare ground score while the lower slope/flat transects recorded the highest bare ground score.

Yandicoogina Revegetation Control Transects 2009 **2009**

Internal reference: RTIO-HSE-0108130

This report summarizes the data collected to date on the transects located on uncleared and less disturbed areas adjacent to the Yandicoogina Mine Site . Data was collected on the range, frequency, density, richness and foliage cover of the species, lifeform, and other components of the physical environment (bare ground and soil analyses).

A total of 82 vascular plant taxa from 45 plant genera and 23 plant families were recorded, one Priority Flora species and no introduced taxa. Relatively recent fire events were observed in the areas of transects. The perennial grasses dominated all components of the landscape with shrubs and trees dominating the remaining lifeforms. Most aspects varied between transects or showed no clear pattern. The midslope transects recorded the lowest bare ground score while the lower slope/flat transects recorded the highest bare ground score.

A Flora and Vegetation Survey of the Billiards Deposit, near Yandi **2009**

Internal reference: RTIO-HSE-0087206

This report details the results of field vegetation and flora surveys of the Billards Deposit.

No DRF or Priority flora were located from the study area, however four prioity species could occur on the basis of the habitats present. Overall the vegetation of the Billiards study area was in very good to excellent condition. No TECs or PECs were recorded from the area, however the vegetation of the major seasonally flowing creekline (Weeli Wolli creek) is considered to be of High conservation significance, whilst the vegetation of Marillana Creek and the Mulga stands are of moderate conservation significance. Seven introduced flora species were recorded, none being declared plants.

Vegetation and Flora Surveys of the Oxbow and Junction South West Deposits, near Yandicoogina **2010**

Internal reference: RTIO-HSE-0083283

This report details the results of field vegetation and flora surveys of the Oxbow and Junction South West Deposits.

The DRF species Lepidium catapycnon was recorded at Oxbow and a Priority 3 species Tephrosia sp. Catherdral Gorge. No DRF species were recorded from the JSW area, however Lepidium catapycnon has the potential to occur. Two priority species, Tephrosia sp. Cathedral Gorge and Goodenia nuda (Priority 4) were recorded at JSW. 12 introduced species were recorded in the Oxbow area and 11 were recorded at JSW, none being declared plants.The vegetation types of the Oxbow and JSW areas were generally in very good to excellent condition. The Oxbow and JSW study areas also contained approximately 16% and 13% of disturbed areas respectively, these areas are considered to be completed degraded. The areas of the creekline vegetation unit, and hillcrest unit, supporting the DRF were identified as having high conservation significance. One moderate conservation significance was also identifid, the area of plains vegetaion supporting a popoulation of the Priroity 3 Tephrosia sp. Catherdral Gorge. No vegetation communities listed as TECs or PECs ocurred in the area.

Flora and Vegetation Survey Yandi Village **2012**

Internal reference: RTIO-HSE-0133995

This report documents the results of a vegetation and flora survey completed in 2011 for a car park at Yandi Village

A total of 7 vegetation types were recorded, non were considered to be of significance and are well represented within the Pilbara bioregion. Vegetation type condition ranged from completely degraded to very good. No DRF or priority species were recorded, nore were any TECs or PECs identified.

Yandi JSW/Oxbow Vegetation and Flora Integration Report **2012**

Internal reference: RTIO-HSE-0175486

This report describes a further botanical survey completed in 2012 to provide additional information on the vegetation and flora values associated with the Yandi JSW and Oxbow study areas. Data from previous surveys were reviewed and included were relevant.

None of the vegetation associations comprised a TEC or PEC. The major creekline (Marillana Ck) represents an ecosystem at risk. 17 weed species were recorded, none which are Declared species. One threatened species (Lepidium catapycnon), One priority 3 (Rostellularia adscendens var. latifolia) and one Priority 4 (Goodenia nuda) species was recorded.

Condition of Flora and Vegetation along Marillana (Yandicoogina) Creeklines **2012**

Internal reference: RTIO-HSE-0191027

This report provides a summary of observations and recordings on the flora and vegetation along the Marillana and Weeli Wolli creek systems. Survey completed in 2012.

No plant taxon listed as DRF or threatened were recorded. In general, all tree species were healthy to slightly stressed. Condition of saplings and mature trees reflect past fire events and a range of local site conditions including heavy grazing, hydrological shifts in Marillana and selected WW transects and seasonal fluctuations across the entire river system. 11 weeds were recorded within the creek survey areas.

Yandi Additional Areas Vegetation and Flora Level 2 Assessment **2013**

Internal reference: RTIO-HSE-0175488

This report describes further botanical survey work completed in 2012 in order to provide additional information on the values associated with the JSW, Oxbow and Billiards project areas.

Sixteen vegetation associations were described for the study area. An additional mapping unit comprised cleared ground. None of the vegetation associations comprise Threatened Ecological Communities (TECs) or Priority Ecological Communities (PECs). A total of 313 native vascular flora species from 125 genera and 45 families were recorded from the study area. This species richness is within the range expected for an area of this size in this locality. No Threatened flora species were recorded within the study area. Fourteen introduced flora species (weeds) were recorded from the study area, none of which are Declared Plants for the Pilbara bioregion. *Cenchrus ciliaris (Buffel Grass) was the most prolific introduced flora species observed in the study area. This species often formed dense populations along creek banks and in floodplains.

Autumn Assessment of Flora and Vegetation Condition along Marillana (Yandicoogina) Creeklines **2014**

Internal reference: RTIO-HSE-0252380

This report provides a summary of observations and recordings on the flora and vegetation along the Marillana and Weeli Wolli creek systems. Survey completed in May 2014.

No plant taxon are listed as threatened or priority species. 12 introduced weed species were recorded during this survey. Changes in foilage cover of understorey species along the creeklines have largely reflected seasonal variation between surveys. All tree species were healthy to slightly stressed among all zones across all transects.

Yandi Billiards Vegetation and Flora Survey - Phase 1 and Phase 2 **2014**

Internal reference: RTIO-HSE-0242328

This report summaries the results of a vegetation and flora survey at Yandi Billiards completed in 2014.

23 vegetation types were described, with most vegetation being in good to very good condition, except creekline and floodplain vegetation which ranged from good to very poor condition due to weed invasion and cattle disturbance. One ecosystem at risk was present, vegetation type C1 occurs along Marillana and Weeli Wolli Creeks. None of the vegetation types represented TECs or PECs. One threatened flora species (Lepidium catapycnon) was located, and two priority species (Priority 3 - Sida sp. Barlee Range and Priority 4 - Goodenia nuda). 18 weed species were recorded, with one (Mexican poppy) being a declared plant for WA.

Spring Assessment of Flora and Vegetation Condition along Marillana (Yandicoogina) Creeklines **2014**

Internal reference: RTIO-HSE-0251693

This report provides a summary of observations and recordings on the flora and vegetation along the Marillana and Weeli Wolli creek systems. Survey completed in October 2014.

No plant taxon are listed as threatened or priority species. 14 introduced weed species were recorded during this survey. To date, understorey vegetation is largely associated with seasonal variation with rainfall influencing species richness and foliage cover. Trees above 10.9 cm DBH are stable across all zones regardless of conditions. Control sites show similar responses to conditions as impact sites.

Fauna

Stygofauna Sampling at Brockman and Yandicoogina: 2003 **2003**

Internal reference: RTIO-HSE-0187099

This report describes the November 2003 stygofauna sampling at Yandicoogina.

17 boreholes were sampled. Specimens recorded include: Amphipoda, Isopoda, Ostracoda, Platyhelminthes, Copepoda, Oligochaeta and Hydracarina. The number of individual stygofauna at Yandicoogina was very high, and exceeded Paraburdoo's previously highest count. The species richness is comparable to other sites, with seven high level taxa collected. The most stygofauna were collected from shallow boreholes that intersected river alluvials. Stygofauna such as Tainisopid isopods and copepods were collected away from Marillana Creek.

Yandi Expansion Desktop Fauna Assessment and Targeted Invertebrate Survey **2004**

Internal reference: RTIO-HSE-0057590

The primary aims of the study were to 1) Collect information on the presence of vertebrate fauna and selected invertebrate taxa (short range endemics); 2) Document the components of the physical environment (ie. the fauna habitats); and 3) Document existing levels of disturbance.

Six major habitat types were identified for the Yandi Expansion area. The habitat types within the Yandi Expansion area do not appear to be unique or significant at the bioregion scale. The riverine habitat is significant on a sub-bioregion scale as it would support a range of species not typically recorded from other habitats in the study area. Short range endemics species identified include: several Araneae (Spiders), six Pseudoscorpionida (Pseudoscorpions), one species of scorpionid, one species of Polyxenid millipede (pin-cushion millipede), one species of land snail (family Pupillidae). Two species of Schedule fauna and one Priority listed species have either been recorded from or are likely to occur in the Yandi Expansion area. One species, the Pilbara Olive Python, is also listed as Vulnerable under the EPBC Act 1999.

Yandi Junction South East (JSE) Expansion. Baseline Stygofauna Assessment **2005**

Internal reference: RTIO-HSE-0013441

This report summaries the results of a baseline Stygofauna assessment completed for the Yandi JSE Expansion. This report was based on analysis of existing specimens collected in Nov 2003 and no additional field collection was undertaken.

17 of the 23 bores sampled contained stygofauna. The abundance and diversity of stygofauna collected was considerable. Seven higher-level taxa were collected: Amphipoda, Copepoda, Hydracarina, Isopoda, Ostracoda, Oligochaeta and Platyhelminthes.

Yandi JSE - Conservation Significant Vegetation, Flora, Fauna and Fauna Habitat Assessment **2005**

Internal reference: RTIO-HSE-0059518

This assessment establishes the conservation significance of and impacts to flora and fauna in the Yandicoogina JSE project area.

Habitat types within the area do not appear to be unique or significant at the bioregional scale. The Major Creek (Riverine) habitat is important at a sub-bioregion scale as it supports a range of species not typically recorded from other habitats, and because all major ephemeral water courses are considered to be ecosystems at risk within the Hamersley subregion (threats from cattle, donkeys and weeds). No gazetted vertebrate fauna species of special conservation significance were recorded. No invertebrate species known to be of elevaated conservation significance were recorded, nor did the targeted Short-range Endemic survey detect any species likely to have an elevated conservation significance. Given these conditions no particular management is required over and above the standard management measures already in place for the project.

Yandicoogina Targeted Northern Quoll Survey **2009**

Internal reference: RTIO-HSE-0083042

This report summaries the results of a single-phase targeted Northern Quoll survey in the Yandi Expansion areas.

The targeted survey recorded no evidence of the Northern Quoll from any of the 277 traps. Additionally, pervious faun surveys completed in the area have yielded no records of this species. This may be attributed to lack of good quality habitat.

Yandi Stygofauna Compliance Summary 2009 **2009**

Internal reference: RTIO-HSE-0081567

This report summaries the results of bi-annual sampling of stygofauna completed in April and Oct 2009. This sampling is to ensure compliance with the Yandi EMP and Stygofauna management plan.

Eight higher-order taxa were represented. A total of 2,333 stygobitic invertebrates were collected from 28 of the 40 drill holes sampled. Most of the specimens came from the phylum Crustacea, with the Amphipoda, Copepoda and Ostracoda being the most abundant.

Yandicoogina Junction South West and Oxbow Fauna Survey **2010**

Internal reference: RTIO-HSE-0087749

This report summaries the results of a single-phase fauna survey conducted in July 2008.

The survey yielded a total of 72 vertebrate species, comprising 46 avifauna, 12 mammals and 14 herpetofauna species. Two priority 4 species were recorded, the Star Finch and the Western Pebble-mound Mouse, both are well represented in similar habitats across the Pilbara. The migratory listed Rainbow Bee-eater was also recorded. Fauna habitats described are considered to be widespread and common throughout the local area and within the wider region.

Yandicoogina Expansion Billiard Deposit Fauna Survey **2010**

Internal reference: RTIO-HSE-0087750

This report summaries the results of a single-phase fauna survey conducted in July 2008 of the proposed Billiard project area.

The survey yielded a total of 62 vertebrate species, comprising 44 avifauna, 18 mammals and 10 herpetofauna species. One priority 4 species was recorded, the Western Pebble Mouse, this species is well represented in simiilar habitats across the Pilbara. The migratory listed Rainbow Bee-eater was also recorded. Fauna habitats described are considered to be widespread and common throughout the local area and within the wider region.

Yandicoogina Subterranean Fauna Assessment Phases I-V **2010**

Internal reference: RTIO-HSE-0101408

The report collates all of the subterranean fauna data collected, including all five phases of stygofauna sampling, and a single troglofauna sampling phase in the Yandicoogina area to date. The report also provides recommendations and direction for how to manage them during operations and describes the mine closure and the rehabilitation option.

A total of 3695 specimens of stygobitic fauna were collected. Specimens represented 6 classes and 9 orders. 35.93% of the total collection are Podocopida. 4 specimens of troglofauna have been collected. The report suggests that on mine closure refuge areas will aid in recolonisation of impacted (dewatered) areas surrounding the mine area. The report comments that salinisation of the groundwater may alter stygal community compositions in favor of those species more tolerant to brackish water and could render groundwater inhabitable for stygobitic fauna; however no limiting water chemistry or salinity values are provided.

Yandicoogina Stygobitic Fauna Compliance Monitoring 2012 **2013**

Internal reference: RTIO-HSE-0180459

This report summaries the results collected during the two phases of stygofauna sampling completed in 2012. This sampling is to ensure compliance with the Yandi EMP and Stygofauna management plan.

Nine orders of fauna in five classes (phylum) were represented, dominated by the phylum Crustacea, comprising 85% of specimens collected. A total of 57 specimens of compliance and conservation significant species were collected.

Pocket and Billiard South Level 2 Seasonal Fauna Survey **2014**

Internal reference: RTIO-HSE-0253611

This report documents the results of the first phase (wet season) and second stage (Dry season) fauna surveys in the study area in March and September 2014 respectively.

Eight species of conservation significance were recorded in the study area: Mulgara Dasycercus (species unconfirmed), Pilbara Olive Python (Schedule 1, Vulnerable), Western Pebble-mound Mouse (Priority 4), Star Finch (Priority 4), Australian Bustard (Priority 4), Fork-tailed Swift (Schedule 3, migratory), Eastern Great Egret (Schedule 3, migratory); and Rainbow Bee-eater (Schedule 3, migratory). The study area was considered to be largely unsuitable for the Northern Quoll, with minimal potential core habitat. Targeted searches for SRE taxa yeilded records of several invertebrate species, which are potential SRE's, however all taxa recorded have documented distributions extending outside of study area.

Biodiversity improvement studies

Evaluation of mine waste materials as alternative rehabilitation growth medium **2010**

Internal reference: RTIO-HSE-0109961

This study reviewed the physical and chemical properties of soil, tailing and mineral waste from select Pilbara mining operations, to identify waste material and material combinations for use as a topsoil substitute or supplement.

The study showed plant-available nutrients held within the waste materials, although variable, was characteristically low and comparable to natural soils in the region. The majority of the waste materials had macro and micro nutrient concentrations within the range or above the levels measured in benchmark Pilbara topsoil and rehabilitated soils. The pH and phosphorus buffering index of most waste materials were also comparable to that of the benchmark topsoil materials. However, some of the waste types and tailings may need to be mixed with rocky material due to poor physical / erodibility characteristics.

Irrigated seed orchard trial **2011**

Internal reference:

Commencing in 2011 (and still ongoing), a trial irrigated seed orchard was established at the Hamersley Agriculture Project (Marandoo). The purpose of the trial was to identify an alternate method of addressing seed deficits. If successful, the project may be implemented at other Rio Tinto operations, such as the Nammuldi agriculture project.

Genetic diversity in Eucalyptus leucophloia across the Pilbara: Provenance zone implications **2011**

Internal reference: RTIO-HSE-0108843

This study was undertaken to define the provenance seed collection zones for a common species of the Pilbara, Eucalyptus leucophloia (Snappy Gum). This report details information on genetic analysis conducted on E. leucophloia. Collections of E. leucophloia were made from 20 populations across the Pilbara bioregion and genetic analysis was conducted using microsatellite markers.

Genetic diversity in E. leucophloia was high and was typical of that found in other eucalypt species with wide spread distributions. Across the species the level of population differentiation was low and the majority of the diversity was maintained within populations with only 6% of variation partitioned between populations. Genetic variation in E. leucophloia showed little structure across the Pilbara with no clustering of populations based on any geographical proximity or in association with obvious topographical, physiogeographical or geological features such as the Hamersley or Chichester Ranges. Populations towards the edges of the species distribution within the Pilbara showed greater levels of differentiation from populations within the species main range. The high levels of genetic diversity and low levels of differentiation within E. leucophloia implies that seed resources for rehabilitation can be selected from a wide range within the Pilbara.

Genetic diversity in Acacia ancistrocarpa across the Pilbara: Provenance zone implications **2011**

Internal reference: RTIO-HSE-0119260

This study was undertaken to define the provenance seed collection zones for Acacia ancistrocarpa (Fitzroy Wattle). This report details information on genetic analysis conducted on Acacia ancistrocarpa. Collections were made from 24 populations across the Pilbara bioregion and genetic analysis was conducted on 16 populations using microsatellite markers.

Genetic diversity in A. ancistrocarpa was high but lower than that in E. leucophloia, another widespread species in the Pilbara. Across the species Pilbara range the level of population differentiation was low and the majority of the diversity was maintained within populations with only 3% of variation partitioned between populations. Genetic variation in A. ancistrocarpa showed little structure across the Pilbara with no clustering of populations based on geographical proximity or in association with obvious topographical, physiogeographical or geological features. Populations towards the edges of the species distribution within the Pilbara showed greater levels of differentiation from populations within the species main range. The high levels of genetic diversity and low levels of differentiation within A. ancistrocarpa implies that seed resources for land rehabilitation and mine-site revegetation programs can be selected from a wide range within the Pilbara

Root hydraulic conductance and aquaporin abundance respond rapidly to partial root-zone drying events in a riparian Melaleuca species **2011**

Internal reference: RTIO-HSE-0252171

This study examined partial root zone drying (PRD) responses of Melaleuca argentea.

The results demonstrate that PRD can induce rapid changes in root hydraulic conductance and aquaporin expression in roots, which may play a role in short-term water uptake adjustments, particularly in species adapted to heterogeneous water availability.

Baseline Terrestrial Fauna Assessment of Pilbara Rehabilitation Areas **2012**

Internal reference: RTIO-HSE-0134168

In 2011 a fauna survey was conducted within established rehabilitation areas at Brockman 2 and Tom Price mine sites, with the aim of identifying whether fauna is recolonising rehabilitation sites in assemblages comparable to reference sites.

The study found that at least 85 species of native vertebrate fauna, as well as representatives from each of six major groups of invertebrate fauna, are using rehabilitation areas at Brockman 2 and Tom Price, with species compositions that were broadly similar to reference sites. Ant collections were typical of the Pilbara bioregion, with an absence of invasive ant species. The study found greater data correlation between monitoring sites at a particular mine site (Tom Price or Brockman 2) than between rehabilitation and reference sites, indicating the importance of selecting local reference sites. The study concluded that the best candidates for bio-indicators are ants and reptiles.

Genetic diversity in Aluta quadrata:Implication for management and provenance zone **2012**

Internal reference:

This study was undertaken to define the provenance seed collection zones for Aluta quadrata. This report details information on genetic analysis conducted on Aluta quadrata. Collections were made from 8 populations across the Pilbara bioregion and genetic analysis was conducted using microsatellite markers.

Genetic diversity in A. quadrata was moderate and lower than in the other two more widespread Pilbara species, E. leucophloia and A. ancistrocarpa. The findings suggest that its populations may have fluctuated significantly in size over time with genetic drift and possibly inbreeding resulting in a reduction in genetic variability, particularly in rare alleles. Despite the narrow geographic range, the level of population differentiation in A.quadrata was relatively high with 25% of the genetic variation maintained between populations and 19% due to differences between the three different locations. This significant genetic structure indicates that A. quadrata consists of three conservation or management units, Western Ranges, Pirraburdoo and Howie's Hole.

Genetic diversity in Acacia atkinsiana across the Pilbara: Provenance zone implications **2012**

Internal reference:

This study was undertaken to define the provenance seed collection zones for Acacia atkinsiana (Atkins wattle). This report details information on genetic analysis conducted on Aluta quadrata. Collections were made from 16 populations across the Pilbara bioregion and genetic analysis was conducted using microsatellite markers.

Genetic diversity in A. atkinsiana was low and lower than that observed in its congener Acacia ancistrocarpa, a widespread species across northern Australia. The level of population differentiation was high and 30% of the diversity was partitioned between populations across the range of A. atkinsiana. Genetic variation in A. atkinsiana showed some structure across the Pilbara with clustering of populations in the western part of the distribution and from the Hamersley Range, along with other populations that were divergent from these groups. The low levels of genetic diversity and high levels of differentiation within A. atkinsiana implies that seed for land rehabilitation and mine-site revegetation programs should be restricted to specific zones. For rehabilitation of sites within the Hamersley Range we recommend seed collections be restricted to that region. Similarly, for rehabilitation in the part of the distribution west of Pannawonica, seed collections should be restricted to that area.

Rehabilitation Quality Metric (RQM) Project **2012**

Internal reference: RTIO-HSE-0164020

Western Australia has no formal process to measure habitat quality and as such RTIO has needed to design its own customised metrics. Vegetation condition scoring has previously been developed by RTIO through a Biodiversity Net Positive Impact Assessment, but a more precise metric was needed. The Rehabilitation Quality Metric (RQM) project was developed to provide a repeatable method to assess rehabilitation quality against pre-determined reference sites, on a site by site basis, to predict rehabilitation ecosystem quality at the time of relinquishment.

The RQM methodology employs seventeen parameters to characterise the landscape, including vegetation, fauna habitat, fauna presence, erosion, and ecosystem function. Parameters are tailored to be an applicable measure for both rehabilitation and native vegetation (reference sites). Parameters are scored, based on measured or observed characteristics, with a value between 0 and 1, with 1 being functional (terrestrial ecosystem is functioning for the maintenance of biodiversity values at a local or property scale) and 0 being dysfunctional (terrestrial ecosystem is failing; indicators of ecosystem function have scored below acceptable levels). Both rehabilitation areas and reference sites are scored. Scores are subsequently determined for the entire mine lease, based on the condition of the land before mining (extrapolated from the reference sites, area weighted) and the likely post-mining conditions (extrapolated from the rehabilitation areas and expected closure domain distribution, area weighted, ie pits with no rehabilitation score 0). The difference between the pre-mining and post-mining scores represents the residual impact of mining.

Propagation of Pilbara spinifex (Triodia sp.) **2012**

Internal reference: RTIO-HSE-0169744

Triodia has often been observed to have very poor establishment from broadcast seed. This project investigated alternatives to growing Triodia (spinifex) from seed, focussing on ways to propagate seedlings from wild harvested material.

The project found the most successful propagating material was stolons. Greatest propagation success was achieved when Triodia were collected when semi to fully dormant (mid Winter-Spring). The 'Moist Root Induction Method' recommended by previous researchers was less successful than the standard propagation techniques employed in this project. Success varied notably between populations. Consequently, any future collections of propagating material should target multiple populations to maximise potential for success.

Pilbara Seed Science Project, Part 2 Final Report Jan 2012 **2013**

Internal reference: RTIO-HSE-0174944

Undertaken between 2009-2012, this seed research investigated germination, biology, dormancy classification and treatments for dormancy alleviation for a range of species from the Pilbara.

The *Acacia atkinsiana, Indigofera monophylla and Sida echinocarpa* seed lots have physical dormancy. Heat treatments and mechanical scarification improved germination on dormant seeds, however, heat treatments killed non-dormant seeds. The treatments used for *Goodenia stobbsiana* seeds failed to overcome dormancy, suggesting deep physiological dormancy. The *Hakea lorea/ chordophylla* seed lots were found to be non-dormant, with very high germination results in the controls. As such, they will not require any pre-treatments prior to direct seeding. The florets surrounding the *Triodia pungens* and *T. wiseana* seeds were found to restrict germination, however, many of the freshly extracted seeds out of the florets were found to be physiologically dormant. Treatments for dormancy include mechanical scarifier to rupture seed coat, hot water (noting potential damage to immature or non-dormant seeds) and increases to germination through wet / dry cycling and / or temperature cycling.

Morphological variation in the western rainbowfish (Melanotaenia australis) among habitats of the Pilbara region of northwest Australia. **2013**

Internal reference: RTIO-HSE-0252169

The aim of this honours thesis was to determine and quantify the extent of morphological variation present in M. australis and relate this to environmental variables, which will provide the first step to understanding how the species copes with environmental change.

This results of this thesis found that there was limited evidence that fish morphology correlated with environmental variables

Patterns of water use by the riparian tree Melaleuca argentea in semi-arid northwest Australia **2013**

Internal reference: RTIO-HSE-0249538

This thesis examines the water use physiology of the riparian tree Melaleuca argentea, and the ways in which this species may respond to anthropogenic disturbances to hydrologic processes.

M. argentea displays highly plastic root-level responses to heterogeneous water availability and to waterlogging, facilitating high rates of water use and growth in the riparian wetland habitats of the Pilbara. Mature M.argentea trees appear to tolerate groundwater drawdown of at least several metres, most likely by employing the same plastic root strategies to access deeper water. M.argentea can also withstand short periods of severe drought, by adopting a 'waiting' strategy of ceasing growth and shedding leaves to avoid moisture loss, a state from which they can then recover. M. argentea populations are unlikely to thrive under large and prolonged reductions in water availability.

Priority Species Seed Quality and Germination Final Report **2013**

Internal reference: RTIO-HSE-0207487

This study investigated the quality and germination biology of a range of priority and keystone (Triodia) plant species from the Pilbara.

Eremophila magnifica subsp. Magnifica has physical & physiological dormancy. Propagation methods other than seed may be more successful. Geijera salicifolia and Olearia mucronata has physiological dormancy. Temperature cycling may be required to stimulate germination. Indigofera ixiocarpa and Indigofera sp. Bungaroo Creek has physical dormancy or is non-dormant. Mechanical scarification may be required. Ptilotus subspinescens is non-dormant and will germinate easily without removal from the perianth sheath. However, seed is likely to lose viability with a few years. Sida echinocarpa and Sida sp. Barlee Range has physical dormancy. Seeds should be removed from the mericarp and then scarified in order to germinate. Triodia pungens has T. wiseana non-deeep or deep physiological dormancy. Germination of de-husked seeds can be improved by applying gibberellic acid or 1% smoke water and wet/dry cycling.

Early physiological flood-tolerance and extensive morphological changes are followed by slow post-flooding root recovery in the dryland tree Eucalyptus camaldulensis subsp. Refulgens **2014**

Internal reference: RTIO-HSE-0252170
